Abstract

Guide to performing setup and maintenance tasks in ForgeRock® Access Management, such as backing up and restoring, managing keystores, tuning the environment, monitoring, and others. ForgeRock Access Management provides authentication, authorization, entitlement, and federation software.

Preface

This guide covers how to set up and maintain core functionality such as realms, data stores and auditing and others, and also how to perform maintenance tasks in ForgeRock Access Management such as backing up and restoring, tuning, and others.

This guide is written for anyone that sets up and maintains AM services for their organizations. This guide covers tasks and configurations you might repeat throughout the life cycle of a deployment in your organization.

About ForgeRock Identity Platform™ Software

ForgeRock Identity Platform™ serves as the basis for our simple and comprehensive Identity and Access Management solution. We help our customers deepen their relationships with their customers, and improve the productivity and connectivity of their employees and partners. For more information about ForgeRock and about the platform, see <https://www.forgerock.com>.

Chapter 1

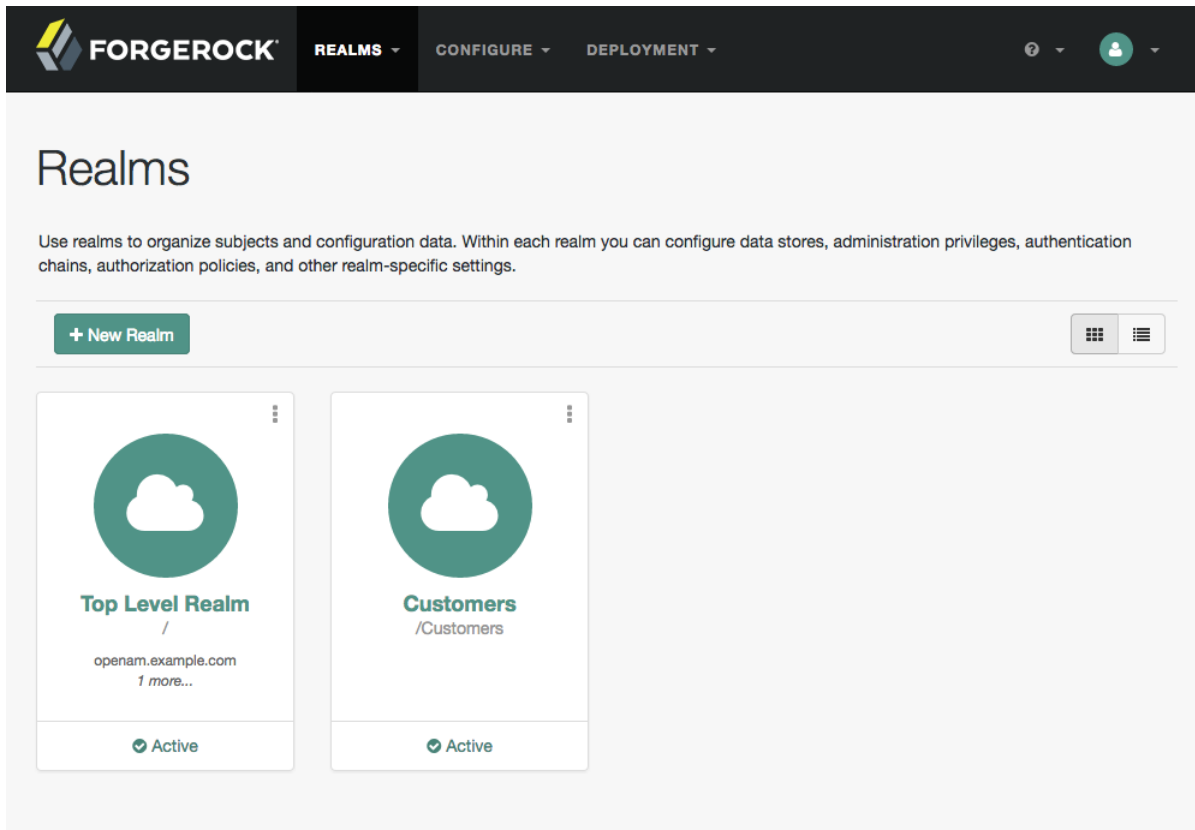

Introducing Administration Interfaces and Tools

This chapter provides a brief introduction to the web-based UI console. It also lists and describes each command-line interface (CLI) administration tool.

Web-Based AM Console

After you install AM, log in to the web-based AM console as AM administrator, `amadmin` with the password you set during installation. Navigate to a URL, such as `https://openam.example.com:8443/openam`. In this case, communications proceed over the HTTP protocol to a FQDN (`openam.example.com`), over a standard Java web container port number (8080), to a specific deployment URI (`/openam`).

The AM Console

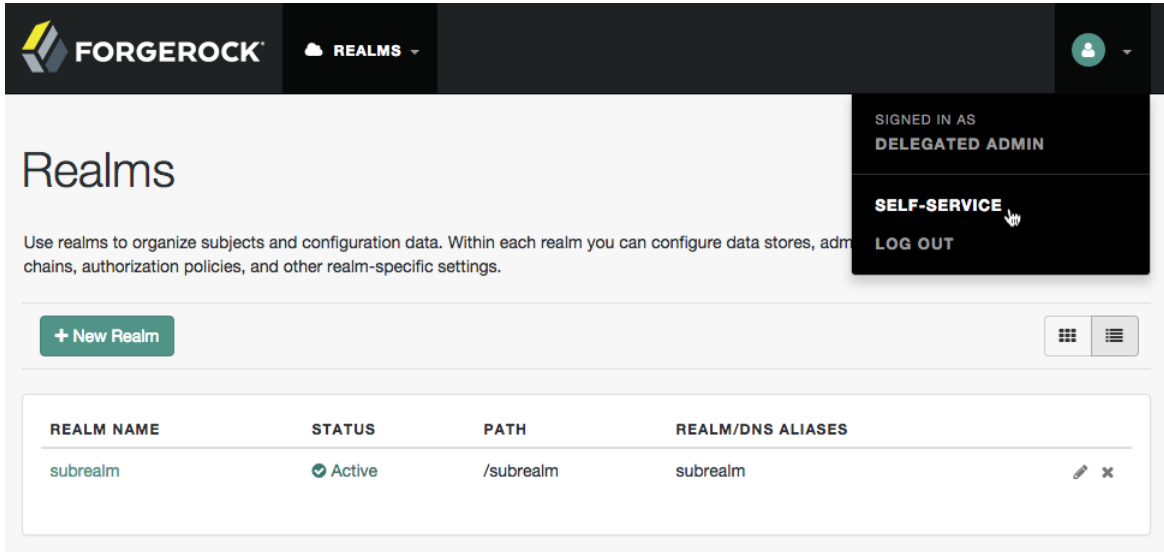

When you log in as the AM administrator, `amadmin`, you have access to the complete AM console. In addition, AM has set a cookie in your browser that lasts until the session expires, you logout, or you close your browser.¹

The `amadmin` account is a special user built-in to AM. The `amadmin` account does not have a user profile and is not present in the configured identity data store, so cannot use functionality that requires a user profile, such as Device Match or Push notifications. You should create users or groups, and delegate administrator privileges to them, as described in "Delegating Realm Administration Privileges".

¹Persistent cookies can remain valid when you close your browser. This section reflects AM default behavior before you configure additional functionality.

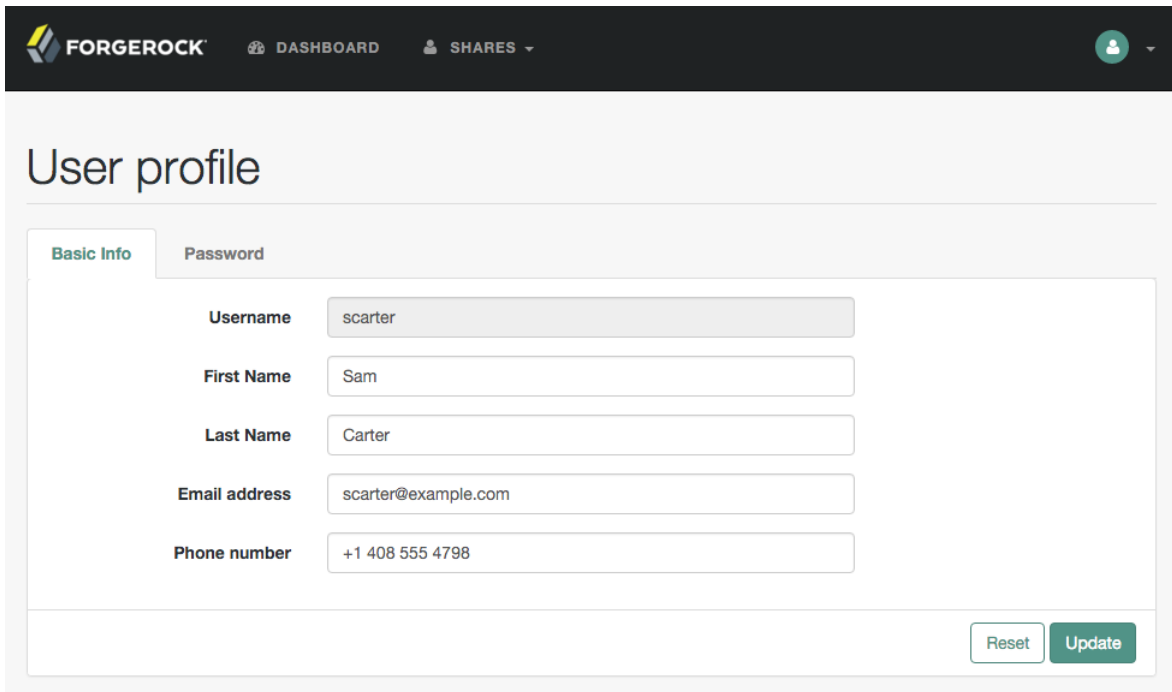

If you configure AM to grant administrative capabilities to users that do have a user profile and appear in the configured identity data store, then that user is able to access both the administration console in the realms they can administrate, and their self-service profile pages:

The AM Console for a Delegated Administrator

When you log in to the AM console as a non-administrative end user, you do not have access to the administrative console. Your access is limited to self-service profile pages and user dashboard.

The AM Console for Non-Administrative Users

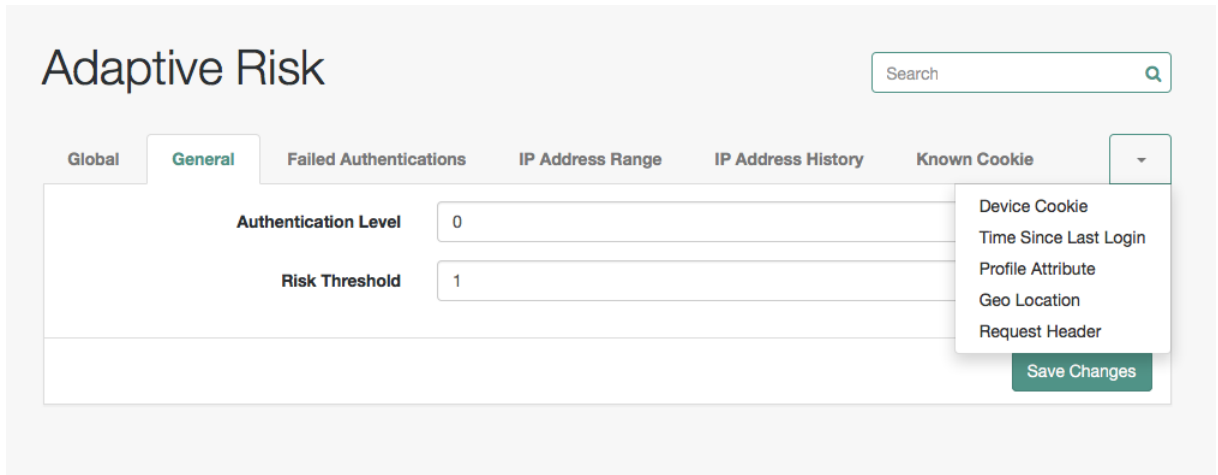

The screenshot shows the ForgeRock AM Console interface. At the top, there is a dark header with the ForgeRock logo, navigation links for 'DASHBOARD' and 'SHARES', and a user profile icon. Below the header, the main content area is titled 'User profile'. There are two tabs: 'Basic Info' (selected) and 'Password'. The 'Basic Info' tab contains several input fields: 'Username' (scarter), 'First Name' (Sam), 'Last Name' (Carter), 'Email address' (scarter@example.com), and 'Phone number' (+1 408 555 4798). At the bottom right of the form, there are two buttons: 'Reset' and 'Update'.

AM Console Responsiveness

The web-based console is a responsive website, which means it would resize some of its features to fit the size of your screen and the layout design.

For example, the header menu would change into a dropdown menu, and those pages with many tabs would shed most of them for a dropdown menu to the left-hand side.

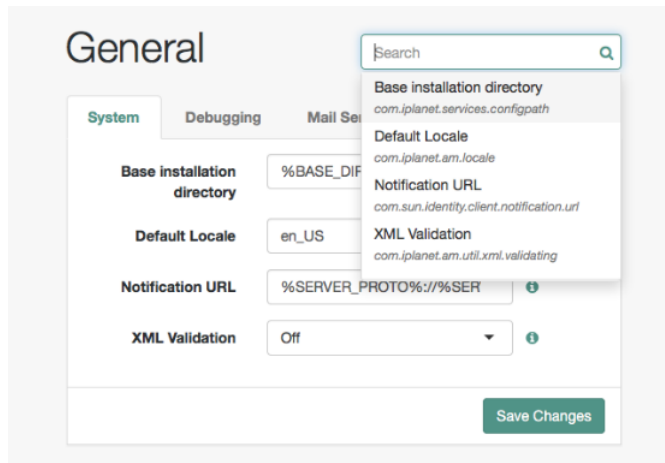

AM Console Responsiveness

The AM Console Search Feature

Use the search box to find any configuration attribute on the section you are in. It can autocomplete the word you are typing, or you can click on the box and display the list of available attributes for you.

The AM Console Search Feature

Amster Command-Line Tool

The **amster** tool provides a lightweight command-line interface, ideal for use in DevOps processes, such as continuous integration and deployment. The **amster** tool manages an AM configuration over REST, so you can store AM server configuration as an artifact and import a stored configuration to set up an AM server.

For details, see the **amster** documentation.

Agentadmin Command-Line Tool

The **agentadmin** tool, installed with AM web and Java agents, lets you manage agent installations.

For details, see the documentation for your web or Java agent.

Deprecated Command-Line Tools

The script tools in the following list have **.bat** versions for use on Microsoft Windows.

You can install the following command-line tools:

ampassword

This tool lets you change Administrator passwords, and display encrypted password values.

Install this from the [SSOAdminTools-5.1.2.24.zip](#).

amverifyarchive

This tool checks log archives for tampering.

Install this from [SSOAdminTools-5.1.2.24.zip](#).

openam-configurator-tool-14.1.2.24.jar

This executable **.jar** file lets you perform a silent installation of an AM server with a configuration file. For example, the **java -jar configurator.jar -f config.file** command couples the [configurator.jar](#) archive with the *config.file*. The [sampleconfiguration](#) file provided with the tool is set up with the format for the *config.file*, and it must be adapted for your environment.

Install this from [SSOConfiguratorTools-5.1.2.24.zip](#).

ssoadm

This tool provides a rich command-line interface for the configuration of core services.

Install this from [SSOAdminTools-5.1.2.24.zip](#).

To translate settings applied in the AM console to service attributes for use with **ssoadm**, log in to the AM console as **amadmin** and access the services page, in a URL, such as <https://openam.example.com:8443/openam/services.jsp>.

The commands access the AM configuration over HTTP (or HTTPS). When using the administration commands in a site configuration, the commands access the configuration through the front end load balancer.

Sometimes a command cannot access the load balancer because:

- Network routing restrictions prevent the tool from accessing the load balancer.
- For testing purposes, the load balancer uses a self-signed certificate for HTTPS, and the tool does not have a way of trusting the self-signed certificate.
- The load balancer is temporarily unavailable.

In such cases you can work around the problem by adding an option for each node, such as the following to the **java** command in the tool's script.

Node 1:

```
-D"com.iplanet.am.naming.map.site.to.server=https://lb.example.com:443/openam=  
http://server1.example.com:8080/openam"
```

Node 2:

```
-D"com.iplanet.am.naming.map.site.to.server=https://lb.example.com:443/openam=  
http://server2.example.com:8080/openam"
```

In the above example the load balancer is on the **lb** host, <https://lb.example.com:443/openam> is the site name, and the AM servers in the site are on **server1** and **server2**.

The **ssoadm** command will only use the latest value in the map, so if you have a mapping like:

```
-D"com.iplanet.am.naming.map.site.to.server=https://lb.example.com:443/openam=  
http://server1.example.com:8080/openam, https://lb.example.com:443/openam=  
http://server2.example.com:8080/openam"
```

The **ssoadm** command will always talk to:

```
http://server2.example.com:8080/openam
```

Chapter 2

Setting Up Realms

This chapter explains what realms are and how to configure and customize them.

Introducing Realms

AM *realms*, are used to group configuration and identities together. For example, you might have one realm for AM administrators and agents, and another realm for users. In this two-realm setup, the AM administrator can log in to the administrative realm to manage the services, but cannot authenticate as AM administrator to the realm that protects web sites with HR and financial information.

AM associates a realm with at least one identity repository and authentication chain. AM also associates the realm with authorization applications and their policies, and with privileges for administrators. Each realm has its own configuration for the services it provides.

When you first configure AM, AM sets up the default Top Level Realm, sometimes referred to as the / realm or root realm. The Top Level Realm contains AM configuration data and allows authentication using the identity repository that you choose during initial configuration. The Top Level Realm might hold the overall configuration for Example.com, for instance.

You create new realms to subdivide authentication and authorization, and to delegate management of subrealms. For example, your organization might require separate realms for payroll, human resources, and IT management domains and their applications.

When a new realm is created, AM copies the configuration of the parent realm to the new realm. For example, authentication chains, authentication trees, policies, and identity store configuration are copied over.

Once the realm is created, its configuration is completely separate from that of the parent realm. Configuration changes done to the parent realm or to the new realm will not be shared.

Note

Identities, identity groups, and privileges are linked to identity stores. If two realms share the same identity store, they will also share identity groups and any privileges granted to them.

To redirect users to a specific realm using the browser, either use the `realm=realm-path` query string parameter, for example, <https://openam.example.com:8443/openam/XUI/?realm=/realm1/subrealm1#login>, or create FQDN aliases for the realm.

To make REST requests to a specific realm, see "Specifying Realms in REST API Calls".

See the following sections to configure realms and realm FQDNs:

- "Implementing Realms Using the AM Console"
- "Implementing Realms using the REST API"

Implementing Realms Using the AM Console

You create and configure realms through the AM console, starting from the Realms page.

Note

AM requires cookies for all configured realms when using DNS aliases. For example, if you install AM in the domain, `openam.example.net` and have realms, `identity.example.org` and `security.example.com` then you must configure cookie domains for `example.net`, `example.org`, and `example.com`. You can set up the cookie domains for each realm by following the procedure in "To Configure DNS Aliases for Accessing a Realm".

This section has the following procedures:

- "To Create a New Realm"
- "To Configure DNS Aliases for Accessing a Realm"

To Create a New Realm

You can create a new realm through the AM console as described below, or by using the **ssoadm create-realm** command:

1. Log in to the AM console as administrator, `amadmin`.
2. On the Realms page, click New Realm. The New Realm page appears. Complete the form to configure the realm.
3. In the Name field, enter a descriptive name for the realm.

Note

Realm names must not match any of the following:

- Existing realm names.
- Existing realm aliases.
- Names of AM REST endpoints.

For example `users`, `groups`, `realms`, `policies` or `applications`.

- The Active button is enabled by default.

Warning

If you configure the realm to be inactive, then users cannot use it to authenticate or be granted access to protected resources.

- In the Parent field, enter the parent of your realm.

Default: the top level realm (/).

- In the Realm Aliases field, enter a simple text alias to represent the realm.
- In the DNS Aliases field, enter fully-qualified domain names (FQDN) that can be used to represent the realm.

A DNS alias is not related to the CNAME record used in DNS database zones. In other words, the option shown in the AM console does not conform to the definition of DNS aliases described in RFC 2219.

Tip

Entering a DNS alias in the AM console also applies required changes to the advanced server property `com.sun.identity.server.fqdnMap`.

For more information, see "To Configure DNS Aliases for Accessing a Realm".

- To enable client-based sessions for the realm, toggle the Use Client-based Sessions switch. For more information on sessions, see "About Sessions" in the *Authentication and Single Sign-On Guide*.
- Click Create to save your configuration.

To Configure DNS Aliases for Accessing a Realm

You can configure realms to be associated with specific fully-qualified domain names (FQDN).

For example, consider a deployment with the following characteristics:

- The FQDN for AM and the top level realm is `openam.example.com`.
- AM also services `realm1.example.com`, and `realm2.example.com`. In other words, AM receives all HTTP(S) connections for these host names. Perhaps they share an IP address, or AM listens on all interfaces.

Without applying DNS aliases to the relevant realm, when a user visits <http://realm1.example.com:8080/openam>, AM redirects that user to the top level realm, <https://openam.example.com:8443/openam>. If the authenticating user is present only in `realm1`, then authentication fails even with correct credentials.

If no DNS alias is configured for a realm, `realm1` users must visit URLs such as <https://openam.example.com:8443/openam/XUI/?realm=/realm1#login>. This format of URL reveals the top level realm, and exposes extra information about the service.

Configure DNS aliases for realms to prevent redirection and having to expose the top level realm domain by performing the following steps:

Note

Realm aliases must be unique within an AM instance, and cannot contain the characters `"`, `#`, `$`, `%`, `&`, `+`, `,`, `/`, `:`, `;`, `<`, `=`, `>`, `?`, `@`, `\`, or spaces.

1. Add the domains that AM services to the list of domains that created cookies will be applicable to, as follows:
 - a. Log in to the AM console as an AM administrator, for example, `amadmin`.
 - b. Navigate to Configure > Global Services > Platform.
 - c. In Cookie Domains, enter the domains that AM will service.

For example, if you installed AM at `openam.example.net`, and intend to have realms associated with FQDNs `realm1.example.org` and `realm2.example.com`, then the Cookie Domains list would include `example.net`, `example.org`, and `example.com`.
2. Set the FQDN for each realm as follows:
 - a. Navigate to Realms > *Realm Name*, and then click Properties.
 - b. In DNS Aliases, enter one or more FQDN values for the realm.
 - c. Save your changes.
3. (Optional) Adding DNS aliases by using the AM console also adds FQDN mappings to the AM server.

To verify these have been created perform the following steps:

- a. Navigate to Configure > Server Defaults > Advanced.
- b. For each FQDN DNS alias configured, verify the existence of a property named `com.sun.identity.server.fqdnMap[Realm FQDN]` with a property value of *Realm FQDN*.

For example, the property may be called `com.sun.identity.server.fqdnMap[realm1.example.com]` with a value of `realm1.example.com`.

If the property does not exist or needs to be changed, manually create the property for each FQDN DNS alias.

- c. Save your changes.

The new realm aliases take effect immediately, it is not necessary to restart AM. You can now use a URL such as `http://realm1.example.com:8080/openam` to access `realm1`, rather than `https://openam.example.com:8443/openam/XUI/?realm=/realm1#login`.

Implementing Realms using the REST API

This section shows how to use the AM RESTful interfaces for identity and realm management.

In this section, long URLs are wrapped to fit the printed page, as some of the output is formatted for easier reading.

Before making a REST API call to manage an identity, make sure that you have:

- Authenticated successfully to AM as a user with sufficient privileges to make the REST API call
- Obtained the session token returned after successful authentication

When making the REST API call, pass the session token in the HTTP header. For more information about the AM session token and its use in REST API calls, see "Using the Session Token After Authentication". For general information about the REST API, see "About the REST API".

Identity Management

This section shows how to create, read, update, delete, and list identities using the RESTful APIs.

Important

AM is not primarily an identity data store, nor is it provisioning software. For storing identity data, consider ForgeRock Directory Services. For provisioning, consider ForgeRock Identity Management. Both of these products provide REST APIs as well.

AM has the `/json/agents`, `/json/groups`, and `/json/users` JSON-based APIs for managing identities. These APIs follow the ForgeRock common REST pattern for creating, reading, updating, deleting, and querying resources.

Examples in this section do not repeat the authentication shown in "Authentication and Logout using REST". For browser-based clients, you can rely on AM cookies rather than construct the header in your application. Managing agent profiles, groups, and users with these APIs requires authentication. The examples shown in this section were performed with the token ID gained after authenticating as an AM administrator, for example `amAdmin`.

Although the examples here show user management, you can use `/json/agents` and `/json/groups` in similar fashion. See "Realm Management" for examples related to realms.

The following sections cover this JSON-based API:

- "Creating Identities using the REST API"
- "Reading Identities using the REST API"
- "Updating Identities using the REST API"
- "Deleting Identities using the REST API"
- "Listing Identities using the REST API"
- "Retrieving Identities Using the Session Cookie"
- "Changing Passwords using the REST API"
- "Creating Groups using the REST API"
- "Adding a User to a Group using the REST API"

Creating Identities using the REST API

AM lets administrators create a user profile with an HTTP POST of the JSON representation of the profile to `/json/subrealm/users/?_action=create`. To add a user to the Top Level Realm, you do not need to specify the realm.

The following example shows an administrator creating a new user. The only required fields are `username` and `userpassword`. If no other name is provided, the entry you make for `username` defaults to both the user id and the user's last name:

```
$ curl \
--request POST \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "Content-Type: application/json" \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--data \
'{
  "username": "bjensen",
  "userpassword": "secret12",
  "mail": "bjensen@example.com"
}' \
https://openam.example.com:8443/openam/json/realms/root/users/?_action=create
{
  "_id": "bjensen",
  "_rev": "-588258934",
  "username": "bjensen",
  "realm": "/",
  "uid": [
    "bjensen"
  ],
  "mail": [
    "bjensen@example.com"
  ]
}
```

```

    ],
    "universalid": [
      "id=bjensen,ou=user,dc=openam,dc=forgerock,dc=org"
    ],
    "objectClass": [
      "iplanet-am-managed-person",
      "inetuser",
      "sunFederationManagerDataStore",
      "sunFMSAML2NameIdentifier",
      "inetorgperson",
      "sunIdentityServerLibertyPPService",
      "devicePrintProfilesContainer",
      "iplanet-am-user-service",
      "iPlanetPreferences",
      "pushDeviceProfilesContainer",
      "forgerock-am-dashboard-service",
      "organizationalperson",
      "top",
      "kbaInfoContainer",
      "person",
      "sunAMAuthAccountLockout",
      "oathDeviceProfilesContainer",
      "iplanet-am-auth-configuration-service"
    ],
    "inetUserStatus": [
      "Active"
    ],
    "dn": [
      "uid=bjensen,ou=people,dc=openam,dc=forgerock,dc=org"
    ],
    "cn": [
      "bjensen"
    ],
    "sn": [
      "bjensen"
    ],
    "createTimestamp": [
      "20180426120642Z"
    ]
  }

```

Alternatively, administrators can create user profiles with specific user IDs by doing an HTTP PUT of the JSON representation of the changes to `/json/users/user-id`, as shown in the following example:

```

$ curl \
  --request PUT \
  --header "Accept-API-Version: protocol=2.1,resource=3.0" \
  --header "iPlanetDirectoryPro: AQIC5w...2NzEz*" \
  --header "Content-Type: application/json" \
  --header "If-None-Match: *" \
  --data \
  '{
    "username": "janedoe",
    "userpassword": "secret12",
    "mail": "janedoe@example.com"
  }' \
  https://openam.example.com:8443/openam/json/realms/root/users/janedoe
{
  "_id": "janedoe",

```

```

    "_rev": "-1686380958",
    "username": "janedoe",
    "realm": "/",
    "uid": [
      "janedoe"
    ],
    "mail": [
      "janedoe@example.com"
    ],
    "universalid": [
      "id=janedoe,ou=user,dc=openam,dc=forgerock,dc=org"
    ],
    "objectClass": [
      "iplanet-am-managed-person",
      "inetuser",
      "sunFederationManagerDataStore",
      "sunFMSAML2NameIdentifier",
      "inetorgperson",
      "sunIdentityServerLibertyPPService",
      "devicePrintProfilesContainer",
      "iplanet-am-user-service",
      "iPlanetPreferences",
      "pushDeviceProfilesContainer",
      "forgerock-am-dashboard-service",
      "organizationalperson",
      "top",
      "kbaInfoContainer",
      "person",
      "sunAMAuthAccountLockout",
      "oathDeviceProfilesContainer",
      "iplanet-am-auth-configuration-service"
    ],
    "dn": [
      "uid=janedoe,ou=people,dc=openam,dc=forgerock,dc=org"
    ],
    "inetUserStatus": [
      "Active"
    ],
    "cn": [
      "janedoe"
    ],
    "sn": [
      "janedoe"
    ],
    "createTimestamp": [
      "20180426121152Z"
    ]
  }

```

As shown in the examples, AM returns the JSON representation of the profile on successful creation. On failure, AM returns a JSON representation of the error including the HTTP status code. For example, version 2.0 of the CREST [/json/users](#), [/json/groups](#), and [/json/agents](#) endpoints return 403 if the user making the request is not authorized to do so.

The same HTTP POST and PUT mechanisms also work for other objects, such as web or Java agent profiles and groups:

```
$ curl \
```

```

--request POST \
--header "Accept-API-Version: protocol=2.0,resource=1.0" \
--header "Content-Type: application/json" \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--data \
'{
  "username": "myAgent",
  "com.sun.identity.agents.config.fqdn.default": [
    "www.example.com"
  ],
  "com.sun.identity.agents.config.repository.location": [
    "centralized"
  ],
  "agenttype": [
    "WebAgent"
  ],
  "serverurl": [
    "https://openam.example.com:8443/openam/"
  ],
  "agenturl": [
    "http://www.example.com:80/"
  ],
  "userpassword": [
    "password"
  ],
  "com.sun.identity.agents.config.login.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#login"
  ],
  "com.sun.identity.agents.config.logout.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#logout"
  ],
  "sunidentityserverdevicestatus": [
    "Active"
  ]
}' \
https://openam.example.com:8443/openam/json/realms/root/agents/?_action=create
{
  "username": "myAgent",
  "realm": "/",
  "com.sun.identity.agents.config.fqdn.default": [
    "www.example.com"
  ],
  "com.sun.identity.agents.config.repository.location": [
    "centralized"
  ],
  "AgentType": [
    "WebAgent"
  ],
  "userpassword": [
    "{SHA-1}W6ph5Mm5Pz8GgiULbPgZG37mj9g="
  ],
  "com.sun.identity.agents.config.login.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#login"
  ],
  "com.sun.identity.agents.config.logout.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#logout"
  ],
  "sunIdentityServerDeviceStatus": [
    "Active"
  ]
}

```

```
]
}
```

Note

The command output above has been truncated to be more readable. When you create an agent profile, AM returns the full profile in JSON format.

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=1.0" \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--data '{
  "username":"newGroup"
}' \
https://openam.example.com:8443/openam/json/realms/root/groups?_action=create
{
  "username":"newGroup",
  "realm":"/",
  "uniqueMember":[
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "cn":[
    "newGroup"
  ],
  "dn":[
    "cn=newGroup,ou=groups,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass":[
    "groupofuniquenames",
    "top"
  ],
  "universalid":[
    "id=newGroup,ou=group,dc=openam,dc=forgerock,dc=org"
  ]
}
```

```

$ curl \
--request PUT \
--header "If-None-Match: *" \
--header "iPlanetDirectoryPro: AqIC5w...2NzEz*" \
--header "Content-Type: application/json" \
--data '{
  "username":"anotherGroup",
  "uniqueMember":["uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"]
}' \
https://openam.example.com:8443/openam/json/realms/root/groups/anotherGroup
{
  "username":"anotherGroup",
  "realm":"/",
  "uniqueMember":[
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "cn":[
    "anotherGroup"
  ],
  "dn":[
    "cn=anotherGroup,ou=groups,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass":[
    "groupofuniquenames",
    "top"
  ],
  "universalid":[
    "id=anotherGroup,ou=group,dc=openam,dc=forgerock,dc=org"
  ]
}
    
```

Reading Identities using the REST API

AM lets users and administrators read profiles by requesting an HTTP GET on `/json/subrealm/users/user-id`. This allows users and administrators to verify user data, status, and directory. If users or administrators see missing or incorrect information, they can write down the correct information and add it using "Updating Identities using the REST API". To read a profile on the Top Level Realm, you do not need to specify the realm.

Users can review the data associated with their own accounts, and administrators can also read other user's profiles.

Note

If an administrator user is reading their own profile, an additional `roles` element, with a value of `ui-admin` is returned in the JSON response. The XUI verifies this element to grant or deny access to the AM Console.

The following example shows an administrator accessing user data belonging to `demo`:

```

$ curl \
--header "iPlanetDirectoryPro: AqIC5w...2NzEz*" \
https://openam.example.com:8443/openam/json/realms/root/users/demo
{
    
```

```

    "_id": "demo",
    "_rev": "-320505756",
    "username": "demo",
    "realm": "/",
    "uid": [
      "demo"
    ],
    "universalid": [
      "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
    ],
    "objectClass": [
      "iplanet-am-managed-person",
      "inetuser",
      "sunFederationManagerDataStore",
      "sunFMSAML2NameIdentifier",
      "devicePrintProfilesContainer",
      "inetorgperson",
      "sunIdentityServerLibertyPPService",
      "iPlanetPreferences",
      "pushDeviceProfilesContainer",
      "iplanet-am-user-service",
      "forgerock-am-dashboard-service",
      "organizationalperson",
      "top",
      "kbaInfoContainer",
      "sunAMAuthAccountLockout",
      "person",
      "oathDeviceProfilesContainer",
      "iplanet-am-auth-configuration-service"
    ],
    "dn": [
      "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
    ],
    "inetUserStatus": [
      "Active"
    ],
    "sn": [
      "demo"
    ],
    "cn": [
      "demo"
    ],
    "createTimestamp": [
      "20170105101638Z"
    ],
    "modifyTimestamp": [
      "20170110102632Z"
    ]
  }

```

Use the `_fields` query string parameter to restrict the list of attributes returned. This parameter takes a comma-separated list of JSON object fields to include in the result. Note that the `_fields` argument is case-sensitive. In the following example, the returned value matches the specified argument, `uid`, whereas `UID` would not:

```
$ curl \
--header "iPlanetDirectoryPro: AQIC5w...2NzEz*" \
https://openam.example.com:8443/openam/json/realms/root/users/demo?_fields=username,uid
{
  "username": "demo",
  "uid": [
    "demo"
  ]
}
```

As shown in the examples, AM returns the JSON representation of the profile on success. On failure, AM returns a JSON representation of the error including the HTTP status code.

Using HTTP GET to read also works for other objects such as agent profiles and groups:

```
$ curl \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: protocol=2.0,resource=1.0" \
https://openam.example.com:8443/openam/json/realms/root/agents/myAgent
{
  "username": "myAgent",
  "realm": "/",
  "com.sun.identity.agents.config.fqdn.default": [
    "www.example.com"
  ],
  "com.sun.identity.agents.config.repository.location": [
    "centralized"
  ],
  "AgentType": [
    "WebAgent"
  ],
  "userpassword": [
    "{SHA-1}W6ph5Mm5Pz8GgiULbPgZG37mj9g="
  ],
  "com.sun.identity.agents.config.login.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#login"
  ],
  "com.sun.identity.agents.config.logout.url": [
    "[0]=https://openam.example.com:8443/openam/XUI/?realm=#logout"
  ],
  "sunIdentityServerDeviceStatus": [
    "Active"
  ]
}
```

Note

The command output above has been truncated to be more readable. When you read an agent profile, AM returns the full profile in JSON format.

Tip

Append the `_prettyPrint=true` query string parameter to make the returned JSON easier to read.

Updating Identities using the REST API

AM lets users update their own profiles, and lets administrators update other users' profiles. To update an identity do an HTTP PUT of the JSON representation of the changes to `/json/subrealm/users/user-id`. To update a profile on the Top Level Realm, you do not need to specify the realm.

The following example shows how users can update their own profiles:

```
$ curl \
--request PUT \
--header "iplanetDirectoryPro: AQIC5..Y3MTax*" \
--header "Content-Type: application/json" \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "If-Match: *" \
--data '{ "mail": "demo@example.com" }' \
https://openam.example.com:8443/openam/json/realms/root/users/demo
{
  "username":"demo",
  "realm":"/",
  "uid":[
    "demo"
  ],
  "mail":[
    "demo@example.com"
  ],
  "universalid":[
    "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
  ],
  "objectClass":[
    "iplanet-am-managed-person",
    "inetuser",
    "sunFederationManagerDataStore",
    "sunFMSAML2NameIdentifier",
    "devicePrintProfilesContainer",
    "inetorgperson",
    "sunIdentityServerLibertyPPService",
    "iPlanetPreferences",
    "pushDeviceProfilesContainer",
    "iplanet-am-user-service",
    "forgerock-am-dashboard-service",
    "organizationalperson",
    "top",
    "kbaInfoContainer",
    "sunAMAuthAccountLockout",
```

```

        "person",
        "oathDeviceProfilesContainer",
        "iplanet-am-auth-configuration-service"
    ],
    "dn": [
        "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
    ],
    "inetUserStatus": [
        "Active"
    ],
    "sn": [
        "demo"
    ],
    "cn": [
        "demo"
    ],
    "createTimestamp": [
        "20170105101638Z"
    ],
    "modifyTimestamp": [
        "20170110105038Z"
    ],
    "roles": [
        "ui-self-service-user"
    ]
}

```

As shown in the example, AM returns the JSON representation of the profile on success. On failure, AM returns a JSON representation of the error including the HTTP status code.

You can use HTTP PUT to update other objects as well, such as web or Java agent profiles and groups.

The following example updates a web agent profile:

```

$ curl \
--request PUT \
--header "iPlanetDirectoryPro: AQIC5...Y3MTax*" \
--header "Accept-API-Version: protocol=2.0,resource=1.0" \
--header "If-Match: *" \
--header "Content-Type: application/json" \
--data '{
    "sunIdentityServerDeviceStatus" : [ "Inactive" ]
}' \
https://openam.example.com:8443/openam/json/realms/root/agents/myAgent
{
    "username": "myAgent",
    "realm": "/",
    "com.sun.identity.agents.config.fqdn.default": [
        "www.example.com"
    ],
    "com.sun.identity.agents.config.repository.location": [
        "centralized"
    ],
    "AgentType": [
        "WebAgent"
    ],
}

```

```

"userpassword": [
  "{SHA-1}W6ph5Mm5Pz8GgiULbPgZG37mj9g="
],
"com.sun.identity.agents.config.login.url": [
  "[0]=https://openam.example.com:8443/openam/XUI/?realm=#login"
],
"com.sun.identity.agents.config.logout.url": [
  "[0]=https://openam.example.com:8443/openam/XUI/?realm=#logout"
],
"sunIdentityServerDeviceStatus": [
  "Inactive"
]
}
    
```

Note

The command output above has been truncated to be more readable. When you update an agent profile, AM returns the full profile in JSON format.

Notice in the following example, which updates `newGroup`, the object class value is not included in the JSON sent to AM:

```

$ curl \
--request PUT \
--header "iPlanetDirectoryPro: AQIC5...Y3MTAx*" \
--header "Content-Type: application/json" \
--data '{
  "uniqueMember": [
    "uid=newUser,ou=people,dc=openam,dc=forgerock,dc=org",
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ]
}' \
https://openam.example.com:8443/openam/json/realms/root/groups/newGroup
{
  "name": "newGroup",
  "realm": "/",
  "uniqueMember": [
    "uid=newUser,ou=people,dc=openam,dc=forgerock,dc=org",
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "cn": [
    "newGroup"
  ],
  "dn": [
    "cn=newGroup,ou=groups,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass": [
    "groupofuniquenames",
    "top"
  ],
  "universalid": [
    "id=newGroup,ou=group,dc=openam,dc=forgerock,dc=org"
  ]
}
    
```

Deleting Identities using the REST API

AM lets administrators delete a user profile by making an HTTP DELETE call to `/json/subrealm/users/user-id`. To delete a user from the Top Level Realm, you do not need to specify the realm.

The following example removes a user from the top level realm. Only administrators should delete users. The user id is the only field required to delete a user:

```
$ curl \
--request DELETE \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "iplanetDirectoryPro: AqIC5w...2NzEz*" \
https://openam.example.com:8443/openam/json/realms/root/users/bjensen
{
  "_id": "bjensen",
  "_rev": "-1870449267",
  "success": "true"
}
```

On success, AM returns a JSON object indicating success. On failure, AM returns a JSON representation of the error including the HTTP status code.

You can use this same logic for other resources such as performing an HTTP DELETE of an agent profile or of a group:

```
$ curl \
--request DELETE \
--header "Accept-API-Version: protocol=2.0,resource=1.0" \
--header "iplanetDirectoryPro: AqIC5w...2NzEz*" \
https://openam.example.com:8443/openam/json/realms/root/agents/my0Auth2ClientAgent
{
  "_id": "my0Auth2ClientAgent",
  "_rev": "-1870449267",
  "success": "true"
}
```

```
$ curl \
--request DELETE \
--header "iplanetDirectoryPro: AqIC5w...2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/realms/root/groups/newGroup
{
  "success": "true"
}
```

Important

Deleting a user does not automatically remove any of the user's sessions. If you are using CTS-based sessions, you can remove a user's sessions by checking for any sessions for the user and then removing them using the

console's Sessions page. If you are using client-based sessions, you cannot remove users' sessions; you must wait for the sessions to expire.

Listing Identities using the REST API

AM lets administrators list identities by making an HTTP GET call to `/json/subrealm/users/?_queryId=*`. To query the Top Level Realm, you do not need to specify the realm:

```
$ curl \
--header "iPlanetDirectoryPro: AQIC5w...2NzEz*" \
"https://openam.example.com:8443/openam/json/realms/root/users?_queryId="
{
  "result": [
    {
      "username": "amAdmin",
      "realm": "dc=openam,dc=forgerock,dc=org",
      "sunIdentityMSISDNNumber": [
      ],
      "mail": [
      ],
      "sn": [
        "amAdmin"
      ],
      "givenName": [
        "amAdmin"
      ],
      "universalid": [
        "id=amAdmin,ou=user,dc=openam,dc=forgerock,dc=org"
      ],
      "cn": [
        "amAdmin"
      ],
      "iplanet-am-user-success-url": [
      ],
      "telephoneNumber": [
      ],
      "roles": [
        "ui-global-admin",
        "ui-realm-admin"
      ],
      "iplanet-am-user-failure-url": [
      ],
      "inetuserstatus": [
        "Active"
      ],
      "postalAddress": [
      ],
      "dn": [
        "uid=amAdmin,ou=people,dc=openam,dc=forgerock,dc=org"
      ],
      "employeeNumber": [
      ]
    }
  ]
}
```

```

    ],
    "iplanet-am-user-alias-list":[
    ]
},
{
  "username":"demo",
  "realm":"dc=openam,dc=forgerock,dc=org",
  "uid":[
    "demo"
  ],
  "createTimestamp":[
    "20160108155628Z"
  ],
  "inetUserStatus":[
    "Active"
  ],
  "mail":[
    "demo.user@example.com"
  ],
  "sn":[
    "demo"
  ],
  "cn":[
    "demo"
  ],
  "objectClass":[
    "devicePrintProfilesContainer",
    "person",
    "sunIdentityServerLibertyPPService",
    "sunFederationManagerDataStore",
    "inetorgperson",
    "oathDeviceProfilesContainer",
    "iPlanetPreferences",
    "iplanet-am-auth-configuration-service",
    "sunFMSAML2NameIdentifier",
    "organizationalperson",
    "inetuser",
    "kbaInfoContainer",
    "forgerock-am-dashboard-service",
    "iplanet-am-managed-person",
    "iplanet-am-user-service",
    "sunAMAuthAccountLockout",
    "top"
  ],
  "kbaInfo":[
    {
      "questionId":"2",
      "answer":{
        "$crypto":{
          "value":{
            "algorithm":"SHA-256",
            "data":"VXGtsnjJMC...MQJ/goU5hkFF"
          },
          "type":"salted-hash"
        }
      }
    }
  ],
},

```

```

        {
          "questionId": "1",
          "answer": {
            "$crypto": {
              "value": {
                "algorithm": "SHA-256",
                "data": "cfYYzi9U...rVfFl0Tdw0iX"
              },
              "type": "salted-hash"
            }
          }
        },
        "dn": [
          "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
        ],
        "universalid": [
          "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
        ],
        "modifyTimestamp": [
          "20160113010610Z"
        ]
      }
    ],
    "resultCount": 2,
    "pagedResultsCookie": null,
    "totalPagedResultsPolicy": "NONE",
    "totalPagedResults": -1,
    "remainingPagedResults": -1
  }
}

```

The `users` endpoint also supports the `_queryFilter` parameter to alter the returned results. For more information, see "Query".

The `_queryId=*` parameter also works for other types of objects, such as agent profiles and groups:

```

$ curl \
--header "iPlanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: protocol=2.0,resource=1.0" \
"https://openam.example.com:8443/openam/json/realms/root/agents?_queryId="
{
  "result": [
    {
      "_id": "myAgent",
      "_rev": "-1078786086",
      "username": "myAgent",
      "realm": "/"
    }
  ],
  "resultCount": 1,
  "pagedResultsCookie": null,
  "remainingPagedResults": -1
}

```

```
$ curl \
--header "iPlanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
"https://openam.example.com:8443/openam/json/realms/root/groups?_queryId=*"
{
  "result" : [ "newGroup", "anotherGroup" ],
  "resultCount" : 2,
  "pagedResultsCookie" : null,
  "remainingPagedResults" : -1
}
```

As the result lists include all objects, this capability to list identity names is mainly useful in testing.

As shown in the examples, AM returns the JSON representation of the resource list if successful. On failure, AM returns a JSON representation of the error including the HTTP status code.

Retrieving Identities Using the Session Cookie

If you only have access to the `iPlanetDirectoryPro` session cookie, you can retrieve the user ID by performing an HTTP POST operation on the `/json/users` endpoint using the `idFromSession` action:

```
$ curl \
--verbose \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "iPlanetDirectoryPro: AQIC5wM2LY4Sfcz...c50Dk4MjYzMzA2MQ...*" \
"https://openam.example.com:8443/openam/json/realms/root/users?_action=idFromSession"
{
  "id": "demo",
  "realm": "/",
  "dn": "id=demo,ou=user,dc=openam,dc=forgerock,dc=org",
  "successURL": "/openam/console",
  "fullLoginURL": "/openam/UI/Login?realm=%2F"
}
```

Changing Passwords using the REST API

Users other than the top-level administrator can change their own passwords with an HTTP POST to `/json/subrealm/users/username?_action=changePassword` including the new password as the value of `userpassword` in the request data.

Note

Changing the top-level administrator's password requires a more complex procedure. See "Changing the amadmin User's Password" for more information.

Users must provide the current password, which is set in the request as the value of the `currentpassword`.

For cases where users have forgotten their password, see "Retrieving Forgotten Usernames" in the *User Self-Service Guide* instead.

The following example shows a successful request to change the `demo` user's password to `password`:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "iPlanetDirectoryPro: AQIC5w...NTcy*" \
--data '{
  "currentpassword":"changeit",
  "userpassword":"password"
}' \
https://openam.example.com:8443/openam/json/realms/root/users/demo?action=changePassword
{}
```

On success, the response is an empty JSON object `{}` as shown in the example.

On failure, AM returns a JSON representation of the error including the HTTP status code. See also "HTTP Status Codes" for more information.

Administrators can change non-administrative users' passwords with an HTTP PUT to `/json/subrealm/users/username` including the new password as the value of `userpassword` in the request data.

Unlike users, administrators do not provide users' current passwords when changing passwords.

The following example shows a successful request by an administrator to change the `demo` user's password to `cangetin`:

```
$ curl \
--request PUT \
--header "iPlanetDirectoryPro: AQIC5w...NTcy*" \
--header "Accept-API-Version: protocol=2.1,resource=3.0" \
--header "Content-Type: application/json" \
--data '{
  "userpassword":"cangetin"
}' \
https://openam.example.com:8443/openam/json/realms/root/users/demo
{
  "_id":"demo",
  "_rev":"-1942782480",
  "username":"demo",
  "realm":"/",
  "uid":[
    "demo"
  ],
  "mail":[
    "demo@example.com"
  ],
  "universalid":[
    "id=demo,ou=user,dc=openam,dc=forgerock,dc=org"
  ],
  "objectClass":[
    "iplanet-am-managed-person",
    "inetuser",
    "sunFederationManagerDataStore",
    "sunFMSAML2NameIdentifier",
    "devicePrintProfilesContainer",
```

```

    "inetorgperson",
    "sunIdentityServerLibertyPPService",
    "iPlanetPreferences",
    "pushDeviceProfilesContainer",
    "iplanet-am-user-service",
    "forgerock-am-dashboard-service",
    "organizationalperson",
    "top",
    "kbaInfoContainer",
    "sunAMAuthAccountLockout",
    "person",
    "oathDeviceProfilesContainer",
    "iplanet-am-auth-configuration-service"
  ],
  "dn": [
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "inetUserStatus": [
    "Active"
  ],
  "sn": [
    "demo"
  ],
  "cn": [
    "demo"
  ],
  "modifyTimestamp": [
    "20170110105705Z"
  ],
  "createTimestamp": [
    "20170105101638Z"
  ]
}

```

As shown in the example, AM returns the JSON representation of the profile on success. On failure, AM returns a JSON representation of the error including the HTTP status code. See also "HTTP Status Codes" for more information.

Creating Groups using the REST API

AM lets administrators create a group with an HTTP POST of the JSON representation of the group to the `/json/subrealm/groups?_action=create` endpoint.

The following example shows how to create a group called `newGroup` in the top level realm using the REST API after authenticating to AM:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=1.0" \
--header "iplanetDirectoryPro: AqIC5w...2NzEz*" \
--data '{
  "username":"newGroup"
}' \
https://openam.example.com:8443/openam/json/realms/root/groups?_action=create
{
  "username":"newGroup",
  "realm":"/",
  "uniqueMember":[
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ],
  "cn":[
    "newGroup"
  ],
  "dn":[
    "cn=newGroup,ou=groups,dc=openam,dc=forgerock,dc=org"
  ],
  "objectclass":[
    "groupofuniquenames",
    "top"
  ],
  "universalid":[
    "id=newGroup,ou=group,dc=openam,dc=forgerock,dc=org"
  ]
}
```

Adding a User to a Group using the REST API

AM lets administrators add a user to an existing group with an HTTP PUT to the JSON representation of the group to the `/json/subrealm/groups/groupName` endpoint.

The following example shows how to add users to an existing group by using the REST API. The example assumes that the DS backend is in use. Make sure to use the `uniqueMember` attribute to specify the user using the DS server:

```
$ curl \
--request PUT \
--header "iPlanetDirectoryPro: AqIC5...Y3MTax*" \
--header "Content-Type: application/json" \
--data '{
  "uniqueMember":[
    "uid=newUser,ou=people,dc=openam,dc=forgerock,dc=org",
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ]
}' \
https://openam.example.com:8443/openam/json/realms/root/groups/newGroup
{
  "name": "newGroup",
  "realm": "/",
  "uniqueMember": [
    "uid=newUser,ou=people,dc=openam,dc=forgerock,dc=org",
    "uid=demo,ou=people,dc=openam,dc=forgerock,dc=org"
  ]
}
```

```

    ],
    "cn": [
        "newGroup"
    ],
    "dn": [
        "cn=newGroup,ou=groups,dc=openam,dc=forgerock,dc=org"
    ],
    "objectclass": [
        "groupofuniquenames",
        "top"
    ],
    "universalid": [
        "id=newGroup,ou=group,dc=openam,dc=forgerock,dc=org"
    ]
}

```

Note

For Active Directory implementations, use the `member` attribute when adding a user to a group using the REST API:

```

$ curl \
--request PUT \
--header "iPlanetDirectoryPro: AQIC5...Y3MTAx*" \
--header "Content-Type: application/json" \
--data '{
  "member": [
    "cn=newUser,cn=users,dc=forgerock,dc=org",
    "cn=demo,cn=users,dc=forgerock,dc=org"
  ]
}' \
https://openam.example.com:8443/openam/json/realms/root/groups/newGroup
{
  "username": "newGroup",
  "realm": "/",
  "sAMAccountName": ["$FL2000-EP4RN8LPBKUS"],
  "universalid": ["id=newGroup,ou=group,dc=forgerock,dc=org"],
  "sAMAccountType": ["268435456"],
  "member": ["cn=newUser,cn=users,dc=forgerock,dc=org", "cn=demo,cn=users,dc=forgerock,dc=org"],
  "name": ["newGroup"],
  "objectClass": [
    "top",
    "group"
  ],
  "distinguishedName": ["CN=newGroup,CN=Users,DC=forgerock,DC=org"],
  "dn": ["CN=newGroup,CN=Users,DC=forgerock,DC=org"],
  "cn": ["newGroup"],
  "objectCategory": ["CN=Group,CN=Schema,CN=Configuration,DC=forgerock,DC=org"]
}

```

Realm Management

This section shows how to create, read, update, and delete realms using the `/json/global-config/realms` endpoint.

Tip

You can use the AM API Explorer for detailed information about this endpoint and to test it against your deployed AM instance.

In the AM console, click the Help icon, and then navigate to API Explorer > /global-config > /realms.

The following sections cover managing realms with the JSON-based RESTful API:

- "Required Properties for Managing Realms"
- "Creating Realms"
- "Listing Realms"
- "Reading Realms"
- "Updating Realms"
- "Deleting Realms"

Required Properties for Managing Realms

The following table shows the required properties when managing realms using the REST API:

Realm Properties for JSON-based API

Realm Property	Purpose
<code>name</code>	The name of the realm. Do not use the names of AM REST endpoints as the name of a realm. Names that should not be used include <code>users</code> , <code>groups</code> , <code>realms</code> , <code>policies</code> , and <code>applications</code> .
<code>active</code>	Whether the realm is to be active, or not. Specify either <code>true</code> or <code>false</code> .
<code>parentPath</code>	The path of the parent realm.
<code>aliases</code>	An array of any applicable aliases associated with the realm. Be aware that an alias can only be used once. Entering an alias used by another realm will remove the alias from that realm and you will lose configuration.

The following shows an example JSON payload when managing a realm:

```
{
  "name": "mySubRealm",
  "active": true,
  "parentPath": "/",
  "aliases": [ "payroll.example.com" ]
}
```

Creating Realms

AM lets administrators create a realm by performing an HTTP POST of the JSON representation of the realm to `/json/global-config/realms`.

The following example creates a new, active subrealm in the top level realm, named `mySubRealm`:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "iplanetDirectoryPro: AQIC5w..2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
--data '{
  "name": "mySubRealm",
  "active": true,
  "parentPath": "/",
  "aliases": [ "payroll.example.com" ]
}' \
https://openam.example.com:8443/openam/json/global-config/realms
{
  "_id": "L2Fub3RoZXJSZWFsbQ",
  "_rev": "-1054013208",
  "parentPath": "/",
  "active": true,
  "name": "mySubRealm",
  "aliases": [ "payroll.example.com" ]
}
```

AM returns a 201 HTTP status code and a JSON representation of the realm on success. The value returned in the `_id` field is used in subsequent REST calls relating to the realm. On failure, AM returns a JSON representation of the error including the HTTP status code. For more information, see "HTTP Status Codes".

Listing Realms

To list and query realms, perform an HTTP GET on the `/json/global-config/realms` endpoint, and set the `_queryFilter` query string parameter to `true` as in the following example, which lists all available realms:

```
$ curl \
--header "iPlanetDirectoryPro: AQIC5..." \
--header "Accept-API-Version: resource=1.0, protocol=2.1" \
https://openam.example.com:8443/openam/json/global-config/realms?_queryFilter=true
{
  "result": [
    {
      "_id": "Lw",
      "_rev": "252584985",
      "parentPath": null,
      "active": true,
      "name": "/",
      "aliases": [
        "openam.example.com",
        "openam"
      ]
    }
  ]
}
```

```

    ],
    {
      "_id": "L215U3ViUmVhbG0",
      "_rev": "949061198",
      "parentPath": "/",
      "active": true,
      "name": "mySubRealm",
      "aliases": [
        "payroll.example.com"
      ]
    }
  ],
  "resultCount": 2,
  "pagedResultsCookie": null,
  "totalPagedResultsPolicy": "NONE",
  "totalPagedResults": -1,
  "remainingPagedResults": -1
}

```

For more information about using the `_queryString` parameter in REST calls, see "Query".

Reading Realms

To read a realm's details, perform an HTTP GET on the `/json/global-config/realms/realm-id` endpoint, where `realm-id` is the value of `_id` for the realm.

The following example shows an administrator receiving information about a realm called `mySubRealm`, which has an `_id` value of `L215U3ViUmVhbG0`:

```

$ curl \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/global-config/realms/L215U3ViUmVhbG0
{
  "_id": "L215U3ViUmVhbG0",
  "_rev": "949061698",
  "parentPath": "/",
  "active": true,
  "name": "mySubRealm",
  "aliases": [
    "payroll.example.com"
  ]
}

```

AM returns a 200 HTTP status code and a JSON representation of the realm on success. On failure, AM returns a JSON representation of the error including the HTTP status code. For more information, see "HTTP Status Codes".

Updating Realms

To update a realm's aliases or to toggle between active and inactive, perform an HTTP PUT on the `/json/global-config/realms/realm-id` endpoint, where `realm-id` is the value of `_id` for the realm.

The request should include an updated JSON representation of the complete realm. Note that you cannot alter the `name` or `parent` properties of a realm.

The following example shows how to update a realm called `mySubRealm`, which has an `_id` value of `L215U3ViUmVhbG0`. The example changes the realm status to inactive:

```
$ curl \
--request PUT \
--header "iplanetDirectoryPro: AQIC5...Y3MTax*" \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=1.0, protocol=1.0" \
--data '{
  "parentPath": "/",
  "active": false,
  "name": "mySubRealm",
  "aliases": [
    "payroll.example.com"
  ]
}' \
https://openam.example.com:8443/openam/json/global-config/realm/L215U3ViUmVhbG0
{
  "_id": "L215U3ViUmVhbG0",
  "_rev": "94906213",
  "parentPath": "/",
  "active": false,
  "name": "mySubRealm",
  "aliases": [
    "payroll.example.com"
  ]
}
```

AM returns a 200 HTTP status code and a JSON representation of the realm on success. On failure, AM returns a JSON representation of the error including the HTTP status code. For more information, see "HTTP Status Codes".

Deleting Realms

To delete a realm, perform an HTTP DELETE on the `/json/global-config/realm/realm-id` endpoint, where `realm-id` is the value of `_id` for the realm.

The following example shows how to delete a realm called `mySubRealm`, which has an `_id` value of `L215U3ViUmVhbG0`.

Caution

Make sure that you do not have any information you need within a realm before deleting it. Once a realm is deleted, the only way to restore it is to return to a previously backed up deployment of AM.

```
$ curl \
--request DELETE \
--header "iplanetDirectoryPro: AQIC5w..2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/global-config/realms/L215U3ViUmVhbG0
{
  "_id": "L215U3ViUmVhbG0",
  "_rev": "949061708",
  "parentPath": "/",
  "active": false,
  "name": "mySubRealm",
  "aliases": [
    "payroll.example.com"
  ]
}
```

AM returns a 200 HTTP status code and a JSON representation of the deleted realm on success. On failure, AM returns a JSON representation of the error including the HTTP status code. For more information, see "HTTP Status Codes".

Customizing Realms

This section shows how to delegate realm administration privileges to users or groups of users and how to configure a web or Java agent to be directed to a realm and application when requesting policy decisions:

- "Delegating Realm Administration Privileges"
- "Working With Realms and AM Agents"

Delegating Realm Administration Privileges

You assign administration privileges to groups of users.

You can grant privileges through the AM console. See "To Delegate Privileges using the AM Console". Alternatively, use the **ssoadm add-privileges** command. See "ssoadm add-privileges" in the *Reference*.

To Delegate Privileges using the AM Console

1. On the Realms page, click the realm for which you want to delegate administration to view the realm configuration.

Delegating administration privileges in the top level realm allows members of the group full administration access to the OpenAM instance. Administration privileges in any other realm allows the group to administrate only in that realm, and any child realms.

2. Navigate to Identities, and on the Groups tab, click the name of the group to which you intend to grant access.
3. Select the administrative privileges to delegate for the realm:
 - (Optional) To grant users in the group access to the administration console for the realm, select **Realm Admin**.

Administrators can use the AM administration console as follows:

- Delegated administrators with the **Realm Admin** privilege can access full administration console functionality within the realms they can administer.
- Administrators with lesser privileges, such as the **Policy Admin** privilege, can not access the AM administration console.
- Both the top level administrator (such as **amadmin**) and delegated administrators in the Top Level Realm with the **Realm Admin** privilege have access to full console functionality in all realms and can access AM's global configuration.
- (Optional) To grant users in the group access to REST endpoints, select them from the list.

For information about the available AM privileges, see "Realm Privileges Configuration Reference".

4. Save your work.

To enable delegated subrealm administrators to invalidate sessions, you must add an attribute to their entry in the data store, as described in the following procedure:

To Enable Delegated Subrealm Administrators to Invalidate Sessions

1. Create an LDIF file that modifies the distinguished name entry of the subrealm administrator, adds the **iplanet-am-session-destroy-sessions** attribute, and sets its value to the subrealm's DN.

In the following example, the delegated administrator is named **subRealmAdmin** and the subrealm is called **mySubRealm**:

```
dn: uid=subrealmadmin,ou=people,dc=openam,dc=forgerock,dc=org
changetype: modify
add: objectClass
objectClass: iplanet-am-session-service
-
add: iplanet-am-session-destroy-sessions
iplanet-am-session-destroy-sessions: o=mysubrealm,ou=services,dc=openam,dc=forgerock,
dc=org
```

Note

All values in the LDIF must be in lowercase, even if the subrealm or administrator name is not.

2. Run the **ldapmodify** command included with DS to apply the LDIF file to the user data store. For example:

```
$ ./ldapmodify -h opendj.example.com -p 1389 -D "cn=Directory Manager" \  
-w myBindPassword -f /path/to/ldif.file  
# Processing MODIFY request for uid=subrealmadmin,ou=people,dc=openam,dc=forgerock,dc=org  
# MODIFY operation successful for DN uid=subrealmadmin,ou=people,dc=openam,dc=forgerock,dc=org
```

The delegated realm administrator will now be able to invalidate sessions created in the subrealm.

Working With Realms and AM Agents

You can configure a web or Java agent to be directed to a realm and application when requesting policy decisions, or to log users into a different realm than the agent's realm:

- "To Specify the Realm and Application for Policy Decisions"
- "To Configure Web Agents and Java Agents to Log In to a Realm"

To Specify the Realm and Application for Policy Decisions

By default, web or Java agents request policy decisions in the Top Level Realm (/) from the default policy set, `iPlanetAMWebAgentService`. When the realm and policy set differ for your web or Java agent, you can specify the realm and policy set in the agent profile. AM then directs requests from the agent to the specified realm and policy set, so this is backwards compatible with existing web or Java agents.

1. In the AM console, browse to Realms > *Realm Name* > Applications > Agents > *Web or Java* > *Agent Name* > OpenAM Services > Policy Client Service.
2. Set the Realm and Policy Set.

Note that Policy Sets are labelled as "Application" in some parts of the user interface.

For example, if the realm is `/hr` and the policy set is `myHRApp`:

- Realm: `/hr`
 - Application: `myHRApp`
3. Save your work.

To Configure Web Agents and Java Agents to Log In to a Realm

You might choose to configure your agent in one realm, yet have your real users authenticate through another realm. In this case, you want your web or Java agents to redirect users to authenticate to their realm, rather than the agent realm.

1. In the AM console, navigate to Realms > *Realm Name* > Applications > Agents > *Web or Java* > *Agent Name* > AM Services.
2. Configure the OpenAM Conditional Login URL property. For more information, see the [Web Policy Agents documentation](#) and the [Java Policy Agents documentation](#).
3. Save your work.

Chapter 3

Setting Up Identity and Data Stores

Setting Up Identity Stores

This section shows what identity data stores are and how to configure and customize them.

Introducing Identity Data Stores

An identity data store, or an identity repository, is a persistent repository of user data. For example, DS or Microsoft Active Directory. At install time you can configure AM to create an embedded DS server that works as an identity data store among other uses, but you can also consider to configure an external identity data store at install time or afterwards.

AM uses other types of data stores, like the configuration data store, the UMA data store, and the Core Token Service (CTS) data store, but those are not being discussed in this chapter.

Implementing Identity Data Stores

When you first set up a realm, the new realm inherits the data store from the parent realm. For example, in an installation where the Top Level Realm has the embedded DS server as the identity data store, any new realm created would have the embedded DS server as the identity data store by default.

Yet, if your administrators are in one realm and your users in another, your new child realm might retrieve users from a different data store.

Note

You should not configure more than one writeable identity repository in a single realm. AM will try to perform write operations on each identity repository configured in a realm, and there is no way to configure which repository is written to.

To manage identities and reconcile differences between multiple identity repositories, use ForgeRock Identity Management.

To see and modify the embedded DS identity data store server configuration, navigate to Realms > *Realm Name* > Identity Stores > embedded.

Before configuring an AM data store as an external identity data store, make sure that you have prepared the external identity data store for AM. For more information, see "Preparing Identity Repositories" in the *Installation Guide*.

To configure an external identity data store, see "To Configure an Identity Data Store".

To Configure an Identity Data Store

1. In the AM console, browse to Realms > *Realm Name* > Identity Stores.
2. Click Add Data Store, enter an ID, and select the type of data store.
3. Click Create
4. In the tabbed view, provide information on how to connect to your data store.

See the following sections for hints depending on the type of data store.

- "Active Directory Configuration Properties"
 - "Active Directory Application Mode Configuration Properties"
 - "Generic LDAPv3 Configuration Properties"
 - "Directory Services Configuration Properties"
 - "Sun/Oracle DSEE Configuration Properties"
 - "Tivoli Directory Server Configuration Properties"
5. (Optional) If you have not applied the schema configuration to your identity data, but your bind account has permission to alter schema, enable the Load Schema option.
 6. Click Save Changes.
 7. To test the connection, navigate to Realms > *Realm Name* > Identities. The identities stored in the external directory server will appear.
 8. If you no longer need the connection to the inherited, embedded data store *in this realm*, then you can delete its entry in the Identity Stores list.

Also, once you change the data store for a realm, you might opt to change the authentication module configuration to use your realm data store, rather than the inherited settings. See "Configuring Authentication Modules" in the *Authentication and Single Sign-On Guide*.

Testing External Identity Repository Access

You should verify that you have configured the repository and administrator privileges correctly. You can test configuration as follows:

- Attempt to create an AM user by navigating to Realms > *Realm Name* > Identities in the AM console. Run this test only if you have given the AM bind account write privileges to your identity repository.

For example, create a `demo` user. When you use the embedded identity repository to evaluate AM software, the setup process creates a `demo` user that is used in many examples in the AM documentation. This user does not exist by default in an external identity repository. When creating a `demo` user's account, set the fields as follows:

Demo User Account Settings

Field	Value
ID	<code>demo</code>
First Name	Leave this field blank.
Last Name	<code>demo</code>
Full Name	<code>demo</code>
Password	<code>changeit</code>
User Status	Active

- Attempt to access an AM user from Realms > *Realm Name* > Identities in the AM console.

If you receive an LDAP error code 65 while attempting to create a user, it indicates that you did not correctly prepare the external identity repository. Error code 65 is an LDAP object class violation and often indicates a problem with the directory schema or permissions.

A common reason for this error while attempting to create a user is that the bind account might not have adequate rights to add data to the directory. Review the DS `access` log and locate the entries for the `add` operation to determine if it is an access rights issue.

For information on setting up Directory Services as an external identity store, see "Installing and Configuring Directory Services for Identity Data" in the *Installation Guide*.

Customizing Identity Data Stores

Follow this section to create custom attributes to store additional information in your identity data stores, or to create identity repository plugins to customize how AM maps users and groups to a realm if your deployment require different functionality than the already built-in AM:

- "Adding User Profile Attributes".
- "Customizing Identity Data Storage".

Adding User Profile Attributes

You can extend user profiles by adding custom attributes. This section demonstrates how to add a custom attribute to a user profile when storing user profiles in the LDAP directory.

Adding a custom attribute involves both updating the identity repository schema to hold the new attribute and updating the XUI. Furthermore, to give users write permissions to the custom attribute, you must also update the AM configuration store.

This section uses DS 5 or later in the examples and includes the following procedures:

- To Update the Identity Repository for the New Attribute
- To Allow Users To Update the New Attribute Using an LDAP Browser
- To Allow Users to Update the New Attribute Using the Command Line
- To Add Custom Attributes to the User Interface

To Update the Identity Repository for the New Attribute

Perform the following steps to update the identity repository schema for the custom attribute, and then update AM to use the custom attribute and object class.

If you intend to use an existing attribute that is already allowed on user profile entries, you can skip this procedure.

1. Prepare the attribute type object class definitions in LDIF format. For example:

```
$ cat custom-attr.ldif
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: ( temp-custom-attr-oid NAME 'customAttribute' EQUALITY case
IgnoreMatch ORDERING caseIgnoreOrderingMatch SUBSTR caseIgnoreSubstrings
Match SYNTAX 1.3.6.1.4.1.1466.115.121.1.15 USAGE userApplications )
-
add: objectClasses
objectClasses: ( temp-custom-oc-oid NAME 'customObjectclass' SUP top AUXILIARY
MAY customAttribute )
```

In the example, the attribute type is called `customAttribute` and the object class is called `customObjectclass`.

2. Add the schema definitions to the directory.

```
$ /path/to/openssl/bin/ldapmodify \
--port 1389 \
--hostname openam.example.com \
--bindDN "cn=Directory Manager" \
--bindPassword password \
custom-attr.ldif
Processing MODIFY request for cn=schema
MODIFY operation successful for DN cn=schema
```

3. In the AM console, browse to Realms > *Realm Name* > Identity Stores > *Identity Store Name* > User Configuration.

4. Add the object class, for example `customObjectclass`, to the LDAP User Object Class list.
5. Add the attribute type, for example `customAttribute`, to the LDAP User Attributes list.
6. Save your work.

To Allow Users To Update the New Attribute Using an LDAP Browser

Perform the following steps to update AM configuration store to give users write permission to the custom attribute.

This procedure assumes you use an LDAP browser, for example Apache Directory Studio. Alternatively, you can follow "To Allow Users to Update the New Attribute Using the Command Line" if you use the command line.

1. Connect to the AM configuration store. You can see the configuration store details by navigating to Deployment > Servers > Directory Configuration > Server.
2. Search for `ou=SelfWriteAttributes`. You should find DN's similar to the following:
 - `dn:ou=SelfWriteAttributes,ou=Policies,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMPolicyService,ou=services,o=sunamhiddenrealmdelegationsservicepermissions,ou=services,dc=openam,dc=forgerock,dc=org`
 - `dn:ou=SelfWriteAttributes,ou=default,ou=default,ou=OrganizationConfig,ou=1.0,ou=sunEntitlementIndexes,ou=services,o=sunamhiddenrealmdelegationsservicepermissions,ou=services,dc=openam,dc=forgerock,dc=org`
3. In the entry under `iPlanetAMPolicyService`, edit the `sunKeyValue` attribute to add the custom attribute to the list of self-writable attributes. For example, `<Value>customAttribute</Value>`.
4. In the entry under `sunEntitlementIndexes`, edit the `sunKeyValue` attribute to add the custom attribute to the list of self-writable attributes. The following is an example of the custom attribute as the first element of the list: `\\"attributes\\": [\\n \\"customAttribute\\",\\n ...`
5. Restart AM or the web container where it runs.

To Allow Users to Update the New Attribute Using the Command Line

Perform the following steps to update the AM configuration store to give users write permission to the custom attribute.

This procedure assumes you use the command line. Alternatively, you can follow "To Allow Users To Update the New Attribute Using an LDAP Browser" if you use an LDAP browser.

1. Search for the value of `sunKeyValue` in `ou=SelfWriteAttributes` by running the following command:

```

$ /path/to/openssl/bin/ldapsrch --hostname openam.example.com --port 1389 \
--bindDn "cn=Directory Manager" --bindPassword forgerock \
--baseDn "dc=openam,dc=forgerock,dc=org" "(ou=SelfWriteAttributes)" sunKeyValue

dn:
ou=SelfWriteAttributes,ou=Policies,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMPolicyService,ou=services
sunKeyValue:: eG1scG9saWN5PTw.....

dn:
ou=SelfWriteAttributes,ou=default,ou=default,ou=OrganizationConfig,ou=1.0,ou=sunEntitlementIndexes,ou=services
sunKeyValue: serializable={"eCondition":{"className":"com.sun....
    
```

Note that the command returns two DNs, and the value of `sunKeyValue` in the first one is base64-encoded.

2. Decode the base64 string of the `iPlanetAMPolicyService` DN. For example:

```

$ ./base64 decode --encodedData eG1scG9saWN5PTw.....
xmlpolicy=<?xml version="1.0" encoding="UTF-8"?>
<Policy name="SelfWriteAttributes" createdby="cn=dsameuser,ou=DSAME
Users,dc=openam,dc=forgerock,dc=org" lastmodifiedby="cn=dsameuser,ou=DSAME
Users,dc=openam,dc=forgerock,dc=org" creationdate="1528296269883" lastmodifieddate="1528296269883"
referralPolicy="false" active="true" >
<Rule name="user-read-rule">
<ServiceName name="sunAMDelegationService" />
<ResourceName name="sms://*dc=openam,dc=forgerock,dc=org/sunIdentityRepositoryService/1.0/
application/*" />
<AttributeValuePair>
<Attribute name="MODIFY" />
<Value>allow</Value>
</AttributeValuePair>
</Rule>
<Subjects name="Subjects" description="">
<Subject name="delegation-subject" type="AuthenticatedUsers" includeType="inclusive">
</Subject>
</Subjects>
<Conditions name="AttrCondition" description="">
<Condition name="condition" type="UserSelfCheckCondition">
<AttributeValuePair><Attribute name="attributes"/><Value>givenname</Value><Value>sn</
Value><Value>cn</Value><Value>userpassword</Value><Value>mail</Value><Value>telephonenumber</
Value><Value>postaladdress</Value><Value>preferredlocale</Value><Value>iplanet-am-user-
password-reset-options</Value><Value>iplanet-am-user-password-reset-question-answer</
Value><Value>description</Value><Value>oath2faEnabled</Value><Value>sunIdentityServerDeviceKeyValue</
Value><Value>sunIdentityServerDeviceStatus</Value>
</AttributeValuePair>
</Condition>
</Conditions>
</Policy>
    
```

3. Create a file with the decoded string. Then, add the custom attribute to the `<AttributeValuePair>` list. For example:

```

$ vi to-encode.xml
....
<Attribute name="attributes"/><Value>customAttribute</Value><Value>givenname</Value>...</
AttributeValuePair>
....
    
```

4. Base64-encode the content of the file. For example:

```
$ ./base64 encode -f to-encode.xml
EG1scG9saWN5PTw22.....
```

5. Create an LDIF file, for example, `change.ldif`, containing the following:

- The LDIF properties and rules required to modify the value of the `sunKeyValue` attribute for both DNs.
- The newly base64-encoded string as the value of the `sunKeyValue` attribute of the `iPlanetAMPolicyService` DN. The string already contains the custom attribute.
- The value of the `sunKeyValue` attribute of the `sunEntitlementIndexes` DN. You must add the custom attribute inside the `attributes` list.

The following excerpt is an example of LDIF file:

```
dn:
ou=SelfWriteAttributes,ou=Policies,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMPolicyService,ou=services
changetype: modify
replace: sunKeyValue
sunKeyValue: EG1scG9saWN5PTw22.....

dn:
ou=SelfWriteAttributes,ou=default,ou=default,ou=OrganizationConfig,ou=1.0,ou=sunEntitlementIndexes,ou=services
changetype: modify
replace: sunKeyValue
sunKeyValue: serializable={"eCondition":{"className": ... \ "properties\ ": {\ "attributes\ ": [\n
\ "customAttribute\ ",\n \ "givenname\ ",\n \ "sn\ ",\n ... \ "values\ ": []\n}}}
```

6. Apply the changes in the LDIF file to the LDAP configuration store, as follows:

```
$ /path/to/openssl/bin/ldapmodify --hostname openam.example.com --port 50389 --bindDn "cn=Directory
Manager" --bindPassword forgerock --filename change.ldif
# MODIFY operation successful for DN
ou=SelfWriteAttributes,ou=Policies,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMPolicyService,ou=services
# MODIFY operation successful for DN
ou=SelfWriteAttributes,ou=default,ou=default,ou=OrganizationConfig,ou=1.0,ou=sunEntitlementIndexes,ou=services
```

7. Restart AM or the web container where it runs.

To Add Custom Attributes to the User Interface

To allow the XUI to show the new attribute in the user profile, you need to download the XUI source, edit it, and then rebuild the XUI.

Perform the following steps to configure the XUI to show the new attribute:

1. Download the XUI source as explained in "Downloading the XUI" in the *UI Customization Guide*.
2. Modify the XUI as follows:

- a. Edit the `openam-ui-ria/src/resources/locales/en/translation.json` file and add a new line with the description for the custom attribute. This description will show in the XUI user's profile page. For example:

```
...
"profile": "Profile",
"username" : "Username",
"emailAddress" : "Email address",
"givenName" : "First Name",
"customAttribute" : "My Custom Attribute",
"sn" : "Last Name",
"changePassword" : "Change password",
...
```

Note that the example adds the custom attribute under the `common.user` JSON path.

Tip

If you have translated the XUI pages, remember to edit all the `translation.json` files in your installation.

- b. Edit the `openam-ui-ria/src/resources/templates/user/UserProfileTemplate.html` file and add a new line for the custom attribute. Consider the following points:
- `property` must contain the name of the custom attribute created in the LDAP. For example, `customAttribute`.
 - `label` must contain the path to the label created in the `translation.json` file. In this case, `common.user.customAttribute`.

For example:

```
{{#user}}
  {> form/_basicInput property="username" label="common.user.username" readonly=true}}
  {> form/_basicInput property="givenName" label="common.user.givenName"}}
  {> form/_basicInput property="sn" label="common.user.sn" required=true}}
  {> form/_basicInput type="email" property="mail" label="common.user.emailAddress"
  extraAttributes='data-validator="validEmailAddressFormat" data-validator-event="keyup' }}
  {> form/_basicInput type="tel" property="telephoneNumber" label="common.user.phoneNumber"
  extraAttributes='data-validator="validPhoneFormat" data-validator-event="keyup' }}
  {> form/_basicInput property="customAttribute" label="common.user.customAttribute"}}
{{/user}}
```

- c. Edit the `openam-ui-ria/src/js/org/forgerock/openam/ui/user/UserModel.js` file and add the custom attribute on the `ServiceInvoker.restCall` function.

Consider the following constraints when modifying this file:

- The file does not support tab indentation. You must use space indentation.

- The file does not support lines longer than 120 characters. If the line you are modifying exceeds this limit, break it in multiple lines.

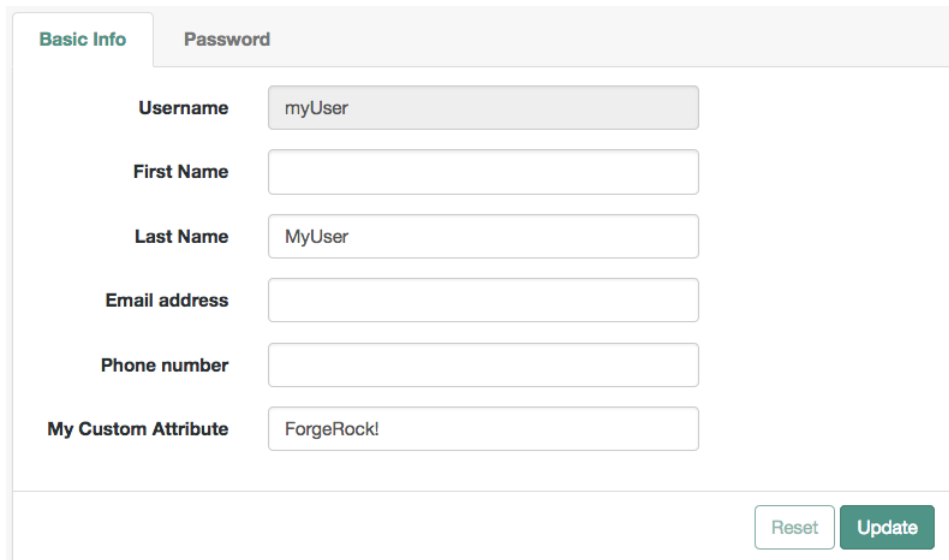

For example:

```
return ServiceInvoker.restCall(_.extend(
{
  type: "PUT",
  data: JSON.stringify(
    _.chain(this.toJSON())
      .pick(["givenName", "sn", "mail", "postalAddress", "telephoneNumber", "customAttribute"])
      .mapValues((val) => {
        ...
      })
  )
})
```

3. Rebuild the XUI by running the **yarn build** command.
4. Test the XUI pages by following the steps detailed in "To Test XUI Pages in a Development Server" in the *UI Customization Guide*.

The XUI user profile page now shows the custom attribute, and users are able to read and write its values:

User Custom Attribute

5. Once you are satisfied with the changes, deploy the output in the **build** directory to the `/path/to/tomcat/webapps/openam/XUI/` directory of your AM instances.

There is no need to restart the AM instance. Subsequent visits to the XUI pages will use the rebuilt files.

Customizing Identity Data Storage

AM maps user and group identities into a realm using data stores. An AM data store relies on a Java identity repository (IdRepo) plugin to implement interaction with the identity repository where the users and groups are stored.

About the Identity Repository Plugin

This section describes how to create a custom identity repository plugin. AM includes built-in support for LDAP identity repositories. For most deployments, you therefore do not need to create your own custom identity repository plugin. Only create custom identity repository plugins for deployments with particular requirements not met by built-in AM functionality.

Tip

Before creating your own identity repository plugin, start by reading the AM source code for the `FilesRepo` or `DatabaseRepo` plugins under `com.sun.identity.idm.plugins`.

IdRepo Inheritance

Your identity repository plugin class must extend the `com.sun.identity.idm.IdRepo` abstract class, and must include a constructor method that takes no arguments.

IdRepo Lifecycle

When AM instantiates your IdRepo plugin, it calls the `initialize()` method.

```
public void initialize(Map configParams)
```

The `configParams` are service configuration parameters for the realm where the IdRepo plugin is configured. The `configParams` normally serve to set up communication with the underlying identity data store. AM calls the `initialize()` method once, and considers the identity repository ready for use.

If you encounter errors or exceptions during initialization, catch and store them in your plugin for use later when AM calls other plugin methods.

After initialization, AM calls the `addListener()` and `removeListener()` methods to register listeners that inform AM client code of changes to identities managed by your IdRepo.

```
public int addListener(SSOToken token, IdRepoListener listener)
public void removeListener()
```

You must handle listener registration in your IdRepo plugin, and also return events to AM through the `IdRepoListener`.

When stopping, AM calls your IdRepo plugin `shutdown()` method.

```
public void shutdown()
```

You are not required to implement `shutdown()` unless your IdRepo plugin has shut down work of its own to do, such as close connections to the underlying identity data store.

IdRepo Plugin Capabilities

Your IdRepo plugin provides AM with a generic means to manage identities—including users and groups but also special types such as roles, realms, and agents— and to create, read, update, delete, and search identities. In order for AM to determine your plugin's capabilities, it calls the methods described in this section.

```
public Set getSupportedTypes()
```

The `getSupportedTypes()` method returns a set of `IdType` objects, such as `IdType.USER` and `IdType.GROUP`. You can either hard-code the supported types into your plugin, or make them configurable through the IdRepo service.

```
public Set getSupportedOperations(IdType type)
```

The `getSupportedOperations()` method returns a set of `IdOperation` objects, such as `IdOperation.CREATE` and `IdOperation.EDIT`. You can also either hard-code these, or make them configurable.

```
public boolean supportsAuthentication()
```

The `supportsAuthentication()` method returns true if your plugin supports the `authenticate()` method.

Identity Repository Plugin Implementation

Your IdRepo plugin implements operational methods depending on what you support. These methods perform the operations in your data store.

Create

AM calls `create()` to provision a new identity in the repository, where `name` is the new identity's name, and `attrMap` holds the attributes names and values.

```
public String create(SSOToken token, IdType type, String name, Map attrMap)
    throws IdRepoException, SSOException
```

Read

AM calls the following methods to retrieve identities in the identity repository, and to check account activity. If your data store does not support binary attributes, return an empty `Map` for `getBinaryAttributes()`.

```
public boolean isExists(
    SSOToken token,
```

```

    IdType type,
    String name
  ) throws IdRepoException, SS0Exception

  public boolean isActive(
    SS0Token token,
    IdType type,
    String name
  ) throws IdRepoException, SS0Exception

  public Map getAttributes(
    SS0Token token,
    IdType type,
    String name
  ) throws IdRepoException, SS0Exception

  public Map getAttributes(
    SS0Token token,
    IdType type,
    String name,
    Set attrNames
  ) throws IdRepoException, SS0Exception

  public Map getBinaryAttributes(
    SS0Token token,
    IdType type,
    String name,
    Set attrNames
  ) throws IdRepoException, SS0Exception

  public RepoSearchResults search(
    SS0Token token,
    IdType type,
    String pattern,
    Map avPairs,
    boolean recursive,
    int maxResults,
    int maxTime,
    Set returnAttrs
  ) throws IdRepoException, SS0Exception

  public RepoSearchResults search(
    SS0Token token,
    IdType type,
    String pattern,
    int maxTime,
    int maxResults,
    Set returnAttrs,
    boolean returnAllAttrs,
    int filterOp,
    Map avPairs,
    boolean recursive
  ) throws IdRepoException, SS0Exception

```

Edit

AM calls the following methods to update a subject in the identity repository.

```
public void setAttributes(
```

```

SSOToken token,
IdType type,
String name,
Map attributes,
boolean isAdd
) throws IdRepoException, SSOException

public void setBinaryAttributes(
    SSOToken token,
    IdType type,
    String name,
    Map attributes,
    boolean isAdd
) throws IdRepoException, SSOException

public void removeAttributes(
    SSOToken token,
    IdType type,
    String name,
    Set attrNames
) throws IdRepoException, SSOException

public void modifyMemberShip(
    SSOToken token,
    IdType type,
    String name,
    Set members,
    IdType membersType,
    int operation
) throws IdRepoException, SSOException

public void setActiveStatus(
    SSOToken token,
    IdType type,
    String name,
    boolean active
)
    
```

Authenticate

AM calls `authenticate()` with the credentials from the `DataStore` authentication module.

```

public boolean authenticate(Callback[] credentials)
    throws IdRepoException, AuthLoginException
    
```

Delete

The `delete()` method removes the subject from the identity repository. The `name` specifies the subject.

```

public void delete(SSOToken token, IdType type, String name)
    throws IdRepoException, SSOException
    
```

Service

The `IdOperation.SERVICE` operation is rarely used in recent AM deployments.

Identity Repository Plugin Deployment

When you build your IdRepo plugin, include `openam-core-6.5.5.jar` in the classpath. This file is found under `WEB-INF/lib/` where AM is deployed.

You can either package your plugin as a `.jar`, and then add it to `WEB-INF/lib/`, or add the classes under `WEB-INF/classes/`.

To register your plugin with AM, you add a `SubSchema` to the `sunIdentityRepositoryService` using the `ssoadm` command. First, you create the `SubSchema` document having the following structure.

```
<SubSchema i18nKey="x4000" inheritance="multiple" maintainPriority="no"
  name="CustomRepo" supportsApplicableOrganization="no" validate="yes">
  <AttributeSchema cosQualifier="default" isSearchable="no"
    name="RequiredValueValidator" syntax="string"
    type="validator" >
    <DefaultValues>
    <Value>com.sun.identity.sm.RequiredValueValidator</Value>
    </DefaultValues>
  </AttributeSchema>
  <AttributeSchema any="required" cosQualifier="default"
    i18nKey="x4001" isSearchable="no"
    name="sunIdRepoClass" syntax="string"
    type="single" validator="RequiredValueValidator" >
    <DefaultValues>
    <Value>org.test.CustomRepo</Value>
    </DefaultValues>
  </AttributeSchema>
  <AttributeSchema cosQualifier="default" i18nKey="x4002" isSearchable="no"
    name="sunIdRepoAttributeMapping" syntax="string" type="list">
    <DefaultValues>
    <Value></Value>
    </DefaultValues>
  </AttributeSchema>
</SubSchema>
```

Also include the `AttributeSchema` required to configure your IdRepo plugin.

Notice the `i18nKey` attributes on `SubSchema` elements. The `i18nKey` attribute values correspond to properties in the `amIdRepoService.properties` file under `WEB-INF/classes/` where AM is deployed. The AM console displays the label for the configuration user interface that it retrieves from the value of the `i18nKey` property in the `amIdRepoService.properties` file.

To make changes to the properties, first extract `amIdRepoService.properties` and if necessary the localized versions of this file from `openam-core-6.5.5.jar` to `WEB-INF/classes/` where AM is deployed. For example, if AM is deployed under `/path/to/tomcat/webapps/openam`, then you could run the following commands.

```
$ cd /path/to/tomcat/webapps/openam/WEB-INF/classes/
$ jar -xvf ../lib/openam-core-6.5.5.jar amIdRepoService.properties
inflated: amIdRepoService.properties
```

Register your plugin using the `ssoadm` command after copy the files into place.

```
$ ssoadm \  
  add-sub-schema \  
    --adminid amadmin \  
    --password-file /tmp/pwd.txt \  
    --servicename sunIdentityRepositoryService \  
    --schematype Organization \  
    --filename customIdRepo.xml
```

Log in to the AM console as administrator, then browse to Realms > *Realm Name* > Identity Stores. In the Identity Stores table, click Add Identity Store to create a store corresponding to your custom IdRepo plugin. In the first screen of the wizard, name the Data Store and select the type corresponding to your plugin. In the second screen of the wizard, add the configuration for your plugin.

After creating the identity store, create a new identity in the realm to check that your plugin works as expected. You can do this under Realms > *Realm Name* > Identities.

If your plugin supports authentication, then users should now be able to authenticate using the [DataStore](#) module for the realm, by using a URL similar to the following:

```
https://openam.example.com:8443/openam/XUI/?realm=/myrealm&module=DataStore#login
```

Setting Up External Data Stores

In addition to the identity store, AM allows you to configure external data stores for different types of data.

Depending on the characteristics of the different data types, it can be beneficial to store them separately from other data types, for example to allow specific tuning of the indexes in the directory server.

AM supports configuration of external data stores for the following data types:

- UMA data.

Provides storage for UMA-related data, such as resources, labels, and pending requests.

For information on setting up external UMA stores, see "Configuring UMA Stores" in the *User-Managed Access (UMA) 2.0 Guide*.

- Core Token Service (CTS) data.

Provides highly available storage for sessions and tokens used by AM.

For information on setting up external CTS stores, see "Configuring CTS in AM" in the *Installation Guide*.

- Policy data.

Provides storage for policy-related data, such as policies, policy sets, and resource types.

Warning

If you change the policy data store, the built-in policy sets and resource types will no longer be available in the realm where you made the change. Either recreate these items manually, or use **Amster** to export them, then import them back after changing to an external store.

For information on setting up external policy stores, see "Setting Up External Policy and Application Stores."

- Application data.

Provides storage for application-related data, such as web and Java agent configuration, federation entities and configuration, and OAuth 2.0 clients definitions.

For information on setting up external application stores, see "Setting Up External Policy and Application Stores."

Setting Up External Policy and Application Stores.

This section covers setting up external policy and application stores in AM.

This section assumes you have already installed the directory server instances you will be configuring in AM as external policy or application stores. For information on how to install an external directory server instance, see "Preparing Policy and Application Stores" in the *Installation Guide*.

Setting up an external policy and/or application store in AM requires two procedures:

1. Configuring the connection between AM and the external directory server.

See "To Connect AM to an External Policy or Application Store".

2. Enabling a realm to use the newly configured directory server.

See "To Enable a Realm to use an External Policy or Application Store".

To Connect AM to an External Policy or Application Store

Perform the steps in this procedure to add a connection in AM to the external policy or application store.

1. In the AM console, navigate to Configure > Global Services > External Data Stores.

2. On the Secondary Configurations tab, click Add a Secondary Configuration.

3. Complete the form as follows:

- a. In the Name field, provide a name for the external data store, for example, **myPolicyStore**

- b. In the Host Urls field, enter one or more connection strings to the external stores to use. The format for each connection string is `HOST:PORT`, for example `policies1.example.com:636`.

AM will use the first connection string in the list, unless the server is unreachable, in which case it will try the subsequent connection strings in the order they are defined.

- c. Enter the Bind DN and Bind Password needed to authenticate to the external data store. The account needs sufficient privileges to read and write to the root suffix of the external data store.
- d. Specify whether to use SSL and/or Start TLS connectivity to the external data store by enabling the relevant option.
- e. Specify whether to access the external data stores by using multiple directory instances in an affinity deployment, rather than a single master directory instance using an active/passive deployment.

If you enable this option, specify each of the directory server instances that form the affinity deployment in the Host Urls field.

4. To save your changes, click Create.

AM will attempt to contact the data store using the specified settings. If successful, AM will attempt to make the required schema and structure changes in the data store. If the user specified in the Bind DN property does not have permissions to alter schema and structure, you will need to manually apply the required settings. See *"Preparing External Stores"* in the *Installation Guide*.

If AM was able to contact the data store using the specified settings, the connection is saved and made available for use as an external policy or application store.

5. (Optional) To edit the connection settings to an external store, perform the following steps:
 - a. On the Secondary Configuration tab, click the name of the data store.
 - b. Edit the configuration as required, and then click Save Changes.
6. (Optional) Repeat the steps above to add any additional external policy or application stores.

You can now continue on to "To Enable a Realm to use an External Policy or Application Store".

To Enable a Realm to use an External Policy or Application Store

Perform the following steps to configure a realm in AM to use an external policy or application store.

Important

Changing the policy or application store will cause any existing policies or applications to become unavailable to the realm.

Either recreate the policies or applications manually, or use Amster to export the existing instances, then import them back after changing to external stores.

1. In the AM console, navigate to Realms > *Realm name* > Services.
2. Configure the External Data Stores service in the realm:
 - If the External Data Stores service has not yet been added to the realm, click Add a Service, and then select External Data Stores.
 - If the External Data Stores service has already been added to the realm, click External Data Stores to edit the configuration.
3. On the External Data Stores page, select the name of the external store to use as the Policy Data Store and/or Application Data Store, and then click Save Changes.

Note

If you choose the **Default Datastore** option for either property, AM will resort to using the configuration data store that was specified during the installation of AM. The default configuration data store may be an embedded instance, or an external instance. For more information on installing an AM server, see "Installing a Single Server" in the *Installation Guide*.

Changes take effect immediately. New policies or applications are created in the relevant external data store, if configured.

To Remove an External Policy or Application Store

To remove an external policy or application store from AM it cannot be in use by any realm.

Perform the following steps to remove an external policy or application store from a realm in AM, and delete a store from the AM instance.

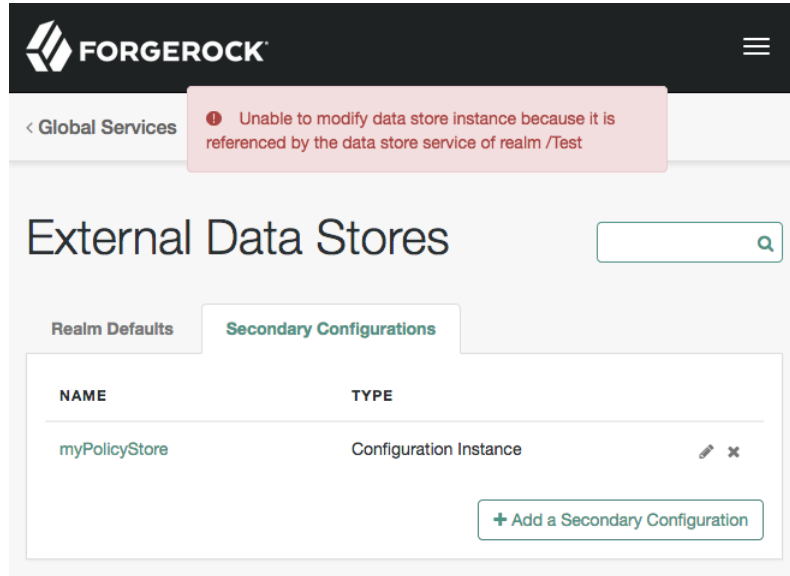

1. For each realm that is using the store, in the administration console, navigate to Realms > *Realm Name* > Services > External Data Stores, and change each of the drop-downs to either **Default Datastore**, or an alternative external data store.

Save your changes.

2. Navigate to Configure > Global Services > External Data Stores > Secondary Configurations. Click the name of the store to remove, and click the delete icon.

If the external data store is still in use, you will see an error message as follows:

```
Unable to modify data store instance because it is referenced by the data store service of
realm /Realm Name
```

The screenshot shows the ForgeRock Admin console interface. At the top, there is a navigation bar with the ForgeRock logo and a hamburger menu icon. Below the navigation bar, there is a breadcrumb trail: < Global Services. A red error message box is displayed, containing the text: "Unable to modify data store instance because it is referenced by the data store service of realm /Test". The main content area is titled "External Data Stores" and includes a search input field. Below the title, there are two tabs: "Realm Defaults" and "Secondary Configurations". The "Secondary Configurations" tab is active, showing a table with the following data:

NAME	TYPE	
myPolicyStore	Configuration Instance	 

Below the table, there is a button labeled "+ Add a Secondary Configuration".

If you receive the error, repeat the first step to remove the external store from the listed realm, and then repeat this step.

Chapter 4

Setting Up Agent Profiles

You install web or Java agents in web servers and web application containers to enforce access policies AM applies to protected web sites and web applications. Web and Java agents depend on AM for all authentication and authorization decisions. Their primary responsibility consists of enforcing what AM decides in a way that is unobtrusive to the user. In organizations with many servers, you might well install many web or Java agents.

Web or Java agents can have local configurations where they are installed. Typically, you store all agent configuration information in the AM configuration store, defining agent profiles for each, and then you let the web or Java agents access their profiles through AM. In this way, you manage all agent configuration changes centrally. This chapter describes how to set up agent profiles in AM for centralized configuration.

Identity Gateway or AM Web and Java Agents?

ForgeRock Identity Gateway and the AM web and Java agents can both enforce policy, redirecting users to authenticate when necessary, and controlling access to protected resources. IG runs as a self-contained reverse proxy located between the users and the protected applications. Web and Java agents are installed into the servers where applications run, intercepting requests in that context.

Use IG to protect access to applications not suited for a web or Java agent, for example, those applications deployed on operating systems or web servers or containers not supported by the agents.

Web and Java agents have the advantage of sitting within your existing server infrastructure. Once you have agents installed into the servers with web applications or sites to protect, then you can manage their configurations centrally from AM.

For organizations with both servers on which you can install web and Java agents and also applications that you must protect without touching the server, you can use agents on the former and IG for the latter.

Types of Agent

You can configure a number of different types of agents.

Each agent type requires an *agent profile* in AM. The agent profile contains essential configuration for agent operation, such as a password to authenticate the agent, and the URL the agent resides at.

For agents that support it, the agent profile can store all agent configuration centrally, rather than locally on the agent server.

Web and Java agents are the most common, requiring the least integration effort. The available agent types are:

Web

You install web agents in web servers to protect web sites.

Java

You install Java agents in web application containers to protect web applications.

Agent Authenticator

The agent authenticator can read agent profiles by connecting to AM with a user name, password combination, but unlike the agent profile administrator, cannot change agent configuration.

SOAP STS Agent

Secure requests from a SOAP STS deployment to AM using this type of agent profile.

Creating Agent Profiles

A web or Java agent requires a profile to connect to and communicate with AM, regardless of whether it is stored centrally in AM or on the agent server.

To Create an Agent Profile in AM Using the Console

Create an agent profile using the AM console by performing the following steps:

1. In the AM console, navigate to **Realms > Realm Name > Applications > Agents > Agent Type**, and then select the **Add Agent Type Agent** button in the Agent tab.
2. Complete the web form using the following hints:

Agent ID

The ID of the agent profile. This ID is used during the agent installation.

Agent URL

The URL the web or Java agent protects. For example, for web agents: `http://www.example.com:80`, and for java agents: `http://www.example.com:80/agentapp`.

In centralized configuration mode, the Agent URL is used to populate the agent profile for services, such as notifications.

Server URL

The full URL to an AM instance. If AM is deployed in a site configuration (behind a load balancer), enter the site URL.

In centralized configuration mode, Server URL is used to populate the agent profile for use with login, logout, naming, and cross-domain SSO.

Password

The password the agent uses to authenticate to AM. Use this password when installing an agent.

Agent ID	<input type="text" value="MyPolicyAgent"/>
Agent URL	<input type="text" value="http://www.openam.example.com:8080/openam"/>
Server URL	<input type="text" value="http://openam.example.com:8080/openam"/>
GLOBAL	
Password	<input type="password" value="....."/>
<input type="button" value="Cancel"/> <input type="button" value="Create"/>	

To Create an Agent Profile Using the `ssoadm` Command

You can create a web or Java agent profile in AM using the **ssoadm** command-line tool. You do so by specifying the agent properties either as a list of attributes, or by using an agent properties file as shown below. Export an existing agent configuration before you start to see what properties you want to set when creating the agent profile.

Perform the following steps to create a web or Java agent profile using the **ssoadm** command:

1. Make sure the **ssoadm** command is installed. See "Setting Up Administration Tools" in the *Installation Guide*.
2. Determine the list of properties to set in the agent profile.

The following properties file shows a minimal configuration for an agent profile:

```
$ cat myAgent.properties
com.ipplanet.am.server.port=8443
com.sun.identity.agents.config.agenturi.prefix=http://www.example.com:80/amagent
com.sun.identity.agents.config.cdsso.cdcervlet.url[0]= \
https://openam.example.com:8443/openam/cdcervlet
com.sun.identity.agents.config.fqdn.default=www.example.com
com.sun.identity.agents.config.login.url[0]= \
http://openam.example.com:8443/openam/XUI/#login
com.sun.identity.agents.config.logout.url[0]= \
http://openam.example.com:8443/openam/XUI/#logout
com.sun.identity.agents.config.remote logfile=amAgent_www_example_com_80.log
com.sun.identity.agents.config.repository.location=centralized
com.sun.identity.client.notification.url= \
http://www.example.com:80/UpdateAgentCacheServlet?shortcircuit=false
sunIdentityServerDeviceKeyValue[0]=agentRootURL=http://www.example.com:80/
sunIdentityServerDeviceStatus=Active
userpassword=password
```

3. Create a password file, for example `$HOME/.pwd.txt`. The file should only contain the password string, on a single line.

The password file must be read-only for the user who creates the agent profile, and must not be accessible to other users:

```
$ chmod 400 $HOME/.pwd.txt
```

4. Create the agent profile, specifying `--agenttype JavaAgent` for Java agents or `--agenttype WebAgent` for web agents:

```
$ ssoadm create-agent \
--realm / \
--agentname myAgent \
--agenttype JavaAgent | WebAgent \
--adminid amadmin \
--password-file $HOME/.pwd.txt \
--datafile myAgent.properties
Agent configuration was created.
```

5. Review the new profile in the AM console under Realms > *Realm Name* > Applications > Agents > *Agent Type* > *Agent Name*.

To Create an Agent Profile Group and Inherit Settings

Agent profile groups let you set up multiple agents to inherit settings from the group. To create a new agent profile group, perform the following steps:

1. In the AM console, navigate to Realms > *Realm Name* > Applications > Agents > *Agent Type*.
2. Select Add Group from the Groups tab, and provide an ID for the group and the URL to the AM server in which to store the profile.

After creating the group profile, you can select the link to the new group profile to fine-tune or export the configuration.

3. Inherit group settings by selecting your agent profile, and then selecting the group name from the Group drop-down list near the top of the profile page.

You can then adjust inheritance by clicking Inheritance Settings on the OpenAM Services agent profile tab.

Delegating Agent Profile Creation

If you want to create agent profiles when installing web or Java agents, then you need the credentials of an AM user who can read and write agent profiles.

You can use the AM administrator account when creating agent profiles. If you delegate web or Java agent installation, then you might not want to share AM administrator credentials with everyone who installs agents.

To Create Agent Administrators for a Realm

Follow these steps to create *agent administrator* users for a realm:

1. In the AM console, browse to Realms > *Realm Name* > Identities.
2. On the Groups tab, click Add Group and create a group for agent administrators.
3. On the Privileges tab, select Realm Admin, and Save your changes.
4. Navigate to Realms > *Realm Name* > Identities. On the Identities tab, create as many agent administrator users as needed.
5. For each agent administrator user, edit the user profile.

On the Groups tab of the user profile, add the user to agent profile administrator group, and then Save your work.

6. Provide each system administrator who installs web or Java agents with their agent administrator credentials.

When installing Java agents with the `--custom-install` option, the system administrator can choose the option to create the profile during installation, and then provide the agent administrator user name and the path to a read-only file containing the agent administrator password. For silent installs, you can add the `--acceptLicense` option to auto-accept the software license agreement.

Configuring AM Web Agents

When you create a web agent profile and install the agent, you can choose to store the agent configuration centrally and configure the agent through the AM console. Alternatively, you can choose to store the agent configuration locally and configure the agent by changing values in

the properties file. For information on the properties used in a centralized configuration, and the corresponding properties for use in a local configuration file where applicable, see the Web Policy Agent documentation.

Configuring Java Agents

When you create a Java agent profile and install the agent, you can choose to store the agent configuration centrally and configure the agent through the AM console. Alternatively, you can store the agent configuration locally and configure the agent by changing values in the properties file. For information on the properties used in a centralized configuration, and the corresponding properties for use in a local configuration file where applicable, see [Create Agent Profiles](#) in the Java Policy Agent documentation.

Configuring Agent Authenticators

An *agent authenticator* has read-only access to multiple agent profiles defined in the same realm, typically allowing an agent to read web service agent profiles.

After creating the agent profile, you access agent properties in the AM console under *Realms > Realm Name > Applications > Agents > Agent Authenticator > Agent Name*.

Password

Specifies the password the agent uses to connect to AM.

Status

Specifies whether the agent profile is active, and so can be used.

Agent Profiles allowed to Read

Specifies which agent profiles in the realm the agent authenticator can read.

Agent Root URL for CDSSO

Specifies the list of agent root URLs for CDSSO. The valid value is in the format *protocol://hostname:port/* where *protocol* represents the protocol used, such as *http* or *https*, *hostname* represents the host name of the system where the agent resides, and *port* represents the port number on which the agent is installed. The slash following the port number is required.

If your agent system also has virtual host names, add URLs with the virtual host names to this list as well. AM checks that *goto* URLs match one of the agent root URLs for CDSSO.

Configuring SOAP STS Agents

A SOAP STS deployment accesses AM using a SOAP STS agent.

After creating the agent profile, you access agent properties in the AM console under Realms > *Realm Name* > Applications > Agents > SOAP STS Agent > *Agent Name*. For information on the available properties, see "Creating a SOAP STS Agent" in the *Security Token Service Guide*.

Chapter 5

Configuring Secrets, Certificates, and Keys

Encryption makes it possible to protect sensitive data, encoding it in such a way that only authorized parties can access it.

Signing allows the receiver of a piece of data to validate the sender's identity and ensures that the data has not been tampered with.

AM depends on signing and encryption to protect network communication and to keep data confidential and unalterable. In turn, signing and encryption depend on keys or secrets, which are generated using cryptographic algorithms.

AM uses the following methods to store keys or secrets:

- **The AM keystore.** Used by some features, it can be configured globally so its configuration is shared by any AM instance in a deployment, or individually per server.

AM also uses this keystore to start up.

During installation, AM deploys a JCEKS and a JKS keystore with several self-signed key aliases, for demo and test purposes only.

- **AM secret stores.** Introduced in 6.5, secret stores are repositories for cryptographic keys and credentials. They can be configured globally, so the configuration is shared by any instance in the site, or by realm.

Note

AM is migrating features from using the AM keystore to use secret stores.

AM supports configuring JVM system properties, key aliases stored in keystores or HSM, or files stored in filesystems or secret volumes, as secrets.

Keystore and Secret Store Configuration After Upgrade

After an upgrade to AM 6.5, keystores and secret stores are deployed and configured depending on the circumstances at the time of the upgrade.

Keystore Changes After Upgrade

• Upgrading from OpenAM

- If OpenAM had a JCEKS keystore configured in Configure > Server Defaults > Security > Key Store at the time of the upgrade, the password strings described in "About the Default JCEKS and JKS Keystore Keys and Aliases" are appended to the existing JCEKS keystore.

The upgrade process creates the `boot.json` bootstrap file, and AM uses it to start up.

The contents of the `.storepass` and the `.keypass` files are converted to cleartext.

- If OpenAM had a JKS keystore configured in > Server Defaults > Security > Key Store at the time of the upgrade, the JCEKS keystore is *not* used, and the upgrade process will *not* create the `boot.json` bootstrap file. AM continues starting in the legacy way.

The contents of the `.storepass` and the `.keypass` files are still encrypted with the AM encryption key.

• Upgrading from AM 5 or later

No keystore changes are required.

The upgrade process does not convert keys from an old keystore to a new one.

Secret Store Changes After Upgrade

• Upgrading from AM 6 or earlier

The upgrade process configures several global secret stores. Additionally, the process also configures realm-level secret stores as required.

Note that the stores are only created in the AM server where you run the upgrade process. For more information, see "To Redeploy Secret Stores to a Site After Upgrade" in the *Upgrade Guide*.

About the Default Keystores and Secret Stores

During installation, AM deploys a JKS and a JCEKS keystore with several self-signed key aliases for demo and test purposes only.

Both the AM keystore and the default secret stores use the default JCEKS keystore. The JKS keystore is not used by default, and can be safely deleted.

Do not use the default keys, keystores, and secret stores in production environments.

About the Default JCEKS and JKS Keystore Keys and Aliases

	JCEKS	JKS
Used by default in AM?	Yes ^a	No
In which path is it?	<code>/path/to/openam/openam/keystore.jceks</code>	<code>/path/to/openam/openam/keystore.jks</code>
Where is its password stored? ^b	<code>/path/to/openam/openam/.storepass</code>	<code>/path/to/openam/openam/.storepass</code>
Which test aliases does it contain?	<code>es256test</code> ^c <code>es384test</code> ^c <code>es512test</code> ^c <code>hmacsigningtest</code> ^d <code>directenctest</code> ^e <code>rsajwtsigningkey</code> ^f <code>selfserviceenctest</code> ^f <code>selfservicesigntest</code> ^g <code>test</code> ^f	<code>test</code> ^f
Which password strings does it contain?	<code>configstorepwd</code> ^h <code>dsameuserpwd</code> ⁱ	None
Where is the private key password file? ^j	<code>/path/to/openam/openam/.keypass</code>	<code>/path/to/openam/openam/.keypass</code>

^a New AM installations use the JCEKS keystore as the default keystore. For more information about upgraded configurations, see "Keystore and Secret Store Configuration After Upgrade".

^b The password of the JCEKS and JKS keystores is a random-generated string stored in cleartext.

^c ECDSA key.

^d Symmetric HMAC key.

^e Symmetric Direct AES encryption key.

^f Asymmetric RSA key.

^g Symmetric secret signing key.

^h The value of the `configstorepwd` is a string. It is the password of the configuration store, which is accessed during AM startup.

ⁱ The value of the `dsameuserpwd` is a string. It is the password of a reserved service account, which is accessed during AM startup.

^j The password for all the key aliases in the JCEKS and JKS keystores is `changeit`, stored in cleartext.

About the Default Secret Stores

- `default-keystore`. This keystore-type secret store is mapped to the default JCEKS keystore.

It also contains ID mappings for several of the AM features that use keys.

For more information about the mappings, see "Secret ID Mapping Defaults".

- **default-password-store**. This filesystem-type secret store is mapped to `/path/to/openam/secrets/encrypted` and it is used to provide the passwords to open the **default-keystore** secret store:
 - The **storepass** file contains the encrypted password of the keystore.
 - The **entrypass** file contains the encrypted password of the keys inside the keystore.

Note

This password configuration is very similar to the one for the default JCEKS keystore. However, the files are different. While the password files for the JCEKS are in cleartext, the password files for the default secret store are encrypted with AM's encryption key.

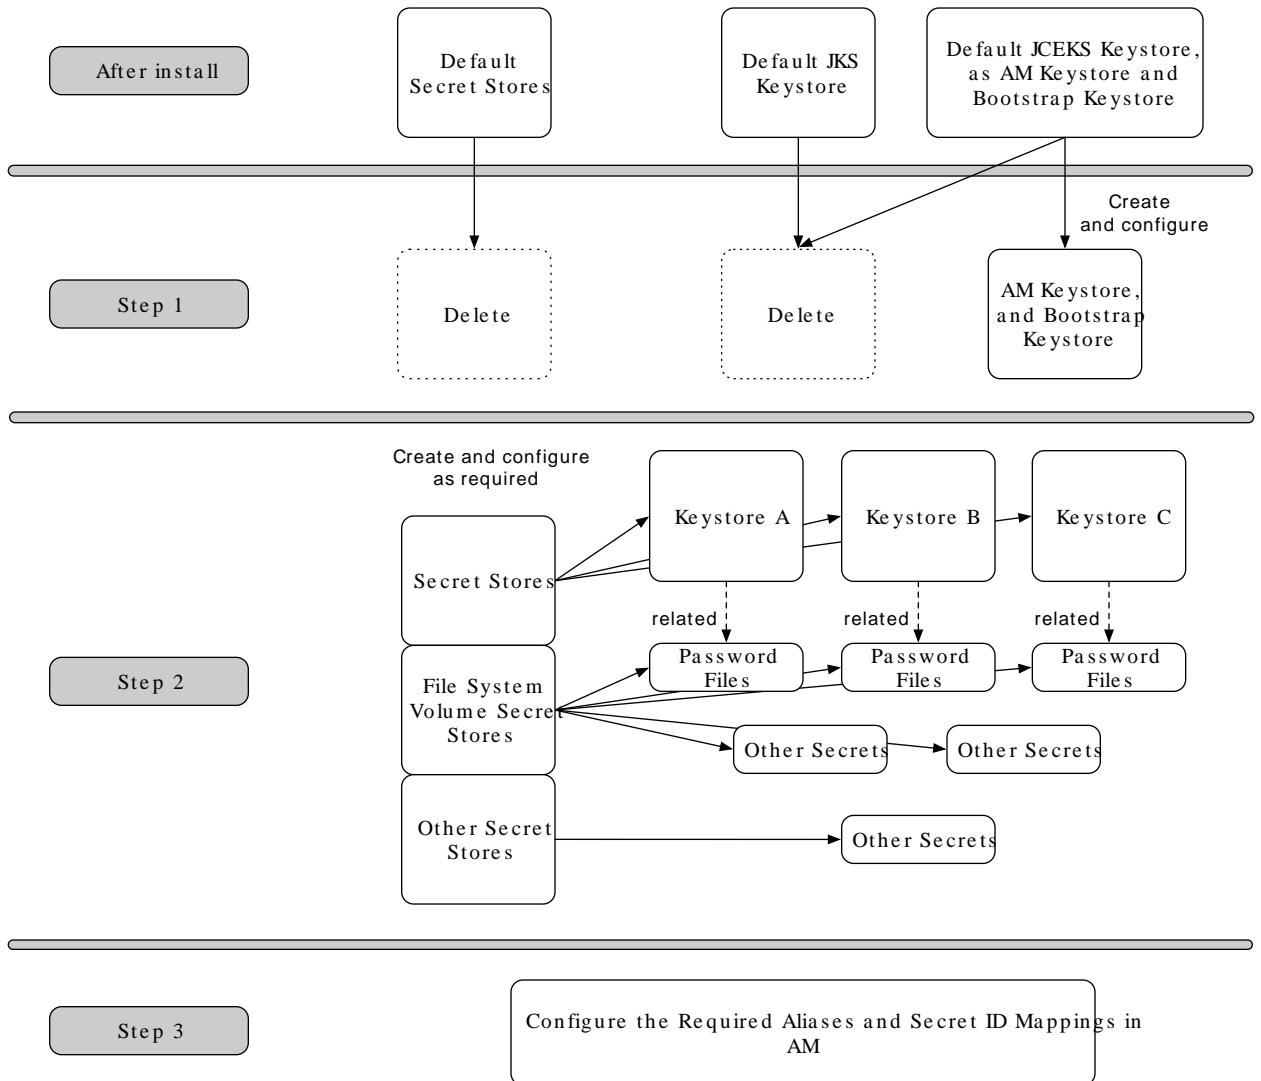

Take into account that the keystore file is the same, which means that if you change the passwords for the JCEKS keystore, you must change them in the default secret store as well.

Tasks to Configure Keystores and Secret Stores

The provided keystores and secret stores are sufficient for testing and demonstrating AM features.

For production and pre-production environments, configure the keystores and secret stores that your environment will use *before* configuring the AM features that use them.

High-Level Steps to Configure Keystores and Secret Stores in Production Environments

The following table guides you through the tasks you need to perform to configure the keys and secrets AM requires:

Task	Resources
Understand AM's Secret Needs	<ul style="list-style-type: none"> "Features in AM That Use Keys"

Task	Resources
<p>Review the list of features that use keys in AM, and their possible keystore and secrets configurations.</p>	
<p>Create a new AM Keystore and Configure It</p> <p>Create and configure a new AM keystore, which will also serve as the AM bootstrap keystore, and delete the default keystores and secret stores.</p>	<ul style="list-style-type: none"> • "Managing the AM Keystore"
<p>Create Secrets as Needed</p> <p>Create as many keystores, key aliases, and/or secrets as required in your environment based on the information you learned when you reviewed the list on the first task. You will configure them in AM in the next steps.</p> <p>Keys and secrets protect the credentials, tokens, and other sensitive information that your environment needs to send and receive. Therefore, ensure that keys and secrets are protected and only shared when required. This may result in configuring multiple keystores and/or secret stores for different features.</p> <p>Do not reuse passwords among keystores or secret stores. This will reduce the amount of compromised keys or secrets if a malicious user is able to leverage one of the passwords.</p>	<ul style="list-style-type: none"> • "Managing Key Aliases and Passwords"
<p>Configure Secret Stores in AM</p> <p>Create new secret stores to map the relevant new keys you created in previous tasks, for example, those for the OAuth 2.0 providers.</p>	<ul style="list-style-type: none"> • "Configuring Secret Stores"
<p>Make Available the Keystores and Secret Stores to All AM Instances</p>	<p>Keystores and secret stores must be available in the same location across of all of the instances.</p> <p>This step may mean mounting a filesystem with the required files across the instances, installing cryptographic cards, and others, if not done already.</p>
<p>Configure Key Aliases and Secrets in AM</p> <p>Change the pre-configured key aliases and secrets with those created in the previous tasks.</p>	<ul style="list-style-type: none"> • "Changing Default Key Aliases" • "Mapping Secrets"

Features in AM That Use Keys

Most features that require storing secrets for signing or encryption use the AM keystore, which is configured by navigating to **Configure > Server Defaults > Security > Key Store**. However, some features may require or support different configurations:

Features that only use the AM keystore

- **SAML v1.x**

Requires one key pair alias for signing XML files. For more information, see "Preparing To Secure SAML v1.x Communications" in the *SAML v1.x Guide*.

- **User self-service**

Requires a JCEKS keystore with a key pair alias for encryption and a key alias for signing. For more information, see "Creating a User Self-Service Service Instance" in the *User Self-Service Guide*.

- **Client-based sessions**

Requires an key pair alias for encryption and a key pair alias for signing. For more information, see "Configuring Client-Based Session and Authentication Session Security" in the *Authentication and Single Sign-On Guide*.

- **Persistent Cookie nodes (authentication trees)**

Requires a key pair alias for encryption. For more information, see "Set Persistent Cookie Node" in the *Authentication and Single Sign-On Guide*.

- **Amster**

Requires a `sms.transport.key` key alias to export and import encrypted passwords. For more information, see the *Amster Command-line Interface Guide*.

- **IDM user self-registration**

Requires copying signing and encryption keys from the IDM installation into the AM keystore. For more information, see "To Delegate User Self-Registration to IDM" in the *User Self-Service Guide*.

Features that use secret stores

- **Web and Java agents**

Web Agents and Java Agents communicate with AM using a built-in OAuth 2.0 provider configured globally in AM. This communication requires a key alias for signing tokens. For more information, see the Web Policy Agents documentation and the Java Policy Agents documentation.

- **OAuth 2.0 providers**

Requires a key alias for signing client-based tokens and OpenID Connect ID tokens. For more information, see "Configuring Client-Based OAuth 2.0 Token Digital Signatures" in the *OAuth 2.0 Guide* and "Configuring Digital Signatures" in the *OpenID Connect 1.0 Guide*.

Also requires a key alias for direct authentication encryption of client-based OAuth 2.0 access and refresh tokens. For more information on enabling encryption, see "Configuring Client-Based OAuth 2.0 Token Encryption" in the *OAuth 2.0 Guide*.

- **Persistent cookie modules (authentication chains)**

Requires a key pair alias for encryption. For more information, see "Persistent Cookie Module" in the *Authentication and Single Sign-On Guide*.

- **Remote Consent Service**

Requires a key alias for signing consent responses, and another key alias for encrypting consent responses. For more information, see "OAuth 2.0 Remote Consent Service" in the *OAuth 2.0 Guide*.

- **Authentication trees**

Requires a key alias to encrypt values stored in the authentication tree's secure state. For more information, see " Storing Secret Values in Transient Tree State " in the *Authentication Node Development Guide*.

- **SAML v2.0 browser-based JWT**

Requires a 256-bit symmetric key to encrypt the JWT stored in the local storage of supported browsers. The JWT tracks SAML v2.0 single sign-on progress in multi-instance deployments. For more information, see "Session State Considerations" in the *SAML v2.0 Guide*.

For a list of the secret ID mappings, see "Secret ID Mapping Defaults".

Features that support different keystore configurations:

- **AM's startup (bootstrap) process**

Requires two password strings. ForgeRock recommends that you use the AM keystore as the bootstrap keystore, but you can configure a bootstrap keystore as long as:

- You keep the password strings updated.
- You overwrite the `boot.json` file before AM starts up.

For more information, see "To Replace the AM Keystore".

- **ForgeRock Authenticator (OATH), ForgeRock Authenticator (PUSH) modules, and the WebAuthn Profile Encryption Service**

Supports configuring a different keystore to encrypt device profiles. They also support different keystore types that are not available to other features. For more information, see "About Multi-Factor Authentication" in the *Authentication and Single Sign-On Guide*.

- **SAML v2.0 providers**

Requires key pairs in the AM keystore to configure signing or encryption. However, they support setting up a specific password for the key pair instead of using the AM keystore password file. For more information, see "SAML v2.0 Configuration Properties" in the *SAML v2.0 Guide*.

Also requires a key pair in the AM keystore to sign entity metadata when using the `exportmetadata.jsp` page or the `ssoadm` command. The key pair can have a password different from that stored in the AM keystore password file.

Features that require different keystore configurations:

- **Java Fedlets**

Require a keystore containing a key pair to sign and verify XML assertions and to encrypt and decrypt SAML assertions. Keystore and key information are configurable in the `FederationConfig.properties` file. For more information, see "Configuring Java Fedlet Properties" in the *SAML v2.0 Guide*.

- **Security Token Service**

Requires configuring a JKS keystore for encrypting SAML v2.0 and OpenID Connect tokens. It does not require files to store the keystore password or the key aliases' passwords. For more information, see "Implementing STS Using the AM Console" in the *Security Token Service Guide*.

- **CSV audit logging handler**

Requires configuring a keystore for tamper-proofing. It does not require a file to store the keystore password; the password is configured in the AM console. For more information, see "Configuring CSV Audit Event Handlers".

Tip

If you are creating your own custom components or plugins, you can implement the `SecretIdProvider` interface for exposing your own custom secrets.

For more information, see the AM 6.5.5 Public API Javadoc.

Managing the AM Keystore

By default, AM installations provide a JCEKS keystore containing several test-only key aliases that are preconfigured in AM.

For production deployments, generate a new keystore with the key aliases you need to use.

Consider the following points before starting:

- Different AM features support different keystore configurations, and some features do not use the default keystore to store their key aliases. For more information, see "Features in AM That Use Keys".
- Key aliases are not migrated from one keystore to another when changing the keystore configuration in AM. You must prepare the new keystore as required before configuring it.
- You must restart AM if you make any changes to the keystore. Changes are, for example, adding or removing keys or changing key or keystore passwords.

Tasks:

- To create a new AM keystore, see "To Replace the AM Keystore".
- To modify the AM keystore configuration without changing the content of the file, see "To Modify the AM Keystore Properties".

About the AM Keystore and the Startup Process

The AM startup process checks a file, called `boot.json`, that contains the settings AM requires to bootstrap. Among these settings are the path to a keystore file and the files containing the keystore and key passwords.

During the startup process, AM needs to find the following aliases inside the keystore configured in the `/path/to/openam/boot.json` file:

configstorepwd

An alias for the password of the AM configuration store. The alias is password-protected, with the password specified by default in the `/path/to/openam/openam/.keypass` file.

To update the value of this alias, navigate to Deployment > Servers > Server Name > Directory Configuration, and modify the configuration store bind password. Every time you change the bind alias, AM modifies the content of the key alias in the keystore file.

dsameuserpwd

An alias for the password of a special user required at AM startup time. The alias is password-protected, with the password specified by default in the `/path/to/openam/openam/.keypass` file.

These strings cannot be recreated manually, but AM will recreate them in a new keystore after a successful start.

The key to successfully changing the AM/bootstrap keystore is to configure the new AM keystore, and restart AM while the old keystore is still accessible. The boot process will use the original keystore for booting up, write the password strings in the new keystore, and rewrite the `boot.json` file.

To Replace the AM Keystore

The AM keystore provides secrets to several features of AM, as explained in "Features in AM That Use Keys", but it also lets AM start up.

Perform the steps in this procedure to create a new keystore containing the password strings that AM needs to start up, and configure it as the new AM keystore:

1. Ensure that AM is running, and that you can access its console as an administrative user.
2. Acquire a new key from your certificate authority and add it to a new keystore, or generate a new self-signed key in a new keystore.

Create the keystore in a directory of your choosing. This directory should be the same for all the instances in the site. For example, `/path/to/openam/openam`.

This example creates a self-signed key alias in a new keystore file, `am_keystore.jceks`, with a new asymmetric RSA key alias, `newkey`.

Note that in production environments, you should use the strongest algorithm you can.

```
$ keytool \  
-genkeypair \  
-alias newkey \  
-keyalg RSA \  
-keysize 2048 \  
-validity 730 \  
-storetype JCEKS \  
-dname 'CN=newkey' \  
-keystore am_keystore.jceks  
Enter keystore password:  
Reenter new password:  
Enter key password for <newkey>  
(RETURN if same as keystore password):  
Reenter new password:
```

Take note of the passwords you entered.

3. Store the keystore passwords in *cleartext* in a directory of your choosing.

This directory should be the same for all the instances in the site. For example, `/path/to/openam/openam`.

For example:

```
$ echo -n newstorepassword > .am_keystore_storepass  
$ echo -n newkeypassword > .am_keystore_keypass
```

Use **echo -n** to avoid inserting hidden trailing newline characters. Even if the **keytool** command is able to use the password in the file, AM may not be able to open the keystore or the key aliases.

4. Make sure the password files have read-only permission for their owner. For example:

```
$ chmod 400 .am_keystore_storepass  
$ chmod 400 .am_keystore_keypass
```

5. Configure the new keystore as the AM keystore in the site. Follow the steps in "To Modify the AM Keystore Properties".

Once AM starts, the new keystore contains the password strings that AM uses to start up. You can delete the default JCEKS keystore now. The default secret stores also use the JCEKS keystore. You can also delete them now.

To Modify the AM Keystore Properties

To modify the AM keystore configuration, perform the following steps:

1. In the AM console, navigate to Configure > Server Defaults > Security > Key Store.
2. Enter the keystore file name and path in the Keystore File field. For example, `/path/to/openam/openam/am_keystore.jceks`.
3. Enter the Keystore Type. For example `JKS`, `JCEKS`, `PKCS11`, or `PKCS12`.
4. In the Keystore Password File field, enter the location of the keystore password file. For example, `/path/to/openam/openam/.am_keystore_storepass`.
5. In the Private Key Password File field, enter the location of the private key password file. For example, `/path/to/openam/openam/.am_keystore_keypass`.
6. Save your changes.

At this point, AM still holds the old keystore configuration in memory, and cannot use key aliases contained in the new keystore.

7. (Optional) If you need to change key aliases in the AM configuration, decide whether to change them before or after restarting the AM instances in the next step.

If you are using client-based sessions, ensure the signing key exists in the new keystore. You can check the configuration for client-based sessions by navigating to Realms > *Realm Name* > Authentication > Settings > Security.

To configure the rest of the features that need key aliases before or after the restart, see "Changing Default Key Aliases".

8. Make the new keystore files available in the same location to all the instances in the site.

This step may mean mounting a filesystem with the required files across the instances, copying the files across instances, and others.

9. Restart the AM instance or instances.

The new default keystore and its keys are ready to use.

Managing Key Aliases and Passwords

Whether you need to create new key aliases because you are using more AM features or because you are installing a new environment, consider the following points:

- Review the list of features in AM to understand which features use the AM keystore and which ones do not, then manage your secrets accordingly. You should avoid sharing certificates among features when possible, which may result in configuring different keystores or secret stores.

For more information, see "Features in AM That Use Keys".

- Make sure keystores, key aliases, and certificates are maintained on every instance; in a site environment, every instance has its own keystore files.
- Make sure keystores and secret stores are in the same location across of all of the instances in the site.

The following table contains a list of the tasks you may need to perform when managing key aliases in your environment:

Task	Resources
Create new key alias in an existing keystore or in a new keystore	"Creating Key Aliases"
Copy key aliases between keystores; for example, when configuring IDM's provisioning.	"Copying Key Aliases"
Change key alias passwords.	"Changing Key Alias Passwords"
Change keystore passwords.	"Changing Keystore Passwords".

Creating Key Aliases

Several AM features require key aliases for signing and encryption. New AM installations pre-configure default key aliases for all of the features, but you should create new key aliases for each of them.

You can create key aliases in a new keystore that, for example, will be configured later as the AM keystore, or you can create key aliases in the existing AM keystore:

- "To Create a Keystore and Key Aliases for Keystore Secret Stores"
- "To Create Key Aliases in an Existing Keystore"
- "To Create Self-Service Key Aliases"

To Create a Keystore and Key Aliases for Keystore Secret Stores

To create a new AM keystore, see "Managing the AM Keystore" instead.

1. Acquire a new key from your certificate authority and add it to a new keystore, or generate a new self-signed key in a new keystore.

This example creates a self-signed key alias in a new keystore file, `keystoreA.jceks`, with a new asymmetric RSA key alias, `newkey`.

Note that in production environments you should use the strongest algorithm you can.

```
$ cd /path/to/openam/openam/
$ keytool \
-genkeypair \
-alias newkey \
-keyalg RSA \
-keysize 2048 \
-validity 730 \
-storetype JCEKS \
-dname 'CN=newkey' \
-keystore keystoreA.jceks
Enter keystore password:
Reenter new password:
Enter key password for <newkey>
(RETURN if same as keystore password):
Reenter new password:
```

Take note of the passwords. You need to make them available within another secret store; for example, by using a file system volume secret store, as shown below:

- a. Go to the directory that the filesystem volume secret store will point to. For example, `/path/to/openam/secrets/mydir`.

Since you can encode the content of the files using different modes, we recommend that you create a directory for each encode mode you plan to use, at least.

- b. Create two files, one for the keystore password, and another for the password of the keys inside the keystore.

The files will contain the passwords encoded expected by the file system secret volume store.

For example, if you choose `Base64 encoded` as the encoding, you must base64-encode the passwords, and then add them to their respective files.

For example:

```
$ echo -n bmV3c3RvcnVwYXNzd29yZA== > keystoreA_storepass
$ echo -n bmV3a2V5cGFzc3dvcmQ= > keystoreA_keypass
```

Important

Use `echo -n` to avoid inserting hidden trailing newline characters. Even if the `keytool` command is able to use the password in the file, AM may not be able to open the keystore or the key aliases.

- c. Make sure the password files have read-only permission for their owner. For example:

```
$ chmod 400 keystoreA_storepass
$ chmod 400 keystoreA_keypass
```

2. Create any other keys and keystores required by your environment by repeating the steps in this procedure and/or following the steps in "To Create Key Aliases in an Existing Keystore".
3. Ensure that password files and keystores are maintained on every instance in your environment. Every AM instance has its own keystores and password files.
4. Configure the keystore in a keystore-type secret store. See "Keystore Secret Stores".

To configure the file system secret store too, see "File System Secret Volumes Secret Stores".

To Create Key Aliases in an Existing Keystore

Perform the following steps to create new key aliases in an existing keystore. For example, the AM keystore:

1. Change directories to the keystore location, for example, `/path/to/openam/openam/`.
2. Acquire a new key from your certificate authority, or generate a new self-signed key.

When you create or import a new key, the `keytool` command adds the new alias to the specified keystore if it exists, or creates a new keystore if it does not exist.

This example creates a self-signed key alias in the AM keystore, `am_keystore.jceks`, with a new asymmetric RSA key alias called `mynewkey`.

Note that in production environments you should use the strongest algorithm you can use.

```
$ cd /path/to/openam/openam/
$ keytool \
-genkeypair \
-alias mynewkey \
-keyalg RSA \
-keysize 2048 \
-validity 730 \
-storetype JCEKS \
-dname 'CN=mynewkey' \
-keystore am_keystore.jceks
Enter keystore password: Enter the password in the .keystore_storepass file.
Enter key password for <mynewkey>
(RETURN if same as keystore password): Enter the password in the .keystore_keypass file.
Reenter new password: Enter the password in the .keystore_keypass file.
```

Remember:

- The contents of the password files of the AM keystore are in cleartext.
 - The contents of the password files in a file system volume secret store are *not* in cleartext by default. This means that you need to decode them before you can use them in the **keytool** command.
3. Ensure that password files and keystores are maintained on every instance in your environment. Every AM instance has its own keystores and password files.
 4. (AM keystore) Restart the AM instances affected by the configuration changes to use the new key aliases.
 5. Configure the new key aliases in AM. For a list of features that use key aliases and links to their relevant sections, see "Features in AM That Use Keys".

To Create Self-Service Key Aliases

User self-service requires a key pair for encryption and a signing secret key to be available in the AM keystore before configuring any of its features. Follow the steps in this procedure to create new key aliases for the user self-service features in the AM keystore:

1. Acquire a new key from your certificate authority, or generate new self-signed keys. The password of the new keys for the user self-service features must match the passwords of those keys already present in the keystore, and configured in the `/path/to/openam/openam/.am_keystore_keypass` file.

This example generates a self-signed key for encryption and a new signing secret key in the `am_keystore.jceks` keystore, but you could also import CA-provided keys to the keystore.

- a. Create the new self-signed encryption key alias:

```
$ cd /path/to/openam/openam/
$ keytool \
  -genkeypair \
  -alias newenckey \
  -keyalg RSA \
  -keysize 2048 \
  -validity 730 \
  -storetype JCEKS \
  -dname 'CN=newenckey' \
  -keystore am_keystore.jceks
Enter keystore password: Enter the password in the .am_keystore_storepass file.
Enter key password for <newenckey>
(RETURN if same as keystore password): Enter the password in the .am_keystore_keypass file.
Reenter new password: Enter the password in the .am_keystore_keypass file.
```

- b. Create the new signing secret key alias:

```

$ cd /path/to/openam/openam/
$ keytool \
-genseckey \
-alias newsigkey \
-keyalg HmacSHA256 \
-keysize 256 \
-storetype JCEKS \
-keystore am_keystore.jceks
Enter keystore password: Enter the password in the .am_keystore_storepass file.
Enter key password for <newsigkey>
(RETURN if same as keystore password): Enter the password in the .am_keystore_keypass file.
Reenter new password: Enter the password in the .am_keystore_keypass file.

```

2. Ensure that password files and keystores are maintained on every instance in your environment. Every AM instance has its own keystores and password files.
3. Restart the AM instances affected by the configuration changes.
4. Configure user self-service to use the new keys. For more information, see "Creating a User Self-Service Service Instance" in the *User Self-Service Guide*.

Copying Key Aliases

Some AM features require access to the key aliases used by other components of the ForgeRock Identity Platform. For example, the IDM Provisioning feature requires access to the key aliases IDM uses for signing and encrypting data.

This section covers copying key aliases from the keystore of a ForgeRock Identity Platform component to AM's default keystore.

To Copy a Key Alias From One Keystore to Another

Use the **keytool** command to export the key from the source component's keystore. Install the result in AM's keystore, by performing the following steps:

1. From the source keystore, export the required key into a temporary keystore that can be transported to AM by executing the following **keytool** command:

```

$ keytool -importkeystore -srcstoretype jceks -srcalias "myKeyAlias" \
-deststoretype jceks -destalias "myKeyAlias" \
-srckeystore "/path/to/openidm/security/keystore.jceks" \
-destkeystore "/path/to/openidm/security/temp_keystore.jceks" \
-srckeypass "changeit" \
-srcstorepass "changeit" \
-destkeypass "myT3mPK3yP4ssword" \
-deststorepass "myT3mPK3yP4ssword"

```

This command exports the `myKeyAlias` key alias, specified by the `srcalias` argument, to a temporary keystore file `/path/to/openidm/security/temp_keystore.jceks`. The store and key password is set to `myT3mPK3yP4ssword`. You need to use the temporary passwords when importing to the AM instance.

2. Move the temporary keystore file created in the previous step, in this example `temp_keystore.jceks`, to the filesystem of the target AM server.
3. On the target AM server, import the key alias into the AM keystore by executing the following **keytool** command:

```
$ keytool -importkeystore -srcstoretype jceks -srcalias "myKeyAlias" \  
-deststoretype jceks -destalias "myKeyAlias" \  
-srckeystore "/path/to/openam/openam/temp_keystore.jceks" \  
-destkeystore "/path/to/openam/openam/am_keystore.jceks" \  
-srckeypass "myT3mPK3yP4ssword" \  
-srcstorepass "myT3mPK3yP4ssword" \  
-destkeypass:file "/path/to/openam/openam/.am_keystore_keypass" \  
-deststorepass:file "/path/to/openam/openam/.am_keystore_storepass"
```

This command imports the key alias from the temporary keystore file `/path/to/openam/openam/temp_keystore.jceks` into the AM keystore, and sets the key password to match the password used by the default AM keystore.

4. (Optional) Repeat the previous steps to copy any additional key aliases from the source keystore to the destination keystore.
5. Restart the AM instance for the key change to take effect.

The AM instance will now be able to correctly encrypt, decrypt, sign or verify data and share it with the source ForgeRock Identity Platform component.

Changing Key Alias Passwords

Decrypting a key alias in a keystore requires a password. This password is initially specified when you generate the key, or when you import the key into a keystore, but you might need to update the password at a later time.

To Change Key Alias Passwords

1. Back up your keystore and password files.
2. (AM keystore) Replace the old password in the `.am_keystore_keypass` file with the new one:

```
$ echo -n newpassword > .am_keystore_keypass
```

Important

Use **echo -n** to avoid inserting hidden trailing newline characters. Even if the **keytool** command is able to use the password in the file, AM may not be able to use the key aliases if there are hidden trailing newline characters in the password file.

3. (Secret stores) Replace the old password in the secret containing it with the new one. If the secret is a file in a file system volume secret store, ensure that the new password is encoded appropriately.

For example, base64-encode the password, and add it to the file:

```
$ echo -n bmV3a2V5cGFzc3dvcmQ= > keystoreA_keypass
```

4. List the keys and password strings contained in the keystore:

```
$ keytool -list -storetype JCEKS -keystore am_keystore.jceks
```

5. Use the **keytool** command to change the password of each of the key aliases.

AM keystore:

```
$ keytool -keypasswd -storetype JCEKS -keystore am_keystore.jceks -alias mykey
Enter keystore password: Enter the password in the .am_keystore_storepass file
New key password for <mykey> Enter the password in the .am_keystore_keypass file
Re-enter new key password for <mykey> Enter the password in the .am_keystore_keypass file
```

Remember to change the passwords of the `configstorepwd` and the `dsameuserpwd` aliases. Failure to do so will render AM unbootable.

Secret Stores:

```
$ keytool -keypasswd -storetype JCEKS -keystore keystoreA.jceks -alias mykey
Enter keystore password: Enter the password in the keystoreA_storepass file
New key password for <mykey> Enter the password in the keystoreA_keypass file
Re-enter new key password for <mykey> Enter the password in the keystoreA_keypass file
```

Secrets in file system volume secret stores are, by default, *not* in cleartext. You need to decode them before using them with the **keytool** command.

6. (Optional) If you also need to change the keystore password, see "To Change the Keystore Password".
7. Ensure that password files and keystores are maintained on every instance in your environment. Every AM instance has its own keystores and password files.
8. (AM keystore) Restart the AM instances affected by the configuration changes.

Changing Keystore Passwords

Decrypting and viewing the contents of a keystore requires a password. This password is specified by the user at the time the keystore is created, but you might need to update the password at a later time.

To Change the Keystore Password

1. (AM keystore) Replace the old password in the `.am_keystore_storepass` file with the new one:

```
$ echo -n newpassword > .am_keystore_storepass
```

Important

Use `echo -n` to avoid inserting hidden trailing newline characters. Even if the `keytool` command is able to use the password in the file, AM may not be able to use the key aliases if there are hidden trailing newline characters in the password file.

2. (Secret stores) Replace the old password in the secret containing it with the new one. If the secret is a file in a file system volume secret store, ensure that the new password is encoded appropriately.

For example, base64-encode the password, and add it to the file:

```
$ echo -n bmV3c3RvcnVwYXNzd29yZA== > keystoreA_storepass
```

3. Change the password of the keystore.

AM keystore:

```
$ keytool -storepasswd -storetype JCEKS -keystore am_keystore.jceks
Enter keystore password: Enter the password in the .am_keystore_storepass file.
New keystore password: Enter the new password.
Re-enter new keystore password:
```

Secret stores:

```
$ keytool -storepasswd -storetype JCEKS -keystore keystoreA.jceks
Enter keystore password: Enter the password in the keystoreA_storepass file.
New keystore password: Enter the new password.
Re-enter new keystore password:
```

Secrets in file system volume secret stores are, by default, *not* in cleartext. That means, you need to decode them before using them with the `keytool` command.

4. (Optional) If you also need to change the key aliases' password, see "To Change Key Alias Passwords".
5. Ensure that password files and keystores are maintained on every instance in your environment. Each AM instance has its own keystores and password files.

- (AM keystore only) Restart the AM instance or instances affected by the configuration changes.

Configuring Secret Stores

Secret stores are repositories for cryptographic keys and credentials. You can configure them globally, which ensures that all realms inherit your secret store settings. You can also configure secret stores by realm, which allows you to set different secret store settings for each realm.

Since secrets must be shared by all the servers in the site, a good practice is to keep them all under the same directory or mount point, for example, `/path/to/openam/secrets`.

AM provides a keystore and a filesystem secret store by default in new installations, but we recommend that you create your own secret stores in production environments.

AM supports the following secret store types:

- Environment and System Properties

AM supports configuring secrets derived from JVM system properties.

- Keystore

AM supports a number of different keystore formats, including JCEKS, JKS, PKCS11, and PKCS12.

- File System Secret Volumes

AM supports secrets that are stored as files in defined folders. For example, in a cloud deployment you could mount a secret volume that AM can access.

- Hardware Security Modules (HSM)

AM supports retrieval of secrets from hardware security modules, either locally or over the network.

Tasks to Configure Secret Stores

Task	Resources

Configure Secret Stores Configure as many secret stores as your environment needs.	<ul style="list-style-type: none"> "The Environment and System Property Secrets Store" "Keystore Secret Stores" "File System Secret Volumes Secret Stores"

Task	Resources
<p>Map Secret IDs to Secrets</p> <p>A number of AM features require the use of secrets for signing and encryption. For each requirement, AM has a secret ID.</p> <p>You can create active aliases in keystore and HSM secret stores.</p>	<ul style="list-style-type: none"> • "HSM Secret Stores" • "Mapping Secrets"

Understanding How AM Resolves Secrets

Most secret stores are configured at the global level, by navigating to `Configure > Secret Stores`, or at the realm level, by navigating to `Realms > Realm Name > Secret Stores`.

Secrets derived from environmental or system properties are configured globally, in a special, persistent secret store.

When resolving secrets, AM will search secret stores in the following order:

1. Any secret store configured for the realm, regardless of their type.
2. Any secret store configured globally, regardless of their type.

If AM cannot find the alias, it will log an error and the operation it was trying to do (for example, signing a client-based session token) will fail.

Caution

Map each secret ID *once* across the secret stores configured for the realm, or globally. For example, in a realm with two secret stores configured (a keystore secret store and a HSM secret store) the `am.services.oauth2.jwt.authenticity.signing` secret ID is mapped only in the keystore secret store and not in the HSM secret store.

The Environment and System Property Secrets Store

There is a global instance of the Environment and System Property Secrets Store configured at all times. You can access the Environment and System Property Secrets Store globally.

Secrets within the environment and system property secrets store are derived from system properties with the same key as the secret value name (for example, `am.services.oauth2.stateless.token.encryption`), or as environment variables with keys that have the secret value name in upper case, and with all period characters replaced with underscores (for example, `AM_SERVICES_OAUTH2_STATELESS_TOKEN_ENCRYPTION`).

AM configures this secret store on startup. Restart AM or the container where it runs to use the new secret mappings.

The only configuration settings that apply for the environment and system property secrets store is the format of the secrets. Secrets that come from this store cannot be rotated, retired (deleted), or removed.

To Configure the Environment and System Property Secrets Store

1. Log in to the AM console as an administrator, for example `amAdmin`.
2. Navigate to Configure > Secret Stores > Environment and System Property Secrets Store.
3. From the Value format drop-down list, select one of the following:
 - Plain Text: the secret is provided in UTF-8 encoded text.
 - Base64 encoded: the secret is provided in Base64 encoded binary values.
 - Encrypted text: the plain text secrets are encrypted using AM's encryption key, found at Deployment > Servers > Security > Encryption.
 - Encrypted Base64 encoded: the Base64 encoded binary values are encrypted using AM's encryption key.
 - Encrypted HMAC key: the Base64 encoded binary representation of the HMAC key is encrypted using AM's encryption key.
 - BASE64_HMAC_KEY: the Base64 encoded binary representation of the HMAC key.
4. Save your changes.

Keystore Secret Stores

A keystore secret store is a secret store that maps to a keystore file, for example, a JKS, JCEKS, PKCS11, or PKCS12 file.

Tip

During installation or after an upgrade from a version of AM earlier than 6.5, AM deploys a number of secret stores. You can use them as an example to configure your own secret stores. For more information, see [About the Default Secret Stores](#).

To Create a Keystore Secret Store

Keystore secret stores can be configured at a global or realm level:

1. To create on a global level:
 - Navigate to Configure > Secret Stores.

To create on a realm level:

- Navigate to Realms > *Realm Name* > Secret Stores.
2. Select Add Secret Store.
 3. Enter the Secret Store ID.
 4. From the Store Type drop-down list, select Keystore.
 5. Enter the keystore file to use.

This file must be available to all AM instances, for example, by storing it on a shared filesystem, or by copying and maintaining the file across instances.

6. Select Create.

To Configure a Keystore Secret Store

1. To configure a global keystore:
 - Navigate to Configure > Secret Stores.

To configure a realm keystore:

- Navigate to Realms > *Realm Name* > Secret Stores.
2. Select the store you want to modify.
 3. Enter the keystore file name in the File field.
 4. Enter the Keystore Type, for example **JKS**, **JCEKS**, **PKCS11**, or **PKCS12**.

The specified keystore type must be supported by, and configured in, the local Java runtime environment.

5. Set the Provider name. If blank, the JRE default will be used.
6. In the Store password secret ID field, enter the secret ID from which AM will resolve the password that opens the keystore file, or none if the password is blank. For example, **storepass**.

AM resolves this secret ID using the other secret stores configured. For example, a file system secret volume secret store mapped to the directory where the file containing the password is stored, or an HSM secret store. For more information about how AM resolves secrets, see "Understanding How AM Resolves Secrets".

7. In the Entry password secret ID field, enter the secret ID from which AM will resolve the password to the keys stored in the keystore, or none if the password is blank. For example, **entrypass**.

AM resolves this secret ID using the other secret stores configured. For example, a file system secret volume secret store mapped to the directory where the file containing the password is stored, or an HSM secret store. For more information about how AM resolves secrets, see "Understanding How AM Resolves Secrets".

8. Set the Key lease expiry time in minutes.
9. Save your changes.

File System Secret Volumes Secret Stores

File System Secret Volumes maps to a directory storing files that contain secrets - one secret per file. For a given secret value, file system secret volumes stores will look for a file with the same name as the secret value name, and read its contents using the configured value format. They can be configured at a global and realm level.

Tip

During installation or after an upgrade from a version of AM earlier than 6.5, AM deploys a number of secret stores. You can use them as an example to configure your own secret stores. For more information, see [About the Default Secret Stores](#).

To Create a File System Secret Volume Store

1. To create on a global level:
 - Navigate to **Configure > Secret Stores**.To create on a realm level:
 - Navigate to **Realms > *Realm Name* > Secret Stores**.
2. Select **Add Secret Store**.
3. Enter the **Secret Store ID**.
4. From the **Store Type** drop-down list, select **File System Secret Volumes**.
5. Enter the name of the directory containing the secret files.

This directory must be available to all AM instances, for example, by converting it to a shared filesystem, or by creating and maintaining it and its files across instances.

6. Select **Create**.

To Configure a File System Secret Volume Store

1. To configure a global file system secret volume store:

- Navigate to Configure > Secret Stores.
- To configure a realm file system secret volume store:
- Navigate to Realms > *Realm Name* > Secret Stores.
2. Select the store you want to modify.
 3. Enter the directory file name in the Directory field.
 4. (Optional) Enter a suffix to add to the name of each secret in the File suffix field. For example, `txt`.
 5. From the Value format drop-down list, select one of the following:
 - Plain Text: the secret is provided in UTF-8 encoded text.
 - Base64 encoded: the secret is provided in Base64 encoded binary values.
 - Encrypted text: the plain text secrets are encrypted using AM's encryption key, found at Deployment > Servers > Security > Encryption.
 - Encrypted Base64 encoded: the Base64 encoded binary values are encrypted using AM's encryption key.
 - Encrypted HMAC key: the Base64 encoded binary representation of the HMAC key is encrypted using AM's encryption key.
 - BASE64_HMAC_KEY: the Base64 encoded binary representation of the HMAC key.
 6. Save your changes.

HSM Secret Stores

An HSM Secret Store maps to a hardware security module. To configure an HSM Secret Store, you need a secret ID that can provide the PIN or password for the HSM, or an extension can be created that provides a Guice binding for a custom PKCS11 `java.security.Provider` to obtain the keystore.

To Create an HSM Secret Store

HSM Secret Stores can be configured at a global and realm level:

1. To create on a global level:
 - Navigate to Configure > Secret Stores.
- To create on a realm level:
- Navigate to Realms > *Realm Name* > Secret Stores.

2. Select Add Secret Store.
3. Enter the Secret Store ID.
4. From the Store Type drop-down list, select HSM.
5. Enter the Configuration File containing initialization configuration for the HSM.
6. In the Provider Guice Key Name field, enter the name of a Guice key that can be used to obtain an initialized provider from which the HSM keystore can be obtained.
7. In the HSM PIN/password secret ID field, enter the secret ID from which HSM's PIN or password can be obtained.

AM resolves this secret ID using the other secret stores configured. For example, a file system secret volume secret store mapped to the directory where the file containing the password is stored, or a keystore secret store. For more information about how AM resolves secrets, see "Understanding How AM Resolves Secrets".

8. Select Create.

To Configure an HSM Secret Store

1. To configure a global HSM secret store:
 - Navigate to Configure > Secret Stores.To configure a realm HSM secret store:
 - Navigate to Realms > *Realm Name* > Secret Stores.
2. Select the store you want to modify.
3. In the Configuration File field, enter the name of the file containing initialization configuration for the HSM.
4. In the Provider Guice Key Name field, enter the name of a Guice key that can be used to obtain an initialized provider from which the HSM keystore can be obtained.
5. In the HSM PIN/password secret ID field, enter the secret ID from which HSM's PIN or password can be obtained.

AM resolves this secret ID using the other secret stores configured. For example, a file system secret volume secret store mapped to the directory where the file containing the password is stored, or a keystore secret store. For more information about how AM resolves secrets, see "Understanding How AM Resolves Secrets".

6. Set the Key lease expiry time in minutes.
7. Save your changes.

Mapping Secrets

A number of AM features require the use of secrets for signing and encryption. For each requirement, AM has a **Secret ID**. To provide AM with the required secret, map one or more aliases from the secret stores you configure to each of the secret IDs. These mappings allow you to choose which is the active aliases, and rotate them when they become expired or compromised.

Active aliases are used for signature generation and encryption, while the non-active aliases are used for signature verification and decryption. An non-active alias can be rotated to become the active alias, while the old alias will still remain valid. Non-active secrets are mainly used for signature verification and decryption. A secret can be retired when it is no longer considered secure.

For example, if you mapped several aliases for signing OAuth 2.0 client-based tokens, new tokens are signed with the active secret, and incoming tokens are verified against both the active and the non-active secrets.

To Map Aliases in Keystore or HSM Secret Stores

1. To map secrets within a global secret store:

- Navigate to **Configure > Secret Stores**.

To map secrets within a realm secret store:

- Navigate to **Realms > *Realm Name* > Secret Stores**.

2. Select the Keystore or HSM store that contains the secrets you want to map.

3. On the Mappings tab, select **Add Mapping**.

4. From the Secret ID drop-down list, select the Secret ID that is to be associated to an alias.

For information about the different secret ID mappings, see "Secret ID Mapping Defaults".

5. Enter any Alias and select the **+** icon.

Note

You can add as many aliases as necessary. The first alias in the list determines which alias is the active one. Active secrets are used for signature generation and encryption, while the non-active secrets are used for signature verification and decryption.

6. Drag and drop to change the order of aliases, and set which alias is active.

7. If an alias is considered no longer secure, it can be retired by clicking the **x** icon.

8. Once your mappings are complete, select **Create**.

To Map Files in File System Secret Volumes Secret Stores

File system secret volumes secret stores do not allow rotating or retiring secrets through mappings like other stores do.

To map secret IDs to files, perform the following steps:

1. Change paths to the directory configured in the secret store. For example, change paths to `/openam/secrets`.
2. Create the required files to store your secrets using the tables in "Secret ID Mapping Defaults" for guidance, and leave them empty.

For example, to create a mapping for the Web and Java agents' OAuth 2.0 provider, create a file called `am.global.services.oauth2.oidc.agent.idtoken.signing`.

You may also create mappings for secret store-specific secrets, such as the keystore secret store password, the keystore secret store entry password, or the HSM guice key. These mappings do not require specific secret IDs. For example, you can create a file called `mykeystorepassword`, and then configure it in the Store password secret ID field of your keystore secret store.

Depending on the configuration of the secret store, you may be able to add a suffix to the file name, such as `.txt`.

3. Store the relevant secret on each file.

The format of the secret depends on the configuration of the secret store. For example, if you have configured File Format to be `Encrypted text`, you must encrypt the secret with AM's encryption key.

Once the secrets are stored in their respective files, AM can start using them.

Changing Default Key Aliases

For demo and test purposes, AM configures different demo key aliases for several features. You can keep the demo key aliases configured in those features you are not using, but you may decide to remove them completely from your production environment.

To replace the default key aliases:

1. Create the required key aliases following the tasks in "Managing Key Aliases and Passwords".
2. Change default key aliases in AM:

SAML v1.x

Navigate to Configure > Server Defaults > Security > Key Store, and replace the `test` key alias in the Certificate Alias field.

Web Agents and Java Agents

See the [Web Policy Agents documentation](#) and the [Java Policy Agents documentation](#) for more information.

Persistent Cookie Module

To change the default mapping for the Persistent Cookie module, navigate to [Realms > *Realm Name* > Authentication > Settings > Security](#) and replace the `test` key alias in the Persistent Cookie Encryption Certificate Alias field with the alias you created for persistent cookies in your secret stores.

For more information about the secret ID mappings used by this feature, see ["Secret ID Mappings for Persistent Cookies"](#).

OAuth 2.0 Providers

OAuth 2.0 providers use the following secret IDs:

- ["Secret ID Mappings for JWT Authenticity Signing"](#).
- ["Secret ID Mappings for Signing Client-Based OAuth 2.0 Tokens"](#).
- ["Secret ID Mappings for Encrypting Client-Based OAuth 2.0 Tokens"](#).
- ["Secret ID Mappings for Signing Remote Consent Requests"](#).
- ["Secret ID Mappings for Decrypting Remote Consent Responses"](#).

OpenID Connect Providers

OpenID Connect providers use the following secret IDs (in addition to the ones specified in the OAuth 2.0 provider section):

- ["Secret ID Mappings for Decrypting OpenID Connect Request Parameters"](#).
- ["Secret ID Mappings for Signing OpenID Connect Tokens"](#).
- ["Secret ID Mappings for JWT Authenticity Signing"](#).

Authentication Trees

Authentication trees use the following secret ID to encrypt data stored in their shared state, such as one-time passwords:

["Secret ID Mapping for Encrypting Authentication Tree's Data in Shared State"](#).

SAML v2.0 Service Configuration

Navigate to Configure > Global Services > SAML v2.0 Service Configuration > Realm Defaults and replace the `test` key alias in the Metadata signing key alias field.

SAML v2.0 also uses the following secret ID:

- "Secret ID Mappings for Encrypting SAML v2.0 Local Storage JWTs".

Client-Based Sessions

Navigate to Configure > Global Services > Session > Client-based Sessions and replace the `test` key alias in the Signing RSA/ECDSA Certificate Alias field and in the Encryption RSA Certificate Alias field.

User Self-Service

Navigate to Realms > *Realm Name* > Services > User Self-Service and populate the values of the Encryption Key Pair Alias and the Signing Secret Key Alias properties.

Note that the name of the demo keys shows with a gray color; that does not mean the fields are filled in.

Note

When possible, the preceding list includes the Global Services or Server Default paths where the demo key aliases are configured. If you already have configured any of the features in a realm, ensure that the key alias is replaced in the realm configuration as well.

Chapter 6

Setting Up Audit Logging

Introducing the Audit Logging Service

AM supports a comprehensive Audit Logging Service that captures key auditing events, critical for system security, troubleshooting, and regulatory compliance.

Audit logs gather operational information about events occurring within an AM deployment to track processes and security data, such as authentication mechanisms, system access, user and administrator activity, error messages, and configuration changes.

This chapter describes the common REST-based Audit Logging Service available in AM. AM also supports a legacy Logging Service, based on a Java SDK. The legacy Logging Service will be deprecated in a future release of AM.

The Audit Logging Service uses a structured message format that adheres to a consistent log structure common across the ForgeRock Identity Platform. This common structure allows correlation between log messages of the different components of the Platform once the transaction IDs are trusted by enabling the ForgeRock trust transaction header system property.

For more information, see [Configuring the Trust Transaction Header System Property](#).

Important

The DS JSON logger is enabled by default. However, the ForgeRock transaction IDs are not trusted initially. You must set `trust-transaction-ids:true` to correlate log messages in DS with log messages in AM. For more information, see [To Enable LDAP JSON Access Logs in the ForgeRock Directory Services Administration Guide](#).

About the Audit Logging Service

AM writes log messages generated from audit events triggered by its instances, web or Java agents, the **ssoadm** tool, and connected ForgeRock Identity Platform implementations.

AM's Audit Logging Service provides a versatile and rich feature set as follows:

- **Global and Realm-Based Log Configuration.** You can configure audit logging globally, which ensures that all realms inherit your global log settings. You can also configure audit logging by realm, which allows you to set different log settings for each realm.
- **Audit Event Handlers.** The Audit Logging Service supports a variety of audit event handlers that allow you to write logs to different types of data stores. See "Configuring Audit Event Handlers" for a list of event handlers available in AM.

- **Audit Event Buffering.** By default, AM writes each log message separately as they are generated. AM supports message buffering, a type of batch processing, that stores log messages in memory and flushes the buffer after a preconfigured time interval or after a certain number of log messages reaches the configured threshold value.
- **Tamper-Evident Logging** for the CSV audit event handler. You can digitally sign your audit to enable the detection of tampering.
- **Log Rotation and Retention Policies.** AM rotates JSON and CSV audit logs when it reaches a specified maximum size. You can also configure a time-based rotation policy, which disables the max-size rotation policy and implements log rotation based on a preconfigured time sequence. AM also provides the option to disable log rotation completely for these file types. AM does not support external log rotation for JSON and CSV audit logs.

For Syslog, JDBC, Elasticsearch, JMS, and Splunk handlers, AM does not control log rotation and retention as they are handled by each respective service.

- **Blacklisting Sensitive Fields.** The Audit Logging Service supports blacklisting, a type of filtering to hide sensitive values or fields, such as HTTP headers, query parameters, cookies, or the entire field value.
- **Reverse DNS Lookup.** The Audit Logging Service supports a reverse DNS lookup feature for network troubleshooting purposes. Reverse DNS lookup is disabled by default as it enacts a performance hit in operation throughput.

Audit Log Topics

AM integrates log messages based on four different audit topics. A *topic* is a category of audit log event that has an associated one-to-one mapping to a schema type. Topics can be broadly categorized as access details, system activity, authentication operations, and configuration changes. The following table shows the basic event topics and associated audit log files for AM's default audit logging configuration, which uses a JSON audit event handler:

Audit Log Topics

Event Topic	File Name	Description
Access	<code>access.audit.json</code>	Captures who, what, when, and output for every access request.
Activity	<code>activity.audit.json</code>	Captures state changes to objects that have been created, updated, or deleted by end users (that is, non-administrators). Session, user profile, and device profile changes are captured in the logs.
Authentication	<code>authentication.audit.json</code>	Captures when and how a subject is authenticated and related events.
Configuration	<code>config.audit.json</code>	Captures configuration changes to the product with a timestamp and by whom. Note that the

Event Topic	File Name	Description
		<code>userId</code> indicating the subject who made the configuration change is not captured in the <code>config.audit.json</code> but may be tracked using the <code>transactionId</code> in the <code>access.audit.json</code> .

Audit Logging in Web and Java Agents

Web and Java agents log audit events for security, troubleshooting, and regulatory compliance. You can store web or Java agent audit event logs in the following ways:

- **Remotely.** Log audit events to the audit event handler configured in the AM realm.
- **Locally.** Log audit events to a file in the web or Java agent installation directory.

For more information about audit logs in agents, see [Auditing in the Web Policy Agents documentation](#), and [Auditing in the Java Policy Agents documentation](#).

Implementing the Audit Logging Service

When implementing the Audit Logging Service, decide whether you require specific audit systems per realm, or if a global configuration suits your deployment. Next, determine which event handlers suit your needs from those supported by AM. See the following sections for more information:

- To configure the Audit Logging Service, see ["Configuring Audit Logging"](#).
- To configure the audit event handlers, see ["Configuring Audit Event Handlers"](#).
- To configure the propagation of the transaction ID across the ForgeRock Identity Platform, see ["Configuring the Trust Transaction Header System Property"](#).

AM also supports the classic Logging Service, based on Java SDK, that will be deprecated in a future release. For more information, see ["Implementing the Classic Logging Service"](#).

Configuring Audit Logging

AM's default audit event handler is the JSON audit event handler, which comes configured and enabled for the global Audit Logging Service. The global configuration is used to control audit logging in realms that do not have the Audit Logging Service added to them. AM also supports configuring an Audit Logging Service on a per-realm basis.

The JSON audit event handler stores its JSON log files under `/path/to/openam/openam/Log`.

- To modify the global audit logging configuration, see ["To Configure Global Audit Logging"](#).

- To override the global audit logging configuration for a realm, see "To Configure Audit Logging in a Realm".

To Configure Global Audit Logging

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Navigate to Configure > Global Services > Audit Logging.
3. Configure the following options on the Global Attributes tab:
 - a. Activate Audit logging to start the audit logging feature.
 - b. In the Field exclusion policies list, enter any values to exclude from your audit events, or change the default exclusions for items that need to be included. To specify a field or value within a field to be filtered out of the event, start the pointer with the event topic (access, activity, authentication, or configuration) followed by the field name or the path to the value in the field.

This feature allows two types of filtering:

- Filter fields from the event. You may not be interested in capturing HTTP headers, query parameters, or potentially sensitive data like passwords in the access logs. For example, to filter out the `userid` field in an access event, specify the pointer as:

```
/access/userid
```

- Filter specific values from within fields that store key-value pairs as JSON, such as the HTTP headers, query parameters, and cookies. For example, to filter out the content type value in the `http.request.headers` field, specify the pointer as:

```
/access/http/request/headers/content-type
```

Important

The Audit Logging Service lets you suppress the output of certain event types, because logging them may have an impact on performance. These event types are not logged by default, regardless of the configuration of the filter lists.

The filter lists will only apply to these event topics if logging is enabled for them.

For more information, see `org.forgerock.openam.audit.identity.activity.events.blacklist` in "Advanced Properties" in the *Reference*.

- c. Save your changes.
4. On the Secondary Configurations tab, you can edit the configuration of the Global JSON Handler, or you can create new audit event handlers. For more information, see "Configuring Audit Event Handlers".

To Configure Audit Logging in a Realm

You can configure the Audit Logging Service for realms, allowing you to configure realm-specific log locations and handler types.

When the Audit Logging Service is added to a realm, it inherits the configuration defined under Configure > Global Services > Audit Logging > Realm Defaults. Properties configured explicitly in the realm-level service override the realm defaults.

To configure the Audit Logging Service in a realm, perform the following steps:

1. Navigate to Realms > *Realm Name* > Services.
2. Select Add a Service.
3. From the Choose a service type drop-down list, select Audit Logging.
4. Select Create.

The Audit Logging Service page appears. Configure the Audit Logging Service as follows:

5. Ensure audit logging is Enabled.
6. In the Field exclusion policies list, enter any values to exclude from your audit events, or delete the ones by default that you do not need. To specify a field or value within a field to be filtered out of the event, start the pointer with the event topic (access, activity, authentication, or configuration) followed by the field name or the path to the value in the field.

This feature allows two types of filtering:

- Filter fields from the event. You may not be interested in capturing HTTP headers, query parameters, or potentially sensitive data like passwords in the access logs. For example, to filter out the `userid` field in an access event, specify the pointer as:

```
/access/userid
```

- Filter specific values from within fields that store key-value pairs as JSON. For example, the HTTP headers, query parameters, and cookies. For example, to filter out the content type value in the `http.request.headers` field, specify the pointer as:

```
/access/http/request/headers/content-type
```

Important

The Audit Logging Service lets you suppress the output of certain event types, because logging them may have an impact on performance. These event types are not logged by default, regardless of the configuration of the filter lists.

The filter lists will only apply to these event topics if logging is enabled for them.

For more information, see [org.forgerock.openam.audit.identity.activity.events.blacklist](#) in "Advanced Properties" in the *Reference*.

7. Save your changes.
8. On the Secondary Configurations tab, select Add a Secondary Configuration. Choose an event handler from the list.

For more information about supported event handlers and how to configure them, see "Configuring Audit Event Handlers".

Configuring Audit Event Handlers

AM supports the following types of audit event handlers:

Audit Event Handlers

Audit Event Handler Type	Publishes to	How to Configure
JSON	JSON files	"Configuring JSON Audit Event Handlers"
CSV	CSV files	"Configuring CSV Audit Event Handlers"
Syslog	The syslog daemon	"Configuring Syslog Audit Event Handlers"
JDBC	A relational database	"Implementing JDBC Audit Event Handlers"
Elasticsearch	An Elasticsearch store	"Implementing Elasticsearch Audit Event Handlers"
JMS	JMS topics	"Implementing JMS Audit Event Handlers"
Splunk	A Splunk server	"Implementing Splunk Audit Event Handlers"

This section provides procedures for configuring each type of audit handler.

Configuring JSON Audit Event Handlers

The following procedure describes how to configure a JSON audit event handler:

To Configure a JSON Audit Event Handler

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to `Configure > Global Services > Audit Logging`.

Note that the JSON audit event handler is already configured in the global configuration. Select it to change its properties.

- To create the event handler in a realm, navigate to Realms > *Realm Name* > Services > Audit Logging.
3. On the Secondary Configurations tab, click Global JSON Handler or the Edit icon on the right if present. If no handler is present, click Add a Secondary Configuration, and select JSON.
 4. Under the New JSON configuration page, enter a name for the event handler. For example, **JSON Audit Event Handler**.
 5. (Optional) In the Rotation Times field, enter a time duration after midnight to trigger file rotation, in seconds. For example, you can provide a value of **3600** to trigger rotation at 1:00 AM. Negative durations are not supported.
 6. Click Create.

After the JSON audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

7. On the General Handler Configuration tab, enable the event handler and configure the topics for your audit logs:
 - a. Select Enabled to activate the event handler, if disabled.
 - b. Choose the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Click Save Changes.
8. On the JSON Configuration tab, configure JSON options:
 - a. Override the default location of your logs if necessary, and save your changes. The default value is `%BASE_DIR%/%SERVER_URI%/Log/`.

Important

Make sure to configure a different log directory for each JSON audit event handler instance. If two instances are writing to the same file, it can interfere with log rotation and tamper-evident logs.

- b. Select ElasticSearch JSON Format Compatible to direct AM to generate JSON formats that are compatible with the ElasticSearch format.
- c. In the File Rotation Retention Check Interval field, edit the time interval (seconds) to check the time-base file rotation policies.
- d. Click Save Changes.

9. On the File Rotation tab, configure how files are rotated when they reach a specified file size or time interval:
 - a. Select Rotation Enabled to activate file rotation. If file rotation is disabled, AM ignores log rotation and appends to the same file.
 - b. In the Maximum File Size field, enter the maximum size of an audit file before rotation.
 - c. (Optional). In the File Rotation Prefix field, enter an arbitrary string that will be prefixed to every audit log to identify it. This parameter is used when time-based or size-based rotation is enabled.
 - d. In the File Rotation Suffix field, enter a timestamp suffix based on the Java SimpleDateFormat that will be added to every audit log. This parameter is used when time-based or size-based log rotation is enabled. The default value is `-yyyy.MM.dd-kk.mm.ss`.
 - e. In the Rotation Interval field, enter a time interval to trigger audit log file rotation in seconds. A negative or zero value disables this feature.
 - f. (Optional) In the Rotation Times field, enter a time duration after midnight to trigger file rotation, in seconds. For example, you can provide a value of `3600` to trigger rotation at 1:00 AM. Negative durations are not supported.
 - g. Click Save Changes.
10. On the File Retention tab, configure how long log files should be retained in your system:
 - a. In the Maximum Number of Historical Files field, enter a number for allowed backup audit files. A value of `-1` indicates an unlimited number of files and disables the pruning of old history files.
 - b. In the Maximum Disk Space field, enter the maximum amount of disk space that the audit files can use. A negative or zero value indicates that this policy is disabled.
 - c. In the Minimum Free Space Required field, enter the minimum amount of disk space required to store audit files. A negative or zero value indicates that this policy is disabled.
 - d. Click Save Changes.
11. On the Buffering tab, configure whether log events should be buffered in memory before they are written to the JSON file:
 - a. In the Batch Size field, enter the maximum number of audit log events that can be buffered.
 - b. In the Write interval field, enter the time interval in milliseconds at which buffered events are written to a file.
 - c. Click Save Changes.

Configuring CSV Audit Event Handlers

The following procedure describes how to configure a comma-separated values (CSV) audit event handler:

To Configure a CSV Audit Event Handler

Important

Due to the security concerns of opening CSV files with Excel, OpenOffice, and other spreadsheet programs, it is recommended that you open CSV files with alternative software, such as a text editor.

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to `Configure > Global Services > Audit Logging`.
3. On the Secondary Configurations tab, select `Add a Secondary Configuration`. Choose CSV from the list.

The New CSV page appears. Enter the basic configuration for the new handler by performing the following actions:

4. Enter a name for the event handler. For example, `CSV Audit Event Handler`.
5. (Optional) In the Rotation Times field, enter a time duration after midnight to trigger file rotation, in seconds. For example, you can provide a value of `3600` to trigger rotation at 1:00 AM. Negative durations are not supported.
6. Enable or disable the Buffering option.
7. Select `Create`.

After the CSV audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

8. On the General Handler Configuration tab, enable the event handler and configure the topics for your audit logs:
 - a. Select `Enabled` to activate the event handler, if disabled.

- b. Choose the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Save your changes.
9. On the CSV Configuration tab, override the default location of your logs if necessary, and save your changes. The default value is `%BASE_DIR%/SERVER_URI%/log/`.

Important

Configure a different log directory for each CSV audit event handler instance. If two instances are writing to the same file, it can interfere with log rotation and tamper-evident logs.

10. On the File Rotation tab, configure how files are rotated when they reach a specified file size or time interval:
- a. Select Rotation Enabled to activate file rotation. If file rotation is disabled, AM ignores log rotation and appends to the same file.
 - b. In the Maximum File Size field, enter the maximum size of an audit file before rotation.
 - c. (Optional). In the File Rotation Prefix field, enter an arbitrary string that will be prefixed to every audit log to identify it. This parameter is used when time-based or size-based rotation is enabled.
 - d. In the File Rotation Suffix field, enter a timestamp suffix based on the Java SimpleDateFormat that will be added to every audit log. This parameter is used when time-based or size-based log rotation is enabled. The default value is `-yyyy.MM.dd-kk.mm.ss`.
 - e. In the Rotation Interval field, enter a time interval to trigger audit log file rotation in seconds. A negative or zero value disables this feature.
 - f. (Optional) In the Rotation Times field, enter a time duration after midnight to trigger file rotation, in seconds. For example, you can provide a value of `3600` to trigger rotation at 1:00 AM. Negative durations are not supported.
 - g. Save your changes.
11. On the File Retention tab, configure how long log files should be retained in your system:
- a. In the Maximum Number of Historical Files field, enter a number for allowed backup audit files. A value of `-1` indicates an unlimited number of files and disables the pruning of old history files.
 - b. In the Maximum Disk Space field, enter the maximum amount of disk space that the audit files can use. A negative or zero value indicates that this policy is disabled.
 - c. In the Minimum Free Space Required field, enter the minimum amount of disk space required to store audit files. A negative or zero value indicates that this policy is disabled.

- d. Save your changes.
12. On the Buffering tab, configure whether log events should be buffered in memory before they are written to the CSV file:
 - a. Select Buffering Enabled to activate buffering.

When buffering is enabled, all audit events are put into an in-memory buffer (one per handled topic), so that the original thread that generated the event can fulfill the requested operation, rather than wait for I/O to complete. A dedicated thread (one per handled topic) constantly pulls events from the buffer in batches and writes them to the CSV file. If the buffer becomes empty, the dedicated thread goes to sleep until a new item gets added. The default buffer size is 5000 bytes.

- b. Enable Flush Each Event Immediately to write all buffered events before flushing.

When the dedicated thread accesses the buffer, it copies the contents to an array to reduce contention, and then iterates through the array to write to the CSV file. The bytes written to the file can be buffered again in Java classes and the underlying operating system.

When Flush Each Event Immediately is enabled, AM flushes the bytes after each event is written. If the feature is disabled (default), the Java classes and underlying operation system determine when to flush the bytes.

- c. Save your changes.

13. On the Tamper Evident Configuration tab, configure whether to detect audit log tampering:

- a. Select Is Enabled to activate the tamper evident feature for CSV logs.

When tamper evident logging is enabled, AM generates an HMAC digest for each audit log event and inserts it into each audit log entry. The digest detects any addition or modification to an entry.

AM also supports another level of tamper evident security by periodically adding a signature entry to a new line in each CSV file. The entry signs the preceding block of events, so that verification can establish if any of these blocks have been added, removed, or edited by some user.

- b. In the Certificate Store Location field, enter the location of the keystore AM will use to sign the CSV logs, by default `%BASE_DIR%/SERVER_URI%/Logger.jks`.

The recommended approach is to create two keystores:

- A keystore for AM to use. This keystore is configured in the Certificate Store Location field and must contain a signing key pair called `signature` and an HMAC key called `password`.
- A keystore for the verification tool. This keystore must contain the HMAC `password` key, and the public key of the `signature` key pair.

You can use a simple script to create your keystores, for example: `create-keystore.sh`.

- c. In the Certificate Store Password field, enter the password of the keystore.
- d. In the Signature Interval field, enter a value in seconds for AM to generate and add a new signature to the audit log entry.
- e. Save your changes.
- f. To verify that rotated logs have not been tampered with, perform the following steps:
 - i. Download the SSOAdminTools-5.1.2.24.zip file from the *ForgeRock BackStage* website.
 - ii. Install the tools by performing the steps in "To Set Up Administration Tools" in the *Installation Guide*.
 - iii. Use the **verifyarchive** tool to verify rotated log files as follows:

```
$ /path/to/AM-SSOAdminTools-5.1.2.24/openam/bin/verifyarchive \
--archive /path/to/openam/openam/log/ \
--topic access \
--suffix -yyyy.MM.dd-HH.mm.ss \
--keystore /path/to/keystore-verifier.jks \
--password password
```

In this example, the tool checks files with a suffix of the type `yyyy.MM.dd-HH.mm.ss` using their counterparts with suffix `.keystore`. For example, the tool checks the `tamper-evident-access-csv-2019.01.12-12.04.33` file against the `tamper-evident-access-csv-2019.01.12-12.04.33.keystore` file. The `.keystore` file contains the HMAC digest the tool uses to validate the signature of the logs.

The tool returns **PASS** or **FAIL** alongside the names of the files that have been tested. For example:

```
PASS tamper-evident-access-csv-2019.01.12-12.04.33
FAIL tamper-evident-access-csv-2019.01.12-12.05.20 The HMac at row 2 is not correct.
```

Tip

Run the tool without any parameters to see the online help.

Configuring Syslog Audit Event Handlers

AM can publish audit events to a syslog server, which is based on a widely-used logging protocol. You can configure your syslog settings on the AM console.

The following procedure describes how to configure a Syslog audit event handler:

To Configure a Syslog Audit Event Handler

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to `Configure > Global Services > Audit Logging`.
 - To create the event handler in a realm, navigate to `Realms > Realm Name > Services > Audit Logging`.
3. On the Secondary Configurations tab, select `Add a Secondary Configuration`. Choose `Syslog` from the list.

The `New Syslog` page appears. Enter the basic configuration for the new handler by performing the following actions:

4. Enter a name for the event handler. For example, `Syslog Audit Event Handler`.
5. In the `Server hostname` field, enter the hostname or IP address of the receiving syslog server.
6. In the `Server port` field, enter the port of the receiving syslog server.
7. In the `Connection timeout` field, enter the number of seconds to connect to the syslog server. If the server has not responded in the specified time, a connection timeout occurs.
8. Enable or disable the `Buffering` option.
9. Select `Create`.

After the syslog audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

10. On the `General Handler Configuration` tab, enable the event handler and configure the topics for your audit logs:
 - a. Select `Enabled` to activate the event handler, if disabled.
 - b. Choose the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Save your changes.
11. On the `Audit Event Handler Factory` tab, keep the default class name for the audit event handler.
12. On the `Syslog Configuration` tab, configure the main syslog event handler properties:
 - a. In the `Server hostname` field, enter the hostname or IP address of the receiving syslog server.
 - b. In the `Server port` field, enter the port of the receiving syslog server.

- c. In the Connection timeout field, enter the number of seconds to connect to the syslog server. If the server has not responded in the specified time, a connection timeout occurs.
- d. From the Transport Protocol drop-down list, select TCP or UDP.
- e. Choose the facility.

A syslog message includes a PRI field that is calculated from the facility and severity values. All topics set the severity to **INFORMATIONAL** but you can choose the facility from the Facility drop-down list:

Syslog Facilities

Facility	Description
AUTH	Security or authorization messages
AUTHPRIV	Security or authorization messages
CLOCKD	Clock daemon
CRON	Scheduling daemon
DAEMON	System daemons
FTP	FTP daemon
KERN	Kernel messages
LOCAL0	Local use 0 (local0)
LOCAL1	Local use 1 (local1)
LOCAL2	Local use 2 (local2)
LOCAL3	Local use 3 (local3)
LOCAL4	Local use 4 (local4)
LOCAL5	Local use 5 (local5)
LOCAL6	Local use 6 (local6)
LOCAL7	Local use 7 (local7)
LOGALERT	Log alert
LOGAUDT	Log audit
LPR	Line printer subsystem
MAIL	Mail system
NEWS	Network news subsystem
NTP	Network time protocol
SYSLOG	Internal messages generated by syslogd
USER	User-level messages

Facility	Description
UUCP	Unix-to-unix-copy (UUCP) subsystem

f. Save your changes.

13. On the Buffering tab, configure whether you want buffering or not:

a. Select Buffering Enabled to activate it.

When buffering is enabled, all audit events that get generated are formatted as syslog messages and put into a queue. A dedicated thread constantly pulls events from the queue in batches and transmits them to the syslog server. If the queue becomes empty, the dedicated thread goes to sleep until a new item gets added. The default queue size is 5000.

b. Save your changes.

Implementing JDBC Audit Event Handlers

You can configure AM to write audit logs to Oracle, MySQL, PostgreSQL, or other JDBC databases. AM writes audit log records to the following tables: `am_auditaccess`, `am_auditactivity`, `am_auditauthentication`, and `am_auditconfig`. For more information on the JDBC table formats for each of the logs, see "JDBC Audit Log Tables".

Before configuring the JDBC audit event handler, you must perform several steps to allow AM to log to the database:

To Prepare for JDBC Audit Logging

1. Create tables in the relational database in which you will write the audit logs. The SQL for Oracle, PostgreSQL, and MySQL table creation is in the `audit.sql` file under `/path/to/tomcat/webapps/openam/WEB-INF/template/sql/db-type`.

If you are using a different relational database, tailor one of the provided `audit.sql` files to conform to your database's SQL syntax.

2. JDBC audit logging requires a database user with read and write privileges for the audit tables. Do one of the following:

- Identify an existing database user and grant that user privileges for the audit tables.
- Create a new database user with read and write privileges for the audit tables.

3. Obtain the JDBC driver from your database vendor. Place the JDBC driver `.zip` or `.jar` file in the container's `WEB-INF/lib` classpath. For example, place the JDBC driver in `/path/to/tomcat/webapps/openam/WEB-INF/lib` if you use Apache Tomcat.

The following procedure describes how to configure a JDBC audit event handler. Perform the following steps after you have created audit log tables in your database and installed the JDBC driver in the AM web container:

To Configure a JDBC Audit Event Handler

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to `Configure > Global Services > Audit Logging`.
 - To create the event handler in a realm, navigate to `Realms > Realm Name > Services > Audit Logging`.

3. On the Secondary Configurations tab, select `Add a Secondary Configuration`. Choose JDBC from the list.

The New JDBC page appears. Enter the basic configuration for the new handler by performing the following actions:

4. Enter a name for the event handler. For example, `JDBC Audit Event Handler`.
5. In the JDBC Database URL field, enter the URL for your database server. For example, `jdbc:oracle:thin:@//host.example.com:1521/0RCL`.
6. In the JDBC Driver field, enter the classname of the driver to connect to the database. For example:
 1. `oracle.jdbc.driver.OracleDriver` - for Oracle databases
 2. `com.mysql.jdbc.Driver` - for MySQL databases
 3. `org.postgresql.Driver` - for PostgreSQL databases
7. In the Database Username field, enter the username to authenticate to the database server.
This user must have read and write privileges for the audit tables.
8. In the Database Password field, enter the password used to authenticate to the database server.
9. Enable or disable the Buffering option.
10. Select the Create button.

After the JDBC audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

11. On the General Handler Configuration tab, enable the handler and configure the topics for your audit logs:
 - a. Select Enabled to activate the event handler, if disabled.
 - b. Select the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Save your changes.
12. On the Audit Event Handler Factory tab, enter the fully qualified class name of your custom JDBC audit event handler and save your changes.
13. On the Database Configuration tab, configure the main JDBC event handler properties:
 - a. From the Database Type drop-down list, select the audit database type. The default value is `Oracle`.
 - b. In the JDBC Database URL field, enter the URL for your database server. For example, `jdbc:oracle:thin:@//host.example.com:1521/ORCL`.
 - c. In the JDBC Driver field, enter the classname of the driver to connect to the database. For example:
 1. `oracle.jdbc.driver.OracleDriver` - for Oracle databases
 2. `com.mysql.jdbc.Driver` - for MySQL databases
 3. `org.postgresql.Driver` - for PostgreSQL databases
 - d. In the Database Username field, enter the username to authenticate to the database server.
This user must have read and write privileges for the audit tables.
 - e. In the Database Password field, enter the password used to authenticate to the database server.
 - f. In the Connection Timeout (seconds) field, enter the maximum wait time before failing the connection.
 - g. In the Maximum Connection Idle Timeout (seconds) field, enter the maximum idle time in seconds before the connection is closed.
 - h. In the Maximum Connection Time (seconds) field, enter the maximum time in seconds for a connection to stay open.
 - i. In the Minimum Idle Connections field, enter the minimum number of idle connections allowed in the connection pool.
 - j. In the Maximum Connections field, enter the maximum number of connections in the connection pools.

- k. Save your changes.
14. On the Buffering tab, configure the buffering settings:
- a. Select Buffering Enabled to start audit event buffering.
 - b. In the Buffer Size (number of events) field, set the size of the event buffer queue where events should queue up before being written to the database.

If the queue reaches full capacity, the process will block until a write occurs.
 - c. In the Write Interval field, set the interval in seconds in which buffered events are written to the database.
 - d. In the Writer Threads field, set the number of threads used to write the buffered events.
 - e. In the Max Batched Events field, set the maximum number of batched statements the database can support per connection.
 - f. Save your changes.

Implementing Elasticsearch Audit Event Handlers

AM supports audit logging to Elasticsearch 5.0. When you store AM's audit logs in an Elasticsearch data store, you can use Kibana to perform data discovery and visualization on your logs.

You can experiment with an Elasticsearch audit handler without enabling any Elasticsearch security features. However, for a more secure deployment, ForgeRock recommends that you use Elasticsearch Shield to require authentication to Elasticshield. Depending on your network topology, you might also want to configure SSL for Elasticsearch Shield.

Before configuring the Elasticsearch audit event handler, you must configure an Elasticsearch index with AM's audit schema:

To Prepare for Elasticsearch Audit Logging

Perform the following steps to prepare an Elasticsearch instance for storing AM audit events.

Note

These steps apply to Elasticsearch 5.0 only. Breaking changes in Elasticsearch 6.0 make it incompatible with the schemas provided in this version of AM.

For more information, see [Breaking Changes in 6.0 in the *Elasticsearch Reference Docs*](#).

1. Review the JSON file containing AM's audit schema. You can find the JSON file for the audit schema at the path `/path/to/tomcat/webapps/openam/WEB-INF/template/elasticsearch/audit.json`.

2. Copy the `audit.json` file to the system from which you will issue the `curl` command to create the Elasticsearch index.

In this example, you create an Elasticsearch index by executing an Elasticsearch REST API call using the `curl` command. Copy the `audit.json` file to a location that is accessible to the `curl` command you will run in the next step.

3. Create an Elasticsearch index for AM auditing by calling the Elasticsearch REST API, specifying the file you copied locally in the previous step, as follows:

```
$ curl \
  --request POST \
  --header "Content-Type: application/json" \
  --data @audit.json \
  http://elasticsearch.example.com:9200/my_openam_audit_index
```

In this example, note the following:

- `elasticsearch.example.com` is the name of the host on which Elasticsearch runs.
- `9200` is the port number that you use to access Elasticsearch's REST API.
- `my_openam_audit_index` is the name of the Elasticsearch index that you want to create.

Tip

For more information on connecting to Elasticsearch, see [Talking to Elasticsearch in the *Elasticsearch* documentation](#).

The following procedure describes how to configure an Elasticsearch audit event handler. Perform the following steps after you have created an Elasticsearch index for AM audit logging:

To Configure an Elasticsearch Audit Event Handler

1. If your Elasticsearch deployment uses Elasticsearch Shield configured for SSL, import the CA certificate used to sign Elasticsearch node certificates into the Java keystore on the host that runs AM. For example:

```
$ keytool \
  -import \
  -trustcacerts \
  -alias elasticsearch \
  -file /path/to/cacert.pem \
  -keystore $JAVA_HOME/jre/lib/security/cacerts
```

If you are running an AM site, import the CA certificate on all the servers in your site.

2. Log in to the AM console as an administrator, for example `amadmin`.

3. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to **Configure > Global Services > Audit Logging**.
 - To create the event handler in a realm, navigate to **Realms > *Realm Name* > Services > Audit Logging**.

4. On the **Secondary Configurations** tab, select **Add a Secondary Configuration**. Choose **Elasticsearch** from the list.

The **New Elasticsearch** page appears. Enter the basic configuration for the new handler by performing the following actions:

5. Enter a name for the event handler. For example, **Elasticsearch Audit Event Handler**.
6. In the **Server Hostname** field, enter the hostname or IP address of the Elasticsearch server to which AM should connect when writing audit events.
7. In the **Server Port** field, enter the port number to access Elasticsearch's REST API.
8. In the **Elasticsearch Index** field, specify the name of the index to be used for AM audit logging. The index you specify in this field must be identical to the index you created in **"To Prepare for Elasticsearch Audit Logging"**.
9. Specify the name and password of an Elasticsearch user if you have configured Elasticsearch Shield for user authentication:
 - a. In the **Username** field, enter the username to authenticate into the Elasticsearch server.
 - b. In the **Password** field, enter the password of the user that authenticates into the Elasticsearch server.
 - c. Save your changes.

If you are not using Elasticsearch Shield for user authentication, you can leave these fields with their default values.

10. Enable or disable the **Buffering** option.
11. Select **Create**.

After the Elasticsearch audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

12. On the **General Handler Configuration** tab, enable the handler and configure the topics for your audit logs:
 - a. Select **Enabled** to activate the event handler, if disabled.
 - b. Select the topics for your audit logs. For a description of each topic, see **"Audit Log Topics"**.

- c. Save your changes.
13. On the Audit Event Handler Factory, keep the default class name for the audit event handler.
 14. On the Elasticsearch Configuration tab, configure the main Elasticsearch event handler properties:
 - a. In the Server Hostname field, enter the hostname or IP address of the Elasticsearch server to which AM should connect when writing audit events.
 - b. In the Server Port field, enter the port number to access Elasticsearch's REST API.
 - c. If SSL is enabled in your Elasticsearch deployment, select SSL Enabled.
 - d. In the Elasticsearch Index field, specify the name of the index to be used for AM audit logging. The index you specify in this field must be identical to the index you created in "To Prepare for Elasticsearch Audit Logging".
 - e. Save your changes.
 15. On the Authentication tab, specify the name and password of an Elasticsearch user if you have configured Elasticsearch Shield for user authentication:
 - a. In the Username field, enter the username to authenticate into the Elasticsearch server.
 - b. In the Password field, enter the password of the user that authenticates into the Elasticsearch server.
 - c. Save your changes.

If you are not using Elasticsearch Shield for user authentication, you can leave these fields with their default values.

16. On the Buffering tab, configure whether log events should be buffered in memory before they are written to the Elasticsearch data store:
 - a. Activate Buffering Enabled to start buffering audit messages.

When buffering is enabled, all audit events are put into an in-memory buffer (one per handled topic), so that the original thread that generated the event can fulfill the requested operation, rather than wait for I/O to complete. A dedicated thread (one per handled topic) constantly pulls events from the buffer in batches and writes them to Elasticsearch. If the buffer becomes empty, the dedicated thread goes to sleep until a new item gets added.
 - b. In the Batch Size field, specify the number of audit events that AM pulls from the audit buffer when writing a batch of events to Elasticsearch.
 - c. In the Queue Capacity field, specify the maximum number of audit events that AM can queue in this audit handler's buffer.

If the number of events to queue exceeds the queue capacity, AM raises an exception and the excess audit events are dropped, and therefore not written to Elasticsearch.

- d. In the Write interval (in millis) field, specify how often AM should write buffered events to Elasticsearch.
- e. Save your changes.

Implementing JMS Audit Event Handlers

AM supports audit logging to a JMS message broker. JMS is a Java API for sending messages between clients using a publish and subscribe model as follows:

- AM audit logging to JMS requires that the JMS message broker supports using JNDI to locate a JMS connection factory. See your JMS message broker documentation to verify that you can make connections to your broker by using JNDI before attempting to implement an AM JMS audit handler.
- AM acts as a JMS publisher client, publishing JMS messages containing audit events to a JMS *topic*.¹
- A JMS subscriber client, which is not part of the AM software and must be developed and deployed separately from AM, subscribes to the JMS topic to which AM publishes audit events. The client then receives the audit events over JMS and processes them as desired.

Before configuring the JMS audit event handler, you must perform several steps to allow AM to publish audit events as a JMS client:

To Prepare for JMS Audit Logging

1. Obtain JNDI connection properties that AM requires to connect to your JMS message broker. The specific connection properties vary depending on the broker. See your JMS message broker documentation for details.

For example, connecting to an Apache ActiveMQ message broker requires the following properties:

Example Apache ActiveMQ JNDI Connection Properties

Property Name	Example Value
<code>java.naming.factory.initial</code>	<code>org.apache.activemq.jndi.ActiveMQInitialContextFactory</code>
<code>java.naming.provider.url</code>	<code>tcp://localhost:61616</code>
<code>topic.audit</code>	<code>audit</code>

¹ Note that AM and JMS use the term *topic* differently. An *AM audit topic* is a category of audit log event that has an associated one-to-one mapping to a schema type. A *JMS topic* is a distribution mechanism for publishing messages delivered to multiple subscribers.

2. Obtain the JNDI lookup name of the JMS connection factory for your JMS message broker.

For example, for Apache ActiveMQ, the JNDI lookup name is `ConnectionFactory`.

3. Obtain the JMS client `.jar` file from your JMS message broker vendor. Add the `.jar` file to AM's classpath by placing it in the `WEB-INF/lib` directory.

For example, place the JMS client `.jar` file in `/path/to/tomcat/webapps/openam/WEB-INF/lib` if you use Apache Tomcat.

The following procedure describes how to configure a JMS audit event handler.

If your JMS message broker requires an SSL connection, you might need to perform additional, broker-dependent configuration tasks. For example, you might need to import a broker certificate into AM's keystore, or provide additional JNDI context properties.

See your JMS message broker's documentation for specific requirements for making SSL connections to your broker, and implement them as needed in addition to the steps in the following procedure.

Perform the following steps after you have installed the JMS client `.jar` file in the AM web container:

To Configure a JMS Audit Event Handler

1. Log in to the AM console as an administrator, for example `amadmin`.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to `Configure > Global Services > Audit Logging`.
 - To create the event handler in a realm, navigate to `Realms > Realm Name > Services > Audit Logging`.
3. On the Secondary Configurations tab, select `Add a Secondary Configuration`. Choose JMS from the list.

The New JMS page appears. Enter the basic configuration for the new handler by performing the following actions:

4. Enter a name for the event handler. For example, `JMS Audit Event Handler`.
5. Select `Create`.

After the JMS audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

6. On the General Handler Configuration tab, enable the handler and configure the topics for your audit logs:

- a. Select Enabled to activate the event handler, if disabled.
 - b. Select the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Save your changes.
7. On the Audit Event Handler Factory tab, keep the default class name for the audit event handler.
8. On the JMS Configuration tab, configure the main JMS event handler properties:
- a. From the Delivery Mode drop-down list, specify the JMS delivery mode.

With persistent delivery, the JMS provider ensures that messages are not lost in transit in case of a provider failure by logging messages to storage when they are sent. Therefore, persistent delivery mode guarantees JMS message delivery, while non-persistent mode provides better performance.

The default delivery mode is **NON-PERSISTENT** delivery. Therefore, if your deployment requires delivery of every audit event to JMS subscriber clients, be sure to set the configuration to **PERSISTENT** delivery.

- b. From the Session Mode drop-down list, leave the default setting, **AUTO**, unless your JMS broker implementation requires otherwise. See your broker documentation for more information.
- c. Specify properties that AM will use to connect to your JMS message broker as key-value pairs in the JNDI Context Properties field.

AM is configured for the **audit** JNDI lookup name and JMS topic, but you can modify or delete this configuration, or add new key-value pairs. To add new key-value pairs, fill the Key and Value fields and select the +add button.

- d. In the JMS Topic field, specify the name of the JMS topic to which AM will publish messages containing audit events.

Subscriber clients that process AM audit events must subscribe to this topic.
- e. In the JMS Connection Factory Name, specify the JNDI lookup name of the JMS connection factory.
- f. Save your changes.

9. On the Batch Events tab, configure whether log events should be batched before they are published to the JMS message broker:
- a. Activate Batch Enabled to start batch publishing of audit events. Audit events will be queued and published to the JMS message broker in batches.

If batch publishing is not enabled, AM publishes audit events to the JMS message broker individually.

- b. In the Capacity field, specify the maximum capacity of the publishing queue. Execution is blocked if the queue size reaches capacity.
- c. In the Max Batched field, specify the maximum number of events to be delivered when AM publishes the events to the JMS message broker.
- d. In the Thread Count field, specify the number of worker threads AM should use to process the batch queue.
- e. Specify the batching timeout configuration as follows:
 - In the Insert Timeout field, specify the amount of time in seconds for queued events to be transmitted to the JMS message broker.
 - In the Polling Timeout field, specify the amount of time in seconds that worker threads wait for new audit events before becoming idle.
 - In the Shutdown Timeout field, specify the amount of time in seconds that worker threads wait for new audit events before shutting down.
- f. Save your changes.

Implementing Splunk Audit Event Handlers

AM supports sending audit logging data to a Splunk HTTP event collector REST endpoint. This endpoint requires an authentication token created in Splunk and configured in the AM event handler.

Before configuring the Splunk audit event handler in AM, configure the endpoint in Splunk:

To Prepare Splunk

Perform the following steps in Splunk:

1. Create a source type to match AM audit logs. Consider the following configuration tips:
 - It must be a structured type.
 - It must not have indexed extractions.
 - It must have event breaks on every line.
 - Timestamp extraction must be automatic.
2. Create an HTTP event collector token that uses the source type you just created.
3. Obtain the HTTP event collector token value for the token you just created. For example, `AD565CB5-BB8A-40FD-8A7C-94F549CEDEC`.

This token, which allows AM to log data to Splunk, is required for the AM audit event handler configuration.

4. Obtain the HTTP event collector port. For example, **8088**.
5. Ensure that the HTTP event collector and its tokens are enabled.

The following procedure describes how to configure a Splunk audit event handler in AM. Perform the following steps after you have created a Splunk HTTP event collector token:

To Configure a Splunk Audit Event Handler

1. Log in to the AM console as an administrator, for example **amadmin**.
2. Determine whether to create the event handler in a realm or use the default global event handler, then take one of the following actions:
 - To create the event handler in the global configuration, navigate to **Configure > Global Services > Audit Logging**.
 - To create the event handler in a realm, navigate to **Realms > *Realm Name* > Services > Audit Logging**.

3. On the Secondary Configurations tab, select **Add a Secondary Configuration**. Choose Splunk from the list.

The New Splunk configuration page appears. Enter the basic configuration for the new handler by performing the following actions:

4. Enter a name for the event handler. For example, **Splunk Audit Event Handler**.
5. In the Server Hostname field, enter the hostname or IP address of the Splunk HTTP event collector to which AM should connect when writing audit events.
6. In the Server Port field, enter the port number to access the Splunk HTTP event collector.
7. In the Authorization Token field, enter the authorization token for the Splunk HTTP event collector REST endpoint.
8. Select **Create**.

After the Splunk audit event handler is created, several configuration tabs appear. To configure the event handler, perform the following steps:

9. On the General Handler Configuration tab, enable the handler and configure the topics for your audit logs:
 - a. Select **Enabled** to activate the event handler, if disabled.

- b. Select the topics for your audit logs. For a description of each topic, see "Audit Log Topics".
 - c. Save your changes.
10. On the Audit Event Handler Factory tab, keep the default class name for the audit event handler.
11. On the Splunk Configuration tab, configure the main Splunk event handler properties:
 - a. In the Server Hostname field, enter the hostname or IP address of the Splunk server to which AM should connect when writing audit events.
 - b. In the Server Port field, enter the port number to access the Splunk HTTP event collector REST endpoint.
 - c. If SSL is enabled and configured between AM and the Splunk server, select SSL Enabled.
 - d. In the Authorization Token field, enter the authorization token for the Splunk HTTP event collector REST endpoint.
 - e. Save your changes.
12. On the Buffering tab, configure options about how log events should be buffered in memory before they are written to the Splunk data store:
 - a. In the Batch Size field, specify the number of audit events that AM pulls from the audit buffer when writing a batch of events to Splunk.

When buffering is enabled, all audit events are put into an in-memory buffer (one per handled topic), so that the original thread that generated the event can fulfill the requested operation, rather than wait for I/O to complete. A dedicated thread (one per handled topic) constantly pulls events from the buffer in batches and writes them to Splunk. If the buffer becomes empty, the dedicated thread goes to sleep until a new item gets added.
 - b. In the Queue Capacity field, specify the maximum number of audit events that AM can queue in this audit handler's buffer.

If the number of events to queue exceeds the queue capacity, AM raises an exception and the excess audit events are dropped, and therefore not written to Splunk.
 - c. In the Write interval (in milliseconds) field, specify how often AM should write buffered events to Splunk.
 - d. Save your changes.

Configuring the Trust Transaction Header System Property

AM supports the propagation of the transaction ID across the ForgeRock platform, such as from DS or IDM to AM, using the HTTP header `X-ForgeRock-TransactionId`. The `X-ForgeRock-TransactionId` header

is automatically set in all outgoing HTTP calls from one ForgeRock product to another. Customers can also set this header themselves from their own applications or scripts calling into the ForgeRock platform.

You can set a new property `org.forgerock.http.TrustTransactionHeader` to `true`, which will trust any incoming `X-ForgeRock-TransactionId` headers. By default, the `org.forgerock.http.TrustTransactionHeader` is set to `false`, so that a malicious actor cannot flood the system with requests using the same transaction ID header to hide their tracks.

To Configure the Trust Transactions Header System Property

1. Log in to the AM console.
2. Navigate to Configure > Server Defaults > Advanced.
3. In the Add a Name field, enter `org.forgerock.http.TrustTransactionHeader`, and enter `true` in the corresponding Add a Value field.
4. Save your changes.

Your AM instance will now accept incoming `X-ForgeRock-TransactionId` headers, which can then be tracked in the audit logs.

5. Repeat this procedure for all servers requiring this property.

Implementing the Classic Logging Service

Note

AM supports two Audit Logging Services: the classic Logging Service, which is based on a Java SDK and is available in AM versions prior to AM 5.0, and a common REST-based Audit Logging Service. The classic Logging Service is deprecated.

To configure AM logging properties, log in to the AM console as AM administrator, and navigate to Configure > Global Services > Logging.

For more information on the available settings, see "Audit Logging" reference.

Audit Logging to Flat Files

By default, AM audit logs are written to files in the configuration directory for the instance, such as `$HOME/openam/log/`.

AM sends messages to different log files, each named after the service logging the message, with two different types log files per service: `.access` and `.error`. Thus, the current log files for the authentication service are named `amAuthentication.access` and `amAuthentication.error`.

For details, see "Log Files and Messages" in the *Reference*.

Audit Logging to a Syslog Server

AM supports sending audit log messages to a syslog server for collation.

You can enable syslog audit logging by using the AM console, or the `ssoadm` command.

Enabling Syslog Audit Logging by Using the AM Console

1. Log in to the AM console as AM administrator, for example `amadmin`.
2. Navigate to Configure > Global Services > Logging.
3. On the Syslog tab, configure the following settings as appropriate for your syslog server, and save your changes:

- Syslog server host
- Syslog server port
- Syslog server protocol
- Syslog facility
- Syslog connection timeout

For information on these settings, see "Logging" in the *Reference*.

4. On the General tab, set the Logging Type drop-down list to `Syslog`, and save your changes.

Enabling Syslog Audit Logging by Using the `ssoadm` Command

1. Create a text file, for example, `MySyslogServerSettings.txt` containing the settings used when audit logging to a syslog server, as shown below:

```
iplanet-am-logging-syslog-port=514
iplanet-am-logging-syslog-protocol=UDP
iplanet-am-logging-type=Syslog
iplanet-am-logging-syslog-connection-timeout=30
iplanet-am-logging-syslog-host=localhost
iplanet-am-logging-syslog-facility=local5
```

2. Use the following SSOADM command to configure audit logging to a syslog server:

```
$ ssoadm \
  set-attr-defs \
  --adminid amadmin \
  --password-file /tmp/pwd.txt \
  --servicename iPlanetAMLoggingService \
  --schematype Global \
  --datafile MySyslogServerSettings.txt
Schema attribute defaults were set.
```

Chapter 7

Setting Up the Dashboard Service

This chapter shows how to configure the Dashboard service.

Introducing the Dashboard Service

The Dashboard Service provides the end user with an interface to access applications secured by AM, both cloud-based applications like SalesForce and internal applications protected by web or Java agents. The Dashboard Service uses SSO to login to the applications when the user clicks on the application icon. For some apps, like SalesForce, you will want to limit access to only a few users. Other apps, like Google Mail or Drive, you will probably want to make available to all users.

User Dashboard Screen

The Dashboard Service is meant to give users a single place to access their applications. Keep in mind that this does not limit user access, only what appears on the user dashboard.

There are three stages to setting up the Dashboard Service:

- Setup the Dashboard Service and add applications.
- Add the service to the realms.
- Assign users applications so that they appear on the users' dashboards. This can be done manually or through a provisioning solution.

Once the Dashboard Service is configured for a user, the user can access their dashboard after logging in through the XUI under `/XUI/?realm=#dashboard/`.

When making a request to the XUI, specify the realm or realm alias as the value of a `realm` parameter in the query string, or the DNS alias in the domain component of the URL. If you do not use a realm

alias, then you must specify the entire hierarchy of the realm, starting at the top-level realm. For example <https://openam.example.com:8443/openam/XUI/?realm=/customers/europe#login/>.

For example, the full URL depending on the deployment might be at <https://openam.example.com:8443/openam/XUI/?realm=/myrealm#dashboard/>.

Implementing the Dashboard Service

Making some applications universally available ensures that all users have the same basic applications. However, some of your applications should be protected from the majority of your users. You will need to single out which users will include the application on their dashboard.

There are three default applications in the Dashboard Service: Google, Salesforce, and ZenDesk.

- To add applications to the Dashboard Service, see "To Add Applications to the Dashboard Service".
- To add the Dashboard Service to a realm, see "To Add the Application Dashboard Service to a Realm".
- To add an application to a user's dashboard, see "To Add an Application to a User's Dashboard".
- To remove an application from a user's dashboard, see "Removing User Access to an Application".

To Add Applications to the Dashboard Service

You can add applications to the Dashboard Service with the following steps. All fields except the dashboard class name and ICF Identifier are required for the application to work properly from the dashboard:

1. Log in to the AM console as AM Administrator, `amadmin`.
2. Navigate to Configure > Global Services > Dashboard > Secondary Configurations, and then click Add a Secondary Configuration to add an application to the Dashboard Service.
3. Provide a unique name for the application.
4. Add a Dashboard Class Name that identifies how the end user will access the app, such as `SAML2ApplicationClass` for a SAML v2.0 application.
5. Add a Dashboard Name for the application.
6. Add a Dashboard Display Name. This name is what the end user will see, such as Google.
7. Add the Dashboard Icon you would like the end user to see for the application. Either use a fully-qualified URL or an appropriate relative URL so that the icon is rendered properly on the user dashboard.
8. Add the Dashboard Login URL to point to the location the end user will go to once they click on the icon.

9. Leave the ICF Identifier blank.
10. Click Add when you are done.

To Add the Application Dashboard Service to a Realm

You must add the Dashboard Service to a realm before it will be available. The following instructions show you how to add an application to a single realm. Before you begin, make sure you have the name of the application as it appears on the Secondary Configuration Instance table under Configure > Global Services > Dashboard:

1. Select Realms > *Realm Name* > Services, and then click Add a Service.
2. Select the Dashboard service, and then click Create.
3. Add or remove the applications you would like to appear on the Dashboard service for the realm.
4. Click Save Changes when you are done.

To Add an Application to a User's Dashboard

Use the following steps to add an application to a user's dashboard:

1. Select Realms > *Realm Name* > Identities and click the user identifier to edit the user's profile.
2. Under Services, click Dashboard.
3. Add the application beside the user name under the user's Assigned Dashboard list.
4. Click Save.

Removing User Access to an Application

You may need to remove an application from user's dashboard, but you do not want to entirely delete the user. The following steps walk you through removing an application from a user's dashboard:

1. Select Realms > *Realm Name* > Identities and click the user identifier to edit the user's profile.
2. Under Services, click Dashboard.
3. Delete the application beside the user name under the user's Assigned Dashboard list.
4. Click Save.

Displaying Dashboard Applications

AM lets administrators configure online applications to display applications on user Dashboards. You can use exposed REST API to display information about the online applications.

/dashboard/assigned

This endpoint retrieves the list of applications assigned to the authenticated user.

```
$ curl \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/realms/root/dashboard/assigned
{
  "google":{
    "dashboardIcon":[
      "Google.gif"
    ],
    "dashboardName":[
      "Google"
    ],
    "dashboardLogin":[
      "http://www.google.com"
    ],
    "ICFIdentifier":[
      ""
    ],
    "dashboardDisplayName":[
      "Google"
    ],
    "dashboardClassName":[
      "SAML2ApplicationClass"
    ]
  }
}
```

/dashboard/available

This endpoint retrieves the list of applications available in the authenticated user's realm. The example is based on two of the default Dashboard applications: Google and Salesforce.

```
$ curl \
--header "iplanetDirectoryPro: AQIC5w...2NzEz*" \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/realms/root/dashboard/available
{
  "google":{
    "dashboardIcon":[
      "Google.gif"
    ],
    "dashboardName":[
      "Google"
    ],
    "dashboardLogin":[
      "http://www.google.com"
    ],
    "ICFIdentifier":[
      ""
    ],
    "dashboardDisplayName":[
      "Google"
    ],
    "dashboardClassName":[

```

If your application runs in a user-agent such as a browser, you can rely on AM to handle authentication.

Chapter 8

Maintaining an Instance

This chapter provides a how-to approach to complete common maintenance tasks.

Backing Up and Restoring Configurations

AM stores configuration data in an LDAP directory server and in files. The directory service replicates configuration data between directory servers, allowing AM to share configuration data across servers in a site. During normal production operations, you rely on directory replication to maintain multiple, current copies of AM service configuration. To recover from the loss of a server or from a serious administrative error, back up directory data and configuration files.

This section shows how to backup and restore AM configuration data by backing up and restoring local configuration files and local (embedded) configuration directory server data. If your deployment uses an external configuration directory server, then refer to the documentation for your external directory server or work with your directory server administrator to back up and restore configuration data stored in the external directory service.

For more information about DS, see the chapter *Backing Up and Restoring Data* in the *ForgeRock Directory Services Administration Guide*.

This section aims to cover the following uses of backup data.

1. Recovery from server failure:
 - "To Back Up All Server Configuration Data"
 - "To Restore All Server Configuration Data"
2. Recovery from serious administrative error:
 - "To Export Only Configuration Data"
 - "To Restore Configuration Data After Serious Error"

To Back Up All Server Configuration Data

This procedure backs up all the configuration data stored with the server. This backup is to be restored when rebuilding a failed server.

Have the following points in mind when using this procedure:

- Use this procedure *only* when AM stores configuration data in the embedded DS server, which means that the embedded DS server files are co-located with other AM configuration files.

If your deployment uses an external configuration directory server, then refer to the documentation for your external directory server or work with your directory server administrator to back up and restore configuration data stored in the external directory service. For more information about DS, see the chapter *Backing Up and Restoring Data* in the *ForgeRock Directory Services Administration Guide*.

- Do not restore configuration data from a backup of a different release of AM. The structure of the configuration data can change from release to release.
- In AM deployments where configuration directory data is replicated, you must take the following points into consideration:
 - Directory replication mechanically applies new changes to ensure that replicated data is the same everywhere. When you restore older backup data, directory replication applies newer changes to the older data.

This includes new changes that the administrator sees as mistakes. To recover from administrative error, you must work around this behavior either by performing a change to be replicated that repairs the error or by restoring all replicas to a state prior to the error.

- When preparing directory server backup and restore operations, also know that data replication purge operations affect the useful lifetime of any data that you back up.

Replication relies on historical data to resolve any conflicts that arise. If directory servers did not eventually purge this historical data, the data would continue to grow until it filled all available space. Directory servers therefore purge older historical data. DS purges historical data older than 3 days by default.

When the directory server encounters a gap in historical data it cannot correctly complete replication operations. You must make sure, therefore, that any data you restore from backup is not older than the replication purge delay. Otherwise your restoration operation could break replication with the likely result that you must restore all servers from backup, losing any changes that occurred in the meantime.

For more information about purge delay, see the *ForgeRock Directory Services Administration Guide* section on *To Restore a Replica*.

Follow these steps for each AM server that you want to back up:

1. Stop AM or the container in which it runs.
2. Back up AM configuration files including those of the configuration directory server but skipping log and lock files.

The following example uses the default configuration location. \$HOME is the home directory of the user who runs the web container where AM is deployed, and AM is deployed in Apache Tomcat under `openam`:

```
$ cd $HOME
$ zip \
  --recurse-paths \
  /path/to/backup-`date -u +15%F-%m-%S`.zip \
  openam .openamcfg/AMConfig_path_to_tomcat_webapps_openam_ \
  --exclude openam/openam/debug/* openam/openam/log/* openam/openam/stats* \
  openam/opends/Logs/* openam/opends/Locks/*
...
$ ls /path/to/backup-2014-12-01-12-00.zip
/path/to/backup-2014-12-01-12-00.zip
```

The backup is valid until the end of the purge delay.

3. Start AM or the container in which it runs.

To Restore All Server Configuration Data

This procedure applies when rebuilding a failed server.

Have the following points in mind when using this procedure:

- This procedure restores all the configuration data for a server, where the configuration data has been backed up as described in "To Back Up All Server Configuration Data".
- Use this procedure *only* when AM stores configuration data in the embedded DS server, which means that the embedded DS server files are co-located with other AM configuration files.

If your deployment uses an external configuration directory server, then refer to the documentation for your external directory server or work with your directory server administrator to back up and restore configuration data stored in the external directory service. For DS, you can find more information in the chapter on *Backing Up and Restoring Data*.

- Do not restore configuration data from a backup of a different release of AM. The structure of the configuration data can change from release to release.
- If AM also stores CTS data in the embedded DS server, then the restore operation overwrites current CTS data with older data. After you restore from backup, users authenticate again as necessary.
- In AM deployments where configuration directory data is replicated, you must take the following points into consideration:
 - Directory replication mechanically applies new changes to ensure that replicated data is the same everywhere. When you restore older backup data, directory replication applies newer changes to the older data.

This includes new changes that the administrator sees as mistakes. To recover from administrative error, you must work around this behavior either by performing a change to be replicated that repairs the error or by restoring all replicas to a state prior to the error.

- When preparing directory server backup and restore operations, also know that data replication purge operations affect the useful lifetime of any data that you back up.

Replication relies on historical data to resolve any conflicts that arise. If directory servers did not eventually purge this historical data, the data would continue to grow until it filled all available space. Directory servers therefore purge older historical data. DS purges historical data older than 3 days by default.

When the directory server encounters a gap in historical data it cannot correctly complete replication operations. You must make sure, therefore, that any data you restore from backup is not older than the replication purge delay. Otherwise your restoration operation could break replication with the likely result that you must restore all servers from backup, losing any changes that occurred in the meantime.

For more information about purge delay, see the *ForgeRock Directory Services Administration Guide* section on *To Restore a Replica*.

Follow these steps for each AM server to restore. If you are restoring AM after a failure, make sure you make a copy of any configuration and log files that you need to investigate the problem before restoring AM from backup:

1. Stop AM or the container in which it runs.
2. Restore files in the configuration directory as necessary, making sure that you restore from a valid backup, one that is newer than the replication purge delay:

```
$ cd $HOME
$ unzip /path/to/backup-2014-12-01-12-00.zip
Archive: /path/to/backup-2014-12-01-12-00.zip
replace openam/.configParam? [y]es, [n]o, [A]ll, [N]one, [r]ename: A
...
```

3. Start AM or the container in which it runs.

To Export Only Configuration Data

LDAP Data Interchange Format (LDIF) is a standard, text-based format for storing LDAP directory data. You can use LDIF excerpts to make changes to directory data.

This procedure takes an LDIF backup of AM configuration data only. Use this LDIF data when recovering from a serious configuration error:

1. Make sure that AM's configuration is in correct working order before exporting configuration data.
2. Use the DS **export-ldif** command to run a task that exports only configuration data, not CTS data.

You can run this command without stopping AM.

Find DS commands under the file system directory that contains AM configuration files.

The bind password for Directory Manager is the same as the password for the AM global administrator (amadmin):

```
$ $HOME/openam/opens/bin/export-ldif \  
--port 4444 \  
--hostname openam.example.com \  
--bindDN "cn=Directory Manager" \  
--bindPassword password \  
--backendID userRoot \  
--includeBranch dc=openam,dc=forgerock,dc=org \  
--excludeBranch ou=tokens,dc=openam,dc=forgerock,dc=org \  
--ldifFile /path/to/backup-`date -u +%F-%m-%s`.ldif \  
--start 0 \  
--trustAll  
Export task 20141208113331302 scheduled to start Dec 8, 2014 11:33:31 AM CET
```

When the task completes, the LDIF file is at the expected location:

```
$ ls /path/to/*.ldif  
/path/to/backup-2014-12-08-12-1418034808.ldif
```

To Restore Configuration Data After Serious Error

A serious configuration error is an error that you cannot easily repair by using AM configuration tools, such as the AM console or the **ssoadm** command.

Use this procedure to recover from a serious configuration error by manually restoring configuration data to an earlier state. This procedure depends on LDIF data that you exported as described in "To Export Only Configuration Data".

1. Read the DS change log to determine the LDAP changes that caused the configuration problem.

The DS change log provides an external change log mechanism that allows you to read changes made to directory data for replicated directory servers.

For instructions on reading the change log, see the *ForgeRock Directory Services Administration Guide* section on *Change Notification For Your Applications*.

2. Based on the data in the change log, determine what changes would reverse the configuration error.

For changes that resulted in one attribute value being replaced by another, you can recover the information from the change log alone.

3. For deleted content not contained in the change log, use the LDIF resulting from "To Export Only Configuration Data" to determine a prior, working state of the configuration entry before the configuration error.
4. Prepare LDIF to modify configuration data in a way that repairs the error by restoring the state of directory entries before the administrative error.
5. Use the DS **ldapmodify** command to apply the modification.

For instructions on making changes to directory data see the section on *Updating the Directory* in the *ForgeRock Directory Services Directory Server Developer's Guide*.

Changing the amadmin User's Password

The built-in `amadmin` account cannot be disabled, deleted, or renamed, since it is hard-coded in the source code of several files.

If you want a user to have administration rights in AM other than `amadmin`, delegate realm administration privileges to the new user. For more information about delegating realm administration privileges, see "Delegating Realm Administration Privileges".

In this section you will find procedures to change the password of the top-level administrator `amadmin`, when:

- AM is configured using an external configuration store.
See "To Change the amadmin User's Password: External Configuration Store".
- AM is configured using the embedded DS server as the configuration store. It may be configured with an external data store, or with the embedded DS server as a data store.
See "To Change the amadmin User's Password: Embedded Configuration Store".

To Change the amadmin User's Password: External Configuration Store

If AM is configured to use an external configuration store, perform the following steps to change the `amadmin` user's password:

1. Log in to the AM console as the administrator, `amadmin`.
2. Navigate to the user avatar (👤) in the top right hand corner of the XUI.
3. Select Change Password.
4. Enter the current password in the Current password field.
5. Enter the new password in the New password and Confirm new password fields.
6. Save your changes.

If your deployment has multiple AM servers, the new password replicates across all servers.

To Change the amadmin User's Password: Embedded Configuration Store

If AM is configured to use the embedded DS server for the configuration store, you must change the passwords of the following two users in the embedded DS accounts to match the new `amadmin` password:

You must change these two passwords in the embedded DS server regardless of whether you use an external or embedded data store.

- The `cn=Directory Manager` user, created during installation.
- The global administrator, created in DS by AM after a second AM server has been added to the deployment.

Some functionality might not work if the DS directory manager, AM administrator `amadmin`, and DS global administrator passwords are not identical. For example, adding new servers to the deployment.

To change the AM `amadmin`, DS directory manager, and DS global administrator passwords and the required bindings, perform the following steps:

1. Back up your deployment as described in "Backing Up and Restoring Configurations".
2. Log in to the AM console as the administrator, `amadmin`.
3. Navigate to the user avatar (👤) in the top right hand corner of the XUI.
4. Select Change Password.
5. Enter the current password in the Current password field.
6. Enter the new password in the New password and Confirm new password fields.
7. Save your changes.

If your deployment has multiple AM servers, the new password replicates across all servers.

8. AM binds to the embedded DS server using the `cn=Directory Manager` account. Change the `cn=Directory Manager` account's bind password in the AM configuration as follows:
 - a. Change the password for the configuration store binding:
 - i. Navigate to Deployment > Servers > *Server Name* > Directory Configuration.
 - ii. Enter the new bind password, which is the new `amadmin` password, and save your changes.

Make this change for each of your AM servers.

Note

Changing the bind password of the configuration store updates the `configstorepwd` alias in the `keystore.jceks` keystore file automatically.

- b. (Optional) If you use the embedded DS server as a data store, change the following bind passwords:
 - i. Navigate to Realms > *Realm Name* > Identity Stores > embedded:

- Enter the new bind password, which is the new `amadmin` password, and save your changes.
Make this change in every AM realm that uses the embedded DS as an identity store.
 - ii. Navigate to Realms > *Realm Name* > Services > Policy Configuration:
 - Enter the new bind password, which is the new `amadmin` password, and save your changes.
Make this change in every AM realm that uses the embedded DS as a data store.
 - iii. Navigate to Realms > *Realm Name* > Authentication > Modules, and select LDAP:
 - Enter the new bind password, which is the new `amadmin` password, and save your changes.
Make this change in every AM realm that uses the embedded DS as a data store.
9. To change the `cn=Directory Manager` and the global administrator passwords in the embedded DS, see [Resetting Administrator Passwords in the *ForgeRock Directory Services Administration Guide*](#).

Monitoring Services

This section covers how to monitor services to ensure appropriate performance and service availability.

Monitoring Interfaces

You can monitor AM through the following interfaces:

- Web Pages
- Java Management Extensions (JMX)
- Simple Network Management Protocol (SNMP)
- Prometheus
- CREST
- Graphite

To configure monitoring services, login to the AM console as AM administrator, and navigate to Configure > Global Services > Monitoring. For more information on monitoring metrics, see "Monitoring Metrics"

Web-Based Monitoring

You can configure AM to allow you to access a web based view of AM MBeans on port 8082 where the core server runs, such as <http://openam-ter.example.com:8082/>. Either use the console, or use the **ssoadm** command:

```
$ ssoadm \  
  set-attr-defs \  
    --servicename iPlanetAMMonitoringService \  
    --schematype Global \  
    --adminid amadmin \  
    --password-file /tmp/pwd.txt \  
    --attributevalues iplanet-am-monitoring-http-enabled=true
```

The default authentication file allows you to authenticate over HTTP as user **demo**, password **changeit**. The user name and password are kept in the file specified, with the password encrypted:

```
$ cat openam/openam/openam_mon_auth  
demo AQICMBCKLwx6G3vzK3TYRbtTpNYAagVIPNP
```

Or:

```
$ cat openam/openam/opensso_mon_auth  
demo AQICvSe+tXEg8TUUT8ekzHb8IRzVSvm1Lc2u
```

You can encrypt a new password using the **ampassword** command. After changing the authentication file, you must restart AM for the changes to take effect.

MBeans in a Browser

MBean View

[Project OpenDMKopendmk-1.0-b02]

- **MBean Name:**
SUN_OPENSSO_SERVER_MIB/ssoServerServerTable:ssoServerServerEntry.serverHostName=openam-ter.example.com,ssoServerServerEntry.serverPort=8080
- **MBean Java Class:** com.sun.identity.monitoring.SsoServerServerEntryImpl

Reload Period in seconds:

[Back to Agent View](#)

MBean description:

Information on the management interface of the MBean

List of MBean attributes:

Name	Type	Access	Value
ServerHostName	java.lang.String	RO	openam-ter.example.com
ServerId	java.lang.Integer	RO	1
ServerPort	java.lang.Integer	RO	8080
ServerProtocol	java.lang.String	RO	http
ServerStatus	java.lang.Integer	RO	1

JMX Monitoring

You can configure AM to allow you to listen for Java Management eXtension (JMX) clients, by default on port 9999. Either use the AM console page under **Configure > Global Services > Monitoring** and make sure both **Monitoring Status** and **Monitoring RMI interface status** are both set to **Enabled**, or use the **ssoadm** command:

```
$ ssoadm \
  set-attr-defs \
  --servicename iPlanetAMMonitoringService \
  --schematype Global \
  --adminid amadmin \
  --password-file /tmp/pwd.txt \
  --attributevalues iplanet-am-monitoring-enabled=true \
  iplanet-am-monitoring-rmi-enabled=true
```

A number of tools support JMX, including **jvisualvm** and **jconsole**. When you use **jconsole** to browse AM MBeans for example, the default URL for the AM running on the local system is `service:jmx:rmi:///jndi/rmi://localhost:9999/server`.

```
$ jconsole service:jmx:rmi:///jndi/rmi://localhost:9999/server &
```

You can also browse the MBeans by connecting to your web application container, and browsing to the AM MBeans. By default, JMX monitoring for your container is likely to be accessible only locally, using the process ID.

JConsole Browsing MBeans

Also see [Monitoring and Management Using JMX](#) for instructions on how to connect remotely, how to use SSL, and so forth.

Important

JMX has a limitation in that some Operations and CTS tables cannot be properly serialized from AM to JMX. As a result, only a portion of AM's monitoring information is available through JMX. SNMP is a preferred monitoring option over JMX and exposes all AM tables, especially for CTS, with no serialization limitations.

SNMP Monitoring

You can configure AM to allow you to listen on port 8085 for SNMP monitoring.

To Enable the SNMP Monitoring Interface

1. Stop the AM instance or the container where it runs.
2. Download the AM 6.5.5 ZIP file from the BackStage website.
3. Extract the contents of the ZIP file.
4. Navigate to the `/snmp` folder, and run the `opendmk.jar` installer file. For example:

```
$ java -jar opendmk.jar
```
5. Accept the License Agreement.
6. Select the install directory you want to install to. For example: `/tmp/opendmk`.
7. Copy the `jdmkrt.jar` file from the `/lib` folder of the extracted archive to the AM `/WEB-INF/lib` folder. For example:

```
$ cp /tmp/opendmk/OpenDMK-bin/lib/jdmkrt.jar /path/to/openam.war/WEB-INF/lib
```
8. Restart the AM instance or the container in which it runs.
9. Navigate to Configure > Global Services > Monitoring.
10. Set the Monitoring Status to enabled.
11. Set the Monitoring SNMP interface status property to Enabled. By default, AM will be set to allow you to listen on port 8085 for SNMP monitoring.
12. Click Save Changes.
13. Restart the AM instance for the change to take effect.

Prometheus Monitoring

Prometheus is third-party software used for gathering and processing monitoring data. AM exposes an endpoint which Prometheus uses to gather metrics from the AM instance. For more information about installing and running Prometheus, see the Prometheus documentation.

When enabled, AM makes the Prometheus-formatted metrics available at the `/json/metrics/prometheus` endpoint.

Configure Prometheus to monitor the AM endpoint, using the `prometheus.yml` configuration file. For more information on configuring Prometheus, see the Prometheus configuration documentation.

Tip

Prometheus provides monitoring and processing for the information provided by AM, but further analysis and visualization may be desired. In this case, you can use tools such as Grafana to create customized charts and graphs based on the information collected by Prometheus. For more information on installing and running Grafana, see the Grafana website.

To Enable the Prometheus Monitoring Interface

Before enabling Prometheus access to monitoring metrics, make sure that you have enabled monitoring. To enable monitoring, navigate to `Configure > Global Services > Monitoring`. Set the Monitoring Status to enabled, and then click Save Changes.

1. Navigate to `Configure > Global Services > Monitoring`.
2. Select the Secondary Configurations tab, and click `prometheus`.
3. Set `prometheus` to Enabled.
4. In the Authentication Type drop-down menu, select one of the following options:
 - **None.** Prometheus does not need to authenticate when accessing the endpoint.
 - **HTTP Basic.** Prometheus must authenticate using a username and a password when accessing the endpoint.
5. (Optional) If Prometheus must authenticate when accessing the endpoint, specify the Username and Password that it will use.
6. Click Save Changes.

CREST Monitoring

CREST is the ForgeRock Common REST API. AM exposes an endpoint which allows REST clients to gather information about your AM installation, in JSON format.

When enabled, AM makes the CREST-formatted metrics available at the `/json/metrics/api` endpoint.

To Enable the CREST Monitoring Interface

Before enabling CREST access to monitoring metrics, make sure that you have enabled monitoring. To enable monitoring, navigate to `Configure > Global Services > Monitoring`. Set the Monitoring Status to enabled, and then click Save Changes.

1. Navigate to Configure > Global Services > Monitoring.
2. Select the Secondary Configurations tab, and click crest.
3. Set CREST to Enabled.
4. Click Save Changes.

Graphite Monitoring

Graphite is third-party software used for storing monitoring data, and rendering graphs of the data. For more information about installing and running Graphite, see the [Graphite documentation](#).

To Enable the Graphite Monitoring Interface

Before enabling Graphite access to monitoring metrics, make sure that you have enabled monitoring. To enable monitoring, navigate to Configure > Global Services > Monitoring. Set the Monitoring Status to enabled, and then click Save Changes.

1. Navigate to Configure > Global Services > Monitoring.
2. Select the Secondary Configurations tab, and click Add a Secondary Configuration.
3. Select Graphite Reporter.
4. Specify the Name and Hostname of the Graphite instance to which to push the metrics data.
5. Click Create.

Monitoring CTS Tokens

The Core Token Service (CTS) provides persistent and highly available token storage for a several components within AM, including user sessions, OAuth 2.0, SAML v2.0 and UMA tokens. For information on configuring the Core Token Service, see "[Implementing the Core Token Service](#)" in the *Installation Guide*.

Depending on system load and usage, the CTS can produce a large quantity of tokens, which can be short lived. This style of usage is significantly different from typical LDAP usage. As such, systems administrators may be interested in monitoring this usage as part of LDAP directory maintenance.

The CTS functions only with one external LDAP service, DS.

To that end, the current state of CTS tokens on a system can be monitored over SNMP. The current state of different types of CTS tokens are associated with different Object Identifiers (OIDs) in a Management Information Base (MIB).

To enable SNMP, see "[To Enable the SNMP Monitoring Interface](#)"

CTS SNMP Monitoring

Once activated, SNMP monitoring works over UDP by default. You may want to install one of many available network monitoring tools. For the purpose of this section, basic SNMP service and monitoring tools have been installed on a GNU/Linux system. The same commands should work on a Mac OS X system.

SNMP depends on labels known as Object Identifiers (OIDs). These are uniquely defined labels, organized in tree format. For AM, they are configured in a `.mib` file named `FORGEROCK-OPENAM-CTS.mib`, found inside the `/path/to/tomcat/webapps/openam/WEB-INF/lib/openam-mib-schema-6.5.5.jar` file of the AM deployment.

For detailed information on configured OIDs, see "Core Token Service (CTS) Object Identifiers" in the *Installation Guide*.

With the OIDs in hand, you can set up an SNMP server to collect the data. You would also need SNMP utility commands with associated OIDs to measure the current state of a component. First, to verify the operation of SNMP on a GNU/Linux system, over port 8085, using SNMP version 2c, run the following command:

```
# snmpstatus -c public -v 2c localhost
```

The output should normally specify communications over UDP. If you get a `timeout` message, the SNMP service may not be running.

You can get the value for a specific OID. For example, the following command would retrieve the cumulative count for CTS create operations, over port 8085:

```
# snmpget -c public -v 2c :8085 enterprises.36733.1.2.3.3.1.1.1
```

If your version of the tool does not support the `enterprises` OID string, use `1.3.6.1.4.1` instead, as in `1.3.6.1.4.1.36733.1.2.3.3.1.1.1`.

For one view of the tree of OIDs, you can use the `snmpwalk` command. For example, the following command lists all OIDs related to CTS:

```
# snmpwalk -c public -v 2c :8085 enterprises.36733.1.2.3
```

A number of CTS OIDs are listed with a `Counter64` value. As defined in RFC 2578, an OID configured in this way has a maximum value of $2^{64} - 1$.

SNMP Monitoring for Policy Evaluation

You can monitor policy evaluation performance over SNMP. AM records statistics for up to a number of recent policy evaluation requests. (You can configure the number in the AM console under Configuration > System > Monitoring. For details, see the reference section "Monitoring".

Interface Stability: Evolving in the *Release Notes*

As described in "CTS SNMP Monitoring", SNMP uses OIDs defined in the `.mib` file, `FORGEROCK-OPENAM-POLICY.mib`, found inside the `/path/to/tomcat/webapps/openam/WEB-INF/lib/openam-mib-schema-6.5.5.jar` file of the AM deployment. This file specifies the statistics AM keeps for policy evaluation operations. Adapt the examples in "CTS SNMP Monitoring" to read monitoring statistics about policy evaluation on the command line.

When monitoring is active, AM records statistics about both the numbers and rates of policy evaluations performed, and also the times taken to process policy evaluations.

The statistics are all read-only. The base OID for policy evaluation statistics is `enterprises.36733.1.2.2.1`. The following table describes the values that you can read:

OIDs Used in SNMP Monitoring For Policy Evaluation

OID	Description	Syntax
<code>enterprises.36733.1.2.2.1.1.1</code>	Cumulative number of policy evaluations for specific resources (self)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.1.2</code>	Average rate of policy evaluations for specific resources (self)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.1.3</code>	Minimum rate of policy evaluations for specific resources (self)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.1.4</code>	Maximum rate of policy evaluations for specific resources (self)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.2.1</code>	Cumulative number of policy evaluations for a tree of resources (subtree)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.2.2</code>	Average rate of policy evaluations for a tree of resources (subtree)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.2.3</code>	Minimum rate of policy evaluations for a tree of resources (subtree)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.2.4</code>	Maximum rate of policy evaluations for a tree of resources (subtree)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.1.2</code>	Average length of time to evaluate a policy for a specific resource (self)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.2.1.2</code>	Slowest evaluation time for a specific resource (self)	<code>SnmpAdminString</code>
<code>enterprises.36733.1.2.2.1.2.2.1</code>	Average length of time to evaluate a policy for a tree of resources (subtree)	<code>Counter64</code>
<code>enterprises.36733.1.2.2.1.2.2.2</code>	Slowest evaluation time for a tree of resources (subtree)	<code>SnmpAdminString</code>

OID	Description	Syntax
<code>enterprises.36733.1.2.2.1.3.1</code>	Slowest individual policy evaluation time overall	<code>SnmpAdminString</code>

SNMP Monitoring for Sessions

You can monitor CTS-based session statistics over SNMP. AM records statistics for up to a configurable number of recent sessions. (You can configure the number in the AM console under Configuration > System > Monitoring. For details, see the system configuration reference section, "Monitoring" in the *Reference*.)

SNMP monitoring is not available for client-based sessions.

Interface Stability: Evolving in the *Release Notes*

As described in "CTS SNMP Monitoring", SNMP uses OIDs defined in a `.mib` file that specifies the statistics AM keeps for policy evaluation operations, the `FORGEROCK-OPENAM-SESSION.mib` file. This file is found inside the `/path/to/tomcat/webapps/openam/WEB-INF/lib/openam-mib-schema-6.5.5.jar` file of the AM deployment. Adapt the examples in "CTS SNMP Monitoring" to read monitoring statistics about sessions on the command line.

When monitoring is active, AM records statistics about both the numbers of internal, remote, and CTS sessions, and also the times taken to process sessions.

The statistics are all read-only. The base OID for session statistics is `enterprises.36733.1.2.1`. Times are expressed in nanoseconds rather than milliseconds, as many operations take less than one millisecond. The following table describes the values that you can read:

OIDs Used in SNMP Monitoring For Sessions

OID	Description	Syntax
<code>enterprises.36733.1.2.1.1.1</code>	Total number of current internal sessions	<code>Counter64</code>
<code>enterprises.36733.1.2.1.1.2</code>	Average time it takes to refresh an internal session	<code>Counter64</code>
<code>enterprises.36733.1.2.1.1.3</code>	Average time it takes to logout an internal session	<code>Counter64</code>
<code>enterprises.36733.1.2.1.1.4</code>	Average time it takes to destroy an internal session	<code>Counter64</code>
<code>enterprises.36733.1.2.1.1.5</code>	Average time it takes to set a property on an internal session	<code>Counter64</code>
<code>enterprises.36733.1.2.1.2.1</code>	Total number of current remote sessions	<code>Counter64</code>
<code>enterprises.36733.1.2.1.2.2</code>	Average time it takes to refresh a remote session	<code>Counter64</code>
<code>enterprises.36733.1.2.1.2.3</code>	Average time it takes to logout a remote session	<code>Counter64</code>

OID	Description	Syntax
<code>enterprises.36733.1.2.1.2.4</code>	Average time it takes to destroy a remote session	Counter64
<code>enterprises.36733.1.2.1.2.5</code>	Average time it takes to set a property on a remote session	Counter64
<code>enterprises.36733.1.2.1.3.1</code>	Total number of sessions currently in the Core Token Service (CTS)	Counter64
<code>enterprises.36733.1.2.1.3.2</code>	Average time it takes to refresh a CTS session	Counter64
<code>enterprises.36733.1.2.1.3.3</code>	Average time it takes to logout a CTS session	Counter64
<code>enterprises.36733.1.2.1.3.4</code>	Average time it takes to destroy a CTS session	Counter64
<code>enterprises.36733.1.2.1.3.5</code>	Average time it takes to set a property on a CTS session	Counter64

Tuning an Instance

This section covers key AM tunings to ensure smoothly performing access and federation management services, and to maximize throughput while minimizing response times.

Note

The recommendations provided here are guidelines for your testing rather than hard and fast rules for every situation. Said another way, the fact that a given setting is configurable implies that no one setting is right in all circumstances.

The extent to which performance tuning advice applies depends to a large extent on your requirements, on your workload, and on what resources you have available. Test suggestions before rolling them out into production.

The suggestions in this section pertain to AM deployments with the following characteristics:

- The deployment has a dedicated DS server for the Core Token Service. The host running this directory server is a high-end server with a large amount of memory and multiple CPUs.
- The AM server is configured to use CTS-based sessions.

The following table summarizes the high-level tasks required to tune an AM instance:

Task	Resources
Tune General AM Settings	"Tuning Server Settings"
Tune Connectivity to LDAP Data Stores	"Tuning LDAP Connectivity"

Task	Resources
Tune the JVM where AM Runs	"Tuning Java Virtual Machine Settings"
Tune the Configuration and User Caches	"Tuning Caching"

Tuning Server Settings

AM has a number of settings that can be tuned to increase performance.

Logging Settings

The following general points apply:

- Set debug logging level to **error**.
- Set container-level logging to a low level, such as **error** or **severe**.

Notification Settings

AM has two thread pools used to send notifications to clients. The Service Management Service (SMS) thread pool can be tuned in the AM console under Configure > Server Defaults > SDK > Data Store:

SMS Notification Setting

Property	Default Value	Suggestions
Notification Pool Size	1	Specifies the size of the thread pool used to send notifications. A value of 1 causes notifications to be processed sequentially, avoiding any potential out-of-order conditions. In production, where configuration is unlikely to change often, keeping the default of 1 is recommended. (<code>com.sun.identity.sm.notification.threadpool.size</code>)

The session service has its own thread pool to send notifications to listeners about changes to CTS-based sessions. This is configured under Configure > Server Defaults > Session > Notification:

Session Service Notification Settings

Property	Default Value	Suggestions
Notification Pool Size	10	This is the size of the thread pool used to send notifications. In production this should be around 25-30. (<code>com.ipplanet.am.notification.threadpool.size</code>)

Property	Default Value	Suggestions
Notification Thread Pool Threshold	5000	This is the maximum number of notifications in the queue waiting to be sent. The default value should be fine in the majority of installations. (<code>com.ipplanet.am.notification.threadpool.threshold</code>)

Session Settings

The Session Service has additional properties to tune, which are configured under `Configure > Server Defaults > Session > Session Limits`. The following suggestion applies to deployments using CTS-based sessions:

Session Settings

Property	Default Value	Suggestion
Maximum Session Cache Size	5000	Maximum number of AM sessions to cache on the server. In production, this value can safely be set into the 100,000s. The maximum session cache size is really controlled by the maximum size of the JVM heap which must be tuned appropriately to match the desired session cache size. (<code>org.forgerock.openam.session.service.access.persistence.caching.maxsize</code>)

Tuning LDAP Connectivity

AM instances use pools of connections when communicating to LDAP data stores. You can tune these connection pools to improve performance, and help with load balancing in the case of failover.

AM provides a global timeout setting for connections in a pool, and each store has properties for the maximum pool size, and in some cases, the minimum pool size.

AM will attempt to use as few connections to LDAP data stores as possible, down to the minimum pool value, if specified. Under heavy load, AM creates additional connections to the configured data stores, up to the maximum pool value. These connections are made to any of the available LDAP data stores that are configured for the relevant purpose.

When the load begins to drop, some of those connections become idle. If a connection is idle for longer than the configured connection idle time, AM closes the connection, until any specified minimum pool size is reached.

By closing idle connections and recreating them when needed, AM balances connections across all available LDAP servers, rather than keeping the entire pool connected to a single server.

Tuning the connection pool settings can increase performance, or make AM more responsive to LDAP data store outages.

To Configure Connection Pool Timeouts

1. To configure the timeout used for connections to LDAP stores:
 - a. Open the `bootstrapConfig.properties` file in the AM classpath; for example, in `/path/to/tomcat/webapps/openam/WEB-INF/classes/`.
 - b. Add, or update the following property, and set the idle timeout, in seconds:

```
com.sun.am.ldap.connection.idle.seconds=300
```
2. You also need to configure the setting in the Advanced section of the server defaults, as follows:
 - a. In the administration console, navigate to Configure > Server Defaults > Advanced.
 - b. Add, or edit the following property, and set the idle timeout, in seconds:

```
com.sun.am.ldap.connection.idle.seconds=300
```
3. Restart AM or the container in which it runs for these changes to take effect.

After configuring the timeout for the stores, you can set the pool sizes assigned to the different stores:

- "Tuning Configuration Store LDAP Connections"
- "Tuning CTS Store LDAP Connections"
- "Tuning Identity Store LDAP Connections"
- "Tuning External Policy and Applications Store LDAP Connections"
- "Tuning UMA Store LDAP Connections"
- "Tuning Authentication Node/Module LDAP Connections"

Tuning Configuration Store LDAP Connections

To change LDAP configuration store settings, navigate to Deployment > Servers > *Server Name* > Directory Configuration.

LDAP Configuration Store Settings

Label	Default	Notes
Minimum Connection Pool	1	Property: <code>minConnectionPool</code>
Maximum Connection Pool	10	Property: <code>maxConnectionPool</code>

Tuning CTS Store LDAP Connections

You can increase the number of connections used for connecting to CTS to increase throughput.

One connection is reserved for cleanup of expired CTS tokens. The remaining connections are allocated for CTS operations such that the number is equal to a power of two. Because of this, you should set the maximum number of connections to $2^n + 1$, as in 9, 17, 33, 65, and so forth.

The default maximum number of connections to the CTS is 10. To alter the default, navigate to Deployment > Servers > *Server Name* > CTS > CTS Token Store, and alter the Max Connections property.

You may need to click the Inherit Value property to unlock the value for editing.

Tip

You can also edit the Max Connections default globally by navigating to Configure > Server Defaults > CTS, click the CTS Token Store tab, and then alter the Max Connection property.

If you need to change the default CTS connection timeout, set the `org.forgerock.services.datalayer.connection.timeout.cts.async` property under Deployment > Servers > *Server Name* > Advanced.

Most CTS requests to the directory server are handled quickly, so the default timeout of 10 seconds is suitable in most cases.

You must restart AM or the container in which it runs for these changes to take effect.

Tuning External Policy and Applications Store LDAP Connections

To change external policy and application data store settings, navigate to Configure > Global Services > External Data Stores > Secondary Configurations > *Store Name*.

Note

Policy and application data is stored in the configuration data store if not configured separately. To manage the configuration store connection pool, see "Tuning Configuration Store LDAP Connections".

LDAP Policy and Application Store Settings

Label	Default	Notes
Minimum Connection Pool Size	1	Must be less than the maximum size to allow reaping to function. Property: <code>minimumConnectionPool</code>
Maximum Connection Pool Size	10	Property: <code>maximumConnectionPool</code>

Tuning Identity Store LDAP Connections

To change LDAP data store settings, navigate to Realms > *Realm Name* > Identity Stores > *Identity Store Name* in the AM console. Each store has its own connection pool—so each store needs its own tuning:

LDAP Identity Store Settings

Label	Default	Notes
LDAP Connection Pool Minimum Size	1	A good tuning value for this property is 10. Property: <code>sun-idrepo-ldapv3-config-connection_pool_min_size</code>
LDAP Connection Pool Maximum Size	10	The maximum LDAP connection pool size; a high tuning value for this property is 65, though you might well be able to reduce this for your deployment. Ensure your LDAP server can cope with the maximum number of clients across all the AM servers. Property: <code>sun-idrepo-ldapv3-config-connection_pool_max_size</code>

Tuning UMA Store LDAP Connections

To change the various UMA-related data store settings, navigate to Deployment > Servers > *Server Name*.

To increase the number of connections used for the various UMA-related data stores, navigate to Deployment > Servers > *Server Name* > UMA > *UMA Store Type*, and alter the Max Connections property.

You may need to click the Inherit Value property to unlock the value for editing.

Tip

You can also edit the Max Connections defaults globally by navigating to Configure > Server Defaults > UMA, click the relevant UMA store tab, and then alter the Max Connection property.

LDAP UMA Store Settings

Label	Default	Notes
UMA Resource Store > Max Connections	10	Property: <code>org.forgerock.services.resourcesets.store.max.connections</code>
UMA Audit Store > Max Connections	10	Property: <code>org.forgerock.services.umaudit.store.max.connections</code>
Pending Requests Store > Max Connections	10	Property: <code>org.forgerock.services.pendingrequests.store.max.connections</code>
UMA Resource Labels Store > Max Connections	2	Property: <code>org.forgerock.services.uma.labels.store.max.connections</code>

Tuning Authentication Node/Module LDAP Connections

To change connection pool settings for the "LDAP Decision Node" in the *Authentication and Single Sign-On Guide* and LDAP Authentication Module in the *Authentication and Single Sign-On Guide*, in the AM console, go to Configure > Authentication > Core Attributes > Global Attributes.

LDAP Authentication Node/Module Settings

Label	Default	Notes
Default LDAP Connection Pool Size	1:10	<p>The minimum and maximum LDAP connection pool used by the LDAP authentication node/module, separated by a colon (:) character.</p> <p>Use 10:65 for production AM instances.</p> <p>Property: <code>iplanet-am-auth-ldap-connection-pool-default-size</code></p>

Tuning Java Virtual Machine Settings

This section gives some initial guidance on configuring the JVM for running AM. These settings provide a strong foundation to the JVM before a more detailed garbage collection tuning exercise, or as best practice configuration for production:

Heap Size Settings

JVM Parameters	Suggested Value	Description
<code>-Xms</code> & <code>-Xmx</code>	At least 1 GB (2 GB with embedded DS), in production environments at least 2 GB to 3 GB. This setting depends on the available physical memory, and on whether a 32- or 64-bit JVM is used.	-
<code>-server</code>	-	Ensures the server JVM is used
<code>-XX:MetaspaceSize</code> & <code>-XX:MaxMetaspaceSize</code>	Set both to 256 MB	Controls the size of the metaspace in the JVM
<code>-Dsun.net.client.defaultReadTimeout</code>	60000	<p>Controls the read timeout in the Java HTTP client implementation</p> <p>This applies only to the Sun/Oracle HotSpot JVM.</p>
<code>-Dsun.net.client.defaultConnectTimeout</code>	<p>High setting:</p> <p>30000 (30 seconds)</p>	Controls the connect timeout in the Java HTTP client implementation

JVM Parameters	Suggested Value	Description
		<p>When you have hundreds of incoming requests per second, reduce this value to avoid a huge connection queue.</p> <p>This applies only to the Sun/Oracle HotSpot JVM.</p>

Security Settings

JVM Parameters	Suggested Value	Description
<code>-Dhttps.protocols</code>	TLSv1.2	<p>Controls the protocols used for outbound HTTPS connections from AM.</p> <p>Specify one or more of the following values, separated by commas:</p> <ul style="list-style-type: none"> • TLSv1 • TLSv1.1 • TLSv1.2 • TLSv1.3^a <p>This setting applies only to Sun/Oracle Java environments.</p>
<code>-Dorg.forgerock.openam.ldap.secure.protocol.version</code>	TLSv1.2	<p>Controls the protocol AM uses to connect to various external resources.</p> <p>Specify one or more of the following values, separated by commas:</p> <ul style="list-style-type: none"> • TLSv1 • TLSv1.1 • TLSv1.2 • TLSv1.3^b

^aSupported from JDK 11.

^bSupported from JDK 11.

Note

For `-Dhttps.protocols`, specify the protocol version(s) Java clients can use to connect to AM.

For `-Dorg.forgerock.openam.ldap.secure.protocol.version`, see "Securing Communications" in the *Installation Guide* for a list of external resources to which communication is affected.

Specify a single protocol if AM will only use that protocol when connecting to affected external resources. For example, a value of `TLSv1.2` configures AM to only use the TLSv1.2 protocol to connect.

Specify a comma-separated list with multiple protocols if AM will use the most secure protocol supported by the external resources. For example, if you are using at least JDK 11 you could specify a value of `TLSv1, TLSv1.1, TLSv1.2, TLSv1.3`, which configures AM to attempt to use the TLSv1.3 protocol to connect to external configuration and user data stores. If a TLSv1.3 connection is not supported, AM attempts to use TLSv1.2 to connect, then TLSv1.1, and if still not supported, AM uses TLSv1.

Garbage Collection Settings

JVM Parameters	Suggested Value	Description
<code>-verbose:gc</code>	-	Verbose garbage collection reporting
<code>-Xloggc:</code>	<code>\$CATALINA_HOME/logs/gc.log</code>	Location of the verbose garbage collection log file
<code>-XX:+PrintClassHistogram</code>	-	Prints a heap histogram when a SIGTERM signal is received by the JVM
<code>-XX:+PrintGCDetails</code>	-	Prints detailed information about garbage collection
<code>-XX:+PrintGCTimeStamps</code>	-	Prints detailed garbage collection timings
<code>-XX:+HeapDumpOnOutOfMemoryError</code>	-	Out of Memory errors generate a heap dump automatically
<code>-XX:HeapDumpPath</code>	<code>\$CATALINA_HOME/logs/heapdump.hprof</code>	Location of the heap dump
<code>-XX:+UseConcMarkSweepGC</code>	-	Use the concurrent mark sweep garbage collector
<code>-XX:+CMSClassUnloadingEnabled</code>	-	Allow class unloading during CMS sweeps

Tuning Caching

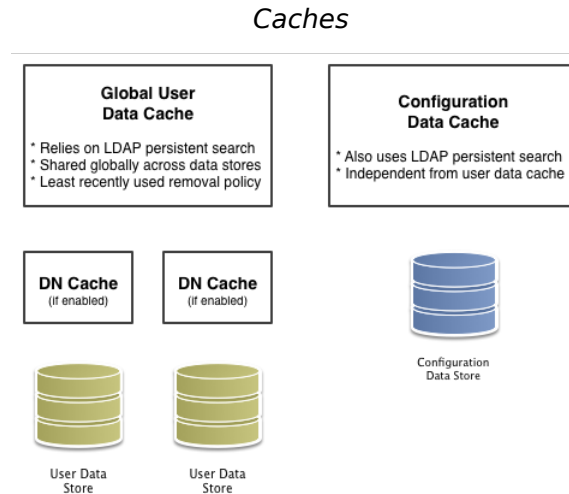

AM caches data to avoid having to query user and configuration data stores each time it needs the information. By default, AM makes use of LDAP persistent search to receive notification of changes to cached data. For this reason, caching works best when data are stored in a directory server that supports LDAP persistent search.

AM has two kinds of configurable cache on the server side: one for configuration data and one for user data. The default settings are usually sufficient for configuration data cache. This section covers the configuration choices for caching user data.

AM implements the global user data cache for its user data stores.

The user data store also supports a *DN cache*, used to cache DN lookups that tend to occur in bursts during authentication. The DN cache can become out of date when a user is moved or renamed in the underlying LDAP store, events that are not always reflected in a persistent search result. You can enable the DN cache when the underlying LDAP store supports persistent search and `modDN` operations (that is, move or rename DN).

The following diagram depicts the two kinds of cache, and also the two types of caching available for user data:

The rest of this section concerns mainly settings for global user data cache and for SDK clients. For a look at data store cache settings, see "LDAP Identity Store Settings".

Overall Server Cache Settings

By default, AM has caching enabled for configuration data and user data. This setting is governed by the server property `com.ipланet.am.sdk.caching.enabled`, which is `true` by default. If you set this advanced property to `false`, you can enable caching independently for configuration data and for user data.

To Turn Off Global User Data Caching

Important

Disabling caching can have a **severe negative impact** on performance. This is because when caching is disabled, AM must query a data store each time it needs data.

If, however, you have at least one identity store that does not support LDAP persistent search, you must disable the *global* cache for user data; otherwise, user data caches cannot stay in sync with changes to user data entries. Disable the global cache as follows:

1. In the AM console, navigate to Deployment > Servers > *Server Name* > Advanced.
2. Set the value of the `com.iplanet.am.sdk.caching.enabled` property to `false` to disable caching overall.
3. Set the value of the `com.sun.identity.sm.cache.enabled` property to `true` to enable configuration data caching.

All supported configuration data stores support LDAP persistent search, so it is safe to enable configuration data caching.

You must explicitly set this property to `true`, because setting the value of the property `com.iplanet.am.sdk.caching.enabled` to `false` in the previous step disables both user and configuration data caching.

4. Save your work.
5. AM starts persistent searches on user data stores when possible ¹ in order to monitor changes. With user data store caching disabled, AM still starts the persistent searches, even though it no longer uses the results.

Therefore, if you disable user data store caching, you should also disable persistent searches on identity stores in your deployment to improve performance. To disable persistent search on an identity store, go to Realms > *Realm Name* > Identity Stores > *Identity Store Name* > Persistent Search Controls and remove the value of the Persistent Search Base DN configuration property (leave it blank).

To Change the Maximum Size of Global User Data Cache

With a large user data store and active user base, the number of user entries in cache can grow large.

1. In the AM console, navigate to Configure > Server Defaults > SDK.
2. Change the value of SDK Caching Maximum Size.

There is no corresponding setting for configuration data, as the number of configuration entries in a large deployment is not likely to grow nearly as large as the number of user entries.

Cache Settings

The table below provides a quick reference, primarily for user data cache settings.

Notice that many properties for configuration data cache have `sm` (for Service Management) in their names, whereas those for user data have `idm` (for Identity Management) in their names:

¹ AM starts persistent searches on user data stores on directory servers that support the `psearch` control.

Cache Properties

Property	Description	Default	Applies To
<code>com.ipianet.am.sdk.cache.maxSize</code>	Maximum number of user entries cached.	10000	Server and SDK
<code>com.ipianet.am.sdk.caching.enabled</code>	<p>Whether to enable caching for both configuration data and also for user data.</p> <p>If <code>true</code>, this setting overrides <code>com.sun.identity.idm.cache.enabled</code> and <code>com.sun.identity.sm.cache.enabled</code>.</p> <p>If <code>false</code>, you can enable caching independently for configuration data and for user data using the aforementioned properties.</p>	<code>true</code>	Server & SDK
<code>com.ipianet.am.sdk.remote.pollingTime</code>	<p>How often in minutes the SDK client, such as a web or a Java agent should poll AM for modified user data entries.</p> <p>The SDK also uses this value to determine the age of the oldest changes requested. The oldest changes requested are 2 minutes older than this setting. In other words, by default the SDK polls for entries changed in the last 3 minutes.</p> <p>Set this to 0 or a negative integer to disable polling.</p>	1 (minute)	SDK
<code>com.sun.am.event.notification.expire.time</code>	How long AM stores a given change to a cached entry, so that clients polling for changes do not miss the change.	30 (minutes)	Server only
<code>com.sun.identity.idm.cache.enabled</code>	<p>If <code>com.ipianet.am.sdk.caching.enabled</code> is <code>true</code>, this property is ignored.</p> <p>Otherwise, set this to <code>true</code> to enable caching of user data.</p>	<code>false</code>	Server & SDK
<code>com.sun.identity.idm.cache.entry.default.expire.time</code>	How many minutes to store a user data entry in the global user data cache.	30 (minutes)	Server & SDK
<code>com.sun.identity.idm.cache.entry.expire.enabled</code>	Whether user data entries in the global user data cache should expire over time.	<code>false</code>	Server & SDK
<code>com.sun.identity.idm.remote.notification.enabled</code>	Whether the SDK client, such as a web or a Java agent should register a notification listener for user data changes with the AM server.	<code>true</code>	SDK

Property	Description	Default	Applies To
	<p>The SDK client uses the URL specified by <code>com.sun.identity.client.notification.url</code> to register the listener so that AM knows where to send notifications.</p> <p>If notifications cannot be enabled for some reason, then the SDK client falls back to polling for changes.</p>		
<code>com.sun.identity.sm.cache.enabled</code>	<p>If <code>com.ipplanet.am.sdk.caching.enabled</code> is <code>true</code>, this property is ignored.</p> <p>Otherwise, set this to <code>true</code> to enable caching of configuration data. It is recommended that you always set this to <code>true</code>.</p>	<code>false</code>	Server & SDK
<code>sun-idrepo-ldapv3-dncache-enabled</code>	Set this to <code>true</code> to enable DN caching of user data.	<code>false</code>	Server & SDK
<code>sun-idrepo-ldapv3-dncache-size</code>	Sets the cache size.	<code>1500</code>	Server & SDK

Managing Sessions

The AM console lets the administrator view and manage active CTS-based user sessions by realm by navigating to Realms > *Realm Name* > Sessions.

Sessions Page

Sessions

Find sessions by entering a user ID.

amAdmin

x Invalidate Selected

AMADMIN		
<input type="checkbox"/> IDLE TIME	IDLE TIME REMAINING	SESSION TIME REMAINING
<input type="checkbox"/> a few seconds	30 minutes	an hour

Your session

To search for active sessions, enter a username in the search box. AM retrieves the sessions for the user and displays them within a table. If no active CTS-based session is found, AM displays a session not found message.

You can end any sessions—except the current `amAdmin` user's session—by selecting it and clicking the Invalidate Selected button. As a result, the user has to authenticate again.

Note

Deleting a user does not automatically remove any of the user's CTS-based sessions. After deleting a user, check for any sessions for the user and remove them on the Sessions page.

Changing Host Names

When you change the AM host name, you must make manual changes to the configuration. This chapter describes what to do. If you must also move an embedded configuration directory from one host to another, see the *ForgeRock Directory Services Administration Guide* chapter, *Moving Servers*.

Changing AM host names involves the following high-level steps.

- Adding the new host name to the Realm/DNS Aliases list.
- Exporting, editing, then importing the configuration.

This step relies on the **ssoadm** command, which you install separately from AM as described in "Setting Up Administration Tools" in the *Installation Guide*.

- Stopping AM and editing configuration files.
- Removing the old host name from the Realm/DNS Aliases list.

Before you start, make sure you have a current backup of your current installation. See "Backing Up and Restoring Configurations" for instructions.

To Add the New Host Name As an Alias

1. Log in to the AM console as administrator, `amadmin`.
2. Under Realms > *Realm Name*, click Properties, add the new host name to the Realm/DNS Aliases list, and then save your work.

To Export, Edit, and Import the Service Configuration

1. Export the service configuration:

```
$ ssoadm \  
  export-svc-cfg \  
  --adminid amadmin \  
  --encryptsecret myEncryptSecretString1234 \  
  --password-file /tmp/pwd.txt \  
  --outfile config.xml  
Service Configuration was exported.
```

AM uses the value entered in `--encryptsecret` to encrypt passwords stored in the backup file. It can be any value, and is required when restoring a configuration.

2. Edit the service configuration file:
 - Change the fully qualified domain name, such as `openam.example.com`, throughout the file.
 - If you are changing the context path, such as `/openam`, then make the following changes:
 - Change the value of `com.ipplanet.am.services.deploymentDescriptor`.
 - Change `contextPath` in the value of the `propertiesViewBeanURL="contextPath/auth/ACServiceInstanceList"`.
 - Change `contextPath` in the value of `propertiesViewBeanURL="contextPath/auth/ACModuleList"`.
 - Change the context path in a `<Value>` element that is a child of an `<AttributeValuePair>` element.
 - Change the context path where it occurs throughout the file in the full URL to AM, such as `http:////openam.example.com:8080/contextPath`.

- If you are changing the port number, then change the value of `com.iplanet.am.server.port`.

Also change the port number in `host:port` combinations throughout the file.

- If you are changing the domain name, then change the cookie domain, such as `<Value>.example.com</Value>` throughout the file.

3. Import the updated service configuration:

```
$ ssoadm \  
import-svc-cfg \  
--adminid amadmin \  
--encryptsecret myEncryptSecretString1234 \  
--password-file /tmp/pwd.txt \  
--xmlfile config.xml  
Directory Service contains existing data. Do you want to delete it? [y|N] y  
Please wait while we import the service configuration...  
Service Configuration was imported.
```

To Edit Configuration Files For the New Host Name

1. Stop AM or the web container where it runs.
2. Edit the boot properties file, such as `/home/user/openam/boot.json`, changing the fully-qualified domain name (FQDN), port, and context path for AM as necessary.
3. If you are changing the context path, then move the folder containing AM configuration, such as `/home/user/openam/`, to match the new context path, such as `/home/user/openam2/`.
4. If you are changing the location or context path, change the name of the file in the `/home/user/.openamcfg` folder, such as `AMConfig_path_to_tomcat_webapps_openam_`, to match the new location and context path.

Also edit the path name in the file to match the change you made when moving the folder.

5. Restart AM or the web container where it runs.

To Remove the Old Host Name As an Alias

1. Log in to the AM console as administrator, `amadmin`.
2. Under Realms > *Realm Name*, click Properties, remove the old host name from the Realm/DNS Aliases list, and then save your work.

Changing the Cookie Domain

Configure AM's cookie domain to ensure only users and entities from trusted domains can be authenticated.

To Change the Cookie Domain

1. Log in to the AM console as an administrator user, for example, `amAdmin`.
2. Navigate to Configure > Global Services > Platform > Cookie Domain.
3. In the Cookie Domain field, set the list of domains into which AM should write cookies. Consider the following points:
 - By default, AM installer sets the cookie domain based on the fully-qualified hostname of the server on which it installs AM.

After installation, if the cookie domain is `openam.example.com`, you may want to change it to `example.com` so AM can communicate with any host in the sub-domain.

- Configure as many cookie domains as your environment requires. For example, for the realms configured with DNS aliases². Browsers ignore any cookies that do not match the current domain to ensure the correct one is used.
- If you do not specify any cookie domain, AM uses the fully qualified name of the server, which implies that a host cookie is set rather than a domain cookie.

When configuring AM for Cross-Domain Single Sign-On (CDSSO), you must protect your AM deployment against cookie hijacking by setting a host cookie rather than a domain cookie. For more information, see "Protecting Against Cookie Hijacking" in the *Authentication and Single Sign-On Guide*.

- Do not configure a top-level domain as your cookie domain; browsers will reject them. Top-level domains are browser-specific. For example, Firefox considers special domains like Amazon's web service (for example, `ap-southeast-2.compute.amazonaws.com`) to be a top-level domain³.
4. Save your changes.
 5. Restart AM.

²For more information, see "To Configure DNS Aliases for Accessing a Realm".

³For a list of effective top-level domains, see https://publicsuffix.org/list/effective_tld_names.dat.

Chapter 9

Troubleshooting

This chapter covers how to get debugging information and troubleshoot issues in deployments.

Is the Instance Running?

You can check over HTTP whether AM is up, using `isAlive.jsp`. Point your application to the file under the deployment URL, such as `https://openam.example.com:8443/openam/isAlive.jsp`.

If you get a success code (with `Server is ALIVE:` in the body of the page returned), then the instance is in operation.

Debug Logging

AM services capture a variety of information in debug logs. Unlike audit log records, debug log records are unstructured. Debug logs contain a variety of types of information that is useful when troubleshooting AM, including stack traces. The level of debug log record output is configurable. Debug log records are always written to flat files.

Setting Debug Logging Levels

To adjust the debug level while AM is running, login to the AM console as AM administrator and navigate to Deployment > Servers > *Server Name* > Debugging. The default level for debug logging is Error. This level is appropriate for normal production operations, in which case no debug log messages are expected.

Setting the debug log level to Warning increases the volume of messages. Setting the debug log level to Message dumps detailed trace messages. Unless told to do so by qualified support personnel, do not use Warning and Message levels in production.

By default, certain components that run in AM's JVM—for example, embedded DS configuration stores—do not generate trace-level messages when you configure the debug log level to Message. If you need trace-level messages for these components, navigate to Deployment > Servers > *Server Name* > Advanced, create a `org.forgerock.openam.slf4j.enableTraceInMessage` property, and set its value to `true`.

Debug Logging to a Single File or to Standard Output

During development, you might find it useful to log all debug messages to a single file. In order to do so, set Merge Debug Files to `on`.

AM logs to a single file immediately after you change this property. You do not need to restart AM or the container in which it runs for the change to take effect.

When Merge Debug Files is `on`, AM can write debug messages to standard output instead of a file. To enable this feature, set the Java system property, `com.sun.identity.util.debug.provider` to `com.sun.identity.shared.debug.impl.StdoutDebugProvider`, in the configuration for the AM web application or the web container where it runs. For example, when using Apache Tomcat, add the following setting to `CATALINA_OPTS`:

```
-Dcom.sun.identity.util.debug.provider=com.sun.identity.shared.debug.impl.StdoutDebugProvider
```

After you change the configuration for a web application or web container, you must restart it for the change to take effect. For details on web application and container configuration, see "Preparing a Web Application Container" in the *Installation Guide*.

Debug Logging By Service

AM lets you capture debug log messages selectively for a specific service. This can be useful when you must turn on debugging in a production system where you want to avoid excessive logging, but must gather messages when you reproduce a problem.

AM also logs information related to client interactions using the `org.apache.http.wire` and `org.apache.http.headers` appenders. The information they collect is useful, for example, when you are developing authentications scripts or when your environment requires STS transformations.

By default, these appenders are always set to the `Warning` level unless logging is disabled. For more information, see the `org.forgerock.allow.http.client.debug` advanced server property.

Perform these steps to capture debug messages for a specific service:

1. Log in to the AM console as administrator, `amadmin`.
2. Browse to `Debug.jsp`, for example `https://openam.example.com:8443/openam/Debug.jsp`.

No links to this page are provided in the AM console.

3. Select the service to debug and also the level required given the hints provided in the `Debug.jsp` page.

The changes takes effect immediately.

4. Promptly reproduce the problem you are investigating.

5. After reproducing the problem, immediately return to the `Debug.jsp` page, and revert to normal log levels to avoid filling up the disk where debug logs are stored.

Rotating Debug Logs

By default AM does not rotate debug logs. To rotate debug logs, edit `WEB-INF/classes/debugconfig.properties` where AM is deployed.

The `debugconfig.properties` file includes the following properties:

`org.forgerock.openam.debug.prefix`

Specifies the debug log file prefix applied when AM rotates a debug log file. The property has no default. It takes a string as the property value.

`org.forgerock.openam.debug.suffix`

Specifies the debug log file suffix applied when AM rotates a debug log file. The property takes a `SimpleDateFormat` string. The default is `-MM.dd.yyyy-kk.mm`.

`org.forgerock.openam.debug.rotation`

Specifies an interval in minutes between debug log rotations. Set this to a value greater than zero to enable debug log rotation based on time passed.

`org.forgerock.openam.debug.rotation.maxsize`

Specifies a maximum log file size in megabytes between debug log rotations. Set this to a value greater than zero to enable debug log rotation based on log file size.

Changes to properties in the `debugconfig.properties` file take effect immediately. You do not need to restart AM or the container in which it runs for the changes to take effect.

Recording Troubleshooting Information

The AM recording facility lets you initiate events to monitor AM while saving output that is useful when performing troubleshooting.

AM recording events save four types of information:

- AM debug logs
- Thread dumps, which show you the status of every active thread, with output similar to a JStack stack trace
- Important run-time properties

- The AM configuration

You initiate a recording event by invoking the **ssoadm start-recording** command or by using the **start** action of the `/json/records` REST API endpoint. Both methods use JSON to control the recording event.

This section describes starting and stopping recording using the **ssoadm** command, using a JSON file to configure the recording event, and locating the output recorded information. For information about using the `/json/records` REST API endpoint to activate and deactivate recording, see "RESTful Troubleshooting Information Recording". For general information about the REST API, see "About the REST API".

Starting and Stopping Recording

Start AM recording with the **ssoadm start-recording** command. For example:

```
$ ssoadm \  
start-recording \  
--servername https://openam.example.com:8443/openam \  
--adminid amadmin \  
--password-file /tmp/pwd.txt \  
--jsonfile recording.json  
  
{  
  "recording":true,  
  "record": {  
    "issueID":103572,  
    "referenceID":"policyEvalFails",  
    "description":"Record everything",  
    "zipEnable":false,  
    "threadDump": {  
      "enable":true,  
      "delay": {  
        "timeUnit":"SECONDS",  
        "value":5  
      }  
    },  
  },  
  "configExport": {  
    "enable":true,  
    "password":"admin password",  
    "sharePassword":true  
  },  
  "debugLogs": {  
    "debugLevel":"message",  
    "autoStop": {  
      "time": {  
        "timeUnit":"MILLISECONDS",  
        "value":15000  
      },  
      "fileSize": {  
        "sizeUnit":"KB",  
        "value":1048576  
      }  
    }  
  },  
  "status":"RUNNING",
```

```
"folder": "/home/openam/debug/record/103572/policyEvalFails/"
}
```

Note

The **ssoadm** command output in the preceding example is shown in indented format for ease of reading. The actual output is *not* indented.

In the preceding **ssoadm start-recording** command example, the `recording.json` file specifies the information to be recorded and under what conditions recording automatically terminates. This file is known as the *recording control file*. "The Recording Control File" describes the format of recording control files and provides an annotated example.

An active recording event stops when:

- You explicitly tell AM to stop recording by executing the **ssoadm stop-recording** command. See the `ssoadm(1)` in the *Reference* for details about this command.
- Another **ssoadm start-recording** command is sent to AM that specifies an issue ID other that differs from the active recording event's issue ID. In this case, the initial recording session terminates and the new recording event starts. Note that you can determine whether an AM recording event is active by using the **ssoadm get-recording-status** command.
- A timer configured in the recording control file determines that the maximum amount of time for the recording event has been reached.
- A file size monitor configured in the recording control file determines that the maximum amount of information in debug logs has been reached.

The Recording Control File

A JSON file that is input to the **ssoadm start-recording** command controls the amount of information AM records, the recording duration, and the location of recording output files.

For more information on the properties that comprise the recording control file, see the reference "Record Control File Configuration Properties".

The following is an example of a recording control file:

```
{
  "issueID": 103572,
  "referenceID": "policyEvalFails",
  "description": "Troubleshooting artifacts in support of case 103572",
  "zipEnable": true,
  "configExport": {
    "enable": true,
```

```

    "password": "5x2RR70",
    "sharePassword": false
  },
  "debugLogs": {
    "debugLevel": "MESSAGE",
    "autoStop": {
      "time": {
        "timeUnit": "SECONDS",
        "value": 15
      },
      "fileSize": {
        "sizeUnit": "GB",
        "value": 1
      }
    }
  },
  "threadDump" : {
    "enable": true,
    "delay" : {
      "timeUnit": "SECONDS",
      "value": 5
    }
  }
}

```

The recording control file properties in the preceding example affect the recording output as follows:

Recording Control File Example Properties and Their Effect on Recording Behavior

Recording Control File Property	Value	Effect
issueID, referenceID	103572, policyEvalFails	Recording output is stored at the path <code>debugFileLocation/record/103572/policyEvalFails_timestamp.zip</code> . For more information about the location of recording output, see "Retrieving Recording Information".
Description	Troubleshooting artifacts in support of case 103572	No effect.
zipEnable	true	Recording output is compressed into a zip file.
configExport / enable	true	The AM configuration is exported at the start of the recording event.
configExport / password	5x2RR70	Knowledge of this password will be required to access the AM configuration that was saved during recording.
configExport / sharePassword	false	The password is not displayed in output messages displayed during the recording event or in the <code>info.json</code> file.
debugLogs / debugLevel	MESSAGE	Recording enables message-level debug logs during the recording event.

Recording Control File Property	Value	Effect
<code>debugLogs / autoStop / time</code>	<code>SECONDS, 15</code>	Because both the <code>time</code> and <code>fileSize</code> properties are set, recording stops after 15 seconds, or after the size of the debug logs exceeds 1 GB, whichever occurs first.
<code>debugLogs / autoStop / fileSize</code>	<code>GB, 1</code>	Because both the <code>time</code> and <code>fileSize</code> properties are set, recording stops after 15 seconds, or after the size of the debug logs exceeds 1 GB, whichever occurs first.
<code>threadDump / enable</code>	<code>true</code>	Thread dumps are taken throughout the recording event.
<code>threadDump / delay</code>	<code>SECONDS, 5</code>	The first thread dump is taken when the recording event starts. Additional thread dumps are taken every five seconds hence.

Retrieving Recording Information

Information recorded by AM is stored at the path `debugFileLocation/record/issueID/referenceID`. For example, if the debug file location is `/home/openam/debug`, the issue ID `103572`, and the reference ID `policyEvalFails`, the path containing recorded information is `/home/openam/debug/record/103572/policyEvalFails`.

When there are multiple recording events with the same `issueID` and `referenceID`, AM appends a timestamp to the `referenceID` of the earliest paths. For example, multiple recording events for issue ID `103572` and reference ID `policyEvalFails` might be stored at the following paths:

- Most recent recording: `debugFileLocation/record/103572/policyEvalFails`
- Next most recent recording: `debugFileLocation/record/103572/policyEvalFails_2015-10-24-11-48-51-902-PDT`
- Earliest recording: `debugFileLocation/record/103572/policyEvalFails_2015-08-10-15-15-10-140-PDT`

AM compresses the output from recording events when you set the `zipEnable` property to `true`. The output file can be found at the path `debugFileLocation/record/issueID/referenceID_timestamp.zip`. For example, compressed output for a recording event for issue ID `103572` and reference ID `policyEvalFails` might be stored at the following path: `debugFileLocation/record/103572/policyEvalFails_2015-08-12-12-19-02-683-PDT.zip`.

Use the `referenceID` property value to segregate output from multiple problem recreations associated with the same case. For example, while troubleshooting case `103572`, you notice that you only have a problem when evaluating policy for members of the Finance realm. You could trigger two recording events as follows:

Segregating Recording Output Using the `referenceID` Value

AM Behavior	<code>referenceID</code> Value	Recording Output Path
Policy evaluation behaves as expected for members of the Engineering realm.	<code>policyEvalSucceeds</code>	<code>debugFileLocation/record/103572/policyEvalSucceeds</code>
Policy evaluation unexpectedly fails for members of the Finance realm.	<code>policyEvalFails</code>	<code>debugFileLocation/record/103572/policyEvalFails</code>

RESTful Troubleshooting Information Recording

This section shows you how to start, stop, and get the status of a troubleshooting recording event using the REST API.

AM provides the `/json/records` REST endpoint for the following:

- **Starting a recording event.** See "Starting a Recording Event".
- **Getting the status of a recording event.** See "Getting the Status of a Recording Event".
- **Stopping a recording event.** See "Stopping a Recording Event".

You must authenticate to AM as an administrative user to obtain an SSO token prior to calling the `/json/records` REST endpoint. You then pass the SSO token in the `iPlanetDirectoryPro` header as proof of authentication.

You can also record troubleshooting information by using the `ssoadm` command. For more information, see "Recording Troubleshooting Information".

Note

The `curl` command output in the examples in this section is indented for ease of reading. The actual output is *not* indented, and the actions available from the `/json/records` endpoint do not support the `_prettyPrint` parameter.

Starting a Recording Event

To start a recording event, perform an HTTP POST using the `/json/records` endpoint, specifying the `_action=start` parameter in the URL. Specify a JSON payload identical in format to the input file for the `ssoadm start-recording` command, as described in "The Recording Control File".

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "iPlanetDirectoryPro: AQIC5..." \
--header "Accept-API-Version: resource=1.0" \
--data '{
  "issueID": 103572,
```

```

"referenceID": "policyEvalFails",
"description": "Troubleshooting artifacts in support of case 103572",
"zipEnable": true,
"configExport": {
  "enable": true,
  "password": "5x2RR70",
  "sharePassword": false
},
"debugLogs": {
  "debugLevel": "MESSAGE",
  "autoStop": {
    "time": {
      "timeUnit": "SECONDS",
      "value": 15
    },
    "fileSize": {
      "sizeUnit": "GB",
      "value": 1
    }
  }
},
"threadDump" : {
  "enable": true,
  "delay" : {
    "timeUnit": "SECONDS",
    "value": 5
  }
}
} \

```

https://openam.example.com:8443/openam/json/records?_action=start

```

{
  "recording":true,
  "record":{
    "issueID":103572,
    "referenceID":"policyEvalFails",
    "description":"Troubleshooting artifacts in support of case 103572",
    "zipEnable":true,
    "threadDump":{
      "enable":true,
      "delay":{
        "timeUnit":"SECONDS",
        "value":5
      }
    },
    "configExport":{
      "enable":true,
      "password":"xxxxxx",
      "sharePassword":false
    },
    "debugLogs":{
      "debugLevel":"message",
      "autoStop":{
        "time":{
          "timeUnit":"MILLISECONDS",
          "value":15000
        },
        "fileSize":{
          "sizeUnit":"KB",
          "value":1048576
        }
      }
    }
  }
}

```

```

    }
  },
  "status": "RUNNING",
  "folder": "/opt/demo/openam/config/openam/debug/record/103572/policyEvalFails/"
}
}

```

Getting the Status of a Recording Event

To get the status of a recording event, perform an HTTP POST using the `/json/records` endpoint, specifying the `_action=status` parameter in the URL:

```

$ curl \
--request POST \
--header "iPlanetDirectoryPro: AQIC5..." \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/records?_action=status

```

If there is no active recording event, the following output appears:

```

{
  "recording": false
}

```

If there is an active recording event, output similar to the following appears:

```

{
  "recording": true,
  "record": {
    "issueID": 103572,
    "referenceID": "policyEvalFails",
    "description": "Troubleshooting artifacts in support of case 103572",
    "zipEnable": true,
    "threadDump": {
      "enable": true,
      "delay": {
        "timeUnit": "SECONDS",
        "value": 5
      }
    },
    "configExport": {
      "enable": true,
      "password": "xxxxxx",
      "sharePassword": false
    },
    "debugLogs": {
      "debugLevel": "message",
      "autoStop": {
        "time": {
          "timeUnit": "MILLISECONDS",
          "value": 15000
        }
      },
      "fileSize": {
        "sizeUnit": "KB",
        "value": 1048576
      }
    }
  }
}

```

```

    }
  },
  "status": "RUNNING",
  "folder": "/opt/demo/openam/config/openam/debug/record/103572/policyEvalFails/"
}
}

```

Stopping a Recording Event

To stop a recording event, perform an HTTP POST using the `/json/records` endpoint, specifying the `action=stop` parameter in the URL:

```

$ curl \
--request POST \
--header "iPlanetDirectoryPro: AQIC5..." \
--header "Accept-API-Version: resource=1.0" \
https://openam.example.com:8443/openam/json/records?_action=stop

```

If there is no active recording event, AM returns a 400 error code.

If there is an active recording event, output similar to the following appears:

```

{
  "recording": false,
  "record": {
    "issueID": 103572,
    "referenceID": "policyEvalFails",
    "description": "Troubleshooting artifacts in support of case 103572",
    "zipEnable": true,
    "threadDump": {
      "enable": true,
      "delay": {
        "timeUnit": "SECONDS",
        "value": 5
      }
    },
  },
  "configExport": {
    "enable": true,
    "password": "xxxxxx",
    "sharePassword": false
  },
  "debugLogs": {
    "debugLevel": "message",
    "autoStop": {
      "time": {
        "timeUnit": "MILLISECONDS",
        "value": 15000
      },
      "fileSize": {
        "sizeUnit": "KB",
        "value": 1048576
      }
    }
  },
  "status": "STOPPED",
  "folder": "/opt/demo/openam/config/openam/debug/record/103572/policyEvalFails/"
}

```

```
}
```

Chapter 10

Reference

This chapter covers AM configuration properties accessible through the AM console, most of which can also be set by using the **ssoadm** command.

For reference information that is not contained on this guide, see the AM Reference Guide or the Reference section included in each of the topic-oriented AM guides.

Identity Store Configuration Properties

Use the following reference to configure different identity store types by navigating to Realms > *Realm Name* > Identity Stores.

Active Directory Configuration Properties

Use these attributes when configuring Active Directory data stores:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first:

1. The first directory server in the list whose `server_ID` matches the current AM server.
2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: `host:port` of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

Default: `CN=Administrator,CN=Users,base-dn`

LDAP Bind Password

Bind password for connecting to the directory server

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: `base-dn`

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server

certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `SECONDS`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB)

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

Default: `userPassword=unicodePwd`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	<code>read</code>	<code>create</code>	<code>edit</code>	<code>delete</code>	<code>service</code>
<code>group</code>	✓	✓	✓	✓	-
<code>realm</code>	✓	✓	✓	✓	✓
<code>user</code>	✓	✓	✓	✓	✓
	Read the identity type	Create new identities of the given identity type	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
group=read,create,edit,delete
realm=read,create,edit,delete,service
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `cn`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data. For example, if you configure the search attribute to `mail`, it could prevent users from being able to update their email addresses in their user profiles.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=person)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

Default: `cn`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

Default: `users`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any such unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings, if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `organizationalPerson, person, top, User,`

LDAP User Attributes

User profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `assignedDashboard, cn, createTimestamp, devicePrintProfiles, displayName, distinguishedName, dn, employeeNumber, givenName, iplanet-am-auth-configuration, iplanet-am-session-destroy-sessions, iplanet-am-session-get-valid-sessions, iplanet-am-session-max-caching-time, iplanet-am-session-max-idle-time, iplanet-am-session-max-session-time, iplanet-am-session-quota-limit, iplanet-am-session-service-status, iplanet-am-user-account-life, iplanet-am-user-admin-start-dn, iplanet-am-user-alias-list, iplanet-am-user-auth-config, iplanet-am-user-auth-modules, iplanet-am-user-failure-url, iplanet-am-user-federation-info, iplanet-am-user-federation-info-key, iplanet-am-user-login-status, iplanet-am-user-password-reset-force-reset, iplanet-am-user-password-reset-options, iplanet-am-user-password-reset-question-answer, iplanet-am-user-success-url, kbaActiveIndex, kbaInfo, mail, modifyTimestamp, name, oath2faEnabled, oathDeviceProfiles, objectGUID, objectclass, postalAddress, preferredLocale, preferredlanguage, preferredtimezone, pushDeviceProfiles, sAMAccountName, sn, sun-fm-saml2-nameid-info, sun-fm-saml2-nameid-infokey, sunAMAuthInvalidAttemptsData, sunIdentityMSISDNNumber, sunIdentityServerDiscoEntries, sunIdentityServerPPAddressCard, sunIdentityServerPPCommonNameAltCN, sunIdentityServerPPCommonNameCN, sunIdentityServerPPCommonNameFN, sunIdentityServerPPCommonNameMN, sunIdentityServerPPCommonNamePT, sunIdentityServerPPCommonNameSN, sunIdentityServerPPDemographicsAge, sunIdentityServerPPDemographicsBirthDay, sunIdentityServerPPDemographicsDisplayLanguage, sunIdentityServerPPDemographicsLanguage, sunIdentityServerPPDemographicsTimeZone, sunIdentityServerPPEmergencyContact, sunIdentityServerPPEmploymentIdentityAlt0, sunIdentityServerPPEmploymentIdentityJobTitle, sunIdentityServerPPEmploymentIdentityOrg, sunIdentityServerPPEncryPTKey, sunIdentityServerPPFacadeGreetSound, sunIdentityServerPPFacadeMugShot, sunIdentityServerPPFacadeNamePronounced, sunIdentityServerPPFacadeWebSite, sunIdentityServerPPFacadegreetmesound, sunIdentityServerPPInformalName, sunIdentityServerPPLegalIdentityAltIdType, sunIdentityServerPPLegalIdentityAltIdValue, sunIdentityServerPPLegalIdentityDOB, sunIdentityServerPPLegalIdentityGender, sunIdentityServerPPLegalIdentityLegalName, sunIdentityServerPPLegalIdentityMaritalStatus,`

`sunIdentityServerPPLegalIdentityVATIdType`, `sunIdentityServerPPLegalIdentityVATIdValue`,
`sunIdentityServerPPMsgContact`, `sunIdentityServerPPSignKey`, `telephoneNumber`, `unicodePwd`,
`userAccountControl`, `userPrincipalname`, `userpassword`

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

The LDAP user profile entries require the Common Name (`cn`) and Surname (`sn`) attributes, so that LDAP constraint violations do not occur when performing an add operation.

The `cn` attribute gets its value from the `uid` attribute, which comes from the User Name field on the AM console's login page. The `sn` attribute gets the value of the `givenName` attribute. Attributes not mapped to another attribute and attributes mapped to themselves (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn, sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `userAccountControl`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: 544

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: 546

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `cn`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectclass=group)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `cn`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

Default: `users`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `Group, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `cn, distinguishedName, dn, member, name, objectCategory, objectclass, sAMAccountName, sAMAccountType`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `member`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

Specify either `SCOPE_BASE` or `SCOPE_ONE`. Do not specify `SCOPE_SUB`, as it can have a severe impact on Active Directory performance.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

ssoadm attribute: `com.ipplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable

DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: false

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server before saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Active Directory Application Mode Configuration Properties

Use these attributes when configuring Active Directory Application Mode (ADAM) Identity Stores:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration.

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

You must add `=n=` before the `host:port`, where *n* is an array index, starting with 0, of servers listed. See the example below.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first:

1. The first directory server in the list whose `server_ID` matches the current AM server.

2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: `host:port` of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

Default: `CN=Administrator,CN=Users,base-dn`

LDAP Bind Password

Bind password for connecting to the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: *base-dn*

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval, use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `second`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

Default: `userPassword=unicodePwd`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	read	create	edit	delete	service
group	✓	✓	✓	✓	-
realm	✓	✓	✓	✓	✓
user	✓	✓	✓	✓	✓
	Read the identity type	Create new identities of the	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated

	read	create	edit	delete	service
		given identity type			with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
group=read,create,edit,delete
realm=read,create,edit,delete,service
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `cn`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data. For example, if you configure the search attribute to `mail`, it could prevent users from being able to update their email addresses in their user profiles.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=person)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings, if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `devicePrintProfilesContainer, forgerock-am-dashboard-service, iPlanetPreferences, iplanet-am-auth-configuration-service, iplanet-am-managed-person, iplanet-am-user-service, kbaInfoContainer, oathDeviceProfilesContainer, organizationalPerson, person, pushDeviceProfilesContainer, sunAMAuthAccountLockout, sunFMSAML2NameIdentifier, sunFederationManagerDataStore, sunIdentityServerLibertyPPService, top, User`

LDAP User Attributes

User profiles have these LDAP attributes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `assignedDashboard, cn, createTimestamp, devicePrintProfiles, displayName, distinguishedName, dn, employeeNumber, givenName, iplanet-am-auth-configuration, iplanet-am-session-destroy-sessions, iplanet-am-session-get-valid-sessions, iplanet-am-session-max-caching-time, iplanet-am-session-max-idle-time, iplanet-am-session-max-session-time, iplanet-am-session-quota-limit, iplanet-am-session-service-status, iplanet-am-user-account-life, iplanet-am-user-admin-start-dn, iplanet-am-user-alias-list, iplanet-am-user-auth-config, iplanet-am-user-auth-modules, iplanet-am-user-failure-url, iplanet-am-user-federation-info, iplanet-am-user-federation-info-key, iplanet-am-user-login-status, iplanet-am-user-password-reset-force-reset, iplanet-am-user-password-reset-options, iplanet-am-user-password-reset-question-answer, iplanet-am-user-success-url, kbaActiveIndex, kbaInfo, mail, modifyTimestamp, msDS-UserAccountDisabled, name, oath2faEnabled, oathDeviceProfiles, objectGUID, objectclass, postalAddress, preferredLocale, preferredlanguage, preferredtimezone, pushDeviceProfiles, sn, sun-fm-saml2-nameid-info, sun-fm-saml2-nameid-infokey, sunAMAuthInvalidAttemptsData, sunIdentityMSISDNNumber, sunIdentityServerDiscoEntries, sunIdentityServerPPAddressCard, sunIdentityServerPPCommonNameAltCN, sunIdentityServerPPCommonNameCN, sunIdentityServerPPCommonNameFN, sunIdentityServerPPCommonNameMN, sunIdentityServerPPCommonNamePT, sunIdentityServerPPCommonNameSN, sunIdentityServerPPDemographicsAge,`

`sunIdentityServerPPDemographicsBirthDay`, `sunIdentityServerPPDemographicsDisplayLanguage`,
`sunIdentityServerPPDemographicsLanguage`, `sunIdentityServerPPDemographicsTimeZone`,
`sunIdentityServerPPEmergencyContact`, `sunIdentityServerPPEmploymentIdentityAlt0`,
`sunIdentityServerPPEmploymentIdentityJobTitle`, `sunIdentityServerPPEmploymentIdentityOrg`,
`sunIdentityServerPPEncryPTKey`, `sunIdentityServerPPFacadeGreetSound`, `sunIdentityServerPPFacadeMugShot`,
`sunIdentityServerPPFacadeNamePronounced`, `sunIdentityServerPPFacadeWebSite`,
`sunIdentityServerPPFacadegreetmesound`, `sunIdentityServerPPInformalName`,
`sunIdentityServerPPLegalIdentityAltIdType`, `sunIdentityServerPPLegalIdentityAltIdValue`,
`sunIdentityServerPPLegalIdentityDOB`, `sunIdentityServerPPLegalIdentityGender`,
`sunIdentityServerPPLegalIdentityLegalName`, `sunIdentityServerPPLegalIdentityMaritalStatus`,
`sunIdentityServerPPLegalIdentityVATIdType`, `sunIdentityServerPPLegalIdentityVATIdValue`,
`sunIdentityServerPPMsgContact`, `sunIdentityServerPPSignKey`, `telephoneNumber`, `unicodePwd`, `userPrincipalname`,
`userpassword`

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

Attributes not mapped to another attribute (for example, `cn`) and attributes mapped to themselves, (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile. The object classes for user profile LDAP entries generally require Common Name (`cn`) and Surname (`sn`) attributes, so this prevents an LDAP constraint violation when performing the add operation.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn, sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `msDS-UserAccountDisabled`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: `FALSE`

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: `TRUE`

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `cn`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectclass=group)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `cn`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `Group, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `cn, distinguishedName, dn, member, name, objectCategory, objectclass, sAMAccountName, sAMAccountType`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `member`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

Specify either `SCOPE_BASE` or `SCOPE_ONE`. Do not specify `SCOPE_SUB`, as it can have a severe impact on Active Directory performance.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

ssoadm attribute: `com.ipplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: false

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server before saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Generic LDAPv3 Configuration Properties

Use these attributes when configuring Generic LDAPv3 compliant data stores:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration.

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first:

1. The first directory server in the list whose `server_ID` matches the current AM server.
2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: `host:port` of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

LDAP Bind Password

Bind password for connecting to the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: *base-dn*

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval, use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `second`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	<code>read</code>	<code>create</code>	<code>edit</code>	<code>delete</code>	<code>service</code>
<code>group</code>	✓	✓	✓	✓	-
<code>realm</code>	✓	✓	✓	✓	✓
<code>user</code>	✓	✓	✓	✓	✓
	Read the identity type	Create new identities of the given identity type	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated

	read	create	edit	delete	service
					with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
group=read,create,edit,delete
realm=read,create,edit,delete,service
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `uid`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data. For example, if you configure the search attribute to `mail`, it could prevent users from being able to update their email addresses in their user profiles.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=inetorgperson)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings, if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `inetorgperson, inetUser, organizationalPerson, person, top,`

LDAP User Attributes

User profiles have these LDAP attributes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `uid, caCertificate, authorityRevocationList, inetUserStatus, mail, sn, manager, userPassword, adminRole, objectClass, givenName, memberOf, cn, telephoneNumber, preferredlanguage, userCertificate, postalAddress, dn, employeeNumber, distinguishedName`

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

Attributes not mapped to another attribute (for example, `cn`) and attributes mapped to themselves (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile. The object classes for user profile LDAP entries generally require Common Name (`cn`) and Surname (`sn`) attributes, so this prevents an LDAP constraint violation when performing the add operation.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn, sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `inetuserstatus`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: `Active`

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: `Inactive`

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `uid`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectclass=groupOfUniqueNames)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `ou`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

Default: `groups`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `groupofuniquenames, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `ou, cn, description, dn, objectclass, uniqueMember`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `uniqueMember`

Attribute Name of Group Member URL

Attribute in the dynamic group's LDAP entry whose value is a URL specifying the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberurl`

Default: `memberUrl`

Default Group Member's User DN

DN of member added to all newly created groups.

ssoadm attribute: `sun-idrepo-ldapv3-config-dftgroupmember`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Filter

LDAP filter to apply when performing persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-filter`

Default: `(objectclass=*)`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

ssoadm attribute: `com.ipplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: false

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server before saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Directory Services Configuration Properties

Use these attributes when configuring DS data stores:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration.

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first:

1. The first directory server in the list whose `server_ID` matches the current AM server.
2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: *host:port* of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the *host:port*, where *n* is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

LDAP Bind Password

Bind password for connecting to the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: `base-dn`

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval, use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `second`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

Affinity Enabled

Enables affinity-based load balanced access to the identity stores. Specify each of the directory server instances that form the affinity deployment in the LDAP Server field.

The directory server instance used for each operation is based on the DN of the identity involved.

Important

When enabled, you **must** use an identical LDAP Server value in every AM instance in the deployment.

ssoadm attribute: `openam-idrepo-ldapv3-affinity-enabled`

Default: `Disabled`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	<code>read</code>	<code>create</code>	<code>edit</code>	<code>delete</code>	<code>service</code>
<code>group</code>	✓	✓	✓	✓	-

	read	create	edit	delete	service
realm	✓	✓	✓	✓	✓
user	✓	✓	✓	✓	✓
	Read the identity type	Create new identities of the given identity type	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
group=read,create,edit,delete
realm=read,create,edit,delete,service
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `uid`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data. For example, if you configure the search attribute to `mail`, it could prevent users from being able to update their email addresses in their user profiles.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=inetorgperson)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

Default: `ou`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

Default: `people`

LDAP Proxied Authorization

When the `force-change-on-reset` password policy is configured on the DS user data store, users resetting their passwords using AM's forgotten password feature may be required to reset their passwords twice (prompted by both AM's User Self-Service and DS's password policy).

When the LDAP Proxied Authorization property is enabled, AM leverages DS's `proxied authorization` to reset user passwords as themselves, rather than as the account configured in the LDAP Bind DN property. This way, DS does not require users to reset their passwords again.

Before enabling this setting, ensure that the account configured in the LDAP Bind DN property has the `proxied-auth` privilege granted. If the account does not have the required privilege, users would not be able to reset their passwords and AM and DS will log an error message.

For examples of setting the privileges required for the password reset feature, see "Installing and Configuring Directory Services for Identity Data" in the *Installation Guide*.

Enable this property only if:

- The `force-change-on-reset` password policy is configured in the DS user data store.
- The forgotten password user self-service feature is configured in AM.
- Users are being forced to reset their passwords twice.

ssoadm attribute: `openam-idrepo-ldapv3-proxied-auth-enabled`

Default: `Disabled`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings, if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `devicePrintProfilesContainer, forgerock-am-dashboard-service, iPlanetPreferences, inetorgperson, inetuser, iplanet-am-auth-configuration-service, iplanet-am-managed-person, iplanet-am-user-service, kbaInfoContainer, oathDeviceProfilesContainer, organizationalperson, person, pushDeviceProfilesContainer, sunAMAuthAccountLockout, sunFMSAML2NameIdentifier, sunFederationManagerDataStore, sunIdentityServerLibertyPPService, top`

LDAP User Attributes

User profiles have these LDAP attributes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `adminRole, assignedDashboard, authorityRevocationList, caCertificate, cn, createTimestamp, devicePrintProfiles, distinguishedName, dn, employeeNumber, givenName, inetUserHttpURL, inetUserStatus, iplanet-am-auth-configuration, iplanet-am-session-destroy-sessions, iplanet-am-session-get-valid-sessions, iplanet-am-session-max-caching-time, iplanet-am-session-max-idle-time, iplanet-am-session-max-session-time, iplanet-am-session-quota-limit, iplanet-am-session-service-status, iplanet-am-user-account-life, iplanet-am-user-admin-start-dn, iplanet-am-user-alias-list, iplanet-am-user-auth-config, iplanet-am-user-auth-modules, iplanet-am-user-failure-url, iplanet-am-user-federation-info, iplanet-am-user-federation-info-key, iplanet-am-user-login-status, iplanet-am-user-password-reset-force-reset, iplanet-am-user-password-reset-options, iplanet-am-user-password-reset-question-answer, iplanet-am-user-success-url, kbaActiveIndex, kbaInfo, mail, manager, memberOf, modifyTimestamp, oath2faEnabled, oathDeviceProfiles, objectClass, postalAddress, preferredLocale, preferredLanguage, preferredtimezone, pushDeviceProfiles, sn, sun-fm-saml2-nameid-info, sun-fm-saml2-nameid-infokey, sunAMAuthInvalidAttemptsData, sunIdentityMSISDNNumber, sunIdentityServerDiscoEntries, sunIdentityServerPPAddressCard, sunIdentityServerPPCommonNameAltCN, sunIdentityServerPPCommonNameCN, sunIdentityServerPPCommonNameFN, sunIdentityServerPPCommonNameMN, sunIdentityServerPPCommonNamePT, sunIdentityServerPPCommonNameSN, sunIdentityServerPPDemographicsAge, sunIdentityServerPPDemographicsBirthDay, sunIdentityServerPPDemographicsDisplayLanguage, sunIdentityServerPPDemographicsLanguage, sunIdentityServerPPDemographicsTimeZone, sunIdentityServerPPEmergencyContact, sunIdentityServerPPEmploymentIdentityAlt0, sunIdentityServerPPEmploymentIdentityJobTitle, sunIdentityServerPPEmploymentIdentityOrg, sunIdentityServerPPEncryPTKey, sunIdentityServerPPFacadeGreetSound, sunIdentityServerPPFacadeMugShot, sunIdentityServerPPFacadeNamePronounced, sunIdentityServerPPFacadeWebSite, sunIdentityServerPPFacadeGreetmesound, sunIdentityServerPPInformalName, sunIdentityServerPPLegalIdentityAltIdType, sunIdentityServerPPLegalIdentityAltIdValue, sunIdentityServerPPLegalIdentityDOB, sunIdentityServerPPLegalIdentityGender, sunIdentityServerPPLegalIdentityLegalName, sunIdentityServerPPLegalIdentityMaritalStatus,`

`sunIdentityServerPPLegalIdentityVATIdType`, `sunIdentityServerPPLegalIdentityVATIdValue`,
`sunIdentityServerPPMsgContact`, `sunIdentityServerPPSignKey`, `telephoneNumber`, `uid`, `userCertificate`,
`userPassword`

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

Attributes not mapped to another attribute (for example, `cn`) and attributes mapped to themselves (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile. The object classes for user profile LDAP entries generally require Common Name (`cn`) and Surname (`sn`) attributes, so this prevents an LDAP constraint violation when performing the add operation.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn`, `sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `inetuserstatus`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: `Active`

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: `Inactive`

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `uid`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectclass=groupOfUniqueNames)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `ou`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

Default: `groups`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `groupofuniquenames, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `cn, dn, objectclass, uniqueMember`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `uniqueMember`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Filter

LDAP filter to apply when performing persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-filter`

Default: `(objectclass=*)`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

The DS data store uses this setting only for persistent searches.

ssoadm attribute: `com.iplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: true

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server when saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Sun/Oracle DSEE Configuration Properties

Use these attributes when configuring data stores for Oracle DSEE or Sun DSEE using AM schema:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration.

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first:

1. The first directory server in the list whose `server_ID` matches the current AM server.
2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: `host:port` of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

Default: `cn=dsameuser,ou=DSAME Users,base-dn`

LDAP Bind Password

Bind password for connecting to the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: `base-dn`

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval, use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `second`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	read	create	edit	delete	service
group	✓	✓	✓	✓	-
realm	✓	✓	✓	✓	✓

	read	create	edit	delete	service
user	✓	✓	✓	✓	✓
role	✓	✓	✓	✓	-
filteredrole	✓	✓	✓	✓	-
	Read the identity type	Create new identities of the given identity type	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
filteredrole=read,create,edit,delete
group=read,create,edit,delete
realm=read,create,edit,delete,service
role=read,create,edit,delete
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `uid`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=inetorgperson)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

Default: `ou`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

Default: `people`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings, if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `devicePrintProfilesContainer, forgerock-am-dashboard-service, iPlanetPreferences, inetadmin, inetorgperson, inetuser, iplanet-am-auth-configuration-service, iplanet-am-managed-person, iplanet-am-user-service, kbaInfoContainer, oathDeviceProfilesContainer, organizationalperson, person, pushDeviceProfilesContainer, sunAMAuthAccountLockout, sunFMSAML2NameIdentifier, sunFederationManagerDataStore, sunIdentityServerLibertyPPService, top`

LDAP User Attributes

User profiles have these LDAP attributes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `assignedDashboard, authorityRevocationList, caCertificate, cn, createTimestamp, devicePrintProfiles, distinguishedName, adminRole, dn, employeeNumber, givenName, inetUserHttpURL,`

inetUserStatus, iplanet-am-auth-configuration, iplanet-am-session-destroy-sessions, iplanet-am-session-get-valid-sessions, iplanet-am-session-max-caching-time, iplanet-am-session-max-idle-time, iplanet-am-session-max-session-time, iplanet-am-session-quota-limit, iplanet-am-session-service-status, iplanet-am-static-group-dn, iplanet-am-user-account-life, iplanet-am-user-admin-start-dn, iplanet-am-user-alias-list, iplanet-am-user-auth-config, iplanet-am-user-auth-modules, iplanet-am-user-failure-url, iplanet-am-user-federation-info, iplanet-am-user-federation-info-key, iplanet-am-user-login-status, iplanet-am-user-password-reset-force-reset, iplanet-am-user-password-reset-options, iplanet-am-user-password-reset-question-answer, iplanet-am-user-success-url, kbaActiveIndex, kbaInfo, mail, manager, memberOf, modifyTimestamp, oath2faEnabled, oathDeviceProfiles, objectClass, postalAddress, preferredLocale, preferredLanguage, preferredTimezone, pushDeviceProfiles, sn, sun-fm-saml2-nameid-info, sun-fm-saml2-nameid-infokey, sunAMAuthInvalidAttemptsData, sunIdentityMSISDNNumber, sunIdentityServerDiscoEntries, sunIdentityServerPPAddressCard, sunIdentityServerPPCommonNameAltCN, sunIdentityServerPPCommonNameCN, sunIdentityServerPPCommonNameFN, sunIdentityServerPPCommonNameMN, sunIdentityServerPPCommonNamePT, sunIdentityServerPPCommonNameSN, sunIdentityServerPPDemographicsAge, sunIdentityServerPPDemographicsBirthDay, sunIdentityServerPPDemographicsDisplayLanguage, sunIdentityServerPPDemographicsLanguage, sunIdentityServerPPDemographicsTimeZone, sunIdentityServerPPEmergencyContact, sunIdentityServerPPEmploymentIdentityAlt0, sunIdentityServerPPEmploymentIdentityJobTitle, sunIdentityServerPPEmploymentIdentityOrg, sunIdentityServerPPEncryPTKey, sunIdentityServerPPFacadeGreetSound, sunIdentityServerPPFacadeMugShot, sunIdentityServerPPFacadeNamePronounced, sunIdentityServerPPFacadeWebSite, sunIdentityServerPPFacadeGreetmesound, sunIdentityServerPPInformalName, sunIdentityServerPPLegalIdentityAltIdType, sunIdentityServerPPLegalIdentityAltIdValue, sunIdentityServerPPLegalIdentityDOB, sunIdentityServerPPLegalIdentityGender, sunIdentityServerPPLegalIdentityLegalName, sunIdentityServerPPLegalIdentityMaritalStatus, sunIdentityServerPPLegalIdentityVATIdType, sunIdentityServerPPLegalIdentityVATIdValue, sunIdentityServerPPMsgContact, sunIdentityServerPPSignKey, telephoneNumber, uid, userCertificate, userPassword

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

Attributes not mapped to another attribute (for example, `cn`) and attributes mapped to themselves (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile. The object classes for user profile LDAP entries generally require Common Name (`cn`) and Surname (`sn`) attributes, so this prevents an LDAP constraint violation when performing the add operation.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn, sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `inetuserstatus`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: `Active`

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: `Inactive`

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `uid`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectClass=groupOfUniqueNames)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `ou`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

Default: `groups`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `groupofuniquenames, iplanet-am-managed-group, iplanet-am-managed-static-group, groupofurls, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `cn, iplanet-am-group-subscribable, dn, objectclass, uniqueMember`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `uniqueMember`

Attribute Name of Group Member URL

Attribute in the dynamic group's LDAP entry whose values are LDAP URLs specifying members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberurl`

Default: `memberUrl`

LDAP Roles Search Attribute

When searching for a role by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-roles-search-attribute`

Default: `cn`

LDAP Roles Search Filter

When searching for roles, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-roles-search-filter`

Default: `(&(objectclass=ldapsubentry)(objectclass=nsmanagedroledefinition))`

LDAP Roles Object Class

Role profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-role-objectclass`

Default: `ldapsubentry, nsmanagedroledefinition, nsroledefinition, nssimpleroledescription, top`

LDAP Filter Roles Search Attribute

When searching for a filtered role by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-filterroles-search-attribute`

Default: `cn`

LDAP Filter Roles Search Filter

When searching for filtered roles, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-filterroles-search-filter`

Default: `(&(objectclass=ldapsubentry)(objectclass=nsfilteredroledefinition))`

LDAP Filter Roles Object Class

Filtered role profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-filterrole-objectclass`

Default: `ldapsubentry, nscomplexroledescription, nsfilteredroledescription, nsroledefinition`

LDAP Filter Roles Attributes

Filtered role profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-filterrole-attributes`

Default: `nsRoleFilter`

Attribute Name for Filtered Role Membership

LDAP attribute in the member's LDAP entry whose values are the filtered roles to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-nsrole`

Default: `nsrole`

Attribute Name of Role Membership

LDAP attribute in the member's LDAP entry whose values are the roles to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-nsroledn`

Default: `nsRoleDN`

Attribute Name of Filtered Role Filter

LDAP attribute whose values are the filters for filtered roles.

ssoadm attribute: `sun-idrepo-ldapv3-config-nsrolefilter`

Default: `nsRoleFilter`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Filter

LDAP filter to apply when performing persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-filter`

Default: `(objectclass=*)`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

ssoadm attribute: `com.ipplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: true

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server before saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Tivoli Directory Server Configuration Properties

Use these attributes when configuring Tivoli Directory Server data stores:

amster service name: `IdRepository`

ssoadm service name: `sunIdentityRepositoryService`

ID

The ID of the data store configuration.

LDAP Server

`host:port` to contact the directory server, with optional `|server_ID|site_ID` for deployments with multiple servers and sites.

AM uses the optional settings to determine which directory server to contact first. AM tries to contact directory servers in the following priority order, with highest priority first.

1. The first directory server in the list whose `server_ID` matches the current AM server.
2. The first directory server in the list whose `site_ID` matches the current AM server.
3. The first directory server in the remaining list.

If the directory server is not available, AM proceeds to the next directory server in the list.

XUI

Default: `host:port` of the initial directory server configured for this AM server.

ssoadm

ssoadm attribute: `sun-idrepo-ldapv3-config-ldap-server`

Default: `=[0]=host:port` of the initial directory server configured for this AM server.

You must add `=[n]=` before the `host:port`, where `n` is an array index, starting with 0, of servers listed. See the example below.

Example:

```
sun-idrepo-ldapv3-config-ldap-server=[0]=localhost:51389|01
sun-idrepo-ldapv3-config-ldap-server=[1]=openam.example.com:52389|02
sun-idrepo-ldapv3-config-ldap-server=[2]=zzz.example.com:1389|01|02
sun-idrepo-ldapv3-config-ldap-server=[3]=xxx.example.com:1389|01|02
```

LDAP Bind DN

Bind DN for connecting to the directory server. Some AM capabilities require write access to directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-authid`

LDAP Bind Password

Bind password for connecting to the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-authpw`

LDAP Organization DN

The base DN under which to find user and group profiles.

Ensure that the identity store is setup with the specified DN before making any changes to this property in AM.

ssoadm attribute: `sun-idrepo-ldapv3-config-organization_name`

Default: `base-dn`

LDAP Connection Mode

Whether to use LDAP, LDAPS or StartTLS to connect to the directory server. When LDAPS or StartTLS are enabled, AM must be able to trust server certificates, either because the server certificates were signed by a CA whose certificate is already included in the trust store used by the container where AM runs, or because you imported the certificates into the trust store.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection-mode`

Possible values: `LDAP`, `LDAPS`, and `StartTLS`

LDAP Connection Pool Maximum Size

Maximum number of connections to the directory server. Make sure the directory service can cope with the maximum number of client connections across all servers.

ssoadm attribute: `sun-idrepo-ldapv3-config-connection_pool_max_size`

Default: 10

LDAP Connection Heartbeat Interval

How often to send a heartbeat request to the directory server to ensure that the connection does not remain idle. Some network administrators configure firewalls and load balancers to drop connections that are idle for too long. You can turn this off by setting the value to 0 or to a negative number. To set the units for the interval, use LDAP Connection Heartbeat Time Unit.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-interval`

Default: 10

LDAP Connection Heartbeat Time Unit

Time unit for the LDAP Connection Heartbeat Interval setting.

ssoadm attribute: `openam-idrepo-ldapv3-heartbeat-timeunit`

Default: `second`

Maximum Results Returned from Search

A cap for the number of search results to return, for example, when viewing profiles under Identities. Rather than raise this number, consider narrowing your search to match fewer directory entries.

ssoadm attribute: `sun-idrepo-ldapv3-config-max-result`

Default: 1000

Search Timeout

Maximum time to wait for search results in seconds. Does not apply to persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-time-limit`

Default: 10

LDAPv3 Plugin Search Scope

LDAP searches can apply to a single entry (`SCOPE_BASE`), entries directly below the search DN (`SCOPE_ONE`), or all entries below the search DN (`SEARCH_SUB`).

ssoadm attribute: `sun-idrepo-ldapv3-config-search-scope`

Default: `SCOPE_SUB`

LDAPv3 Repository Plugin Class Name

AM identity repository implementation.

ssoadm attribute: `sunIdRepoClass`

Default: `org.forgerock.openam.idrepo.ldap.DJLDAPv3Repo`

Attribute Name Mapping

Map of AM profile attribute names to directory server attribute names.

ssoadm attribute: `sunIdRepoAttributeMapping`

LDAPv3 Plugin Supported Types and Operations

Specifies the identity types supported by the data store, such as `user`, `group`, or `realm`, and which operations can be performed on them.

The following table illustrates the identity types supported by this data store, and the operations that can be performed on them:

Supported Identity Types and Operations

	read	create	edit	delete	service
group	✓	✓	✓	✓	-
realm	✓	✓	✓	✓	✓
user	✓	✓	✓	✓	✓
	Read the identity type	Create new identities of the given identity type	Edit entities of the given identity type	Delete entities of the given identity type	Read and write service settings associated with the given identity type.

You can remove permissions based on your data store needs. For example, if the data store should not be written to, you can set the operations to `read` only for the identity types.

The `service` operation is only relevant to the `realm` and the `user` identity types. For example, the Session Service configuration can be stored by realm, and a user can have specific session timeout settings.

ssoadm attribute: `sunIdRepoSupportedOperations`

Default:

```
group=read,create,edit,delete
realm=read,create,edit,delete,service
user=read,create,edit,delete,service
```

LDAP Users Search Attribute

When searching for a user by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-attribute`

Default: `cn`

Warning

Do not modify the value of the search attribute in user profiles. Modifying this attribute value can result in incorrectly cached identity data. For example, if you configure the search attribute to `mail`, it could prevent users from being able to update their email addresses in their user profiles.

LDAP Users Search Filter

When searching for users, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-users-search-filter`

Default: `(objectclass=inetorgperson)`

LDAP People Container Naming Attribute

RDN attribute of the LDAP base DN which contains user profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-name`

Default: `ou`

LDAP People Container Value

RDN attribute value of the LDAP base DN which contains user profiles.

If specified, AM will limit searches for user profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-people-container-value`

LDAP User Object Class

User profiles have these LDAP object classes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

For example, with default settings if you request that AM execute a search that asks for the `mailAlternateAddress` attribute, AM does the search, but does not request `mailAlternateAddress`. In the same way, AM does perform an update operation with a request to set the value of an unlisted attribute like `mailAlternateAddress`, but it drops the unlisted attribute from the update request.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-objectclass`

Default: `devicePrintProfilesContainer, forgerock-am-dashboard-service, inetorgperson, inetuser, iplanet-am-auth-configuration-service, iplanet-am-managed-person, iplanet-am-user-service, iPlanetPreferences, organizationalperson, person, sunAMAuthAccountLockout, sunFederationManagerDataStore, sunFMSAML2NameIdentifier, sunIdentityServerLibertyPPService, top`

LDAP User Attributes

User profiles have these LDAP attributes.

AM handles only those attributes listed in this setting. AM discards any unlisted attributes from requests and the request proceeds without the attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-user-attributes`

Default: `adminRole, assignedDashboard, authorityRevocationList, caCertificate, cn, devicePrintProfiles, distinguishedName, dn, employeeNumber, givenName, inetUserHttpURL, inetUserStatus, iplanet-am-auth-`

configuration, iplanet-am-session-add-session-listener-on-all-sessions, iplanet-am-session-destroy-sessions, iplanet-am-session-get-valid-sessions, iplanet-am-session-max-caching-time, iplanet-am-session-max-idle-time, iplanet-am-session-max-session-time, iplanet-am-session-quota-limit, iplanet-am-session-service-status, iplanet-am-user-account-life, iplanet-am-user-admin-start-dn, iplanet-am-user-alias-list, iplanet-am-user-auth-config, iplanet-am-user-auth-modules, iplanet-am-user-failure-url, iplanet-am-user-federation-info-key, iplanet-am-user-federation-info, iplanet-am-user-login-status, iplanet-am-user-password-reset-force-reset, iplanet-am-user-password-reset-options, iplanet-am-user-password-reset-question-answer, iplanet-am-user-success-url, mail, manager, memberOf, objectClass, postalAddress, preferredlanguage, preferredLocale, preferredtimezone, sn, sun-fm-saml2-nameid-info, sun-fm-saml2-nameid-infokey, sunAMAuthInvalidAttemptsData, sunIdentityMSISDNNumber, sunIdentityServerDiscoEntries, sunIdentityServerPPAddressCard, sunIdentityServerPPCommonNameAltCN, sunIdentityServerPPCommonNameCN, sunIdentityServerPPCommonNameFN, sunIdentityServerPPCommonNameMN, sunIdentityServerPPCommonNamePT, sunIdentityServerPPCommonNameSN, sunIdentityServerPPDemographicsAge, sunIdentityServerPPDemographicsBirthDay, sunIdentityServerPPDemographicsDisplayLanguage, sunIdentityServerPPDemographicsLanguage, sunIdentityServerPPDemographicsTimeZone, sunIdentityServerPPEmergencyContact, sunIdentityServerPPEmploymentIdentityAlt0, sunIdentityServerPPEmploymentIdentityJobTitle, sunIdentityServerPPEmploymentIdentityOrg, sunIdentityServerPPEncryPTKey, sunIdentityServerPPFacadegreetmesound, sunIdentityServerPPFacadeGreetSound, sunIdentityServerPPFacadeMugShot, sunIdentityServerPPFacadeNamePronounced, sunIdentityServerPPFacadeWebSite, sunIdentityServerPPInformalName, sunIdentityServerPPLegalIdentityAltIdType, sunIdentityServerPPLegalIdentityAltIdValue, sunIdentityServerPPLegalIdentityDOB, sunIdentityServerPPLegalIdentityGender, sunIdentityServerPPLegalIdentityLegalName, sunIdentityServerPPLegalIdentityMaritalStatus, sunIdentityServerPPLegalIdentityVATIdType, sunIdentityServerPPLegalIdentityVATIdValue, sunIdentityServerPPMsgContact, sunIdentityServerPPSignKey, telephoneNumber, uid, userCertificate, userPassword

Create User Attribute Mapping

When creating a user profile, apply this map of AM profile attribute names to directory server attribute names.

Attributes not mapped to another attribute (for example, `cn`) and attributes mapped to themselves (for example, `cn=cn`) take the value of the username unless the attribute values are provided when creating the profile. The object classes for user profile LDAP entries generally require Common Name (`cn`) and Surname (`sn`) attributes, so this prevents an LDAP constraint violation when performing the add operation.

ssoadm attribute: `sun-idrepo-ldapv3-config-createuser-attr-mapping`

Default: `cn, sn`

Attribute Name of User Status

Attribute to check/set user status.

ssoadm attribute: `sun-idrepo-ldapv3-config-isactive`

Default: `inetuserstatus`

User Status Active Value

Active users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-active`

Default: `Active`

User Status Inactive Value

Inactive users have the user status attribute set to this value.

ssoadm attribute: `sun-idrepo-ldapv3-config-inactive`

Default: `Inactive`

Authentication Naming Attribute

RDN attribute for building the bind DN when given a username and password to authenticate a user against the directory server.

ssoadm attribute: `sun-idrepo-ldapv3-config-auth-naming-attr`

Default: `cn`

LDAP Groups Search Attribute

When searching for a group by name, match values against this attribute.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-attribute`

Default: `cn`

LDAP Groups Search Filter

When searching for groups, apply this LDAP search filter as well.

ssoadm attribute: `sun-idrepo-ldapv3-config-groups-search-filter`

Default: `(objectclass=groupOfNames)`

LDAP Groups Container Naming Attribute

RDN attribute of the LDAP base DN which contains group profiles.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-name`

Default: `ou`

LDAP Groups Container Value

RDN attribute value of the LDAP base DN which contains group profiles.

If specified, AM will limit searches for group profiles to the provided base DN. Otherwise, AM searches the entire directory.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-container-value`

LDAP Groups Object Class

Group profiles have these LDAP object classes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-objectclass`

Default: `groupofnames, top`

LDAP Groups Attributes

Group profiles have these LDAP attributes.

ssoadm attribute: `sun-idrepo-ldapv3-config-group-attributes`

Default: `cn, description, dn, member, objectclass, ou`

Attribute Name for Group Membership

LDAP attribute in the member's LDAP entry whose values are the groups to which a member belongs.

ssoadm attribute: `sun-idrepo-ldapv3-config-memberof`

Attribute Name of Unique Member

Attribute in the group's LDAP entry whose values are the members of the group.

ssoadm attribute: `sun-idrepo-ldapv3-config-uniquemember`

Default: `member`

Default Group Member's User DN

DN of member added to all newly created groups.

ssoadm attribute: `sun-idrepo-ldapv3-config-dftgroupmember`

Persistent Search Base DN

Base DN for LDAP-persistent searches used to receive notification of changes in directory server data.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearchbase`

Default: `base-dn`

Persistent Search Filter

LDAP filter to apply when performing persistent searches.

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-filter`

Default: `(objectclass=*)`

Persistent Search Scope

LDAP searches can apply to a single entry (SCOPE_BASE), entries directly below the search DN (SCOPE_ONE), or all entries below the search DN (SEARCH_SUB).

ssoadm attribute: `sun-idrepo-ldapv3-config-psearch-scope`

Default: `SCOPE_SUB`

The Delay Time Between Retries

How long to wait after receiving an error result that indicates AM should try the LDAP operation again.

ssoadm attribute: `com.ipplanet.am.ldap.connection.delay.between.retries`

Default: 1000 milliseconds

DN Cache Enabled

Whether to enable the DN cache, which is used to cache DN lookups that can happen in bursts during authentication. As the cache can become stale when a user is moved or renamed, enable DN caching when the directory service allows move/rename operations (Mod DN), and when AM uses persistent searches to obtain notification of such updates.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-enabled`

Default: true

DN Cache Size

Maximum number of DN's cached when caching is enabled.

ssoadm attribute: `sun-idrepo-ldapv3-dncache-size`

Default: 1500 items

Load Schema

Import appropriate LDAP schema to the directory server before saving the configuration. The LDAP Bind DN user must have access to perform this operation.

This option is not available for use with the **ssoadm** command.

Default: Disabled.

Realm Privileges Configuration Reference

The following table describes privileges that you can assign in the AM console or by using the **ssoadm add-privileges** command:

Privileges

Privilege as it Appears in the AM console	Privilege Name to Use With the ssoadm add-privileges Command	Notes
Read and write access to all realm and policy properties	Realm Admin	Assign this privilege to administrators in order to let them modify or read any part of an AM realm. Use this privilege when you do not require granularity in your delegation model. All other AM privileges are included with this privilege. Administrators using the AM administration console must have this privilege.
Read and write access to all configured agents	Agent Admin	Provides access to centralized agent configuration; subset of the RealmAdmin privilege.
Read and write access to all log files	Log Admin	Subset of the Realm Admin privilege.
Read access to all log files	Log Read	Subset of the Realm Admin privilege.
Write access to all log files	Log Write	Subset of the RealmAdmin privilege.
Read and write access to all federation metadata configurations	Federation Admin	Subset of the Realm Admin privilege.
REST calls for reading realms	Realm Read Access	Subset of the Realm Admin privilege.
Read and write access only for policy properties, including REST calls	Policy Admin	Assign this privilege to policy administrators in order to let them modify or read any part of the AM policy configuration. This privilege lets an administrator modify or read all policy

Privilege as it Appears in the AM console	Privilege Name to Use With the ssoadm add-privileges Command	Notes
		components: policies, applications, subject types, condition types, subject attributes, and decision combiners. All other AM privileges that affect policy components are included with this privilege. Subset of the Realm Admin privilege.
REST calls for policy evaluation	Entitlement Rest Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading policies	Privilege Rest Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for managing policies	Privilege Rest Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading policy applications	Application Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for modifying policy applications	Application Modify Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading policy resource types	Resource Type Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for modifying policy resource types	Resource Type Modify Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading policy application types	Application Types Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading environment conditions	Condition Types Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading subject conditions	Subject Types Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading decision combiners	Decision Combiners Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for reading subject attributes	Subject Attributes Read Access	Subset of the Realm Admin and Policy Admin privileges.
REST calls for modifying session properties	Session Property Modify Access	Subset of the Realm Admin and Policy Admin privileges.

Record Control File Configuration Properties

The following properties comprise the recording control file:

issueID

Type: Number

Required. The issue identifier—a positive integer stored internally as a Java `long` data type. A case number is a good choice for the `issueID` value.

The `issueID` is a component of the path at which recorded information is stored. See "Retrieving Recording Information" for more information.

`referenceID`

Type: String

Required. A second identifier for the recording event. Use this property to segregate multiple recording events for the same issue.

The `referenceID` is a component of the path at which recorded information is stored. See "Retrieving Recording Information" for more information.

Note that spaces are not allowed in the `referenceID` value.

`Description`

Type: String

Required. A textual description of the recording event.

`zipEnable`

Type: Boolean

Required. Whether to compress the output directory into a zip file when recording has stopped.

`configExport`

Type: Object

Required. An object containing the following properties:

`enable`

Type: Boolean

Required. Whether to export the AM configuration upon completion of the recording event. Exporting the AM configuration is a best practice, because it is extremely useful to have access to the configuration when troubleshooting.

`password`

Type: String

Required if `enable` is `true`. A key required to import the exported configuration. The key is used the same way that the `ssoadm export-svc-cfg` command uses the `-e` argument.

`sharePassword`

Type: Boolean

Required if `enable` is `true`. Whether to show the `password` value in the `ssoadm start-recording`, `ssoadm get-recording-status`, and `ssoadm stop-recording` output, and in the `info.json` file, which is output during recording events, and which contains run-time properties.

`debugLogs`

Type: Object

Required. An object containing the following properties:

`debugLevel`

Type: String

Required. The debug level to set for the recording event. Set the value of `debugLevel` to `MESSAGE` to get the most troubleshooting information from your recording period. Other acceptable but less commonly used values are `ERROR` and `WARNING`.

`autoStop`

Type: Object

Optional. Contains another object used to specify an event that automatically ends a recording period. For time-based termination, specify a `time` object; for termination based on uncompressed file size, specify a `fileSize` object. If you specify both `time` and `fileSize` objects, the event that occurs first causes recording to stop.

Specifying `fileSize` and `time` objects is a best practice, because it ensures that the recorded output does not occupy a larger than expected amount of space on your file system, and that recording events end in a timely fashion.

`time`

Type: Object

Optional; must be specified in the `autoStop` object if `fileSize` is not specified. Configures a recording period to terminate recording after this amount of time.

`timeUnit`

Type: String

Required. Acceptable values are `MILLISECONDS`, `SECONDS`, `MINUTES`, `HOURS`, and `DAYS`.

`value`

Type: Numeric

Required. Values in `MILLISECONDS` are rounded down to the second. The minimum acceptable value for `autoStop` is one second.

fileSize

Type: Object

Optional; must be specified in the **autoStop** object if **time** is not specified. Configures a recording period to terminate after the aggregate size of uncompressed debug logs has reached this size.

sizeUnit

Type: String

Required. Acceptable values are **B**, **KB**, **MB**, and **GB**.

value

Type: Numeric

Required.

threadDump

Type: Object

Required. An object containing the following properties:

enable

Type: Boolean

Required. Whether to dump threads during the recording event. Thread dumps are especially useful when troubleshooting performance issues and issues with unresponsive servers.

delay

Type: Object

Required if **enable** is **true**. Contains another object used to specify an interval at which thread dumps are taken. The initial thread dump is taken at the start of the recording event; subsequent thread dumps are taken at multiples of the **delay** interval.

timeUnit

Type: String

Required. Acceptable values are **MILLISECONDS**, **SECONDS**, **MINUTES**, **HOURS**, and **DAYS**.

value

Type: Numeric

Required. The minimum acceptable value is one second. Time units that are smaller than seconds, such as **MILLISECONDS**, are rounded to the closest second.

Secret ID Mapping Defaults

This section covers the default secret ID mappings provided in an AM instance.

For more information on secret ID mappings and secret stores, see "*Configuring Secrets, Certificates, and Keys*".

Secret ID Mappings for the Agents' OAuth 2.0 Provider

Secret ID	Default Alias	Algorithms
am.global.services.oauth2.oidc.agent.idtoken.signing	rsajwtsigningkey	RS256 RS384 RS512

Secret ID Mappings for JWT Authenticity Signing

Secret ID	Default Alias	Algorithms
am.services.oauth2.jwt.authenticity.signing	hmacsigningtest	HS256 HS384 HS512

Note

This key is used to sign the following tokens and requests:

- OpenID Connect tokens for Web and Java Agents.
- OpenID Connect tokens that are signed with an HMAC algorithm.
- Consent requests to remote consent agents that are signed with an HMAC algorithm.

Secret ID Mapping for Encrypting Authentication Tree's Data in Shared State

The following table shows the default secret ID mapping used to encrypt data in the shared state of the authentication tree:

Secret ID	Default Alias	Algorithms
am.authn.nodes.sharedstate.encryption	directenctest	AES 256-bit

For more information, see "HOTP Generator Node" in the *Authentication and Single Sign-On Guide*

Secret ID Mappings for Encrypting Client-Based OAuth 2.0 Tokens

Secret ID	Default Alias	Algorithms
am.services.oauth2.stateless.token.encryption	directentest	A128CBC-HS256

For more information, see "Configuring Client-Based OAuth 2.0 Token Encryption" in the *OAuth 2.0 Guide*.

Secret ID Mappings for Signing Client-Based OAuth 2.0 Tokens

Secret ID	Default Alias	Algorithms
am.services.oauth2.stateless.signing.ES256	es256test	ES256
am.services.oauth2.stateless.signing.ES384	es384test	ES384
am.services.oauth2.stateless.signing.ES512	es512test	ES512
am.services.oauth2.stateless.signing.HMAC	hmacsigningtest	HS256 HS384 HS512
am.services.oauth2.stateless.signing.RSA	rsajwt signingkey	PS256 PS384 PS512 RS256 RS384 RS512

For more information, see "Configuring Client-Based OAuth 2.0 Token Digital Signatures" in the *OAuth 2.0 Guide*.

Secret ID Mappings for Decrypting OpenID Connect Request Parameters

Secret ID	Default Alias	Algorithms ^a
am.services.oauth2.oidc.decryption.RSA1.5	test	RSA with PKCS#1 v1.5 padding
am.services.oauth2.oidc.decryption.RSA.OAEP	test	RSA with OAEP with SHA-1 and MGF-1
am.services.oauth2.oidc.decryption.RSA.OAEP.256	test	RSA with OAEP with SHA-256 and MGF-1

^a The following applies to confidential clients only:

If you select an AES algorithm (**A128KW**, **A192KW**, or **A256KW**) or the direct encryption algorithm (**dir**), the value of the Client Secret field in the OAuth 2.0 Client is used as the secret instead of an entry from the secret stores.

The following signing and encryption algorithms use the Client Secret field to store the secret:

- Signing ID tokens with an HMAC algorithm
- Encrypting ID tokens with AES or direct encryption
- Encrypting parameters with AES or direct encryption

Store only *one* secret in the Client Secret field; AM will use different mechanisms to sign and encrypt depending on the algorithm, as explained in the OpenID Connect Core 1.0 errata set 1 specification.

For more information, see "Configuring AM for OpenID Connect 1.0" in the *OpenID Connect 1.0 Guide*.

Secret ID Mappings for Signing OpenID Connect Tokens

Secret ID	Default Alias	Algorithms ^a
am.services.oauth2.oidc.signing.ES256	es256test	ES256
am.services.oauth2.oidc.signing.ES384	es384test	ES384
am.services.oauth2.oidc.signing.ES512	es512test	ES512
am.services.oauth2.oidc.signing.RSA	rsajwt signingkey	PS256 PS384 PS512 RS256 RS384 RS512

^a The following applies to confidential clients only:

If you select an HMAC algorithm for signing ID tokens ([HS256](#), [HS384](#), or [HS512](#)), the Client Secret property value in the OAuth 2.0 Client is used as the HMAC secret instead of an entry from the secret stores.

Since the HMAC secret is shared between AM and the client, a malicious user compromising the client could potentially create tokens that AM would trust. Therefore, to protect against misuse, AM also signs the token using a non-shared signing key configured in the [am.services.oauth2.jwt.authenticity.signing](#) secret ID.

For more information, see "To Configure Digital Signatures for OpenID Connect Tokens" in the *OpenID Connect 1.0 Guide*.

Secret ID Mappings for Persistent Cookies

The following table shows the default secret ID mappings used to encrypt and then sign persistent cookies:

Secret ID	Default Alias	
am.default.authentication.modules.persistentcookie.encryption	test	
am.default.authentication.modules.persistentcookie.signing	hmacsigningtest	

For each instance of a persistent cookie module available in a realm, there is a dynamic secret ID associated with that module configuration instance.

For example, in a single realm you can have a Persistent Cookie module instance with the name *helloworld*, and a separate Persistent Cookie module instance with the name *hellomars*.

The following secret ID mappings could be used to encrypt and then sign persistent cookies:

Secret ID	Default Alias	
am.authentication.modules.persistentcookie. <i>helloworld</i> .encryption	<i>helloworld</i>	
am.authentication.modules.persistentcookie. <i>helloworld</i> .signing	hmacsigning <i>helloworld</i>	
am.authentication.modules.persistentcookie. <i>hellomars</i> .encryption	<i>hellomars</i>	
am.authentication.modules.persistentcookie. <i>hellomars</i> .signing	hmacsigning <i>hellomars</i>	

AM will attempt to look up the secrets with the Persistent Cookie module instance name. If unsuccessful, AM will look up the secrets using the default secret ID.

For more information, see "Persistent Cookie Module" in the *Authentication and Single Sign-On Guide*.

Secret ID Mappings for Encrypting SAML v2.0 Local Storage JWTs

The following table shows the secret ID mapping used to encrypt the JWTs SAML v2.0 creates in local storage:

Secret ID	Default Alias	Algorithms
am.global.services.saml2.client.storage.jwt.encryption	directentest	A256GCM

Secret ID Mappings for Signing Remote Consent Requests

The following table shows the default secret ID mappings used to sign remote consent requests:

Secret ID	Default Alias	Algorithms ^a
am.applications.agents.remote.consent.request.signing	RS256test	ES256
am.applications.agents.remote.consent.request.signing	RS384test	ES384
am.applications.agents.remote.consent.request.signing	RS512test	ES512
am.applications.agents.remote.consent.request.signing	RSAjwtsigningkey	RS256 RS384 RS512 PS256 PS384 PS512

^a If you select an HMAC algorithm for signing consent requests (**HS256**, **HS384**, or **HS512**), the value of the Remote Consent Service secret property is used, instead of an entry from the secret stores.

Since the HMAC secret is shared between AM and the remote consent client, a malicious user compromising the client could potentially create tokens that AM would trust. Therefore, to protect against misuse, AM also signs the token using a non-shared signing key configured in the **am.services.oauth2.jwt.authenticity.signing** secret ID.

For more information, see "OAuth 2.0 Remote Consent Agent Settings" in the *OAuth 2.0 Guide*.

Secret ID Mappings for Decrypting Remote Consent Responses

The following table shows the default secret ID mapping used to decrypt remote consent responses:

Secret ID	Default Alias	Algorithms ^a
am.services.oauth2.remote.consent.response.decryption	test	RSA-OAEP-256

^a If you select an algorithm other than **RSA-OAEP-256** for decrypting consent responses, the value of the Remote Consent Service secret property is used, instead of an entry from the secret stores.

For more information, see "OAuth 2.0 Remote Consent Agent Settings" in the *OAuth 2.0 Guide*.

Audit Logging File Format

AM writes log messages generated from audit events triggered by its components, instances, and other ForgeRock-based stack products.

Audit Log Format

This section presents the audit log format for each topic-based file, event names, and audit constants used in its log messages.

Access Log Format

Access Log Format

Schema Property	Description
<code>_id</code>	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-491</code> .
<code>timestamp</code>	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.653Z</code>
<code>eventName</code>	Specifies the name of the audit event. For example, <code>AM-ACCESS-ATTEMPT</code> and <code>AM-ACCESS-OUTCOME</code> . For a list of audit event names, see "Audit Log Event Names".
<code>transactionId</code>	<p>Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID even for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code>.</p> <p>AM supports a feature where trusted AM deployment with multiple instances, components, and ForgeRock stack products can propagate the transaction ID through each call across the stack. AM reads the <code>X-ForgeRock-TransactionId</code> HTTP header and appends an integer to the transaction ID. Note that this feature is disabled by default. When enabled, this feature should filter the <code>X-ForgeRock-TransactionId</code> HTTP header for connections from untrusted sources.</p>
<code>user.id</code>	Specifies the universal identifier for authenticated users. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
<code>trackingIds</code>	<p>Specifies a unique random string generated as an alias for each AM session ID and OAuth 2.0 token. In releases prior to OpenAM 13.0.0, the <code>contextId</code> log property used a random string as an alias for the session ID. The <code>trackingIds</code> property also uses an alias when referring to session IDs, for example, <code>["45b17894529cf74301"]</code>.</p> <p>OpenAM 13.0.0 extended this property to handle OAuth 2.0 tokens. In this case, whenever AM generates an access or grant token, it also generates unique random value and logs it as an alias. In this way, it is possible to trace back an access token back to its originating grant token, trace the grant token back to the</p>

Schema Property	Description
	session in which it was created, and then trace how the session was authenticated. An example of a <code>trackingIds</code> property in an OAuth 2.0/ OpenID Connect 1.0 environment is: ["1979edf68543ead001", "8878e51a-f2aa-464f-b1cc-b12fd6daa415", "3df9a5c3-8d1e-4ee3-93d6-b9bbe58163bc"]
<code>server.ip</code>	Specifies the IP address of the AM server. For example, <code>127.0.0.1</code> .
<code>server.port</code>	Specifies the port number used by the AM server. For example, <code>8080</code> .
<code>client.host</code>	Specifies the client hostname. This field is only populated if reverse DNS lookup is enabled.
<code>client.ip</code>	Specifies the client IP address.
<code>client.port</code>	Specifies the client port number.
<code>authorizationId.roles</code>	Specifies the list of roles for the authorized user.
<code>authorizationId.component</code>	Specifies the component part of the authorized ID, such as
<code>request.protocol</code>	Specifies the protocol associated with the request operation. Possible values: <code>CREST</code> and <code>PLL</code> .
<code>request.operation</code>	Specifies the request operation. For CREST operations, possible values are: <code>READ</code> , <code>ACTION</code> , <code>QUERY</code> . For PLL operations, possible values are: <code>LoginIndex</code> , <code>SubmitRequirements</code> , <code>GetSession</code> , <code>REQUEST_ADD_POLICY_LISTENER</code> .
<code>request.detail</code>	Specifies the detailed information about the request operation. For example: <ul style="list-style-type: none"> <code>{"action": "idFromSession"}</code> <code>{"action": "validateGoto"}</code> <code>{"action": "validate"}</code> <code>{"action": "logout"}</code> <code>{"action": "schema"}</code> <code>{"action": "template"}</code>
<code>http.method</code>	Specifies the HTTP method requested by the client. For example, <code>GET</code> , <code>POST</code> , <code>PUT</code> .
<code>http.path</code>	Specifies the path of the HTTP request. For example, <code>https://openam.example.com:8443/openam/json/realms/root/authenticate</code> .
<code>http.queryParameters</code>	Specifies the HTTP query parameter string. For example: <ul style="list-style-type: none"> <code>{ "_action": ["idFromSession"] }</code> <code>{ "_queryFilter": ["true"] }</code> <code>{ "_action": ["validate"] }</code> <code>{ "_action": ["logout"] }</code>

Schema Property	Description
	<ul style="list-style-type: none"> • { "realm": ["/shop"] } • { "_action": ["validateGoto"] }
http.request.headers	<p>Specifies the HTTP header for the request. For example:</p> <pre data-bbox="425 331 1325 1413"> { "accept":["application/json, text/javascript, */*; q=0.01"], "Accept-API-Version":["protocol=1.0"], "accept-encoding":["gzip, deflate"], "accept-language":["en-US;q=1,en;q=0.9"], "cache-control":["no-cache"], "connection":["Keep-Alive"], "content-length":["0"], "host":["forgerock-am.openrock.org"], "pragma":["no-cache"], "referer":["https://forgerock-am.openrock.org/openam/XUI/"], "user-agent":["Mozilla/5.0 (X11; Linux x86_64; rv:31.0) Gecko/20100101 Firefox/31.0"], "x-nosession":["true"], "x-requested-with":["XMLHttpRequest"], "x-username":["anonymous"] } </pre> <p>Note: line feeds and truncated values in the example are for readability purposes.</p>
http.request.cookies	<p>Specifies a JSON map of key-value pairs and appears as its own property to allow for blacklisting fields or values.</p>

Schema Property	Description
<code>http.response.cookies</code>	Not used in AM.
<code>response.status</code>	Specifies the response status of the request. For example, <code>SUCCESS</code> , <code>FAILURE</code> , or <code>null</code> .
<code>response.statusCode</code>	Specifies the response status code, depending on the protocol. For CREST, HTTP failure codes are displayed but not HTTP success codes. For PLL endpoints, PLL error codes are displayed.
<code>response.detail</code>	Specifies the message associated with <code>response.statusCode</code> . For example, the <code>response.statusCode</code> of <code>401</code> has a <code>response.detail</code> of <code>{ "reason": "Unauthorized" }</code> .
<code>response.elapsedTime</code>	Specifies the time to execute the access event, usually in millisecond precision.
<code>response.elapsedTimeUnits</code>	Specifies the elapsed time units of the response. For example, <code>MILLISECONDS</code> .
<code>component</code>	Specifies the AM service utilized. For example, <code>Server Info</code> , <code>Users</code> , <code>Config</code> , <code>Session</code> , <code>Authentication</code> , <code>Policy</code> , <code>OAuth</code> , <code>Web Policy Agent</code> , or <code>Java Policy Agent</code> .
<code>realm</code>	Specifies the realm where the operation occurred. For example, the Top Level Realm (<code>"/</code>) or the sub-realm name (<code>"/shop</code>).

Activity Log Format

Activity Log Format

Property	Description
<code>_id</code>	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-487</code> .
<code>timestamp</code>	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.652Z</code>
<code>eventName</code>	Specifies the name of the audit event. For example, <code>AM-SESSION_CREATED</code> , <code>AM-SESSION-LOGGED_OUT</code> , <code>AM-IDENTITY-CHANGE</code> . For a list of audit event names, see "Audit Log Event Names".
<code>transactionId</code>	Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for same even for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code> .
<code>user.id</code>	Specifies the universal identifier for authenticated users. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
<code>trackingIds</code>	Specifies an array containing a random context ID that identifies the session and a random string generated from an OAuth 2.0/OpenID Connect 1.0 flow that could track an access token ID or an grant token ID. For example, <code>["45b17894529cf74301"]</code> .

Property	Description
<code>runAs</code>	Specifies the user to run the activity as. May be used in delegated administration. For example, <code>id=dsameuser,ou=user,dc=example,dc=com</code> .
<code>objectId</code>	Specifies the identifier of an object that has been created, updated, or deleted. For logging sessions, the session <code>trackingId</code> is used in this field. For example, ["45b17894529cf74301"]
<code>operation</code>	Specifies the state change operation invoked: <code>CREATE</code> , <code>MODIFY</code> , or <code>DELETE</code> .
<code>before</code>	Not used.
<code>after</code>	Not used.
<code>changedFields</code>	Not used.
<code>revision</code>	Not used.
<code>component</code>	Specifies the AM service utilized. For example, <code>Session</code> or <code>Self-Service</code> .
<code>realm</code>	Specifies the realm where the operation occurred. For example, the Top Level Realm ("/") or the sub-realm name ("/shop").

Authentication Log Format

Authentication Log Format

Property	Description
<code>_id</code>	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-485</code> .
<code>timestamp</code>	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.640Z</code>
<code>eventName</code>	Specifies the name of the audit event. For example, <code>AM-LOGOUT</code> and <code>AM-LOGIN-MODULE-COMPLETED</code> . For a list of audit event names, see "Audit Log Event Names".
<code>transactionId</code>	Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for same even for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code> .
<code>user.id</code>	Specifies the universal identifier for authenticated users. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
<code>trackingIds</code>	Specifies an array containing a unique random context ID. For example: <ul style="list-style-type: none"> For OAuth 2.0/OpenID Connect flows, it identifies the session and a random string generated that can track an access token ID or a grant token ID. For authentication trees, it identifies an authentication tree flow.
<code>result</code>	Depending on the event being logged, specifies the outcome of:

Property	Description
	<ul style="list-style-type: none"> A single authentication module within a chain The result for an authentication tree <p>Possible values are SUCCESSFUL or FAILED.</p>
<code>principal</code>	Specifies the array of accounts used to authenticate, such as [<code>"amadmin"</code>] and [<code>"scarter"</code>].
<code>context</code>	Not used
<code>entries</code>	<p>Specifies the JSON representation of the details of an authentication module, chain, tree or node. AM creates an event as each module or node completes and a final event at the end of the chain or tree. Examples:</p> <pre> "entries":[{ "moduleId":"DataStore", "info":{ "moduleClass":"DataStore", "ipAddress":"127.0.0.1", "moduleName":"DataStore", "authLevel":"0" } }] </pre> <pre> "entries":[{ "info":{ "nodeOutcome":"true", "treeName":"Example", "displayName":"Data Store Decision", "nodeType":"DataStoreDecisionNode", "nodeId":"e5ec495a-2ae2-4eca-8afb-9781dea04170", "authLevel":"0" } }] </pre>
<code>component</code>	Specifies the AM service utilized. For example, Authentication .
<code>realm</code>	Specifies the realm where the operation occurred. For example, the Top Level Realm (<code>/</code>) or the sub-realm name (<code>/shop</code>).

Config Log Format

Config Log Format

Property	Description
<code>_id</code>	Specifies a universally unique identifier (UUID) for the message object. For example, <code>6a568d4fe-d655-49a8-8290-bfc02095bec9-843</code> .

Property	Description
timestamp	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example, <code>2015-11-14T00:21:03.490Z</code>
eventName	Specifies the name of the audit event. For example, <code>AM-CONFIG-CHANGE</code> . For a list of audit event names, see "Audit Log Event Names".
transactionId	Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for different audit event topics. For example, <code>301d1a6e-67f9-4e45-bfeb-5e4047a8b432</code> .
user.id	Not used. You can determine the value for this field by linking to the access event using the same <code>transactionId</code> .
trackingIds	Not used.
runAs	Specifies the user to run the activity as. May be used in delegated administration. For example, <code>id=amadmin,ou=user,dc=example,dc=com</code> .
objectId	Specifies the identifier of a system object that has been created, modified, or deleted. For example, <code>ou=SamuelTwo,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMAuthSAML2Service,ou=services,o=shop,ou=services,dc=example,dc=com</code> .
operation	Specifies the state change operation invoked: <code>CREATE</code> , <code>MODIFY</code> , or <code>DELETE</code> .
before	Specifies the JSON representation of the object prior to the activity. For example: <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <pre> { "sunsmpriority": ["0"], "objectclass": ["top", "sunServiceComponent", "organizationalUnit"], "ou": ["SamuelTwo"], "sunserviceID": ["serverconfig"] } </pre> </div>
after	Specifies the JSON representation of the object after the activity. For example:

Property	Description
	<pre>{ "sunKeyValue": ["forgerock-am-auth-saml2-auth-level=0", "forgerock-am-auth-saml2-meta-alias=/sp", "forgerock-am-auth-saml2-entity-name=http://", "forgerock-am-auth-saml2-authn-context-decl-ref=", "forgerock-am-auth-saml2-force-authn=none", "forgerock-am-auth-saml2-is-passive=none", "forgerock-am-auth-saml2-login-chain=", "forgerock-am-auth-saml2-auth-comparison=none", "forgerock-am-auth-saml2-req-binding= urn:names:tc:SAML:2.0:bindings:HTTP-Redirect", "forgerock-am-auth-saml2-binding= urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Artifact", "forgerock-am-auth-saml2-authn-context-class-ref=", "forgerock-am-auth-saml2-slo-relay=http://", "forgerock-am-auth-saml2-allow-create=false", "forgerock-am-auth-saml2-name-id-format= urn:oasis:names:tc:SAML:2.0:nameid-format:persistent"] }</pre>
<code>changedFields</code>	Specifies the fields that were changed. For example, [<code>"sunKeyValue"</code>].
<code>revision</code>	Not used.
<code>component</code>	Not used.
<code>realm</code>	Specifies the realm where the operation occurred. For example, the Top Level Realm (<code>"/"</code>) or the sub-realm name (<code>"/shop"</code>).

Audit Log Event Names

The following section presents the predefined names for the audit events:

Audit Log Event Names

Topic	EventName
<code>access</code>	<code>AM-ACCESS_ATTEMPT</code>
<code>access</code>	<code>AM-ACCESS_OUTCOME</code>
<code>activity</code>	<code>AM-SELFSERVICE-REGISTRATION-COMPLETED</code>
<code>activity</code>	<code>AM-SELFSERVICE-PASSWORDCHANGE-COMPLETED</code>
<code>activity</code>	<code>AM-SESSION-CREATED</code>
<code>activity</code>	<code>AM-SESSION-IDLE_TIME_OUT</code>
<code>activity</code>	<code>AM-SESSION-MAX_TIMED_OUT</code>
<code>activity</code>	<code>AM-SESSION-LOGGED_OUT</code>

Topic	EventName
activity	AM-SESSION-DESTROYED
activity	AM-SESSION-PROPERTY_CHANGED
activity	AM-IDENTITY-CHANGE
activity	AM-GROUP-CHANGE
authentication	AM-LOGOUT
authentication	AM-LOGIN-COMPLETED
authentication	AM-LOGIN-MODULE-COMPLETED
authentication	AM-NODE-LOGIN-COMPLETED
authentication	AM-TREE-LOGIN-COMPLETED
config	AM-CONFIG-CHANGE

Audit Log Components

The following section presents the predefined audit event components that make up the log messages:

Audit Log Event Components

Event Component	AM Component, Service, or Feature
OAuth	OAuth 2.0, OpenID Connect 1.0, and UMA
CTS	Core Token Service
AM Agents	Web and Java agents
Authentication	Authentication service
Dashboard	Dashboard service
Server Info	Server information service
Users	Users component
Groups	Groups component
Oath	Mobile authentication
Devices	Trusted devices
Policy	Policies
Realms	Realms and sub-realms
Session	Session service
Script	Scripting service
Batch	Batch service
Config	Configuration

Event Component	AM Component, Service, or Feature
STS	Secure Token Service: REST and SOAP
Record	Recording service
Audit	Auditing service
Radius	RADIUS server
Self-Service	User Self-Service service
ssoadm	ssoadm command
SAML2	SAML v2.0
Push	Push Notification service

Audit Log Failure Reasons

The following section presents the predefined audit event failure reasons:

Audit Log Event Authentication Failure Reasons

Failure	Description
LOGIN_FAILED	Incorrect/invalid credentials presented.
INVALID_PASSWORD	Invalid credentials entered.
NO_CONFIG	Authentication chain does not exist.
NO_USER_PROFILE	No user profile found for this user.
USER_INACTIVE	User is not active.
LOCKED_OUT	Maximum number of failure attempts exceeded. User is locked out.
ACCOUNT_EXPIRED	User account has expired.
LOGIN_TIMEOUT	Login timed out.
MODULE_DENIED	Authentication module is denied.
MAX_SESSION_REACHED	Limit for maximum number of allowed sessions has been reached.
INVALID_REALM	Realm does not exist.
REALM_INACTIVE	Realm is not active.
USER_NOTE_FOUND	Role-based authentication: user does not belong to this role.
AUTH_TYPE_DENIED	Authentication type is denied.
SESSION_CREATE_ERROR	Cannot create a session.
INVALID_LEVEL	Level-based authentication: Invalid authentication level.

JDBC Audit Log Tables

AM writes audit events to relational databases using the JDBC audit event handler. This section presents the columns for each audit table.

am_auditaccess

am_auditaccess

Column	Datatype	Description
id	VARCHAR(56) NOT NULL	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-491</code> .
timestamp_	VARCHAR(29) NULL	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.653Z</code>
transactionid	VARCHAR(255) NULL	Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code> . AM supports a feature where a trusted AM deployment with multiple instances, components, and ForgeRock products can propagate a transaction ID through each call across the stack. AM reads the <code>X-ForgeRock-TransactionId</code> HTTP header and appends an integer to the transaction ID. Note that this feature is disabled by default. When enabled, this feature should filter the <code>X-ForgeRock-TransactionId</code> HTTP header for connections from untrusted sources.
eventname	VARCHAR(255)	Specifies the name of the audit event. For example, <code>AM-ACCESS-ATTEMPT</code> and <code>AM-ACCESS-OUTCOME</code> . For a list of audit event names, see "Audit Log Event Names".
userid	VARCHAR(255) NULL	Specifies the universal identifier for the authenticated user. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
trackingids	MEDIUMTEXT	Specifies the tracking IDs of the event, used by all topics.
server_ip	VARCHAR(40)	Specifies the IP address of the AM server.
server_port	VARCHAR(5)	Specifies the port number used by the AM server. For example, <code>8080</code> .
client_host	VARCHAR(255)	Specifies the client hostname. This column is only populated if reverse DNS lookup is enabled.
client_ip	VARCHAR(40)	Specifies the client IP address.
client_port	VARCHAR(5)	Specifies the client port number.

Column	Datatype	Description
request_protocol	VARCHAR(255) NULL	Specifies the protocol associated with the request operation. Possible values: CREST and PLL .
request_operation	VARCHAR(255) NULL	Specifies the request operation. For CREST operations, possible values: READ , ACTION , QUERY . For PLL operations, possible values: LoginIndex , SubmitRequirements , GetSession , REQUEST_ADD_POLICY_LISTENER .
request_detail	TEXT NULL	Specifies the detailed information about the request operation. For example: <ul style="list-style-type: none"> • {"action": "idFromSession"} • {"action": "validateGoto"} • {"action": "validate"} • {"action": "logout"} • {"action": "schema"} • {"action": "template"}
http_request_secure	BOOLEAN NULL	Specifies the HTTP method requested by the client. For example, true or false . Note that false does not mean the client connection is insecure as there may be a reverse proxy terminating the HTTPS connection.
http_request_method	VARCHAR(7) NULL	Specifies the HTTP method requested by the client. For example, GET , POST , PUT .
http_request_path	VARCHAR(255) NULL	Specifies the path of the HTTP request. For example, https://openam.example.com:8443/openam/json/realms/root/authenticate .
http_request_queryparameters	MEDIUMTEXT NULL	Specifies the HTTP query parameter string. For example: <ul style="list-style-type: none"> • { "_action": ["idFromSession"] } • { "_queryFilter": ["true"] } • { "_action": ["validate"] } • { "_action": ["logout"] } • { "realm": ["/shop"] } • { "_action": ["validateGoto"] }
http_request_headers	MEDIUMTEXT NULL	Specifies the HTTP headers for the request. For example: <pre> { "accept": ["application/json, text/javascript, */*; q=0.01"], "Accept-API-Version": [</pre>

Column	Datatype	Description
		<pre> "protocol=1.0"], "accept-encoding": ["gzip, deflate"], "accept-language": ["en-US;q=1,en;q=0.9"], "cache-control": ["no-cache"], "connection": ["Keep-Alive"], "content-length": ["0"], "host": ["forgerock-am.openrock.org"], "pragma": ["no-cache"], "referer": ["https://forgerock-am.openrock.org/openam/XUI/"], "user-agent": ["Mozilla/5.0 (X11; Linux x86_64; rv:31.0) Gecko/20100101 Firefox/31.0"], "x-nosession": ["true"], "x-requested-with": ["XMLHttpRequest"], "x-username": ["anonymous"]] } </pre> <p>Note: line feeds and truncated values in the example are for readability purposes.</p>
<code>http_request_cookies</code>	MEDIUMTEXT NULL	<p>Specifies a JSON map of key-value pairs and appears as its own property to allow for blacklisting fields or values. For example:</p> <pre>"cookies": "amlbcookie=01; iPlanetDirectoryPro=\AQIC5wM2LY...AAJTSQACMfwT...*\"; iPlanetDirectoryPro=eyJ0eXAiOiJK...eyJzdWIiOiJkZ..."</pre> <p>Note: line feeds and truncated values in the example are for readability purposes.</p>
<code>http_response_headers</code>	MEDIUMTEXT NULL	<p>Captures the headers returned by AM to the client (that is, the inverse of <code>http_request_headers</code>). Note that AM does not currently populate this field.</p>

Column	Datatype	Description
response_status	VARCHAR(10) NULL	Specifies the response status of the request. For example, SUCCESS , FAILURE , ALLOWED , DENIED , or NULL .
response_statuscode	VARCHAR(255) NULL	Specifies the response status code, depending on the protocol. For CREST, HTTP failure codes are displayed but not HTTP success codes. For PLL endpoints, PLL error codes are displayed.
response_detail	TEXT NULL	Specifies the message associated with the response status code. For example, a response status code of 401 has a response detail of { "reason": "Unauthorized" }.
response_elapsedtime	VARCHAR(255) NULL	Specifies the time to execute the access event, usually in millisecond precision.
response_elapsedtimeunits	VARCHAR(255) NULL	Specifies the elapsed time units of the response. For example, MILLISECONDS .
component	VARCHAR(255) NULL	Specifies the AM service utilized. For example, Server Info , Users , Config , Session , Authentication , Policy , OAuth .
realm	VARCHAR(255) NULL	Specifies the realm where the operation occurred. For example, the Top Level Realm ("/") or the sub-realm name ("/shop").

am_auditauthentication

am_auditauthentication

Column	Datatype	Description
id	VARCHAR(56) NOT NULL	Specifies a universally unique identifier (UUID) for the message object, such as a568d4fe-d655-49a8-8290-bfc02095bec9-491 .
timestamp_	VARCHAR(29) NULL	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: yyyy-MM-ddTHH:mm:ss.msZ . For example: 2015-11-14T00:16:04.653Z
transactionid	VARCHAR(255) NULL	<p>Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for different audit event topics. For example, 9c9e8d5c-2941-4e61-9c3c-8a990088e801.</p> <p>AM supports a feature where a trusted AM deployment with multiple instances, components, and ForgeRock products can propagate a transaction ID through each call across the stack. AM reads the X-ForgeRock-TransactionId HTTP header and appends an integer to the transaction ID. Note that this feature is disabled by default. When enabled, this feature should filter the X-ForgeRock-TransactionId HTTP header for connections from untrusted sources.</p>

Column	Datatype	Description
eventname	VARCHAR(255) NULL	Specifies the name of the audit event. For example, AM-LOGIN-MODULE-COMPLETED and AM-LOGOUT . For a list of audit event names, see "Audit Log Event Names".
userid	VARCHAR(255) NULL	Specifies the universal identifier for authenticated users. For example, id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com .
trackingids	MEDIUMTEXT	Specifies the tracking IDs of the event, used by all topics.
result	VARCHAR(255) NULL	Depending on the event being logged, specifies the outcome of: <ul style="list-style-type: none"> A single authentication module within a chain The result for an authentication tree Possible values are SUCCESSFUL or FAILED .
principals	MEDIUMTEXT	Specifies the array of accounts used to authenticate, such as ["amadmin"] and ["scarter"].
context	N/A	MEDIUMTEXT. Not used.
entries	MEDIUMTEXT	Specifies the JSON representation of the details of an authentication module, chain, tree or node. AM creates an event as each module or node completes and a final event at the end of the chain or tree. For example: <pre> "entries":[{ "moduleId":"DataStore", "info":{ "moduleClass":"DataStore", "ipAddress":"127.0.0.1", "moduleName":"DataStore", "authLevel":"0" } }] </pre> <pre> "entries":[{ "info":{ "nodeOutcome":"true", "treeName":"Example", "displayName":"Data Store Decision", "nodeType":"DataStoreDecisionNode", "nodeId":"e5ec495a-2ae2-4eca-8afb-9781dea04170", "authLevel":"0" } }] </pre>
component	VARCHAR(255) NULL	Specifies the AM service utilized. For example, Server Info, Users, Config, Session, Authentication, Policy, OAuth .

Column	Datatype	Description
realm	VARCHAR(255) NULL	Specifies the realm where the operation occurred. For example, the Top Level Realm ("/") or the sub-realm name ("/shop").

am_auditactivity

am_auditactivity

Column	Datatype	Description
id	VARCHAR(56) NOT NULL	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-491</code> .
timestamp_	VARCHAR(29) NOT NULL	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.653Z</code>
transactionid	VARCHAR(255) NULL	Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code> . AM supports a feature where a trusted AM deployment with multiple instances, components, and ForgeRock products can propagate a transaction ID through each call across the stack. AM reads the <code>X-ForgeRock-TransactionId</code> HTTP header and appends an integer to the transaction ID. Note that this feature is disabled by default. When enabled, this feature should filter the <code>X-ForgeRock-TransactionId</code> HTTP header for connections from untrusted sources.
eventname	VARCHAR(255) NULL	Specifies the name of the audit event. For example, <code>AM-SESSION-CREATED</code> and <code>AM-SESSION-DESTROYED</code> . For a list of audit event names, see "Audit Log Event Names".
userid	VARCHAR(255) NULL	Specifies the universal identifier for authenticated users. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
trackingids	MEDIUMTEXT	Specifies the tracking IDs of the event, used by all topics.
runas	VARCHAR(255) NULL	Specifies the user to run the activity as. May be used in delegated administration. For example, <code>id=amadmin,ou=user,dc=example,dc=com</code> .
objectid	VARCHAR(255) NULL	Specifies the identifier of a system object that has been created, modified, or deleted. For example, <code>ou=SamuelTwo,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMAuthSAML2Service,ou=services,o=shop,ou=services,dc=example,dc=com</code> .
operation	VARCHAR(255) NULL	Specifies the state change operation invoked: <code>CREATE</code> , <code>MODIFY</code> , or <code>DELETE</code> .

Column	Datatype	Description
beforeObject	MEDIUMTEXT NULL	Specifies the JSON representation of the object prior to the activity. For example: <pre>{ "sunsmpriority": ["0"], "objectclass": ["top", "sunServiceComponent", "organizationalUnit"], "ou": ["SamuelTwo"], "sunserviceID": ["serverconfig"] }</pre>
afterObject	MEDIUMTEXT NULL	Specifies the JSON representation of the object after the activity. For example: <pre>{ "sunKeyValue": ["forgerock-am-auth-saml2-auth-level=0", "forgerock-am-auth-saml2-meta-alias=/sp", "forgerock-am-auth-saml2-entity-name=http://", "forgerock-am-auth-saml2-authn-context-decl-ref=", "forgerock-am-auth-saml2-force-auth=none", "forgerock-am-auth-saml2-is-passive=none", "forgerock-am-auth-saml2-login-chain=", "forgerock-am-auth-saml2-auth-comparison=none", "forgerock-am-auth-saml2-req-binding= urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect", "forgerock-am-auth-saml2-binding= urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Artifact", "forgerock-am-auth-saml2-authn-context-class-ref=", "forgerock-am-auth-saml2-slo-relay=http://", "forgerock-am-auth-saml2-allow-create=false", "forgerock-am-auth-saml2-name-id-format= urn:oasis:names:tc:SAML:2.0:nameid-format:persistent"] }</pre>
changedfields	VARCHAR(255) NULL	Specifies the columns that were changed. For example, ["sunKeyValue"].
rev	VARCHAR(255) NULL	Not used.
component	VARCHAR(255) NULL	Specifies the AM service utilized. For example, Server Info , Users , Config , Session , Authentication , Policy , OAuth .
realm	VARCHAR(255) NULL	Specifies the realm where the operation occurred. For example, the Top Level Realm ("/") or the sub-realm name ("/shop").

am_auditconfig

am_auditconfig

Column	Datatype	Description
<code>id</code>	<code>VARCHAR(56) NOT NULL</code>	Specifies a universally unique identifier (UUID) for the message object, such as <code>a568d4fe-d655-49a8-8290-bfc02095bec9-491</code> .
<code>timestamp_</code>	<code>VARCHAR(29) NULL</code>	Specifies the timestamp when AM logged the message, in UTC format to millisecond precision: <code>yyyy-MM-ddTHH:mm:ss.msZ</code> . For example: <code>2015-11-14T00:16:04.653Z</code>
<code>transactionid</code>	<code>VARCHAR(255) NULL</code>	<p>Specifies the UUID of the transaction, which identifies an external request when it comes into the system boundary. Any events generated while handling that request will be assigned that transaction ID, so that you may see the same transaction ID for different audit event topics. For example, <code>9c9e8d5c-2941-4e61-9c3c-8a990088e801</code>.</p> <p>AM supports a feature where a trusted AM deployment with multiple instances, components, and ForgeRock products can propagate a transaction ID through each call across the stack. AM reads the <code>X-ForgeRock-TransactionId</code> HTTP header and appends an integer to the transaction ID. Note that this feature is disabled by default. When enabled, this feature should filter the <code>X-ForgeRock-TransactionId</code> HTTP header for connections from untrusted sources.</p>
<code>eventname</code>	<code>VARCHAR(255) NULL</code>	Specifies the name of the audit event. For example, <code>AM-CONFIG-CHANGE</code> . For a list of audit event names, see "Audit Log Event Names".
<code>userid</code>	<code>VARCHAR(255) NULL</code>	Specifies the universal identifier for authenticated users. For example, <code>id=scarter,ou=user,o=shop,ou=services,dc=example,dc=com</code> .
<code>trackingids</code>	<code>MEDIUMTEXT</code>	Specifies the tracking IDs of the event, used by all topics.
<code>runas</code>	<code>VARCHAR(255) NULL</code>	Specifies the user to run the activity as. May be used in delegated administration. For example, <code>id=amadmin,ou=user,dc=example,dc=com</code> .
<code>objectid</code>	<code>VARCHAR(255) NULL</code>	Specifies the identifier of a system object that has been created, modified, or deleted. For example, <code>ou=SamuelTwo,ou=default,ou=OrganizationConfig,ou=1.0,ou=iPlanetAMAuthSAML2Service,ou=services,o=shop,ou=services,dc=example,dc=com</code> .
<code>operation</code>	<code>VARCHAR(255) NULL</code>	Specifies the state change operation invoked: <code>CREATE</code> , <code>MODIFY</code> , or <code>DELETE</code> .
<code>beforeObject</code>	<code>MEDIUMTEXT NULL</code>	Specifies the JSON representation of the object prior to the activity. For example:

Column	Datatype	Description
		<pre>{ "sunsmpriority": ["0"], "objectclass": ["top", "sunServiceComponent", "organizationalUnit"], "ou": ["SamuelTwo"], "sunserviceID": ["serverconfig"] }</pre>
afterObject	MEDIUMTEXT NULL	<p>Specifies the JSON representation of the object after the activity. For example:</p> <pre>{ "sunKeyValue": ["forgerock-am-auth-saml2-auth-level=0", "forgerock-am-auth-saml2-meta-alias=/sp", "forgerock-am-auth-saml2-entity-name=http://", "forgerock-am-auth-saml2-authn-context-decl-ref=", "forgerock-am-auth-saml2-force-auth=none", "forgerock-am-auth-saml2-is-passive=none", "forgerock-am-auth-saml2-login-chain=", "forgerock-am-auth-saml2-auth-comparison=none", "forgerock-am-auth-saml2-req-binding=urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Redirect", "forgerock-am-auth-saml2-binding=urn:oasis:names:tc:SAML:2.0:bindings:HTTP-Artifact", "forgerock-am-auth-saml2-authn-context-class-ref=", "forgerock-am-auth-saml2-slo-relay=http://", "forgerock-am-auth-saml2-allow-create=false", "forgerock-am-auth-saml2-name-id-format=urn:oasis:names:tc:SAML:2.0:nameid-format:persistent"] }</pre>
changedfields	VARCHAR(255) NULL	Specifies the columns that were changed. For example, ["sunKeyValue"].
rev	VARCHAR(255)	Not used.
component	VARCHAR(255) NULL	Specifies the AM service utilized. For example, Server Info, Users, Config, Session, Authentication, Policy, OAuth .
realm	VARCHAR(255) NULL	Specifies the realm where the operation occurred. For example, the Top Level Realm ("/") or the sub-realm name ("/shop").

Audit Logging

amster service name: AuditLogging

Global Attributes

The following settings appear on the **Global Attributes** tab:

Audit logging

Enable audit logging in AM.

Default value: `true`

amster attribute: `auditEnabled`

Field exclusion policies

A list of fields or values (JSON pointers) to exclude from the audit event.

To specify a field or value within a field to be filtered out of the event, start the pointer with the event topic, for example `access`, `activity`, `authentication`, or `config`, followed by the field name or the path to the value in the field.

For example, to filter out the `userId` field in an access event the pointer will be `/access/userId`.

To filter out the `content-type` value in the `http.request.headers` field the pointer will be `/access/http/request/headers/content-type`.

Only values that are made up of JSON strings can be manipulated in this way.

Default value:

```
/access/http/request/headers/cache-control  
/access/http/request/queryParameters/redirect_uri  
/activity/before/userCertificate  
/activity/before/webauthnDeviceProfiles  
/activity/before/kbaInfo  
/config/after  
/access/http/request/headers/proxy-authorization  
/access/http/response/headers/X-OpenIDM-Password  
/activity/before/userPKCS12  
/access/http/request/headers/connection  
/access/http/request/cookies/%AM_COOKIE_NAME%  
/access/http/request/headers/accept-encoding  
/activity/after/userPKCS12  
/access/http/request/queryParameters/tokenId  
/activity/after/pushDeviceProfiles  
/access/http/request/headers/accept-language  
/activity/after/kbaInfo  
/access/http/response/headers/Set-Cookie
```

```

/activity/before/userPassword
/access/http/request/queryParameters/access_token
/access/http/request/cookies/session-jwt
/access/http/request/queryParameters/requester
/access/http/response/headers/Authorization
/activity/after/oathDeviceProfiles
/access/http/request/headers/authorization
/activity/after/iplanet-am-user-password-reset-question-answer
/access/http/request/headers/x-password
/config/before
/access/http/request/queryParameters/IDToken1
/access/http/request/queryParameters/sessionUpgradeSSOTokenId
/activity/after/userCertificate
/access/http/request/queryParameters/code
/activity/before/oathDeviceProfiles
/access/http/request/queryParameters/Login.Token1
/activity/after/userPassword
/activity/before/iplanet-am-user-password-reset-question-answer
/activity/before/userSMIMECertificate
/access/http/request/headers/%AM_AUTH_COOKIE_NAME%
/activity/before/pushDeviceProfiles
/access/http/request/headers/X-OpenAM-Password
/access/http/request/queryParameters/id_token_hint
/access/http/request/queryParameters/%AM_COOKIE_NAME%
/access/http/request/headers/content-type
/access/http/request/headers/X-OpenIDM-Password
/access/http/request/headers/content-length
/activity/after/webauthnDeviceProfiles
/access/http/request/headers/%AM_COOKIE_NAME%
/activity/after/userSMIMECertificate

```

amster attribute: `fieldFilterPolicy`

Realm Defaults

The following settings appear on the **Realm Defaults** tab:

Audit logging

Enable audit logging in AM.

Default value: `true`

amster attribute: `auditEnabled`

Field exclusion policies

A list of fields or values (JSON pointers) to exclude from the audit event.

To specify a field or value within a field to be filtered out of the event, start the pointer with the event topic, for example `access`, `activity`, `authentication`, or `config`, followed by the field name or the path to the value in the field.

For example, to filter out the `userId` field in an access event the pointer will be `/access/userId`.

To filter out the `content-type` value in the `http.request.headers` field the pointer will be `/access/http/request/headers/content-type`.

Only values that are made up of JSON strings can be manipulated in this way.

Default value:

```
/access/http/request/headers/cache-control
/access/http/request/queryParameters/redirect_uri
/activity/before/userCertificate
/activity/before/webauthnDeviceProfiles
/activity/before/kbaInfo

```

amster attribute: `fieldFilterPolicy`

Secondary Configurations

This service has the following Secondary Configurations.

JMS

A configured secondary instance of the JMS type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.JmsAuditEventHandlerFactory`

amster attribute: `handlerFactory`

JMS Configuration

The JMS Configuration tab contains the following secondary configuration properties:

Delivery Mode

Specifies whether JMS messages used to transmit audit events use persistent or non-persistent delivery.

With persistent delivery, the JMS provider ensures that messages are not lost in transit in case of a provider failure by logging messages to storage when they are sent.

Specify the delivery mode as persistent if it is unacceptable for delivery of audit events to be lost in JMS transit. If the possible loss of audit events is acceptable, choose non-persistent delivery, which provides better performance.

Default value: `NON_PERSISTENT`

amster attribute: `deliveryMode`

Session Mode

Specifies the JMS session acknowledgement mode: `AUTO`, `CLIENT`, or `DUPS_OK`.

- Auto mode guarantees once-only delivery of JMS messages used to transmit audit events.
- Duplicates OK mode ensures that messages are delivered at least once.
- Client mode does not ensure delivery.

Use the default setting unless your JMS broker implementation requires otherwise. See your broker documentation for more information.

Default value: `AUTO`

amster attribute: `sessionMode`

JNDI Context Properties

Specifies JNDI properties that AM uses to connect to the JMS message broker to which AM will publish audit events.

AM acts as a JMS client, using a JMS connection factory to connect to your JMS message broker. In order for AM to connect to the broker, the JNDI context properties must conform to those needed by the broker. See the documentation for your JMS message broker for required values.

The default properties are example properties for connecting to Apache ActiveMQ.

Default value:

```
topic.audit=audit
java.naming.factory.initial=org.apache.activemq.jndi.ActiveMQInitialContextFactory
java.naming.provider.url=tcp://localhost:61616
```

amster attribute: `jndiContextProperties`

JMS Topic Name

JNDI lookup name for the JMS topic

Default value: `audit`

amster attribute: `jndiTopicName`

JMS Connection Factory Name

Specifies the JNDI lookup name for the connection factory exposed by your JMS message broker. AM performs a JNDI lookup on this name to locate your broker's connection factory.

See the documentation for your JMS message broker for the required value.

The default is the connection factory name for Apache ActiveMQ.

Default value: `ConnectionFactory`

amster attribute: `jndiConnectionFactoryName`

Batch Events

The Batch Events tab contains the following secondary configuration properties:

Batch enabled

Boolean for batch delivery of audit events.

Default value: `true`

amster attribute: `batchEnabled`

Capacity

Maximum event count in the batch queue; additional events are dropped.

Default value: `1000`

amster attribute: `batchCapacity`

Max Batched

Maximum number of events per batch.

Default value: `100`

amster attribute: `maxBatchedEvents`

Thread Count

Number of concurrent threads that pull events from the batch queue.

Default value: 3

amster attribute: `batchThreadCount`

Insert Timeout

Waiting period (seconds) for available capacity, when a new event enters the queue.

Default value: 60

amster attribute: `insertTimeoutSec`

Polling Timeout

Worker thread waiting period (seconds) for the next event, before going idle.

Default value: 10

amster attribute: `pollTimeoutSec`

Shutdown Timeout

Application waiting period (seconds) for worker thread termination.

Default value: 60

amster attribute: `shutdownTimeoutSec`

JSONStdout

A configured secondary instance of the JSONStdout type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.JsonStdoutAuditEventHandlerFactory`

amster attribute: `handlerFactory`

JSON Configuration

The JSON Configuration tab contains the following secondary configuration properties:

ElasticSearch JSON Format Compatible

JSON format should be transformed to be compatible with ElasticSearch format restrictions.

Default value: `false`

amster attribute: `elasticsearchCompatible`

Elasticsearch

A configured secondary instance of the Elasticsearch type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.ElasticsearchAuditEventHandlerFactory`

amster attribute: `handlerFactory`

Elasticsearch Configuration

The Elasticsearch Configuration tab contains the following secondary configuration properties:

Server Hostname

Host name or IP address of the Elasticsearch server.

amster attribute: `host`

Server Port

Specifies the port number used to access Elasticsearch's REST API.

amster attribute: `port`

SSL Enabled

Specifies whether SSL is configured on the Elasticsearch server.

If SSL is enabled, be sure to import the CA certificate used to sign Elasticsearch node certificates into the Java keystore on the host that runs AM before attempting to log audit events to Elasticsearch.

Default value: `false`

amster attribute: `sslEnabled`

Elasticsearch Index

Specifies the name of the Elasticsearch index to be used for AM audit logging.

amster attribute: `index`

Authentication

The Authentication tab contains the following secondary configuration properties:

Username

Specifies the username to access the Elasticsearch server.

Required if Elasticsearch Shield authentication is configured.

amster attribute: `username`

Password

Specifies the password to access the Elasticsearch server.

Required if Elasticsearch Shield authentication is configured.

amster attribute: `password`

Buffering

The Buffering tab contains the following secondary configuration properties:

Buffering Enabled

Default value: `true`

amster attribute: `bufferingEnabled`

Batch Size

Maximum number of events that can be buffered (default: 10000)

Default value: `500`

amster attribute: `batchSize`

Queue Capacity

Maximum number of audit logs in the batch queue. Additional audit events are dropped.

Default value: 10000

amster attribute: `maxEvents`

Write interval (in milliseconds)

Specifies the interval in milliseconds at which buffered events are written to Elasticsearch.

Default value: 250

amster attribute: `writeInterval`

Syslog

A configured secondary instance of the Syslog type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.SyslogAuditEventHandlerFactory`

amster attribute: `handlerFactory`

Syslog Configuration

The Syslog Configuration tab contains the following secondary configuration properties:

Server hostname

Host name or IP address of receiving syslog server.

amster attribute: `host`

Server port

Port number of receiving syslog server.

amster attribute: `port`

Transport Protocol

Default value: `TCP`

amster attribute: `transportProtocol`

Connection timeout

Timeout for connecting to syslog server, in seconds.

amster attribute: `connectTimeout`

Facility

Syslog facility value to apply to all events.

Default value: `USER`

amster attribute: `facility`

Buffering

The Buffering tab contains the following secondary configuration properties:

Buffering Enabled

Enables or disables audit event buffering.

Default value: `true`

amster attribute: `bufferingEnabled`

Buffer Size

Maximum number of events that can be buffered (default/minimum: 5000)

Default value: `5000`

amster attribute: `bufferingMaxSize`

CSV

A configured secondary instance of the CSV type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.CsvAuditEventHandlerFactory`

amster attribute: `handlerFactory`

CSV Configuration

The CSV Configuration tab contains the following secondary configuration properties:

Log Directory

Directory in which to store audit log CSV files.

Default value: `%BASE_DIR%/%SERVER_URI%/log/`

amster attribute: `location`

File Rotation

The File Rotation tab contains the following secondary configuration properties:

Rotation Enabled

Enables and disables audit file rotation.

Default value: `true`

amster attribute: `rotationEnabled`

Maximum File Size

Maximum size, in bytes, which an audit file can grow to before rotation is triggered. A negative or zero value indicates this policy is disabled.

Default value: `100000000`

amster attribute: `rotationMaxFileSize`

File Rotation Prefix

Prefix to prepend to audit files when rotating audit files.

amster attribute: `rotationFilePrefix`

File Rotation Suffix

Suffix to append to audit files when they are rotated. Suffix should be a timestamp.

Default value: `-yyyy.MM.dd-HH.mm.ss`

amster attribute: `rotationFileSuffix`

Rotation Interval

Interval to trigger audit file rotations, in seconds. A negative or zero value disables this feature.

Default value: `-1`

amster attribute: `rotationInterval`

Rotation Times

Durations after midnight to trigger file rotation, in seconds.

amster attribute: `rotationTimes`

File Retention

The File Retention tab contains the following secondary configuration properties:

Maximum Number of Historical Files

Maximum number of backup audit files allowed. A value of `-1` disables pruning of old history files.

Default value: `1`

amster attribute: `retentionMaxNumberOfHistoryFiles`

Maximum Disk Space

The maximum amount of disk space the audit files can occupy, in bytes. A negative or zero value indicates this policy is disabled.

Default value: `-1`

amster attribute: `retentionMaxDiskSpaceToUse`

Minimum Free Space Required

Minimum amount of disk space required, in bytes, on the system where audit files are stored. A negative or zero value indicates this policy is disabled.

Default value: `-1`

amster attribute: `retentionMinFreeSpaceRequired`

Buffering

The Buffering tab contains the following secondary configuration properties:

Buffering Enabled

Enables or disables buffering.

Default value: `true`

amster attribute: `bufferingEnabled`

Flush Each Event Immediately

Performance may be improved by writing all buffered events before flushing.

Default value: `false`

amster attribute: `bufferingAutoFlush`

Tamper Evident Configuration

The Tamper Evident Configuration tab contains the following secondary configuration properties:

Is Enabled

Enables the CSV tamper evident feature.

Default value: `false`

amster attribute: `securityEnabled`

Certificate Store Location

Path to Java keystore.

Default value: `%BASE_DIR%/SERVER_URI%/Logger.jks`

amster attribute: `securityFilename`

Certificate Store Password

Password for Java keystore.

amster attribute: `securityPassword`

Signature Interval

Signature generation interval, in seconds.

Default value: `900`

amster attribute: `securitySignatureInterval`

JDBC

A configured secondary instance of the JDBC type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.JdbcAuditEventHandlerFactory`

amster attribute: `handlerFactory`

Database Configuration

The Database Configuration tab contains the following secondary configuration properties:

Database Type

Select the database to use for logging audit events.

Identifies the database in use, for example MySQL, Oracle, or SQL.

Default value: `oracle`

amster attribute: `databaseType`

JDBC Database URL

URL of the JDBC database.

amster attribute: `jdbcUrl`

JDBC Driver

Fully qualified JDBC driver class name.

amster attribute: `driverClassName`

Database Username

Specifies the username to access the database server.

amster attribute: `username`

Database Password

Specifies the password to access the database server.

amster attribute: `password`

Connection Timeout (seconds)

Specifies the maximum wait time before failing the connection, in seconds.

Default value: `30`

amster attribute: `connectionTimeout`

Maximum Connection Idle Timeout (seconds)

Specifies the maximum idle time before the connection is closed, in seconds.

Default value: `600`

amster attribute: `idleTimeout`

Maximum Connection Time (seconds)

Specifies the maximum time a JDBC connection can be open, in seconds.

Default value: `1800`

amster attribute: `maxLifetime`

Minimum Idle Connections

Specifies the minimum number of idle connections in the connection pool.

Default value: 10

amster attribute: `minIdle`

Maximum Connections

Specifies the maximum number of connections in the connection pool.

Default value: 10

amster attribute: `maxPoolSize`

Buffering

The Buffering tab contains the following secondary configuration properties:

Buffering Enabled

Enables or disables audit event buffering.

Default value: `true`

amster attribute: `bufferingEnabled`

Buffer Size (number of events)

Size of the queue where events are buffered before they are written to the database.

This queue has to be big enough to store all incoming events that have not yet been written to the database.

If the queue reaches capacity, the process will block until a write occurs.

Default value: `100000`

amster attribute: `bufferingMaxSize`

Write Interval

Specifies the interval (seconds) at which buffered events are written to the database.

Default value: `5`

amster attribute: `bufferingWriteInterval`

Writer Threads

Specifies the number of threads used to write the buffered events.

Default value: `1`

amster attribute: `bufferingWriterThreads`

Max Batched Events

Specifies the maximum number of batched statements the database can support per connection.

Default value: `100`

amster attribute: `bufferingMaxBatchedEvents`

JSON

A configured secondary instance of the JSON type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.JsonAuditEventHandlerFactory`

amster attribute: `handlerFactory`

JSON Configuration

The JSON Configuration tab contains the following secondary configuration properties:

Log Directory

Directory in which to store audit log JSON files.

Default value: `%BASE_DIR%/%SERVER_URI%/log/`

amster attribute: `location`

ElasticSearch JSON Format Compatible

JSON format should be transformed to be compatible with ElasticSearch format restrictions.

Default value: `false`

amster attribute: `elasticsearchCompatible`

File Rotation Retention Check Interval

Interval to check time-based file rotation policies, in seconds.

Default value: `5`

amster attribute: `rotationRetentionCheckInterval`

File Rotation

The File Rotation tab contains the following secondary configuration properties:

Rotation Enabled

Enables and disables audit file rotation.

Default value: `true`

amster attribute: `rotationEnabled`

Maximum File Size

Maximum size, in bytes, which an audit file can grow to before rotation is triggered. A negative or zero value indicates this policy is disabled.

Default value: `100000000`

amster attribute: `rotationMaxFileSize`

File Rotation Prefix

Prefix to prepend to audit files when rotating audit files.

amster attribute: `rotationFilePrefix`

File Rotation Suffix

Suffix to append to audit files when they are rotated. Suffix should be a timestamp.

Default value: `-yyyy.MM.dd-HH.mm.ss`

amster attribute: `rotationFileSuffix`

Rotation Interval

Interval to trigger audit file rotations, in seconds. A negative or zero value disables this feature.

Default value: `-1`

amster attribute: `rotationInterval`

Rotation Times

Durations after midnight to trigger file rotation, in seconds.

amster attribute: `rotationTimes`

File Retention

The File Retention tab contains the following secondary configuration properties:

Maximum Number of Historical Files

Maximum number of backup audit files allowed. A value of `-1` disables pruning of old history files.

Default value: `1`

amster attribute: `retentionMaxNumberOfHistoryFiles`

Maximum Disk Space

The maximum amount of disk space the audit files can occupy, in bytes. A negative or zero value indicates this policy is disabled.

Default value: `-1`

amster attribute: `retentionMaxDiskSpaceToUse`

Minimum Free Space Required

Minimum amount of disk space required, in bytes, on the system where audit files are stored. A negative or zero value indicates this policy is disabled.

Default value: `-1`

amster attribute: `retentionMinFreeSpaceRequired`

Buffering

The Buffering tab contains the following secondary configuration properties:

Batch Size

Maximum number of events that can be buffered (default/minimum: 100000)

Default value: `100000`

amster attribute: `bufferingMaxSize`

Write interval

Interval at which buffered events are written to a file, in milliseconds.

Default value: `5`

amster attribute: `bufferingWriteInterval`

Splunk

A configured secondary instance of the Splunk type has the following tabs:

General Handler Configuration

The General Handler Configuration tab contains the following secondary configuration properties:

Enabled

Enables or disables an audit event handler.

Default value: `true`

amster attribute: `enabled`

Topics

List of topics handled by an audit event handler.

Default value:

```
access
activity
config
authentication
```

amster attribute: `topics`

Audit Event Handler Factory

The Audit Event Handler Factory tab contains the following secondary configuration properties:

Factory Class Name

The fully qualified class name of the factory responsible for creating the Audit Event Handler. The class must implement `org.forgerock.openam.audit.AuditEventHandlerFactory`.

Default value: `org.forgerock.openam.audit.events.handlers.SplunkAuditEventHandlerFactory`

amster attribute: `handlerFactory`

Splunk Configuration

The Splunk Configuration tab contains the following secondary configuration properties:

Authorization Token

Authorization token used to connect to Splunk HTTP Event Collector endpoint.

amster attribute: `authzToken`

Server Hostname

Host name or IP address of Splunk server.

amster attribute: `host`

Server Port

Port number of Splunk server.

amster attribute: `port`

SSL Enabled

Use HTTPS protocol for communication with Splunk.

Default value: `false`

amster attribute: `sslEnabled`

Buffering

The Buffering tab contains the following secondary configuration properties:

Batch Size

Maximum number of events that can be buffered (default: 10000).

Default value: `500`

amster attribute: `batchSize`

Queue Capacity

Maximum number of audit evens in the batch queue; additional events are dropped.

Default value: `10000`

amster attribute: `maxEvents`

Write interval (in milliseconds)

Interval at which buffered events are written to Splunk.

Default value: `250`

amster attribute: `writeInterval`

External Data Stores

amster service name: `DataStoreService`

Realm Defaults

The following settings appear on the **Realm Defaults** tab:

Policy Data Store

Select a data store configuration to be used for policy storage

The possible values for this property are:

- `fd270e31-1788-4193-8734-eb2d500c47f3`. Default Data Store

Default value: `fd270e31-1788-4193-8734-eb2d500c47f3`

amster attribute: `policyDataStoreId`

Application Data Store

Select a data store configuration to be used for application storage

The possible values for this property are:

- `fd270e31-1788-4193-8734-eb2d500c47f3`. Default Data Store

Default value: `fd270e31-1788-4193-8734-eb2d500c47f3`

amster attribute: `applicationDataStoreId`

Secondary Configurations

This service has the following Secondary Configurations.

config

Host Urls

An ordered list of connection strings for LDAP directories. Each connection string is composed as follows: HOST:PORT. serverHostname = Host Name

amster attribute: `serverUrls`

Bind DN

amster attribute: `bindDN`

Bind Password

amster attribute: `bindPassword`

Minimum Connection Pool Size

Default value: `1`

amster attribute: `minimumConnectionPool`

Maximum Connection Pool Size

Default value: `10`

amster attribute: `maximumConnectionPool`

Use SSL

amster attribute: `useSsl`

Start TLS

amster attribute: `useStartTLS`

Affinity Enabled

amster attribute: `affinityEnabled`

Logging

amster service name: `Logging`

General

The following settings appear on the **General** tab:

Log Status

Enable the AM logging system.

AM supports two Audit Logging Services: the legacy Logging Service, which is based on a Java SDK and is available in AM versions prior to AM 13.5, and a new common REST-based Audit Logging Service available from AM 13.5.

The legacy Logging Service will be deprecated in a future release.

The possible values for this property are:

- `ACTIVE`
- `INACTIVE`

Default value: `INACTIVE`

amster attribute: `status`

Logging Type

Specifies whether to log to a database, Syslog, or to the filing system.

If you choose database then be sure to set the connection attributes correctly, including the JDBC driver to use.

The possible values for this property are:

- `File`
- `DB`

- Syslog

Default value: `File`

amster attribute: `type`

Configurable Log Fields

Controls the fields that are logged by AM.

This property is the list of fields that are logged by default. Administrators can choose to limit the information logged by AM.

Default value:

```
IPAddr  
LoggedBy  
LoginID  
NameID  
ModuleName  
ContextID  
Domain  
LogLevel  
HostName  
MessageID
```

amster attribute: `fields`

Log Verification Frequency

The frequency (in seconds) that AM verifies security of the log files.

When secure logging is enabled, this is the period that AM will check the integrity of the log files.

Default value: `3600`

amster attribute: `verifyPeriod`

Log Signature Time

The frequency (in seconds) that AM will digitally sign the log records.

When secure logging is enabled, this is the period that AM will digitally signed the contents of the log files. The log signatures form the basis of the log file integrity checking.

Default value: `900`

amster attribute: `signaturePeriod`

Secure Logging

Enable or Disable secure logging.

Enabling this setting will cause AM to digitally sign and verify the contents of the log files to help prevent and detect log file tampering. A certificate must be configured for this functionality to be enabled.

The possible values for this property are:

- `ON`
- `OFF`

Default value: `OFF`

amster attribute: `security`

Secure Logging Signing Algorithm

Determines the algorithm used to digitally sign the log records.

The possible values for this property are:

- `MD2withRSA`. MD2 with RSA
- `MD5withRSA`. MD5 with RSA
- `SHA1withDSA`. SHA1 with DSA
- `SHA1withRSA`. SHA1 with RSA

Default value: `SHA1withRSA`

amster attribute: `signingAlgorithm`

Logging Certificate Store Location

The path to the Java keystore containing the logging system certificate.

The secure logging system will use the certificate alias of `Logger` to locate the certificate in the specified keystore.

Default value: `%BASE_DIR%/SERVER_URI%/Logger.jks`

amster attribute: `certificateStore`

Number of Files per Archive

Controls the number of logs files that will be archived by the secure logging system.

Default value: `5`

amster attribute: `filesPerKeystore`

Buffer Size

The number of log records held in memory before the log records will be flushed to the logfile or the database.

Default value: 25

amster attribute: `bufferSize`

Buffer Time

The maximum time (in seconds) AM will hold log records in memory before flushing to the underlying repository.

Default value: 60

amster attribute: `bufferTime`

Time Buffering

Enable or Disable log buffering

When enabled AM holds all log records in a memory buffer that it periodically flush to the repository. The period is set in the *Buffer Time* property.

The possible values for this property are:

- ON
- OFF

Default value: ON

amster attribute: `buffering`

Logging Level

Control the level of JDK logging within AM.

The possible values for this property are:

- OFF
- SEVERE
- WARNING
- INFO
- CONFIG

- FINE
- FINER
- FINEST

Default value: INFO

amster attribute: `jdkLoggingLevel`

File

The following settings appear on the **File** tab:

Log Rotation

Enable log rotation to cause new log files to be created when configured thresholds are reached, such as *Maximum Log Size* or *Logfile Rotation Interval*.

Default value: `true`

amster attribute: `rotationEnabled`

Maximum Log Size

Maximum size of a log file, in bytes.

Default value: `100000000`

amster attribute: `maxFileSize`

Number of History Files

Sets the number of history files for each log that AM keeps, including time-based histories.

The previously live file is moved and is included in the history count, and a new log is created to serve as the live log file. Any log file in the history count that goes over the number specified here will be deleted.

For time-based logs, a new set of logs will be created when AM is started because of the time-based file names that are used.

Default value: `1`

amster attribute: `numberHistoryFiles`

Logfile Rotation Prefix

The name of the log files will be prefixed with the supplied value.

This field defines the log file prefix. The prefix will be added to the name of all logfiles.

Note: Only used when time-based log rotation is enabled.

amster attribute: `prefix`

Logfile Rotation Suffix

The name of the log files will be suffixed with the supplied value.

This field defines the log file suffix. If no suffix is provided, then the following default suffix format will be used: `-MM.dd.yy-kk.mm`. The suffix allows use of Date and Time patterns defined in `SimpleDateFormat`

Note: This field is only used if the time based rotation is enabled.

Default value: `-MM.dd.yy-kk.mm`

amster attribute: `suffix`

Logfile Rotation Interval

The rotation interval (in minutes).

The rotation interval determines the frequency of when the log files will be rotated. If the value is `-1`, then time based rotation is disabled and log file size based rotation is enabled.

Default value: `-1`

amster attribute: `rotationInterval`

Log File Location

The path to the location of the log files

This property controls the location of the log files; the value of this property varies on whether File or DB logging is in use:

- File: The full pathname to the directory containing the log files.
- DB: The JDBC URL to the database used to store the log file database.

Default value: `%BASE_DIR%/SERVER_URI%/log/`

amster attribute: `location`

Database

The following settings appear on the **Database** tab:

Database User Name

When logging to a database, set this to the user name used to connect to the database. If this attribute is incorrectly set, AM performance suffers.

Default value: `dbuser`

amster attribute: `user`

Database User Password

When logging to a database, set this to the password used to connect to the database. If this attribute is incorrectly set, AM performance suffers.

amster attribute: `password`

Database Driver Name

When logging to a database, set this to the class name of the JDBC driver used to connect to the database.

The default is for Oracle. AM also works with the MySQL database driver.

Default value: `oracle.jdbc.driver.OracleDriver`

amster attribute: `driver`

Maximum Number of Records

The maximum number of records read from the logs via the Logging API

Default value: `500`

amster attribute: `maxRecords`

DB Failure Memory Buffer Size

Max number of log records held in memory if DB logging fails.

This is the maximum number of log records that will be held in memory if the database is unavailable. When the buffer is full, new log records cause the oldest record in the buffer to be cleared. AM monitoring records the number of log entries cleared when the database was unavailable.

If the value of this property is less than that of the *Buffer Size* then the buffer size value will take precedence.

Default value: `2`

amster attribute: `databaseFailureMemoryBufferSize`

Syslog

The following settings appear on the **Syslog** tab:

Syslog server host

The URL or IP address of the syslog server, for example `http://mysyslog.example.com`, or `localhost`.

Default value: `localhost`

amster attribute: `host`

Syslog server port

The port number the syslog server is configured to listen to.

Default value: `514`

amster attribute: `port`

Syslog transport protocol

The protocol to use to connect to the syslog server.

The possible values for this property are:

- `UDP`
- `TCP`

Default value: `UDP`

amster attribute: `protocol`

Syslog facility

Syslog uses the facility level to determine the type of program that is logging the message.

The possible values for this property are:

- `kern`
- `user`
- `mail`
- `daemon`
- `auth`
- `syslog`

- `lpr`
- `news`
- `uucp`
- `cron`
- `authpriv`
- `ftp`
- `local0`
- `local1`
- `local2`
- `local3`
- `local4`
- `local5`
- `local6`
- `local7`

Default value: `local5`

amster attribute: `facility`

Syslog connection timeout

The amount of time to wait when attempting to connect to the syslog server before reporting a failure, in seconds.

Default value: `30`

amster attribute: `timeout`

Monitoring Reference

This section contains reference information for the monitoring service, metric types, and monitoring metrics.

Monitoring

amster service name: `Monitoring`

Configuration

The following settings appear on the **Configuration** tab:

Monitoring Status

Enable / Disable the monitoring system

Default value: `false`

amster attribute: `enabled`

Monitoring HTTP Port

Port number for the HTTP monitoring interface

Default value: `8082`

amster attribute: `httpPort`

Monitoring HTTP interface status

Enable / Disable the HTTP access to the monitoring system

Default value: `false`

amster attribute: `httpEnabled`

Monitoring HTTP interface authentication file path

Path to the monitoring system authentication file

The `openam_mon_auth` file contains the username and password of the account used to protect the monitoring interfaces. The default username is `demo` with a password of `changeit`. Use the `ampassword` command to encrypt a new password.

Default value: `%BASE_DIR%/SERVER_URI/openam_mon_auth`

amster attribute: `authfilePath`

Monitoring RMI Port

Port number for the JMX monitoring interface

Default value: `9999`

amster attribute: `rmiPort`

Monitoring RMI interface status

Enable / Disable the JMX access to the monitoring system

Default value: `false`

amster attribute: `rmiEnabled`

Monitoring SNMP Port

Port number for the SNMP monitoring interface

Default value: `8085`

amster attribute: `snmpPort`

Monitoring SNMP interface status

Enable / Disable the SNMP access to the monitoring system

Default value: `false`

amster attribute: `snmpEnabled`

Policy evaluation monitoring history size

Size of the window of most recent policy evaluations to record to expose via monitoring system.
Valid range is 100 - 1000000.

Default value: `10000`

amster attribute: `policyHistoryWindowSize`

Session monitoring history size

Size of the window of most recent session operations to record to expose via monitoring system.
Valid range is 100 - 1000000.

Default value: `10000`

amster attribute: `sessionHistoryWindowSize`

Secondary Configurations

This service has the following Secondary Configurations.

crest

Enabled

Default value: `false`

amster attribute: `enabled`

graphite

Hostname

The hostname of the Graphite server to which metrics should be published.

amster attribute: `host`

Port

The port of the Graphite server to which metrics should be published.

Default value: `2004`

amster attribute: `port`

Frequency

The frequency (in seconds) at which metrics should be published.

Default value: `30`

amster attribute: `frequency`

prometheus

Enabled

Default value: `false`

amster attribute: `enabled`

Authentication Type

Default value: `BASIC`

amster attribute: `authenticationType`

Username

Default value: `prometheus`

amster attribute: `username`

Password

amster attribute: `password`

Monitoring Metric Types

This section describes the monitoring metric types that are available in AM. The available types are:

- Summary
- Timer
- Gauge
- DistinctCounter

Summary

Metric that samples observations, providing a count of observations, sum total of observed amounts, average rate of events, and moving average rates across sliding time windows.

- Fields

When using the CREST, JMX, or Graphite interfaces, the **Summary** metric type has the following fields:

Field	Description
<code>_id</code>	The metric ID.
<code>_type</code>	The metric type.
<code>count</code>	The number of events recorded for this metric.
<code>total</code>	The sum of the values of events recorded for this metric.
	<div style="background-color: #e1f5fe; padding: 10px;"> <p>Note</p> <p>As the increment is always 1, the total and the count will always be equal.</p> </div>
<code>m1_rate</code>	The one-minute average rate.
<code>m5_rate</code>	The five-minute average rate.
<code>m15_rate</code>	The fifteen-minute average rate.
<code>mean_rate</code>	The average rate.
<code>units</code>	A description of the units the metric is presented in.

The following is an example of the `authentication.success` metric from the CREST endpoint:

```
{
  "_id" : "authentication.success",
  "_type" : "summary",
  "count" : 2,
  "total" : 2.0,
  "m1_rate" : 3.2668341885586836E-14,
  "m5_rate" : 7.794695663154025E-5,
  "m15_rate" : 0.01377545747021923,
  "mean_rate" : 8.238608027596704E-4,
  "units" : "events/second"
}
```

- Prometheus Fields

The Prometheus endpoint does not provide rate-based statistics, as rates can be calculated from the time-series data.

When using the Prometheus interface, the **Summary** metric type has the following fields:

Field	Description
# TYPE	The metric ID, and type. Formatted as a comment.
_count	The number of events recorded.
_total	The sum of the amounts of events recorded

The following is an example of the `am_authentication{outcome="success"}` metric from the Prometheus endpoint:

```
# TYPE am_authentication summary
am_authentication_count{outcome="success"} 2.0
am_authentication_total{outcome="success"} 2.0
```

Timer

Metric that combines both rate and duration information.

- Fields

When using the CREST, JMX, or Graphite interfaces, the **Timer** metric type has the following fields:

Field	Description
_id	The metric ID.
_type	The metric type.
count	The number of events recorded for this metric.
total	The sum of the durations recorded for this metric.
min	The minimum duration recorded for this metric.
max	The maximum duration recorded for this metric.
mean	The mean average duration recorded for this metric.
stddev	The standard deviation of durations recorded for this metric.
duration_units	The units used for measuring the durations in the metric.
p50	50% of the durations recorded are at or below this value.
p75	75% of the durations recorded are at or below this value.
p95	95% of the durations recorded are at or below this value.
p98	98% of the durations recorded are at or below this value.
p99	99% of the durations recorded are at or below this value.

Field	Description
p999	99.9% of the durations recorded are at or below this value.
m1_rate	The one-minute average rate.
m5_rate	The five-minute average rate.
m15_rate	The fifteen-minute average rate.
mean_rate	The average rate.
rate_units	The units used for measuring the rate of the metric.

Note

Duration-based values, such as `min`, `max`, and `p50`, are weighted towards newer data. By representing approximately the last five minutes of data, the timers make it easier to see recent changes in behavior, rather than a uniform average of recordings since the server was started.

The following is an example of the `cts.connection.success` metric from the CREST endpoint:

```
{
  "_id" : "cts.connection.success",
  "_type" : "timer",
  "count" : 486,
  "total" : 80.0,
  "min" : 0.0,
  "max" : 1.0,
  "mean" : 0.1905615495053855,
  "stddev" : 0.39274399467782056,
  "duration_units" : "milliseconds",
  "p50" : 0.0,
  "p75" : 0.0,
  "p95" : 1.0,
  "p98" : 1.0,
  "p99" : 1.0,
  "p999" : 1.0,
  "m1_rate" : 0.1819109974890356,
  "m5_rate" : 0.05433445522996721,
  "m15_rate" : 0.03155662103953588,
  "mean_rate" : 0.020858521722211427,
  "rate_units" : "calls/second"
}
```

- Prometheus Fields

The Prometheus endpoint does not provide rate-based statistics, as rates can be calculated from the time-series data.

When using the Prometheus interface, the `Timer` metric type has the following fields:

Field	Description
# TYPE	The metric ID, and type. Note that the <code>Timer</code> metric type is reported as a <code>Summary</code> type. Formatted as a comment.

Field	Description
<code>_count</code>	The number of events recorded.
<code>_total</code>	The sum of the durations recorded.
<code>{quantile="0.5"}</code>	50% of the durations are at or below this value.
<code>{quantile="0.75"}</code>	75% of the durations are at or below this value.
<code>{quantile="0.95"}</code>	95% of the durations are at or below this value.
<code>{quantile="0.98"}</code>	98% of the durations are at or below this value.
<code>{quantile="0.99"}</code>	99% of the durations are at or below this value.
<code>{quantile="0.999"}</code>	99.9% of the durations are at or below this value.

Note

Duration-based quantile values are weighted towards newer data. By representing approximately the last five minutes of data, the timers make it easier to see recent changes in behavior, rather than a uniform average of recordings since the server was started.

The following is an example of the `am_authentication{outcome="success"}` metric from the Prometheus endpoint:

```
# TYPE am_cts_connection_seconds summary
am_cts_connection_seconds{outcome="success",quantile="0.5",} 0.0
am_cts_connection_seconds{outcome="success",quantile="0.75",} 0.0
am_cts_connection_seconds{outcome="success",quantile="0.95",} 0.001
am_cts_connection_seconds{outcome="success",quantile="0.98",} 0.001
am_cts_connection_seconds{outcome="success",quantile="0.99",} 0.001
am_cts_connection_seconds{outcome="success",quantile="0.999",} 0.001
am_cts_connection_count{outcome="success",} 492.0
am_cts_connection_seconds_total{outcome="success",} 0.081
```

Gauge

Metric for a numerical value that can increase or decrease. The value for a gauge is calculated when requested, and represents the state of the metric at that specific time.

- Fields

When using the CREST, JMX, or Graphite interfaces, the `Timer` metric type has the following fields:

Field	Description
<code>_id</code>	The metric ID.
<code>_type</code>	The metric type.
<code>value</code>	The current value of the metric.

The following is an example of the `jvm.used-memory` metric from the CREST endpoint:

```
{
  "_id" : "jvm.used-memory",
  "_type" : "gauge",
  "value" : 2.13385216E9
}
```

- Prometheus Fields

When using the Prometheus interface, the `Timer` metric type has the following fields:

Field	Description
<code># TYPE</code>	The metric ID, and type. Formatted as a comment.
<code>{Metric ID}</code>	The current value. Large values may be represented in scientific E-notation.

The following is an example of the `am_jvm_used_memory_bytes` metric from the Prometheus endpoint:

```
# TYPE am_jvm_used_memory_bytes gauge
am_jvm_used_memory_bytes 2.13385216E9
```

DistinctCounter

Metric providing an estimate of the number of *unique* values recorded.

For example, this could be used to estimate the number of unique users who have authenticated, or unique client IP addresses.

Note

The `DistinctCounter` metric is calculated per instance of AM, and cannot be aggregated across multiple instances to get a site-wide view.

- Fields

When using the CREST, JMX, or Graphite interfaces, the `DistinctCounter` metric type has the following fields:

Field	Description
<code>_id</code>	The metric ID.
<code>_type</code>	The metric type. Note that the <code>distinctCounter</code> type is reported as a <code>gauge</code> type. The output formats are identical.
<code>value</code>	The calculated estimate of the number of unique values recorded in the metric.

The following is an example of the `authentication.unique-uuid.success` metric from the CREST endpoint:

```
{
  "_id" : "authentication.unique-uuid.success",
  "_type" : "gauge",
  "value" : 3.0
}
```

- Prometheus Fields

When using the Prometheus interface, the `distinctCounter` metric type has the following fields:

Field	Description
<code># TYPE</code>	The metric ID, and type. Note that the <code>distinctCounter</code> type is reported as a <code>gauge</code> type. The output formats are identical. Formatted as a comment.
<code>{Metric ID}</code>	The calculated estimate of the number of unique values recorded in the metric.

The following is an example of the `am_authentication_unique_uuid{outcome="success"}` metric from the Prometheus endpoint:

```
# TYPE am_authentication_unique_uuid gauge
am_authentication_unique_uuid{outcome="success"} 3.0
```

Monitoring Metrics

AM exposes the monitoring metrics described in this section.

Authentication Metrics

AM exposes the following authentication-related monitoring metrics:

`authentication.module.<auth-module-name>.<outcome>`

Rate of successful/unsuccessful authentication module outcomes. (Summary)

Prometheus syntax:

```
am_authentication_module{module=<auth-module-name>,outcome=<outcome>}
```

Labels:

`<auth-module-name>`

Classname of the authentication module, for example:

`Application`

`DataStore`

<outcome>

success

failure

timeout

authentication.unique-uuid.success

Count of unique identities which have successfully logged in. (DistinctCounter)

Prometheus syntax:

```
am_authentication_unique_uuid{outcome=success}
```

authentication.<outcome>

Rate of successful/unsuccessful/timed-out authentication flows. (Summary)

Prometheus syntax:

```
am_authentication{outcome=<outcome>}
```

Labels:

<outcome>

success

failure

timeout

Authorization Metrics

AM exposes the following authorization-related monitoring metrics:

authorization.policy-set.<policy-set-name>.evaluate.action.<policy-action-name>.<outcome>

Rate of policy evaluation allowed/denied actions being returned under a given policy set. (Summary)

Prometheus syntax:

```
am_authorization_policy_set_evaluate_action{policy_set=<policy-set-name>, action-type=<policy-action-name>, outcome=<outcome>}
```

Labels:

`<policy-set-name>`

Name of the policy set, for example:

`iPlanetAMWebAgentService`

`oauth2Scopes`

`<policy-action-name>`

Name of the action as specified in the policy, for example:

`GET`

`POST`

`GRANT`

`<outcome>`

`allow`

`deny`

`authorization.policy-set.<policy-set-name>.evaluate.advice.<policy-advice-type-name>`

Rate of policy evaluation advice types being returned under a given policy set. (Summary)

Prometheus syntax:

```
am_authorization_policy_set_evaluate_advice{policy_set=<policy-set-name>,advice-type=<policy-advice-type-name>}
```

Labels:

`<policy-set-name>`

Name of the policy set, for example:

`iPlanetAMWebAgentService`

`oauth2Scopes`

`<policy-advice-type-name>`

Name of the policy condition advice, for example:

`AuthSchemeConditionAdvice`

AuthenticateToServiceConditionAdvice

AuthLevelConditionAdvice

AuthenticateToTreeConditionAdvice

AuthenticateToRealmConditionAdvice

TransactionConditionAdvice

authorization.policy-set.evaluate.subject-cache.size

Number of cached subject membership relationships. (Gauge)

Prometheus syntax:

```
am_authorization_policy_set_evaluate_subject_cache_size
```

authorization.policy-set.<policy-set-name>.evaluate.<outcome>

Rate of successful/unsuccessful policy evaluation calls under a given policy set and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_authorization_policy_set_evaluate{policy_set=<policy-set-name>,outcome=<outcome>}
```

Labels:

<policy-set-name>

Name of the policy set, for example:

iPlanetAMWebAgentService

oauth2Scopes

<outcome>

success

failure

timeout

authorization.policy-set.<policy-set-name>.policy.<operation>

Number of policies created/updated/deleted under a given policy set since this AM instance was started. (Summary)

Prometheus syntax:

```
am_authorization_policy_set_policy{policy_set=<policy-set-name>,operation=<operation>}
```

Labels:

<policy-set-name>

Name of the policy set, for example:

iPlanetAMWebAgentService

oauth2Scopes

<operation>

create

update

delete

Blacklisting Metrics

AM exposes the following blacklisting-related monitoring metrics:

<blacklist-type>.blacklist.bloomfilter.check.<outcome>

Rate of bloom filter blacklist checks. (Summary)

Prometheus syntax:

```
am_blacklist_bloomfilter_check{blacklist_type=<blacklist-type>,outcome=<outcome>}
```

Labels:

<blacklist-type>

session.client-based (Prometheus: session_client_based)

oauth2

<outcome>

negative. The bloom filter reports that the checked token is not blacklisted.

false-positive. The bloom filter reports that the checked token may be blacklisted, but the token was not blacklisted.

positive. The bloom filter reports that the checked token may be blacklisted, and this was found to be true.

<blacklist-type>.blacklist.cache.hit

Rate of cache hits of the blacklist cache layer. (Summary)

Prometheus syntax:

```
am_blacklist_cache{blacklist_type=<blacklist-type>,outcome=hit}
```

Labels:

<blacklist-type>

`session.client-based` (Prometheus: `session_client_based`)

`oauth2`

<blacklist-type>.blacklist.cache.miss

Rate of cache misses of the blacklist cache layer. (Summary)

Prometheus syntax:

```
am_blacklist_cache{blacklist_type=<blacklist-type>,outcome=miss}
```

Labels:

<blacklist-type>

`session.client-based` (Prometheus: `session_client_based`)

`oauth2`

<blacklist-type>.blacklist.check.<outcome>

Rate of blacklist checks. (Summary)

Prometheus syntax:

```
am_blacklist_check{blacklist_type=<blacklist-type>,outcome=<outcome>}
```

Labels:

<blacklist-type>

`session.client-based` (Prometheus: `session_client_based`)

`oauth2``<outcome>``true`. The token is blacklisted.`false`. The token is not blacklisted.`<blacklist-type>.blacklist.cts.search.result`

Rate of blacklist entries returned by searches. (Summary)

Prometheus syntax:

```
am_blacklist_cts_search_result{blacklist_type=<blacklist-type>}
```

Labels:

`<blacklist-type>``session.client-based` (Prometheus: `session_client_based`)`oauth2``<blacklist-type>.blacklist.cts.search.<outcome>`

Tracks time to search CTS for blacklist entries. (Timer)

Prometheus syntax:

```
am_blacklist_cts_search{blacklist_type=<blacklist-type>,outcome=<outcome>}
```

Labels:

`<blacklist-type>``session.client-based` (Prometheus: `session_client_based`)`oauth2``<outcome>``success``failure`

CTS Metrics

AM exposes the following CTS-related monitoring metrics:

cts.connection.<outcome>

Rate of successful/unsuccessful CTS connections to DS and time taken to obtain the connection. (Timer)

Prometheus syntax:

```
am_cts_connection{outcome=<outcome>}
```

Labels:

<outcome>

success

failure

cts.reaper.cache.size

Number of entries in the token reaper cache. (Gauge)

Prometheus syntax:

```
am_cts_reaper_cache_size
```

cts.reaper.cache.<token-type>.deletion.<outcome>

Rate of successful/unsuccessful token deletions from cache by token type. (Summary)

Prometheus syntax:

```
am_cts_reaper_deletion{reaper_type=cache,token_type=<token-type>,outcome=<outcome>}
```

Labels:

<token-type>

session

saml2

JVM Metrics

AM exposes the JVM-related monitoring metrics covered in this section.

To get the metric name used by Prometheus, prepend `am_` to the names below, and replace period (.) and hyphen (-) characters with underscore (_) characters.

For example, the `jvm.available-cpus` metric is named `am_jvm_available_cpus` in Prometheus.

Note

These metrics may depend on the JVM version and configuration. In particular, garbage-collector-related metrics depend on the garbage collector that the server uses. The garbage-collector metric names are *unstable*, and can change even in a minor JVM release.

JVM Metrics by Name

Name	Description
<code>jvm.available-cpus</code>	Number of processors available to the Java virtual machine. (Gauge)
<code>jvm.class-loading.loaded</code>	Number of classes loaded since the Java virtual machine started. (Gauge)
<code>jvm.class-loading.unloaded</code>	Number of classes unloaded since the Java virtual machine started. (Gauge)
<code>jvm.garbage-collector.PS-MarkSweep.count</code>	Number of collections performed by the "parallel scavenge mark sweep" garbage collection algorithm. (Gauge)
<code>jvm.garbage-collector.PS-MarkSweep.time</code>	Approximate accumulated time taken by the "parallel scavenge mark sweep" garbage collection algorithm. (Gauge)
<code>jvm.garbage-collector.PS-Scavenge.count</code>	Number of collections performed by the "parallel scavenge" garbage collection algorithm. (Gauge)
<code>jvm.garbage-collector.PS-Scavenge.time</code>	Approximate accumulated time taken by the "parallel scavenge" garbage collection algorithm. (Gauge)
<code>jvm.memory-usage.heap.init</code>	Amount of heap memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.heap.max</code>	Maximum amount of heap memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.heap.committed</code>	Amount of heap memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.heap.used</code>	Amount of heap memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.total.init</code>	Amount of memory that the Java virtual machine initially requested from the operating system. (Gauge)

Name	Description
<code>jvm.memory-usage.total.max</code>	Maximum amount of memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.non-heap.init</code>	Amount of non-heap memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.non-heap.max</code>	Maximum amount of non-heap memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.non-heap.committed</code>	Amount of non-heap memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.non-heap.used</code>	Amount of non-heap memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.pools.Code-Cache.init</code>	Amount of "code cache" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.Code-Cache.max</code>	Maximum amount of "code cache" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.Code-Cache.committed</code>	Amount of "code cache" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.Code-Cache.used</code>	Amount of "code cache" memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.pools.Compressed-Class-Space.init</code>	Amount of "compressed class space" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.Compressed-Class-Space.init</code>	Maximum amount of "compressed class space" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.Compressed-Class-Space.committed</code>	Amount of "compressed class space" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.Compressed-Class-Space.used</code>	Amount of "compressed class space" memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.pools.Metaspace.init</code>	Amount of "metaspace" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.Metaspace.max</code>	Maximum amount of "metaspace" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.Metaspace.committed</code>	Amount of "metaspace" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.Metaspace.used</code>	Amount of "metaspace" memory used by the Java virtual machine. (Gauge)

Name	Description
<code>jvm.memory-usage.pools.PS-Eden-Space.init</code>	Amount of "parallel scavenge eden space" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.PS-Eden-Space.max</code>	Maximum amount of "parallel scavenge eden space" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Eden-Space.committed</code>	Amount of "parallel scavenge eden space" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Eden-Space.used-after-gc</code>	Amount of "parallel scavenge eden space" memory after the last time garbage collection recycled unused objects in this memory pool. (Gauge)
<code>jvm.memory-usage.pools.PS-Eden-Space.used</code>	Amount of "parallel scavenge eden space" memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.pools.PS-Old-Gen.init</code>	Amount of "parallel scavenge old generation" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.PS-Old-Gen.max</code>	Maximum amount of "parallel scavenge old generation" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Old-Gen.committed</code>	Amount of "parallel scavenge old generation" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Old-Gen.used-after-gc</code>	Amount of "parallel scavenge old generation" memory after the last time garbage collection recycled unused objects in this memory pool. (Gauge)
<code>jvm.memory-usage.pools.PS-Old-Gen.used</code>	Amount of "parallel scavenge old generation" memory used by the Java virtual machine. (Gauge)
<code>jvm.memory-usage.pools.PS-Survivor-Space.init</code>	Amount of "parallel scavenge survivor space" memory that the Java virtual machine initially requested from the operating system. (Gauge)
<code>jvm.memory-usage.pools.PS-Survivor-Space.max</code>	Maximum amount of "parallel scavenge survivor space" memory that the Java virtual machine will attempt to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Survivor-Space.committed</code>	Amount of "parallel scavenge survivor space" memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.pools.PS-Survivor-Space.used-after-gc</code>	Amount of "parallel scavenge survivor space" memory after the last time garbage collection recycled unused objects in this memory pool. (Gauge)
<code>jvm.memory-usage.pools.PS-Survivor-Space.used</code>	Amount of "parallel scavenge survivor space" memory used by the Java virtual machine. (Gauge)

Name	Description
<code>jvm.memory-usage.total.committed</code>	Amount of memory that is committed for the Java virtual machine to use. (Gauge)
<code>jvm.memory-usage.total.used</code>	Amount of memory used by the Java virtual machine. (Gauge)
<code>jvm.thread-state.blocked.count</code>	Number of threads in the BLOCKED state. (Gauge)
<code>jvm.thread-state.count</code>	Number of live threads including both daemon and non-daemon threads. (Gauge)
<code>jvm.thread-state.daemon.count</code>	Number of live daemon threads. (Gauge)
<code>jvm.thread-state.new.count</code>	Number of threads in the NEW state. (Gauge)
<code>jvm.thread-state.runnable.count</code>	Number of threads in the RUNNABLE state. (Gauge)
<code>jvm.thread-state.terminated.count</code>	Number of threads in the TERMINATED state. (Gauge)
<code>jvm.thread-state.timed_waiting.count</code>	Number of threads in the TIMED_WAITING state. (Gauge)
<code>jvm.thread-state.waiting.count</code>	Number of threads in the WAITING state. (Gauge)

OAuth 2.0 Metrics

AM exposes the following CTS-related monitoring metrics:

`oauth2.grant.<grant-type>`

Rate of OAuth 2.0 grant completion by grant type. (Summary)

Prometheus syntax:

```
am_oauth2_grant{grant_type=<grant-type>}
```

Labels:

`<grant-type>`

`authorization-code` (Prometheus: `authorization_code`)

`client-credentials` (Prometheus: `client_credentials`)

`device-code` (Prometheus: `device_code`)

`implicit`

`refresh`

`resource-owner-password` (Prometheus: `resource_owner_password`)

oauth2.grant.revoke

Rate of OAuth 2.0 grant revocation. (Summary)

Prometheus syntax:

```
am_oauth2_grant_revoke
```

oauth2.token.<token-type>.issue

Rate of OAuth 2.0 token issuance by token type. (Summary)

Prometheus syntax:

```
am_oauth2_token_issue{token_type=<token-type>}
```

Labels:

<token-type>

access-token (Prometheus: **access_token**)

authorization-code (Prometheus: **authorization_code**)

device-code (Prometheus: **device_code**)

id-token. OpenID Connect ID token. (Prometheus: **id_token**)

ops. OpenID Connect Ops token for session management.

permission-ticket. User-Managed Access permission ticket. (Prometheus: **permission_ticket**)

refresh-token (Prometheus: **refresh_token**)

oauth2.token.access-token.revoke

Rate of OAuth 2.0 access token revocation. (Summary)

Prometheus syntax:

```
am_oauth2_token_revoke{token_type=access_token}
```

oauth2.token.read-as-jwt.<outcome>

Rate of successfully/unsuccessfully reading OAuth 2.0 JSON Web Tokens (JWT). (Timer)

Prometheus syntax:

```
am_oauth2_token_read_as_jwt{outcome=<outcome>}
```

Labels:

<outcome>

success

failure

Session Metrics

AM exposes the following session-related monitoring metrics:

session.authentication-in-memory.store.size

Number of authentication sessions stored in the in-memory authentication session store. (Gauge)

Prometheus syntax:

```
am_session_authentication_in_memory_store_size
```

session.cts-based.cache.eviction

Rate of evictions from the session cache. (Summary)

Prometheus syntax:

```
am_session_cts_based_cache_eviction
```

session.cts-based.cache.size

Number of sessions in the session cache. (Gauge)

Prometheus syntax:

```
am_session_cts_based_cache_size
```

session.cts-based.cache.hit

Rate of cache hits for the session cache. (Summary)

Prometheus syntax:

```
am_session_cts_based_cache{outcome=hit}
```

session.cts-based.cache.miss

Rate of cache misses for the session cache. (Summary)

Prometheus syntax:

```
am_session_cts_based_cache{outcome=miss}
```

`session.<session-type>.lifetime`

Rate of session lifetimes. (Timer)

Prometheus syntax:

```
am_session_lifetime{session_type=<session-type>}
```

Labels:

`<session-type>`

`authentication-in-memory`. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

`authentication-cts-based`. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

`authentication-client-based`. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

`cts-based`. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

`client-based`. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

`session.<session-type>.add-listener.<outcome>`

Rate of successful/unsuccessful p-search listener adds and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=add-listener, outcome=<outcome>}
```

Labels:

`<session-type>`

`authentication-in-memory`. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

`authentication-cts-based`. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

`authentication-client-based`. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

session.<session-type>.add-pll-listener.<outcome>

Rate of successful/unsuccessful PLL listener adds and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=add-pll-listener, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

session.<session-type>.check-exists.<outcome>

Rate of successful/unsuccessful calls to check if a session exists and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=check-exists, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

`session.<session-type>.create.<outcome>`

Rate of successful/unsuccessful session creation and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=create, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.destroy.<outcome>

Rate of successful/unsuccessful session destroy and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=destroy, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.get-restricted-token-id.<outcome>

Rate of successful/unsuccessful restricted token ID dereferencing and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=get-restricted-token-id, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.idle-timeout.<outcome>

Rate of successful/unsuccessful session idle time out and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=idle-timeout, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

`session.<session-type>.logout.<outcome>`

Rate of successful/unsuccessful session logout and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=logout, outcome=<outcome>}
```

Labels:

`<session-type>`

`authentication-in-memory`. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

`authentication-cts-based`. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

`authentication-client-based`. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

`cts-based`. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

`client-based`. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

`<outcome>`

success

failure

`session.<session-type>.max-timeout.<outcome>`

Rate of successful/unsuccessful session end of life and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=max-timeout, outcome=<outcome>}
```

Labels:

`<session-type>`

`authentication-in-memory`. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

`authentication-cts-based`. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

`authentication-client-based`. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

`cts-based`. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

`client-based`. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

`session.<session-type>.read-all.<outcome>`

Rate of successful/unsuccessful requests to read all sessions and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=read-all, outcome=<outcome>}
```

Labels:

<session-type>

`authentication-in-memory`. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

`authentication-cts-based`. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

`authentication-client-based`. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

`cts-based`. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

`client-based`. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

session.<session-type>.read.<outcome>

Rate of successful/unsuccessful session reads and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=read, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

`success`

`failure`

session.<session-type>.refresh.<outcome>

Rate of successful/unsuccessful session refresh and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=refresh, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.search.<outcome>

Rate of successful/unsuccessful session searches and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=search, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.set-external-property.<outcome>

Rate of successful/unsuccessful setting a property on a session and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=set-external-property, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.set-property.<outcome>

Rate of successful/unsuccessful session property setting and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=set-property, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

session.<session-type>.validate.<outcome>

Rate of successful/unsuccessful session validation and time taken to perform this operation. (Timer)

Prometheus syntax:

```
am_session{session_type=<session-type>,operation=validate, outcome=<outcome>}
```

Labels:

<session-type>

authentication-in-memory. In-memory *authentication* sessions used to track authentication progress. (Prometheus: `authentication_in_memory`)

authentication-cts-based. CTS-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_cts_based`)

authentication-client-based. Client-based *authentication* sessions used to track authentication progress. (Prometheus: `authentication_client_based`)

cts-based. CTS-based sessions issued after successful authentication. (Prometheus: `cts_based`)

client-based. Client-based sessions, for example in a browser cookie, issued after successful authentication. (Prometheus: `client_based`)

<outcome>

success

failure

OAuth2 Provider

amster service name: OAuth2Provider

Global Attributes

The following settings appear on the **Global Attributes** tab:

Token Blacklist Cache Size

Number of blacklisted tokens to cache in memory to speed up blacklist checks and reduce load on the CTS.

Default value: `10000`

amster attribute: `blacklistCacheSize`

Blacklist Poll Interval (seconds)

How frequently to poll for token blacklist changes from other servers, in seconds.

How often each server will poll the CTS for token blacklist changes from other servers. This is used to maintain a highly compressed view of the overall current token blacklist improving performance. A lower number will reduce the delay for blacklisted tokens to propagate to all servers at the cost of increased CTS load. Set to 0 to disable this feature completely.

Default value: `60`

amster attribute: `blacklistPollInterval`

Blacklist Purge Delay (minutes)

Length of time to blacklist tokens beyond their expiry time.

Allows additional time to account for clock skew to ensure that a token has expired before it is removed from the blacklist.

Default value: `1`

amster attribute: `blacklistPurgeDelay`

Client-Based Grant Token Upgrade Compatibility Mode

Enable AM to consume and create client-based OAuth 2.0 tokens in two different formats simultaneously.

Enable this option when upgrading AM to allow the new instance to create and consume client-based OAuth 2.0 tokens in both the previous format, and the new format. Disable this option once all AM instances in the cluster have been upgraded.

Default value: `false`

amster attribute: `statelessGrantTokenUpgradeCompatibilityMode`

CTS Storage Scheme

Storage scheme to be used when storing OAuth2 tokens to CTS.

In order to support rolling upgrades, this should be set to the latest storage scheme supported by all AM instances within your cluster. Select the latest storage scheme once all AM instances in the cluster have been upgraded.

One-to-One Storage Scheme

Under this storage scheme, each OAuth2 token maps to an individual CTS entry.

This storage scheme is deprecated.

Grant-Set Storage Scheme

Under this storage scheme, multiple authorization code, access token and refresh token for a given OAuth2 client and resource owner can be stored within a single CTS entry.

The Grant-Set storage scheme is more efficient than the One-to-One storage scheme so should be used once all servers have been upgraded to a version which supports this storage scheme

The possible values for this property are:

- `CTS_ONE_TO_ONE_MODEL`. One-to-One Storage Scheme
- `CTS_GRANT_SET_MODEL`. Grant-Set Storage Scheme

Default value: `CTS_ONE_TO_ONE_MODEL`

amster attribute: `storageScheme`

Enforce JWT Unreasonable Lifetime

Enable the enforcement of JWT token unreasonable lifetime during validation.

The JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants specification (<https://www.rfc-editor.org/rfc/rfc7523.html#section-3>) states that an authorization server may reject JWTs with an "exp" claim value that is unreasonably far in the future and an "iat" claim value that is unreasonably far in the past. This enforcement may be disabled, but should only be done if the security implications have been evaluated.

Default value: `true`

amster attribute: `jwtTokenLifetimeValidationEnabled`

JWT Unreasonable Lifetime (seconds)

Specify the lifetime (in seconds) of a JWT which should be considered unreasonable and rejected by validation.

The JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants specification (<https://www.rfc-editor.org/rfc/rfc7523.html#section-3>) states that an authorization server may reject JWTs with an "exp" claim value that is unreasonably far in the future and an "iat" claim value that is unreasonably far in the past. During token validation AM enforces that

the token must expire within the specified duration and if the "iat" claim value is present, the token must not be older than the specified duration.

Default value: `86400`

amster attribute: `jwtTokenUnreasonableLifetime`

Core

The following settings appear on the **Core** tab:

Use Client-Based Access & Refresh Tokens

When enabled, AM issues access and refresh tokens that can be inspected by resource servers.

Default value: `false`

amster attribute: `statelessTokensEnabled`

Authorization Code Lifetime (seconds)

The time an authorization code is valid for, in seconds.

Default value: `120`

amster attribute: `codeLifetime`

Refresh Token Lifetime (seconds)

The time in seconds a refresh token is valid for. If this field is set to `-1`, the refresh token will never expire.

Default value: `604800`

amster attribute: `refreshTokenLifetime`

Access Token Lifetime (seconds)

The time an access token is valid for, in seconds. Note that if you set the value to `0`, the access token will not be valid. A maximum lifetime of 600 seconds is recommended.

Default value: `3600`

amster attribute: `accessTokenLifetime`

Issue Refresh Tokens

Whether to issue a refresh token when returning an access token.

Default value: `true`

amster attribute: `issueRefreshToken`

Issue Refresh Tokens on Refreshing Access Tokens

Whether to issue a refresh token when refreshing an access token.

Default value: `true`

amster attribute: `issueRefreshTokenOnRefreshedToken`

Use Policy Engine for Scope decisions

With this setting enabled, the policy engine is consulted for each scope value that is requested.

If a policy returns an action of GRANT=true, the scope is consented automatically, and the user is not consulted in a user-interaction flow. If a policy returns an action of GRANT=false, the scope is not added to any resulting token, and the user will not see it in a user-interaction flow. If no policy returns a value for the GRANT action, then if the grant type is user-facing (i.e. authorization or device code flows), the user is asked for consent (or saved consent is used), and if the grant type is not user-facing (password or client credentials), the scope is not added to any resulting token.

Default value: `false`

amster attribute: `usePolicyEngineForScope`

OAuth2 Access Token Modification Script

The script that is executed when issuing an access token. The script can change the access token's internal data structure to include or exclude particular fields.

The possible values for this property are:

- `d22f9a0c-426a-4466-b95e-d0f125b0d5fa`. OAuth2 Access Token Modification Script
- `[Empty]`. --- Select a script ---

Default value: `d22f9a0c-426a-4466-b95e-d0f125b0d5fa`

amster attribute: `accessTokenModificationScript`

Advanced

The following settings appear on the **Advanced** tab:

Custom Login URL Template

Custom URL for handling login, to override the default AM login page.

Supports Freemarker syntax, with the following variables:

Variable	Description
<code>gotoUrl</code>	The URL to redirect to after login.
<code>acrValues</code>	The Authentication Context Class Reference (acr) values for the authorization request.
<code>realm</code>	The AM realm the authorization request was made on.
<code>module</code>	The name of the AM authentication module requested to perform resource owner authentication.
<code>service</code>	The name of the AM authentication chain requested to perform resource owner authentication.
<code>locale</code>	A space-separated list of locales, ordered by preference.

The following example template redirects users to a non-AM front end to handle login, which will then redirect back to the `/oauth2/authorize` endpoint with any required parameters:

```
http://mylogin.com/login?goto=${goto}<#if acrValues??>&acr_values=${acrValues}</#if><#if realm??>&realm=${realm}</#if><#if module??>&module=${module}</#if><#if service??>&service=${service}</#if><#if locale??>&locale=${locale}</#if>
```

NOTE: Default AM login page is constructed using "Base URL Source" service.

amster attribute: `customLoginUrlTemplate`

Scope Implementation Class

The class that contains the required scope implementation, must implement the `org.forgerock.oauth2.core.ScopeValidator` interface.

Default value: `org.forgerock.openam.oauth2.OpenAMScopeValidator`

amster attribute: `scopeImplementationClass`

Response Type Plugins

List of plugins that handle the valid `response_type` values.

OAuth 2.0 clients pass response types as parameters to the OAuth 2.0 Authorization endpoint (`/oauth2/authorize`) to indicate which grant type is requested from the provider. For example, the client passes `code` when requesting an authorization code, and `token` when requesting an access token.

Values in this list take the form `response-type|plugin-class-name`.

Default value:

```
code|org.forgerock.oauth2.core.AuthorizationCodeResponseTypeHandler
```

```
device_code|org.forgerock.oauth2.core.TokenResponseTypeHandler  
token|org.forgerock.oauth2.core.TokenResponseTypeHandler
```

amster attribute: `responseTypeClasses`

User Profile Attribute(s) the Resource Owner is Authenticated On

Names of profile attributes that resource owners use to log in. You can add others to the default, for example `mail`.

Default value: `uid`

amster attribute: `authenticationAttributes`

User Display Name attribute

The profile attribute that contains the name to be displayed for the user on the consent page.

Default value: `cn`

amster attribute: `displayNameAttribute`

Supported Scopes

The set of supported scopes, with translations.

Scopes may be entered as simple strings or pipe-separated strings representing the internal scope name, locale, and localized description.

For example: `read|en|Permission to view email messages in your account`

Locale strings are in the format: `language_country_variant`, for example `en`, `en_GB`, or `en_US_WIN`.

If the locale and pipe is omitted, the description is displayed to all users that have undefined locales.

If the description is also omitted, nothing is displayed on the consent page for the scope. For example specifying `read|` would allow the scope `read` to be used by the client, but would not display it to the user on the consent page when requested.

amster attribute: `supportedScopes`

Subject Types supported

List of subject types supported. Valid values are:

- `public` - Each client receives the same subject (`sub`) value.
- `pairwise` - Each client receives a different subject (`sub`) value, to prevent correlation between clients.

Default value: `public`

amster attribute: `supportedSubjectTypes`

Default Client Scopes

List of scopes a client will be granted if they request registration without specifying which scopes they want. Default scopes are NOT auto-granted to clients created through the AM console.

amster attribute: `defaultScopes`

OAuth2 Token Signing Algorithm

Algorithm used to sign client-based OAuth 2.0 tokens in order to detect tampering.

AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `HS256` - HMAC with SHA-256.
- `HS384` - HMAC with SHA-384.
- `HS512` - HMAC with SHA-512.
- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- `ES384` - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- `ES512` - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- `RS256` - RSASSA-PKCS-v1_5 using SHA-256.

The possible values for this property are:

- `HS256`
- `HS384`
- `HS512`
- `RS256`
- `RS384`
- `RS512`
- `ES256`
- `ES384`
- `ES512`

- PS256
- PS384
- PS512

Default value: HS256

amster attribute: `tokenSigningAlgorithm`

Client-Based Token Compression

Whether client-based access and refresh tokens should be compressed.

amster attribute: `tokenCompressionEnabled`

Encrypt Client-Based Tokens

Whether client-based access and refresh tokens should be encrypted.

Enabling token encryption will disable token signing as encryption is performed using direct symmetric encryption.

Default value: `false`

amster attribute: `tokenEncryptionEnabled`

Subject Identifier Hash Salt

If *pairwise* subject types are supported, it is *STRONGLY RECOMMENDED* to change this value. It is used in the salting of hashes for returning specific `sub` claims to individuals using the same `request_uri` or `sector_identifier_uri`.

For example, you might set this property to: *changeme*

amster attribute: `hashSalt`

Code Verifier Parameter Required

If enabled, requests using the authorization code grant require a `code_challenge` attribute.

For more information, read the specification for this feature.

The possible values for this property are:

- `true`. All requests
- `public`. Requests from all public clients
- `passwordless`. Requests from all passwordless public clients

- `false`. No requests

Default value: `false`

amster attribute: `codeVerifierEnforced`

Modified Timestamp Attribute Name

The identity Data Store attribute used to return modified timestamp values.

This attribute is paired together with the *Created Timestamp Attribute Name* attribute (`createdTimestampAttribute`). You can leave both attributes unset (default) or set them both. If you set only one attribute and leave the other blank, the access token fails with a 500 error.

For example, when you configure AM as an OpenID Connect Provider in a Mobile Connect application and use DS as an identity data store, the client accesses the `userinfo` endpoint to obtain the `updated_at` claim value in the ID token. The `updated_at` claim obtains its value from the `modifiedTimestampAttribute` attribute in the user profile. If the profile has never been modified the `updated_at` claim uses the `createdTimestampAttribute` attribute.

amster attribute: `modifiedTimestampAttribute`

Created Timestamp Attribute Name

The identity Data Store attribute used to return created timestamp values.

amster attribute: `createdTimestampAttribute`

Password Grant Authentication Service

The authentication service (chain or tree) that will be used to authenticate the username and password for the resource owner password credentials grant type.

The possible values for this property are:

- `[Empty]`
- `ldapService`
- `amsterService`
- `Example`
- `Agent`
- `RetryLimit`
- `PersistentCookie`
- `HmacOneTimePassword`

- `Facebook-ProvisionIDMAccount`
- `Google-AnonymousUser`
- `Google-DynamicAccountCreation`

amster attribute: `passwordGrantAuthService`

Enable Auth Module Messages for Password Credentials Grant

If enabled, authentication module failure messages are used to create Resource Owner Password Credentials Grant failure messages. If disabled, a standard authentication failed message is used.

The Password Grant Type requires the `grant_type=password` parameter.

Default value: `false`

amster attribute: `moduleMessageEnabledInPasswordGrant`

Grant Types

The set of Grant Types (OAuth2 Flows) that are permitted to be used by this client.

If no Grant Types (OAuth2 Flows) are configured nothing will be permitted.

Default value:

```
implicit
urn:ietf:params:oauth:grant-type:saml2-bearer
refresh_token
password
client_credentials
urn:ietf:params:oauth:grant-type:device_code
authorization_code
urn:openid:params:grant-type:ciba
urn:ietf:params:oauth:grant-type:uma-ticket
urn:ietf:params:oauth:grant-type:jwt-bearer
```

amster attribute: `grantTypes`

Trusted TLS Client Certificate Header

HTTP Header to receive TLS client certificates when TLS is terminated at a proxy.

Leave blank if not terminating TLS at a proxy. Ensure that the proxy is configured to strip this header from incoming requests. Best practice is to use a random string.

amster attribute: `tlsClientCertificateTrustedHeader`

Support TLS Certificate-Bound Access Tokens

Whether to bind access tokens to the client certificate when using TLS client certificate authentication.

Default value: `true`

amster attribute: `tlsCertificateBoundAccessTokensEnabled`

Client Dynamic Registration

The following settings appear on the **Client Dynamic Registration** tab:

Require Software Statement for Dynamic Client Registration

When enabled, a software statement JWT containing at least the `iss` (issuer) claim must be provided when registering an OAuth 2.0 client dynamically.

Default value: `false`

amster attribute: `dynamicClientRegistrationSoftwareStatementRequired`

Required Software Statement Attested Attributes

The client attributes that are required to be present in the software statement JWT when registering an OAuth 2.0 client dynamically. Only applies if Require Software Statements for Dynamic Client Registration is enabled.

Leave blank to allow any attributes to be present.

Default value: `redirect_uris`

amster attribute: `requiredSoftwareStatementAttestedAttributes`

Allow Open Dynamic Client Registration

Allow clients to register without an access token. If enabled, you should consider adding some form of rate limiting. For more information, see Client Registration in the OpenID Connect specification.

Default value: `false`

amster attribute: `allowDynamicRegistration`

Generate Registration Access Tokens

Whether to generate Registration Access Tokens for clients that register by using open dynamic client registration. Such tokens allow the client to access the Client Configuration Endpoint as per the OpenID Connect specification. This setting has no effect if Allow Open Dynamic Client Registration is disabled.

Default value: `true`

amster attribute: `generateRegistrationAccessTokens`

Scope to give access to dynamic client registration

Mandatory scope required when registering a new OAuth2 client.

Default value: `dynamic_client_registration`

amster attribute: `dynamicClientRegistrationScope`

OpenID Connect

The following settings appear on the **OpenID Connect** tab:

OIDC Claims Script

The script that is run when issuing an ID token or making a request to the *userinfo* endpoint during OpenID requests.

The script gathers the scopes and populates claims, and has access to the access token, the user's identity and, if available, the user's session.

The possible values for this property are:

- OIDC Claims Script

Default value: `OIDC Claims Script`

amster attribute: `oidcClaimsScript`

ID Token Signing Algorithms supported

Algorithms supported to sign OpenID Connect `id_tokens`.

AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `HS256` - HMAC with SHA-256.
- `HS384` - HMAC with SHA-384.
- `HS512` - HMAC with SHA-512.
- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- `ES384` - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- `ES512` - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- `RS256` - RSASSA-PKCS-v1_5 using SHA-256.
- `RS384` - RSASSA-PKCS-v1_5 using SHA-384.

- **RS512** - RSASSA-PKCS-v1_5 using SHA-512.
- **PS256** - RSASSA-PSS using SHA-256.
- **PS384** - RSASSA-PSS using SHA-384.
- **PS512** - RSASSA-PSS using SHA-512.

Default value:

```
PS384
ES384
RS384
HS256
HS512
ES256
RS256
HS384
ES512
PS256
PS512
RS512
```

amster attribute: [supportedIDTokenSigningAlgorithms](#)

ID Token Encryption Algorithms supported

Encryption algorithms supported to encrypt OpenID Connect ID tokens in order to hide its contents.

AM supports the following ID token encryption algorithms:

- **RSA-OAEP** - RSA with Optimal Asymmetric Encryption Padding (OAEP) with SHA-1 and MGF-1.
- **RSA-OAEP-256** - RSA with OAEP with SHA-256 and MGF-1.
- **A128KW** - AES Key Wrapping with 128-bit key derived from the client secret.
- **RSA1_5** - RSA with PKCS#1 v1.5 padding.
- **A256KW** - AES Key Wrapping with 256-bit key derived from the client secret.
- **dir** - Direct encryption with AES using the hashed client secret.
- **A192KW** - AES Key Wrapping with 192-bit key derived from the client secret.

Default value:

```
RSA-OAEP
RSA-OAEP-256
A128KW
A256KW
```

```
RSA1_5
dir
A192KW
```

amster attribute: `supportedIDTokenEncryptionAlgorithms`

ID Token Encryption Methods supported

Encryption methods supported to encrypt OpenID Connect ID tokens in order to hide its contents.

AM supports the following ID token encryption algorithms:

- `A128GCM`, `A192GCM`, and `A256GCM` - AES in Galois Counter Mode (GCM) authenticated encryption mode.
- `A128CBC-HS256`, `A192CBC-HS384`, and `A256CBC-HS512` - AES encryption in CBC mode, with HMAC-SHA-2 for integrity.

Default value:

```
A256GCM
A192GCM
A128GCM
A128CBC-HS256
A192CBC-HS384
A256CBC-HS512
```

amster attribute: `supportedIDTokenEncryptionMethods`

Supported Claims

Set of claims supported by the OpenID Connect `/oauth2/userinfo` endpoint, with translations.

Claims may be entered as simple strings or pipe separated strings representing the internal claim name, locale, and localized description.

For example: `name|en|Your full name..`

Locale strings are in the format: `language + "_" + country + "_" + variant`, for example `en`, `en_GB`, or `en_US_WIN`. If the locale and pipe is omitted, the description is displayed to all users that have undefined locales.

If the description is also omitted, nothing is displayed on the consent page for the claim. For example specifying `family_name|` would allow the claim `family_name` to be used by the client, but would not display it to the user on the consent page when requested.

amster attribute: `supportedClaims`

OpenID Connect JWT Token Lifetime (seconds)

The amount of time the JWT will be valid for, in seconds.

Default value: `3600`

amster attribute: `jwtTokenLifetime`

Advanced OpenID Connect

The following settings appear on the **Advanced OpenID Connect** tab:

Remote JSON Web Key URL

The Remote URL where the providers JSON Web Key can be retrieved.

If this setting is not configured, then AM provides a local URL to access the public key of the private key used to sign ID tokens.

amster attribute: `jkwsURI`

Idtokeninfo Endpoint Requires Client Authentication

When enabled, the `/oauth2/idtokeninfo` endpoint requires client authentication if the signing algorithm is set to `HS256`, `HS384`, or `HS512`.

Default value: `true`

amster attribute: `idTokenInfoClientAuthenticationEnabled`

Enable "claims_parameter_supported"

If enabled, clients will be able to request individual claims using the `claims` request parameter, as per section 5.5 of the OpenID Connect specification.

Default value: `false`

amster attribute: `claimsParameterSupported`

OpenID Connect acr_values to Auth Chain Mapping

Maps OpenID Connect ACR values to authentication chains. For more details, see the `acr_values` parameter in the OpenID Connect authentication request specification.

amster attribute: `loaMapping`

Default ACR values

Default requested Authentication Context Class Reference values.

List of strings that specifies the default acr values that the OP is being requested to use for processing requests from this Client, with the values appearing in order of preference. The Authentication Context Class satisfied by the authentication performed is returned as the

acr Claim Value in the issued ID Token. The acr Claim is requested as a Voluntary Claim by this parameter. The `acr_values_supported` discovery element contains a list of the acr values supported by this server. Values specified in the `acr_values` request parameter or an individual acr Claim request override these default values.

amster attribute: `defaultACR`

OpenID Connect `id_token amr` Values to Auth Module Mappings

Specify `amr` values to be returned in the OpenID Connect `id_token`. Once authentication has completed, the authentication modules that were used from the authentication service will be mapped to the `amr` values. If you do not require `amr` values, or are not providing OpenID Connect tokens, leave this field blank.

amster attribute: `amrMappings`

Always Return Claims in ID Tokens

If enabled, include scope-derived claims in the `id_token`, even if an access token is also returned that could provide access to get the claims from the `userinfo` endpoint.

If not enabled, if an access token is requested the client must use it to access the `userinfo` endpoint for scope-derived claims, as they will not be included in the ID token.

Default value: `false`

amster attribute: `alwaysAddClaimsToToken`

Store Ops Tokens

Whether AM will store the `ops` tokens corresponding to OpenID Connect sessions in the CTS store. Note that session management related endpoints will not work when this setting is disabled.

Default value: `true`

amster attribute: `storeOpsTokens`

Request Parameter Signing Algorithms Supported

Algorithms supported to verify signature of Request parameterAM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `HS256` - HMAC with SHA-256.
- `HS384` - HMAC with SHA-384.
- `HS512` - HMAC with SHA-512.
- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.

- **ES384** - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- **ES512** - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- **RS256** - RSASSA-PKCS-v1_5 using SHA-256.

Default value:

```
PS384
ES384
RS384
HS256
HS512
ES256
RS256
HS384
ES512
PS256
PS512
RS512
```

amster attribute: `supportedRequestParameterSigningAlgorithms`

Request Parameter Encryption Algorithms Supported

Encryption algorithms supported to decrypt Request parameter.

AM supports the following ID token encryption algorithms:

- **RSA-OAEP** - RSA with Optimal Asymmetric Encryption Padding (OAEP) with SHA-1 and MGF-1.
- **RSA-OAEP-256** - RSA with OAEP with SHA-256 and MGF-1.
- **A128KW** - AES Key Wrapping with 128-bit key derived from the client secret.
- **RSA1_5** - RSA with PKCS#1 v1.5 padding.
- **A256KW** - AES Key Wrapping with 256-bit key derived from the client secret.
- **dir** - Direct encryption with AES using the hashed client secret.
- **A192KW** - AES Key Wrapping with 192-bit key derived from the client secret.

Default value:

```
RSA-OAEP
RSA-OAEP-256
A128KW
A256KW
RSA1_5
dir
A192KW
```

amster attribute: `supportedRequestParameterEncryptionAlgorithms`

Request Parameter Encryption Methods Supported

Encryption methods supported to decrypt Request parameter.

AM supports the following Request parameter encryption algorithms:

- [A128GCM](#), [A192GCM](#), and [A256GCM](#) - AES in Galois Counter Mode (GCM) authenticated encryption mode.
- [A128CBC-HS256](#), [A192CBC-HS384](#), and [A256CBC-HS512](#) - AES encryption in CBC mode, with HMAC-SHA-2 for integrity.

Default value:

```
A256GCM
A192GCM
A128GCM
A128CBC-HS256
A192CBC-HS384
A256CBC-HS512
```

amster attribute: [supportedRequestParameterEncryptionEnc](#)

Supported Token Endpoint JWS Signing Algorithms.

Supported JWS Signing Algorithms for 'private_key_jwt' JWT based authentication method.

Default value:

```
PS384
ES384
RS384
HS256
HS512
ES256
RS256
HS384
ES512
PS256
PS512
RS512
```

amster attribute: [supportedTokenEndpointAuthenticationSigningAlgorithms](#)

Authorized OIDC SSO Clients

Clients authorized to use OpenID Connect ID tokens as SSO Tokens.

Allows clients to act with the full authority of the user. Grant this permission only to trusted clients.

amster attribute: [authorisedOpenIdConnectSSOClients](#)

UserInfo Signing Algorithms Supported

Algorithms supported to verify signature of the UserInfo endpoint. AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- **HS256** - HMAC with SHA-256.
- **HS384** - HMAC with SHA-384.
- **HS512** - HMAC with SHA-512.
- **ES256** - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- **ES384** - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- **ES512** - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- **RS256** - RSASSA-PKCS-v1_5 using SHA-256.

Default value:

```
ES384  
HS256  
HS512  
ES256  
RS256  
HS384  
ES512
```

amster attribute: `supportedUserInfoSigningAlgorithms`

UserInfo Encryption Algorithms Supported

Encryption algorithms supported by the UserInfo endpoint.

AM supports the following UserInfo endpoint encryption algorithms:

- **RSA-0AEP** - RSA with Optimal Asymmetric Encryption Padding (OAEP) with SHA-1 and MGF-1.
- **RSA-0AEP-256** - RSA with OAEP with SHA-256 and MGF-1.
- **A128KW** - AES Key Wrapping with 128-bit key derived from the client secret.
- **RSA1_5** - RSA with PKCS#1 v1.5 padding.
- **A256KW** - AES Key Wrapping with 256-bit key derived from the client secret.
- **dir** - Direct encryption with AES using the hashed client secret.
- **A192KW** - AES Key Wrapping with 192-bit key derived from the client secret.

Default value:

```
RSA-OAEP
RSA-OAEP-256
A128KW
A256KW
RSA1_5
dir
A192KW
```

amster attribute: `supportedUserInfoEncryptionAlgorithms`

UserInfo Encryption Methods Supported

Encryption methods supported by the UserInfo endpoint.

AM supports the following UserInfo endpoint encryption methods:

- `A128GCM`, `A192GCM`, and `A256GCM` - AES in Galois Counter Mode (GCM) authenticated encryption mode.
- `A128CBC-HS256`, `A192CBC-HS384`, and `A256CBC-HS512` - AES encryption in CBC mode, with HMAC-SHA-2 for integrity.

Default value:

```
A256GCM
A192GCM
A128GCM
A128CBC-HS256
A192CBC-HS384
A256CBC-HS512
```

amster attribute: `supportedUserInfoEncryptionEnc`

Use Force Authentication for `prompt=login`

This setting is applied only when you've implemented modules or chains, and you've specified the `prompt=login` parameter. The default value is `false`.

When set to `false`, AM forces the end user to authenticate even if they already have a valid session. After re-authentication, AM creates a new session.

When set to `true`, AM forces the end user to authenticate even if they already have a valid session. But, after re-authentication, AM returns the same session ID. Setting this to `false`, to create new a session, is recommended to increase the level of security.

Device Flow

The following settings appear on the **Device Flow** tab:

Verification URL

The URL that the user will be instructed to visit to complete their OAuth 2.0 login and consent when using the device code flow.

amster attribute: `verificationUrl`

Device Completion URL

The URL that the user will be sent to on completion of their OAuth 2.0 login and consent when using the device code flow.

amster attribute: `completionUrl`

Device Code Lifetime (seconds)

The lifetime of the device code, in seconds.

Default value: `300`

amster attribute: `deviceCodeLifetime`

Device Polling Interval

The polling frequency for devices waiting for tokens when using the device code flow.

Default value: `5`

amster attribute: `devicePollInterval`

Consent

The following settings appear on the **Consent** tab:

Saved Consent Attribute Name

Name of a multi-valued attribute on resource owner profiles where AM can save authorization consent decisions.

When the resource owner chooses to save the decision to authorize access for a client application, then AM updates the resource owner's profile to avoid having to prompt the resource owner to grant authorization when the client issues subsequent authorization requests.

amster attribute: `savedConsentAttribute`

Allow Clients to Skip Consent

If enabled, clients may be configured so that the resource owner will not be asked for consent during authorization flows.

Default value: `false`

amster attribute: `clientsCanSkipConsent`

Enable Remote Consent

Default value: `false`

amster attribute: `enableRemoteConsent`

Remote Consent Service ID

The ID of an existing remote consent service agent.

The possible values for this property are:

- `[Empty]`

amster attribute: `remoteConsentServiceId`

Remote Consent Service Request Signing Algorithms Supported

Algorithms supported to sign `consent_request` JWTs for Remote Consent Services.

AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `HS256` - HMAC with SHA-256.
- `HS384` - HMAC with SHA-384.
- `HS512` - HMAC with SHA-512.
- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- `ES384` - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- `ES512` - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- `RS256` - RSASSA-PKCS-v1_5 using SHA-256.

Default value:

```
PS384
ES384
RS384
HS256
HS512
ES256
RS256
HS384
ES512
PS256
PS512

```

amster attribute: `supportedRcsRequestSigningAlgorithms`

Remote Consent Service Request Encryption Algorithms Supported

Encryption algorithms supported to encrypt Remote Consent Service requests.

AM supports the following encryption algorithms:

- `RSA1_5` - RSA with PKCS#1 v1.5 padding.
- `RSA-0AEP` - RSA with Optimal Asymmetric Encryption Padding (OAEP) with SHA-1 and MGF-1.
- `RSA-0AEP-256` - RSA with OAEP with SHA-256 and MGF-1.
- `A128KW` - AES Key Wrapping with 128-bit key derived from the client secret.
- `A192KW` - AES Key Wrapping with 192-bit key derived from the client secret.
- `A256KW` - AES Key Wrapping with 256-bit key derived from the client secret.
- `dir` - Direct encryption with AES using the hashed client secret.

Default value:

```
RSA-0AEP
RSA-0AEP-256
A128KW
RSA1_5
A256KW
dir
A192KW
```

amster attribute: `supportedRcsRequestEncryptionAlgorithms`

Remote Consent Service Request Encryption Methods Supported

Encryption methods supported to encrypt Remote Consent Service requests.

AM supports the following encryption methods:

- `A128GCM`, `A192GCM`, and `A256GCM` - AES in Galois Counter Mode (GCM) authenticated encryption mode.
- `A128CBC-HS256`, `A192CBC-HS384`, and `A256CBC-HS512` - AES encryption in CBC mode, with HMAC-SHA-2 for integrity.

Default value:

```
A256GCM
A192GCM
A128GCM
A128CBC-HS256
A192CBC-HS384
```

```
A256CBC-HS512
```

amster attribute: `supportedRcsRequestEncryptionMethods`

Remote Consent Service Response Signing Algorithms Supported

Algorithms supported to verify signed consent_response JWT from Remote Consent Services.

AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `HS256` - HMAC with SHA-256.
- `HS384` - HMAC with SHA-384.
- `HS512` - HMAC with SHA-512.
- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- `ES384` - ECDSA with SHA-384 and NIST standard P-384 elliptic curve.
- `ES512` - ECDSA with SHA-512 and NIST standard P-521 elliptic curve.
- `RS256` - RSASSA-PKCS-v1_5 using SHA-256.

Default value:

```
PS384  
ES384  
RS384

amster attribute: `supportedRcsResponseSigningAlgorithms`

Remote Consent Service Response Encryption Algorithms Supported

Encryption algorithms supported to decrypt Remote Consent Service responses.

AM supports the following encryption algorithms:

- `RSA1_5` - RSA with PKCS#1 v1.5 padding.
- `RSA-OAEP` - RSA with Optimal Asymmetric Encryption Padding (OAEP) with SHA-1 and MGF-1.
- `RSA-OAEP-256` - RSA with OAEP with SHA-256 and MGF-1.

- **A128KW** - AES Key Wrapping with 128-bit key derived from the client secret.
- **A192KW** - AES Key Wrapping with 192-bit key derived from the client secret.
- **A256KW** - AES Key Wrapping with 256-bit key derived from the client secret.
- **dir** - Direct encryption with AES using the hashed client secret.

Default value:

```
RSA-OAEP
RSA-OAEP-256
A128KW
A256KW
RSA1_5
dir
A192KW
```

amster attribute: `supportedRcsResponseEncryptionAlgorithms`

Remote Consent Service Response Encryption Methods Supported

Encryption methods supported to decrypt Remote Consent Service responses.

AM supports the following encryption methods:

- **A128GCM**, **A192GCM**, and **A256GCM** - AES in Galois Counter Mode (GCM) authenticated encryption mode.
- **A128CBC-HS256**, **A192CBC-HS384**, and **A256CBC-HS512** - AES encryption in CBC mode, with HMAC-SHA-2 for integrity.

Default value:

```
A256GCM
A192GCM
A128GCM
A128CBC-HS256
A192CBC-HS384
A256CBC-HS512
```

amster attribute: `supportedRcsResponseEncryptionMethods`

CIBA

The following settings appear on the **CIBA** tab:

Back Channel Authentication ID Lifetime (seconds)

The time back channel authentication request id is valid for, in seconds.

Default value: **600**

amster attribute: `cibaAuthReqIdLifetime`

Polling Wait Interval (seconds)

The minimum amount of time in seconds that the Client should wait between polling requests to the token endpoint

Default value: `2`

amster attribute: `cibaMinimumPollingInterval`

Signing Algorithms Supported

Algorithms supported to sign the CIBA request parameter.

AM supports signing algorithms listed in JSON Web Algorithms (JWA): "alg" (Algorithm) Header Parameter Values for JWS:

- `ES256` - ECDSA with SHA-256 and NIST standard P-256 elliptic curve.
- `PS256` - RSASSA-PSS using SHA-256.

Default value:

```
ES256
PS256
```

amster attribute: `supportedCibaSigningAlgorithms`

Dashboard

amster service name: `DashboardUserService`

Realm Defaults

The following settings appear on the **Realm Defaults** tab:

Available Dashboard Apps

List of application dashboard names available by default for realms with the Dashboard service configured.

amster attribute: `assignedDashboard`

Secondary Configurations

This service has the following Secondary Configurations.

instances

Dashboard Class Name

Identifies how to access the application, for example `SAML2ApplicationClass` for a SAML v2.0 application.

amster attribute: `className`

Dashboard Name

The application name as it will appear to the administrator for configuring the dashboard.

amster attribute: `name`

Dashboard Display Name

The application name that displays on the dashboard client.

amster attribute: `displayName`

Dashboard Icon

The icon name that will be displayed on the dashboard client identifying the application.

amster attribute: `icon`

Dashboard Login

The URL that takes the user to the application.

amster attribute: `login`

ICF Identifier

amster attribute: `icfIdentifier`

Command-line Tool Reference

Name

ampassword — change passwords for the AM Administrator

Synopsis

```
ampassword {options}
```

Description

This command allows you to change passwords held in the configuration store, and to encrypt passwords.

Options

The following options are supported.

```
-a | --admin [ -o | --old old-password-file -n | --new new-password-file ]
```

Change the password for `amAdmin` from the value stored in *old-password-file* to the value stored in *new-password-file*.

```
-p | --proxy [ -o | --old old-password-file -n | --new new-password-file ]
```

Change the password for the proxy administrator from the value stored in *old-password-file* to the value stored in *new-password-file*.

The proxy administrator password is shown encrypted in the output from `ssoadm get-svrcfg-xml`.

```
-e | --encrypt [ password-file ]
```

Display the password value provided encrypted with the key generated during AM installation.

```
-h | --help
```

Display the usage message.

Examples

The following example encrypts the password contained within a text file.

- Create a text file, for example `$HOME/.pwd.txt`, containing the password string on a single line.
- Encrypt the password by using the `ampassword` command:

```
$ ampassword -e $HOME/.pwd.txt
AQICkZs3qy5QUCXir9tebIEEZYGFIXI2lCC4B
```

Appendix A. About the REST API

This appendix shows how to use the RESTful interfaces for direct integration between web client applications and ForgeRock Access Management.

Introducing REST

Representational State Transfer (REST) is an architectural style that sets certain constraints for designing and building large-scale distributed hypermedia systems.

As an architectural style, REST has very broad applications. The designs of both HTTP 1.1 and URIs follow RESTful principles. The World Wide Web is no doubt the largest and best known REST application. Many other web services also follow the REST architectural style. Examples include OAuth 2.0, OpenID Connect 1.0, and User-Managed Access (UMA).

The ForgeRock Common REST (CREST) API applies RESTful principles to define common verbs for HTTP-based APIs that access web resources and collections of web resources.

Interface Stability: Evolving

Most native AM REST APIs use the CREST verbs. (In contrast, OAuth 2.0, OpenID Connect 1.0 and UMA APIs follow their respective standards.)

About ForgeRock Common REST

ForgeRock® Common REST is a common REST API framework. It works across the ForgeRock platform to provide common ways to access web resources and collections of resources. Adapt the examples in this section to your resources and deployment.

Note

This section describes the full Common REST framework. Some platform component products do not implement all Common REST behaviors exactly as described in this section. For details, refer to the product-specific examples and reference information in other sections of this documentation set.

Common REST Resources

Servers generally return JSON-format resources, though resource formats can depend on the implementation.

Resources in collections can be found by their unique identifiers (IDs). IDs are exposed in the resource URIs. For example, if a server has a user collection under `/users`, then you can access a user at `/users/user-id`. The ID is also the value of the `_id` field of the resource.

Resources are versioned using revision numbers. A revision is specified in the resource's `_rev` field. Revisions make it possible to figure out whether to apply changes without resource locking and without distributed transactions.

Common REST Verbs

The Common REST APIs use the following verbs, sometimes referred to collectively as CRUDPAQ. For details and HTTP-based examples of each, follow the links to the sections for each verb.

Create

Add a new resource.

This verb maps to HTTP PUT or HTTP POST.

For details, see "Create".

Read

Retrieve a single resource.

This verb maps to HTTP GET.

For details, see "Read".

Update

Replace an existing resource.

This verb maps to HTTP PUT.

For details, see "Update".

Delete

Remove an existing resource.

This verb maps to HTTP DELETE.

For details, see "Delete".

Patch

Modify part of an existing resource.

This verb maps to HTTP PATCH.

For details, see "Patch".

Action

Perform a predefined action.

This verb maps to HTTP POST.

For details, see "Action".

Query

Search a collection of resources.

This verb maps to HTTP GET.

For details, see "Query".

Common REST Parameters

Common REST reserved query string parameter names start with an underscore, `_`.

Reserved query string parameters include, but are not limited to, the following names:

```
_action  
_api  
_crestapi  
_fields  
_mimeType  
_pageSize  
_pagedResultsCookie  
_pagedResultsOffset  
_prettyPrint  
_queryExpression
```

`_queryFilter`
`_queryId`
`_sortKeys`
`_totalPagedResultsPolicy`

Note

Some parameter values are not safe for URLs, so URL-encode parameter values as necessary.

Continue reading for details about how to use each parameter.

Common REST Extension Points

The *action* verb is the main vehicle for extensions. For example, to create a new user with HTTP POST rather than HTTP PUT, you might use `/users?_action=create`. A server can define additional actions. For example, `/tasks/1?_action=cancel`.

A server can define *stored queries* to call by ID. For example, `/groups?_queryId=hasDeletedMembers`. Stored queries can call for additional parameters. The parameters are also passed in the query string. Which parameters are valid depends on the stored query.

Common REST API Documentation

Common REST APIs often depend at least in part on runtime configuration. Many Common REST endpoints therefore serve *API descriptors* at runtime. An API descriptor documents the actual API as it is configured.

Use the following query string parameters to retrieve API descriptors:

`_api`

Serves an API descriptor that complies with the OpenAPI specification.

This API descriptor represents the API accessible over HTTP. It is suitable for use with popular tools such as Swagger UI.

`_crestapi`

Serves a native Common REST API descriptor.

This API descriptor provides a compact representation that is not dependent on the transport protocol. It requires a client that understands Common REST, as it omits many Common REST defaults.

Note

Consider limiting access to API descriptors in production environments in order to avoid unnecessary traffic.

To provide documentation in production environments, see "To Publish OpenAPI Documentation" instead.

To Publish OpenAPI Documentation

In production systems, developers expect stable, well-documented APIs. Rather than retrieving API descriptors at runtime through Common REST, prepare final versions, and publish them alongside the software in production.

Use the OpenAPI-compliant descriptors to provide API reference documentation for your developers as described in the following steps:

1. Configure the software to produce production-ready APIs.

In other words, the software should be configured as in production so that the APIs are identical to what developers see in production.

2. Retrieve the OpenAPI-compliant descriptor.

The following command saves the descriptor to a file, `myapi.json`:

```
$ curl -o myapi.json endpoint?_api
```

3. (Optional) If necessary, edit the descriptor.

For example, you might want to add security definitions to describe how the API is protected.

If you make any changes, then also consider using a source control system to manage your versions of the API descriptor.

4. Publish the descriptor using a tool such as Swagger UI.

You can customize Swagger UI for your organization as described in the documentation for the tool.

Create

There are two ways to create a resource, either with an HTTP POST or with an HTTP PUT.

To create a resource using POST, perform an HTTP POST with the query string parameter `action=create` and the JSON resource as a payload. Accept a JSON response. The server creates the identifier if not specified:

```
POST /users?_action=create HTTP/1.1
Host: example.com
Accept: application/json
Content-Length: ...
Content-Type: application/json
{ JSON resource }
```

To create a resource using PUT, perform an HTTP PUT including the case-sensitive identifier for the resource in the URL path, and the JSON resource as a payload. Use the `If-None-Match: *` header. Accept a JSON response:

```
PUT /users/some-id HTTP/1.1
Host: example.com
Accept: application/json
Content-Length: ...
Content-Type: application/json
If-None-Match: *
{ JSON resource }
```

The `_id` and content of the resource depend on the server implementation. The server is not required to use the `_id` that the client provides. The server response to the create request indicates the resource location as the value of the `Location` header.

If you include the `If-None-Match` header, its value must be `*`. In this case, the request creates the object if it does not exist, and fails if the object does exist. If you include the `If-None-Match` header with any value other than `*`, the server returns an HTTP 400 Bad Request error. For example, creating an object with `If-None-Match: revision` returns a bad request error. If you do not include `If-None-Match: *`, the request creates the object if it does not exist, and *updates* the object if it does exist.

Parameters

You can use the following parameters:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

Read

To retrieve a single resource, perform an HTTP GET on the resource by its case-sensitive identifier (`_id`) and accept a JSON response:

```
GET /users/some-id HTTP/1.1
Host: example.com
Accept: application/json
```

Parameters

You can use the following parameters:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

`_mimeType=mime-type`

Some resources have fields whose values are multi-media resources such as a profile photo for example.

By specifying both a single `field` and also the `mime-type` for the response content, you can read a single field value that is a multi-media resource.

In this case, the content type of the field value returned matches the `mime-type` that you specify, and the body of the response is the multi-media resource.

The `Accept` header is not used in this case. For example, `Accept: image/png` does not work. Use the `_mimeType` query string parameter instead.

Update

To update a resource, perform an HTTP PUT including the case-sensitive identifier (`_id`) as the final element of the path to the resource, and the JSON resource as the payload. Use the `If-Match: _rev` header to check that you are actually updating the version you modified. Use `If-Match: *` if the version does not matter. Accept a JSON response:

```
PUT /users/some-id HTTP/1.1
Host: example.com
Accept: application/json
Content-Length: ...
Content-Type: application/json
If-Match: _rev
{ JSON resource }
```

When updating a resource, include all the attributes to be retained. Omitting an attribute in the resource amounts to deleting the attribute unless it is not under the control of your application. Attributes not under the control of your application include private and read-only attributes. In addition, virtual attributes and relationship references might not be under the control of your application.

Parameters

You can use the following parameters:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

Delete

To delete a single resource, perform an HTTP DELETE by its case-sensitive identifier (`_id`) and accept a JSON response:

```
DELETE /users/some-id HTTP/1.1
Host: example.com
Accept: application/json
```

Parameters

You can use the following parameters:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

Patch

To patch a resource, send an HTTP PATCH request with the following parameters:

- `operation`
- `field`
- `value`
- `from` (optional with copy and move operations)

You can include these parameters in the payload for a PATCH request, or in a JSON PATCH file. If successful, you'll see a JSON response similar to:

```
PATCH /users/some-id HTTP/1.1
Host: example.com
Accept: application/json
Content-Length: ...
Content-Type: application/json
If-Match: _rev
{ JSON array of patch operations }
```

PATCH operations apply to three types of targets:

- **single-valued**, such as an object, string, boolean, or number.
- **list semantics array**, where the elements are ordered, and duplicates are allowed.
- **set semantics array**, where the elements are not ordered, and duplicates are not allowed.

ForgeRock PATCH supports several different `operations`. The following sections show each of these operations, along with options for the `field` and `value`:

Patch Operation: Add

The `add` operation ensures that the target field contains the value provided, creating parent fields as necessary.

If the target field is single-valued, then the value you include in the PATCH replaces the value of the target. Examples of a single-valued field include: object, string, boolean, or number.

An **add** operation has different results on two standard types of arrays:

- **List semantic arrays:** you can run any of these **add** operations on that type of array:
 - If you **add** an array of values, the PATCH operation appends it to the existing list of values.
 - If you **add** a single value, specify an ordinal element in the target array, or use the **{-}** special index to add that value to the end of the list.
- **Set semantic arrays:** The value included in the patch is merged with the existing set of values. Any duplicates within the array are removed.

As an example, start with the following list semantic array resource:

```
{
  "fruits" : [ "orange", "apple" ]
}
```

The following add operation includes the pineapple to the end of the list of fruits, as indicated by the **-** at the end of the **fruits** array.

```
{
  "operation" : "add",
  "field" : "/fruits/-",
  "value" : "pineapple"
}
```

The following is the resulting resource:

```
{
  "fruits" : [ "orange", "apple", "pineapple" ]
}
```

Note that you can add only one array element one at a time, as per the corresponding JSON Patch specification. If you add an array of elements, for example:

```
{
  "operation" : "add",
  "field" : "/fruits/-",
  "value" : ["pineapple", "mango"]
}
```

The resulting resource would have the following invalid JSON structure:

```
{
  "fruits" : [ "orange", "apple", ["pineapple", "mango"] ]
}
```

Patch Operation: Copy

The copy operation takes one or more existing values from the source field. It then adds those same values on the target field. Once the values are known, it is equivalent to performing an **add** operation on the target field.

The following `copy` operation takes the value from a field named `mail`, and then runs a `replace` operation on the target field, `another_mail`.

```
[
  {
    "operation": "copy",
    "from": "mail",
    "field": "another_mail"
  }
]
```

If the source field value and the target field value are configured as arrays, the result depends on whether the array has list semantics or set semantics, as described in "Patch Operation: Add".

Patch Operation: Increment

The `increment` operation changes the value or values of the target field by the amount you specify. The value that you include must be one number, and may be positive or negative. The value of the target field must accept numbers. The following `increment` operation adds `1000` to the target value of `/user/payment`.

```
[
  {
    "operation" : "increment",
    "field" : "/user/payment",
    "value" : "1000"
  }
]
```

Since the `value` of the `increment` is a single number, arrays do not apply.

Patch Operation: Move

The move operation removes existing values on the source field. It then adds those same values on the target field. It is equivalent to performing a `remove` operation on the source, followed by an `add` operation with the same values, on the target.

The following `move` operation is equivalent to a `remove` operation on the source field, `surname`, followed by a `replace` operation on the target field value, `lastName`. If the target field does not exist, it is created.

```
[
  {
    "operation": "move",
    "from": "surname",
    "field": "lastName"
  }
]
```

To apply a `move` operation on an array, you need a compatible single-value, list semantic array, or set semantic array on both the source and the target. For details, see the criteria described in "Patch Operation: Add".

Patch Operation: Remove

The **remove** operation ensures that the target field no longer contains the value provided. If the remove operation does not include a value, the operation removes the field. The following **remove** deletes the value of the **phoneNumber**, along with the field.

```
[
  {
    "operation" : "remove",
    "field" : "phoneNumber"
  }
]
```

If the object has more than one **phoneNumber**, those values are stored as an array.

A **remove** operation has different results on two standard types of arrays:

- **List semantic arrays:** A **remove** operation deletes the specified element in the array. For example, the following operation removes the first phone number, based on its array index (zero-based):

```
[
  {
    "operation" : "remove",
    "field" : "/phoneNumber/0"
  }
]
```

- **Set semantic arrays:** The list of values included in a patch are removed from the existing array.

Patch Operation: Replace

The **replace** operation removes any existing value(s) of the targeted field, and replaces them with the provided value(s). It is essentially equivalent to a **remove** followed by a **add** operation. If the arrays are used, the criteria is based on "Patch Operation: Add". However, indexed updates are not allowed, even when the target is an array.

The following **replace** operation removes the existing **telephoneNumber** value for the user, and then adds the new value of **+1 408 555 9999**.

```
[
  {
    "operation" : "replace",
    "field" : "/telephoneNumber",
    "value" : "+1 408 555 9999"
  }
]
```

A PATCH replace operation on a list semantic array works in the same fashion as a PATCH remove operation. The following example demonstrates how the effect of both operations. Start with the following resource:

```
{
  "fruits" : [ "apple", "orange", "kiwi", "lime" ],
}
```

Apply the following operations on that resource:

```
[
  {
    "operation" : "remove",
    "field" : "/fruits/0",
    "value" : ""
  },
  {
    "operation" : "replace",
    "field" : "/fruits/1",
    "value" : "pineapple"
  }
]
```

The PATCH operations are applied sequentially. The `remove` operation removes the first member of that resource, based on its array index, (`fruits/0`), with the following result:

```
[
  {
    "fruits" : [ "orange", "kiwi", "lime" ],
  }
]
```

The second PATCH operation, a `replace`, is applied on the second member (`fruits/1`) of the intermediate resource, with the following result:

```
[
  {
    "fruits" : [ "orange", "pineapple", "lime" ],
  }
]
```

Patch Operation: Transform

The `transform` operation changes the value of a field based on a script or some other data transformation command. The following `transform` operation takes the value from the field named `/objects`, and applies the `something.js` script as shown:

```
[
  {
    "operation" : "transform",
    "field" : "/objects",
    "value" : {
      "script" : {
        "type" : "text/javascript",
        "file" : "something.js"
      }
    }
  }
]
```

Patch Operation Limitations

Some HTTP client libraries do not support the HTTP PATCH operation. Make sure that the library you use supports HTTP PATCH before using this REST operation.

For example, the Java Development Kit HTTP client does not support PATCH as a valid HTTP method. Instead, the method `HttpURLConnection.setRequestMethod("PATCH")` throws `ProtocolException`.

Parameters

You can use the following parameters. Other parameters might depend on the specific action implementation:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

Action

Actions are a means of extending Common REST APIs and are defined by the resource provider, so the actions you can use depend on the implementation.

The standard action indicated by `_action=create` is described in "Create".

Parameters

You can use the following parameters. Other parameters might depend on the specific action implementation:

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in the body of the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

Query

To query a resource collection (or resource container if you prefer to think of it that way), perform an HTTP GET and accept a JSON response, including at least a `_queryExpression`, `_queryFilter`, or `_queryId` parameter. These parameters cannot be used together:

```
GET /users?_queryFilter=true HTTP/1.1
Host: example.com
Accept: application/json
```

The server returns the result as a JSON object including a "results" array and other fields related to the query string parameters that you specify.

Parameters

You can use the following parameters:

`_queryFilter=filter-expression`

Query filters request that the server return entries that match the filter expression. You must URL-escape the filter expression.

The string representation is summarized as follows. Continue reading for additional explanation:

```
Expr           = OrExpr
OrExpr         = AndExpr ( 'or' AndExpr ) *
AndExpr       = NotExpr ( 'and' NotExpr ) *
NotExpr       = '!' PrimaryExpr | PrimaryExpr
PrimaryExpr   = '(' Expr ')' | ComparisonExpr | PresenceExpr | LiteralExpr
ComparisonExpr = Pointer OpName JsonValue
PresenceExpr  = Pointer 'pr'
LiteralExpr   = 'true' | 'false'
Pointer       = JSON pointer
OpName        = 'eq' | # equal to
               'co' | # contains
               'sw' | # starts with
               'lt' | # less than
               'le' | # less than or equal to
               'gt' | # greater than
               'ge' | # greater than or equal to
               STRING # extended operator
JsonValue     = NUMBER | BOOLEAN | ''' UTF8STRING '''
STRING        = ASCII string not containing white-space
UTF8STRING    = UTF-8 string possibly containing white-space
```

JsonValue components of filter expressions follow RFC 7159: *The JavaScript Object Notation (JSON) Data Interchange Format*. In particular, as described in section 7 of the RFC, the escape character in strings is the backslash character. For example, to match the identifier `test\`, use `_id eq 'test\\'`. In the JSON resource, the `\` is escaped the same way: `"_id":"test\\"`.

When using a query filter in a URL, be aware that the filter expression is part of a query string parameter. A query string parameter must be URL encoded as described in RFC 3986: *Uniform Resource Identifier (URI): Generic Syntax* For example, white space, double quotes ("), parentheses, and exclamation characters need URL encoding in HTTP query strings. The following rules apply to URL query components:

```

query      = *( pchar / "/" / "?" )
pchar     = unreserved / pct-encoded / sub-delims / ":" / "@"
unreserved = ALPHA / DIGIT / "-" / "." / "_" / "~"
pct-encoded = "%" HEXDIG HEXDIG
sub-delims = "!" / "$" / "&" / "'" / "(" / ")"
           / "*" / "+" / "," / ";" / "="

```

ALPHA, DIGIT, and HEXDIG are core rules of RFC 5234: *Augmented BNF for Syntax Specifications*:

```

ALPHA     = %x41-5A / %x61-7A ; A-Z / a-z
DIGIT     = %x30-39 ; 0-9
HEXDIG    = DIGIT / "A" / "B" / "C" / "D" / "E" / "F"

```

As a result, a backslash escape character in a *JsonValue* component is percent-encoded in the URL query string parameter as %5C. To encode the query filter expression `_id eq 'test\\'`, use `_id +eq+'test%5C%5C'`, for example.

A simple filter expression can represent a comparison, presence, or a literal value.

For comparison expressions use *json-pointer comparator json-value*, where the *comparator* is one of the following:

```

eq (equals)
co (contains)
sw (starts with)
lt (less than)
le (less than or equal to)
gt (greater than)
ge (greater than or equal to)

```

For presence, use *json-pointer pr* to match resources where:

- The JSON pointer is present.
- The value it points to is not `null`.

Literal values include `true` (match anything) and `false` (match nothing).

Complex expressions employ `and`, `or`, and `!` (not), with parentheses, (*expression*), to group expressions.

`_queryId=identifier`

Specify a query by its identifier.

Specific queries can take their own query string parameter arguments, which depend on the implementation.

`_pagedResultsCookie=string`

The string is an opaque cookie used by the server to keep track of the position in the search results. The server returns the cookie in the JSON response as the value of `pagedResultsCookie`.

In the request `_pageSize` must also be set and non-zero. You receive the cookie value from the provider on the first request, and then supply the cookie value in subsequent requests until the server returns a `null` cookie, meaning that the final page of results has been returned.

The `_pagedResultsCookie` parameter is supported when used with the `_queryFilter` parameter. The `pagedResultsCookie` parameter is not guaranteed to work when used with the `_queryExpression` and `_queryId` parameters.

The `_pagedResultsCookie` and `_pagedResultsOffset` parameters are mutually exclusive, and not to be used together.

`_pagedResultsOffset=integer`

When `_pageSize` is non-zero, use this as an index in the result set indicating the first page to return.

The `_pagedResultsCookie` and `_pagedResultsOffset` parameters are mutually exclusive, and not to be used together.

`_pageSize=integer`

Return query results in pages of this size. After the initial request, use `_pagedResultsCookie` or `_pageResultsOffset` to page through the results.

`_totalPagedResultsPolicy=string`

When a `_pageSize` is specified, and non-zero, the server calculates the "totalPagedResults", in accordance with the `totalPagedResultsPolicy`, and provides the value as part of the response. The "totalPagedResults" is either an estimate of the total number of paged results (`_totalPagedResultsPolicy=ESTIMATE`), or the exact total result count (`_totalPagedResultsPolicy=EXACT`). If no count policy is specified in the query, or if `_totalPagedResultsPolicy=NONE`, result counting is disabled, and the server returns value of -1 for "totalPagedResults".

`_sortKeys=[+]field [, [+]field ...]`

Sort the resources returned based on the specified field(s), either in `+` (ascending, default) order, or in `-` (descending) order.

Because ascending order is the default, including the `+` character in the query is unnecessary. If you do include the `+`, it must be URL-encoded as `%2B`, for example:

```
http://localhost:8080/api/users?_prettyPrint=true&_queryFilter=true&_sortKeys=%2Bname/givenName
```

The `_sortKeys` parameter is not supported for predefined queries (`_queryId`).

`_prettyPrint=true`

Format the body of the response.

`_fields=field[,field...]`

Return only the specified fields in each element of the "results" array in the response.

The `field` values are JSON pointers. For example if the resource is `{"parent":{"child":"value"}}`, `parent/child` refers to the `"child":"value"`.

If the `field` is left blank, the server returns all default values.

HTTP Status Codes

When working with a Common REST API over HTTP, client applications should expect at least the following HTTP status codes. Not all servers necessarily return all status codes identified here:

200 OK

The request was successful and a resource returned, depending on the request.

201 Created

The request succeeded and the resource was created.

204 No Content

The action request succeeded, and there was no content to return.

304 Not Modified

The read request included an `If-None-Match` header, and the value of the header matched the revision value of the resource.

400 Bad Request

The request was malformed.

401 Unauthorized

The request requires user authentication.

403 Forbidden

Access was forbidden during an operation on a resource.

404 Not Found

The specified resource could not be found, perhaps because it does not exist.

405 Method Not Allowed

The HTTP method is not allowed for the requested resource.

406 Not Acceptable

The request contains parameters that are not acceptable, such as a resource or protocol version that is not available.

409 Conflict

The request would have resulted in a conflict with the current state of the resource.

410 Gone

The requested resource is no longer available, and will not become available again. This can happen when resources expire for example.

412 Precondition Failed

The resource's current version does not match the version provided.

415 Unsupported Media Type

The request is in a format not supported by the requested resource for the requested method.

428 Precondition Required

The resource requires a version, but no version was supplied in the request.

500 Internal Server Error

The server encountered an unexpected condition that prevented it from fulfilling the request.

501 Not Implemented

The resource does not support the functionality required to fulfill the request.

503 Service Unavailable

The requested resource was temporarily unavailable. The service may have been disabled, for example.

Cross-Site Request Forgery (CSRF) Protection

AM includes a global filter to harden AM's protection against CSRF attacks. The filter applies to all REST endpoints under `json/` and requires that all requests other than GET, HEAD, or OPTIONS include, at least, one of the following headers:

- `X-Requested-With`

This header is often sent by Javascript frameworks, and the XUI already sends it on all requests.

- **Accept-API-Version**

This header specifies which version of the REST API to use. Use this header in your requests to ensure future changes to the API do not affect your clients.

For more information about API versioning, see "REST API Versioning".

Failure to include at least one of the headers would cause the REST call to fail with a **403 Forbidden** error, even if the SSO token is valid.

To disable the filter, navigate to Configure > Global Services > REST APIs > and turn off Enable CSRF Protection.

The `json/` endpoint is not vulnerable to CSRF attacks when the filter is disabled, since it requires the "Content-Type: `application/json`" header, which currently triggers the same protection in browsers. This may change in the future, so it is recommended to enable the CSRF filter.

REST API Versioning

In OpenAM 12.0.0 and later, REST API features are assigned version numbers.

Providing version numbers in the REST API helps ensure compatibility between releases. The version number of a feature increases when AM introduces a non-backwards-compatible change that affects clients making use of the feature.

AM provides versions for the following aspects of the REST API.

resource

Any changes to the structure or syntax of a returned response will incur a *resource* version change. For example changing `errorMessage` to `message` in a JSON response.

protocol

Any changes to the methods used to make REST API calls will incur a *protocol* version change. For example changing `_action` to `$action` in the required parameters of an API feature.

To ensure your clients are always compatible with a newer version of AM, you should always include resource versions in your REST calls.

Supported REST API Versions

For information about the supported protocol and resource versions available in AM, see the API Explorer in the *Development Guide* available in the AM console.

The *AM Release Notes* section, "Changes and Deprecated Functionality" in the *Release Notes* describes the differences between API versions.

Specifying an Explicit REST API Version

You can specify which version of the REST API to use by adding an `Accept-API-Version` header to the request. The following example requests *resource* version 2.0 and *protocol* version 1.0:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
```

You can configure the default behavior AM will take when a REST call does not specify explicit version information. For more information, see "Configuring the Default REST API Version for a Deployment".

Configuring the Default REST API Version for a Deployment

You can configure the default behavior AM will take when a REST call does not specify explicit version information using either of the following procedures:

- "Configure Versioning Behavior by using the AM Console"
- "Configure Versioning Behavior by Using the ssoadm Command"

The available options for default behavior are as follows:

Latest

The latest available supported version of the API is used.

This is the preset default for new installations of AM.

Oldest

The oldest available supported version of the API is used.

This is the preset default for upgraded AM instances.

Note

The oldest supported version may not be the first that was released, as APIs versions become deprecated or unsupported. See "Deprecated Functionality" in the *Release Notes*.

None

No version will be used. When a REST client application calls a REST API without specifying the version, AM returns an error and the request fails.

Configure Versioning Behavior by using the AM Console

1. Log in as AM administrator, `amadmin`.
2. Click Configure > Global Services, and then click REST APIs.
3. In Default Version, select the required response to a REST API request that does not specify an explicit version: `Latest`, `Oldest`, or `None`.
4. (Optional) Optionally, enable `Warning Header` to include warning messages in the headers of responses to requests.
5. Save your work.

Configure Versioning Behavior by Using the `ssoadm` Command

- Use the `ssoadm set-attr-defs` command with the `openam-rest-apis-default-version` attribute set to either `Latest`, `Oldest` or `None`, as in the following example:

```
$ ssh openam.example.com
$ cd /path/to/openam-tools/admin/openam/bin
$ ./ssoadm \
  set-attr-defs \
  --adminid amadmin \
  --password-file /tmp/pwd.txt \
  --servicename RestApisService \
  --schematype Global \
  --attributevalues openam-rest-apis-default-version=None
Schema attribute defaults were set.
```

REST API Versioning Messages

AM provides REST API version messages in the JSON response to a REST API call. You can also configure AM to return version messages in the response headers.

Messages include:

- Details of the REST API versions used to service a REST API call.
- Warning messages if REST API version information is not specified or is incorrect in a REST API call.

The `resource` and `protocol` version used to service a REST API call are returned in the `Content-API-Version` header, as shown below:

```
$ curl \
-i \
--request POST \
--header "Content-Type: application/json" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
HTTP/1.1 200 OK
Content-API-Version: protocol=1.0,resource=2.0
Server: Restlet-Framework/2.1.7
Content-Type: application/json;charset=UTF-8

{
  "tokenId":"AQIC5wM...TU30Q*",
  "successUrl":"/openam/console"
}
```

If the default REST API version behavior is set to **None**, and a REST API call does not include the **Accept-API-Version** header, or does not specify a **resource** version, then a **400 Bad Request** status code is returned, as shown below:

```
$ curl \
--header "Content-Type: application/json" \
--header "Accept-API-Version: protocol=1.0" \
https://openam.example.com:8443/openam/json/realms/root/serverinfo/*
{
  "code":400,
  "reason":"Bad Request",
  "message":"No requested version specified and behavior set to NONE."
}
```

If a REST API call does include the **Accept-API-Version** header, but the specified **resource** or **protocol** version does not exist in AM, then a **404 Not Found** status code is returned, as shown below:

```
$ curl \
--header "Content-Type: application/json" \
--header "Accept-API-Version: protocol=1.0, resource=999.0" \
https://openam.example.com:8443/openam/json/realms/root/serverinfo/*
{
  "code":404,
  "reason":"Not Found",
  "message":"Accept-API-Version: Requested version \"999.0\" does not match any routes."
}
```

Tip

For more information on setting the default REST API version behavior, see "Specifying an Explicit REST API Version".

Specifying Realms in REST API Calls

This section describes how to work with realms when making REST API calls to AM.

Realms can be specified in the following ways when making a REST API call to AM:

DNS Alias

When making a REST API call, the DNS alias of a realm can be specified in the subdomain and domain name components of the REST endpoint.

To list all users in the top-level realm use the DNS alias of the AM instance, for example, the REST endpoint would be:

```
https://openam.example.com:8443/openam/json/users?_queryId=*
```

To list all users in a realm with DNS alias `suppliers.example.com` the REST endpoint would be:

```
https://suppliers.example.com:8443/openam/json/users?_queryId=*
```

Path

When making a REST API call, specify the realm in the path component of the endpoint. You must specify the entire hierarchy of the realm, starting at the top-level realm. Prefix each realm in the hierarchy with the `realms/` keyword. For example `/realms/root/realms/customers/realms/europe`.

To authenticate a user in the top-level realm, use the `root` keyword. For example:

```
https://openam.example.com:8443/openam/json/realms/root/authenticate
```

To authenticate a user in a subrealm named `customers` within the top-level realm, the REST endpoint would be:

```
https://openam.example.com:8443/openam/json/realms/root/realms/customers/authenticate
```

If realms are specified using both the DNS alias and path methods, the path is used to determine the realm.

For example, the following REST endpoint returns users in a subrealm of the top-level realm named `europe`, not the realm with DNS alias `suppliers.example.com`:

```
https://suppliers.example.com:8443/openam/json/realms/root/realms/europe/users?_queryId=*
```

Authentication and Logout using REST

You can use REST-like APIs under `/json/authenticate` and `/json/sessions` for authentication and for logout.

The `/json/authenticate` endpoint does not support the CRUDPAQ verbs and therefore does not technically satisfy REST architectural requirements. The term *REST-like* describes this endpoint better than *REST*.

After a successful authentication, AM returns a `tokenId` object that applications can present as a cookie value for other operations that require authentication. This object is a session in the *Authentication and Single Sign-On Guide* token—a representation of the exchange of information and credentials between AM and the user or identity.

The type of `tokenId` returned varies depending on where AM stores the sessions for the realm to which the user authenticates:

- If CTS-based sessions are enabled, the `tokenId` object is a reference to the session state stored in the CTS token store.
- If client-based sessions are enabled, the `tokenId` object is the session state for that particular user or identity.

Developers should be aware that the size of the `tokenId` for client-based sessions—2000 bytes or greater—is considerably longer than for CTS-based sessions—approximately 100 bytes. For more information about session tokens, see "Session Cookies" in the *Authentication and Single Sign-On Guide*.

Authenticating to AM using REST

To log in to AM using REST, make an HTTP POST request to the `json/authenticate` endpoint. You must specify the entire hierarchy of the realm, starting at the Top Level Realm. Prefix each realm in the hierarchy with the `realms/` keyword. For example, `/realms/root/realms/customers/realms/europe`.

AM uses the default authentication service configured for the realm. You can override the default by specifying authentication services and other options in the REST request.

AM provides both simple authentication methods, such as providing user name and password, and complex authentication journeys that may involve a tree with inner tree evaluation and/or multi-factor authentication.

For authentication journeys where providing a user name and password is enough, you can log in to AM using a `curl` command similar to the following:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
{
  "tokenId": "AQIC5w...NTcy*",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

The user name and password are sent in headers. This zero page login mechanism works only for name/password authentication.

Note that the POST body is empty; otherwise, AM interprets the body as a continuation of an existing authentication attempt, one that uses a supported callback mechanism. AM implements callback mechanisms to support complex authentication journeys, such as those where the user needs to be redirected to a third party or interact with a device as part of multi-factor authentication.

When a client makes a call to the `/json/authenticate` endpoint appending a valid SSO token, AM returns the `tokenId` field **empty** when `HttpOnly` cookies are enabled. For example:

```
{
  "tokenId": "",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

Tip

About Success and Failure URLs

On authentication success, AM returns an SSO token and a success URL. By default, users are redirected to `/openam/console`.

No failure URL is configured by default. When configured, on authentication failure, AM returns HTTP status code 401 Unauthorized and the failure URL:

```
{
  "code": 401,
  "reason": "Unauthorized",
  "message": "Login failure",
  "failureUrl": "http://www.example.com/401.html"
}
```

For more information about configuring successful or failed authentication, see "Configuring Success and Failure Redirection URLs" in the *Authentication and Single Sign-On Guide*.

Using UTF-8 User Names

To use UTF-8 user names and passwords in calls to the `/json/authenticate` endpoint, base64-encode the string, and then wrap the string as described in RFC 2047:

```
encoded-word = "=?" charset "?" encoding "?" encoded-text "=?"
```

For example, to authenticate using a UTF-8 username, such as `dëmjø`, perform the following steps:

1. Encode the string in base64 format: `yZfDq8mxw7g=`.
2. Wrap the base64-encoded string as per RFC 2047: `=?UTF-8?B?yZfDq8mxw7g=?=`.
3. Use the result in the `X-OpenAM-Username` header passed to the authentication endpoint as follows:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "X-OpenAM-Username: =?UTF-8?B?yZfDq8mxw7g=?=" \
--header "X-OpenAM-Password: changeit" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realm/root/authenticate'
{
  "tokenId": "AQIC5w...NTcy*",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

Authenticating to Specific Authentication Services

You can provide AM with additional information about how you are authenticating. For example, you can specify the authentication tree you want to use, or request from AM a list of the authentication services that would satisfy a particular authentication condition.

The following example shows how to specify the `ldapService` chain by using the `authIndexType` and `authIndexValue` query string parameters:

```
$ curl \
--request POST \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?
authIndexType=service&authIndexValue=ldapService'
```

You can exchange the `ldapService` chain with any other chain or tree.

For more information about using the `authIndexType` parameter to authenticate to specific services, see "Authenticate Endpoint Parameters".

Authenticate Endpoint Parameters

To authenticate to AM using REST, make an HTTP POST request to the `/json/authenticate` endpoint. You must specify the entire hierarchy of the realm, starting at the Top Level Realm. Prefix each realm in the hierarchy with the `realms/` keyword. For example, `/realms/root/realms/customers/realms/europe`.

The following list describes the `/json/authenticate` endpoint supported parameters:

`authIndexType`

Specifies the type of authentication the user will perform. Always use in conjunction with the `authIndexValue` parameter to provide additional information about the way the user is authenticating.

If not specified, AM authenticates the user against the default authentication service configured for the realm.

The `authIndexType` parameter supports the following types:

- `composite_advice`

Specifies that the value of the `authIndexValue` parameter is a URL-encoded composite advice string.

Use `composite_advice` when you want to give AM hints of which authentication services to use when logging in a user. For example, use an authentication service that provides an authentication level of 10 or higher:

```
$ curl -get \
--request POST \
--header "Content-Type: application/json" \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
--data-urlencode 'authIndexType=composite_advice' \
--data-urlencode 'authIndexValue=<Advices>
  <AttributeValuePair>
    <Attribute name="AuthLevelConditionAdvice"/>
    <Value>10</Value>
  </AttributeValuePair>
</Advices>' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
```

Note that the previous `curl` command URL-encodes the XML values, and the `-G` parameter appends them as query string parameters to the URL.

Possible options for advices are:

- **TransactionConditionAdvice**. Requires the unique ID of a transaction token. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="TransactionConditionAdvice"/>
    <Value>9dae2c80-fe7a-4a36-b57b-4fb1271b0687</Value>
  </AttributeValuePair>
</Advices>
```

For more information, see *"Implementing Transactional Authorization"* in the *Authorization Guide*.

- **AuthenticateToServiceConditionAdvice**. Requires the name of an authentication chain or tree. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthenticateToServiceConditionAdvice"/>
    <Value>myExampleTree</Value>
  </AttributeValuePair>
</Advices>
```

- **AuthSchemeConditionAdvice**. Requires the name of an authentication module. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthSchemeConditionAdvice"/>
    <Value>DataStoreModule</Value>
  </AttributeValuePair>
</Advices>
```

- **AuthenticateToRealmConditionAdvice**. Requires the name of a realm. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthenticateToRealmConditionAdvice"/>
    <Value>myRealm</Value>
  </AttributeValuePair>
</Advices>
```

- **AuthLevelConditionAdvice**. Requires an authentication level. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthLevelConditionAdvice"/>
    <Value>10</Value>
  </AttributeValuePair>
</Advices>
```

- **AuthenticateToTreeConditionAdvice**. Requires the name of an authentication tree. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthenticateToTreeConditionAdvice"/>
    <Value>PersistentCookieTree</Value>
  </AttributeValuePair>
</Advices>
```

You can specify multiple advice conditions and combine them. For example:

```
<Advices>
  <AttributeValuePair>
    <Attribute name="AuthenticateToServiceConditionAdvice"/>
    <Value>ldapService</Value>
  </AttributeValuePair>
  <AttributeValuePair>
    <Attribute name="AuthenticateToServiceConditionAdvice"/>
    <Value>Example</Value>
  </AttributeValuePair>
  <AttributeValuePair>
    <Attribute name="AuthLevelConditionAdvice"/>
    <Value>10</Value>
  </AttributeValuePair>
</Advices>
```

- level

Specifies that the value of the `authIndexValue` parameter is the minimum authentication level an authentication service must satisfy to log in the user.

For example, to log into AM using an authentication service that provides a minimum authentication level of 10, you could use the following:

```
$ curl \
  --request POST \
  --header 'Accept-API-Version: resource=2.0, protocol=1.0' \
  'https://openam.example.com:8443/openam/json/realms/root/authenticate?
  authIndexType=level&authIndexValue=10'
```

- module

Specifies that the value of the `authIndexValue` parameter is the name of the authentication module AM must use to log in the user.

For example, to log into AM using the built-in `DataStore` authentication module, you could use the following:

```
$ curl \
--request POST \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?
authIndexType=module&authIndexValue=DataStore'
```

- resource

Specifies that the value of the `authIndexValue` parameter is a URL protected by an AM policy.

For example, to log into AM using a policy matching the `http://www.example.com` resource, you could use the following:

```
$ curl \
--request POST \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?
authIndexType=resource&authIndexValue=http%3A%2F%2Fwww.example.com'
```

Note that the resource must be URL-encoded. Authentication will fail if no policy matches the resource.

- service

Specifies that the value of the `authIndexValue` parameter is the name of an authentication tree or authentication chain AM must use to log in the user.

For example, to log in to AM using the built-in `ldapService` authentication chain, you could use the following:

```
$ curl \
--request POST \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?
authIndexType=service&authIndexValue=ldapService'
```

- user

Specifies that the value of the `authIndexValue` parameter is a valid user ID. AM will then authenticate the user against the chain configured in the User Authentication Configuration field of that user's profile.

For example, for the user `demo` to log into AM using the chain specified in their user profile, you could use the following:

```
$ curl \
--request POST \
--header 'Accept-API-Version: resource=2.0, protocol=1.0' \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?
authIndexType=user&authIndexValue=demo'
```

Authentication will fail if the User Authentication Configuration field is empty for the user.

If several authentication services that satisfy the authentication requirements are available, AM presents them as a choice callback to the user. Return the required callbacks to AM to authenticate.

Required: No.

authIndexValue

Specifies the value of the **authIndexType** parameter.

Required: Yes, when using the **authIndexType** parameter.

noSession

When set to **true**, specifies that AM should not return a session when authenticating a user. For example:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate?noSession=true'
{
  "message": "Authentication Successful",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

Required: No.

Returning Callback Information to AM

The `/json/authenticate` endpoint supports callback mechanisms to perform complex authentication journeys. Whenever AM needs to return or request information, it will return a JSON object with the authentication step, the authentication identifier, and the related callbacks.

The following types of callbacks are available:

- *Read-only callbacks.* AM uses read-only callbacks to provide information to the user, such as text messages or the amount of time that the user needs to wait before continuing their authentication journey.

- *Interactive callbacks.* AM uses interactive callbacks ask the user for information. For example, to request their user name and password, or to request that the user chooses between different options.
- *Backchannel callbacks.* AM uses backchannel callbacks when it needs to access additional information from the user's request. For example, when it requires a particular header or a certificate.

Read-only and interactive callbacks have an array of **output** elements suitable for displaying to the end user. The JSON returned in interactive callbacks also contains an array of **input** elements, which must be completed and returned to AM. For example:

```
"output": [
  {
    "name": "prompt",
    "value": " User Name: "
  }
],
"input": [
  {
    "name": "IDToken1",
    "value": ""
  }
]
```

The value of some interactive callbacks can be returned as headers, such as the **X-OpenAM-Username** and **X-OpenAM-Password** headers, but most of them must be returned in JSON as a response to the request.

Depending on how complex the authentication journey is, AM may return several callbacks sequentially. Each must be completed and returned to AM until authentication is successful.

The following example shows a request for authentication, and AM's response of the **NameCallback** and **PasswordCallback** callbacks:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'

{
  "authId": "eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9.eyJvdiIjOiJ... ", ❶

```

Key:

- ❶ The JWT that uniquely identifies the authentication context to AM.
- ❷ A template to customize the look of the authentication module, if exists. For more information, see [How do I customize the Login page?](#) in the *ForgeRock Knowledge Base*.
- ❸ The authentication module stage where the authentication journey is at the moment.
- ❹ The type of callback. It must be one the "Supported Callbacks".
- ❺ The information AM offers about this callback. Usually, this information would be displayed to the user in the UI.
- ❻ The information AM is requesting. The user must fill the "value": "" object with the required information.

To respond to a callback, send back the whole JSON object with the missing values filled. The following example shows how to respond to the `NameCallback` and `PasswordCallback` callbacks, with the `demo` and `changeit` values filled:

```

$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
--data '{
  "authId": ""eyJ0eXAiOiJKV1QiLCJhbGciOiJIUzI1NiJ9.eyJvdGsiOiJ...",
  "template": "",
  "stage": "DataStore1",
  "callbacks": [
    {
      "type": "NameCallback",
      "output": [
        {
          "name": "prompt",
          "value": " User Name: "
        }
      ]
    }
  ]
}

```

```

    ],
    "input": [
      {
        "name": "IDToken1",
        "value": "demo"
      }
    ]
  },
  {
    "type": "PasswordCallback",
    "output": [
      {
        "name": "prompt",
        "value": " Password: "
      }
    ],
    "input": [
      {
        "name": "IDToken2",
        "value": "changeit"
      }
    ]
  }
]
}
} \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
{
  "tokenId": "AQIC5wM2...U3MTE4NA..*",
  "successUrl": "/openam/console",
  "realm": "/"
}

```

On complex authentication journeys, AM may send several callbacks sequentially. Each must be completed and returned to AM until authentication is successful.

Supported Callbacks

The following types of callbacks are available:

- Interactive Callbacks
- Read-only Callbacks
- Backchannel Callbacks

Interactive Callbacks

AM returns the following callbacks to request information from the user:

ChoiceCallback

Used to display a list of choices and retrieve the selected choice. To indicate that the user selected the first choice, return a value of **0** to AM. For the second choice, return a value of **1**, and so forth. For example:

```

"callbacks":[
  {
    "type":"ChoiceCallback",
    "output":[
      {
        "name":"prompt",
        "value":"Choose one"
      },
      {
        "name":"choices",
        "value":[
          "Choice A",
          "Choice B",
          "Choice C"
        ]
      },
      {
        "name":"defaultChoice",
        "value":2
      }
    ],
    "input":[
      {
        "name":"IDToken1",
        "value":0
      }
    ]
  }
]

```

Class to import: `javax.security.auth.callback.ChoiceCallback`

ConfirmationCallback

Used to ask for a boolean-style confirmation, such as yes/no or true/false, and retrieve the response. Also can present a "Cancel" option. To indicate that the user selected the first choice, return a value of `0` to AM. For the second choice, return a value of `1`, and so forth. For example:

```

"callbacks":[
  {
    "type":"ConfirmationCallback",
    "output":[
      {
        "name":"prompt",
        "value":""
      },
      {
        "name":"messageType",
        "value":0
      },
      {
        "name":"options",
        "value":[
          "Submit",
          "Start Over",
          "Cancel"
        ]
      }
    ]
  }
]

```

```
    },
    {
      "name": "optionType",
      "value": -1
    },
    {
      "name": "defaultOption",
      "value": 1
    }
  ],
  "input": [
    {
      "name": "IDToken2",
      "value": 0
    }
  ]
}
]
```

Class to import: `javax.security.auth.callback.ConfirmationCallback`

NameCallback

Used to retrieve a data string which can be entered by the user. Usually used for collecting user names. For example:

```
"callbacks": [
  {
    "type": "NameCallback",
    "output": [
      {
        "name": "prompt",
        "value": "User Name"
      }
    ],
    "input": [
      {
        "name": "IDToken1",
        "value": ""
      }
    ]
  }
]
```

Class to import: `javax.security.auth.callback.NameCallback`

PasswordCallback

Used to retrieve a password value. For example:

```
"callbacks":[
  {
    "type":"PasswordCallback",
    "output":[
      {
        "name":"prompt",
        "value":"Password"
      }
    ],
    "input":[
      {
        "name":"IDToken1",
        "value":""
      }
    ]
  }
]
```

Class to import: `javax.security.auth.callback.PasswordCallback`

TextInputCallback

Used to retrieve text input from the end user. For example

```
"callbacks":[
  {
    "type":"TextInputCallback",
    "output":[
      {
        "name":"prompt",
        "value":"User Name"
      }
    ],
    "input":[
      {
        "name":"IDToken1",
        "value":""
      }
    ]
  }
]
```

Class to import: `javax.security.auth.callback.TextInputCallback`

Read-only Callbacks

HiddenValueCallback

Used to return form values that are not visually rendered to the end user. For example:

```
"callbacks":[
  {
    "type":"HiddenValueCallback",
    "output":[
      {
        "name":"value",
        "value":"6186c911-b3be-4dbc-8192-bdf251392072"
      },
      {
        "name":"id",
        "value":"jwt"
      }
    ],
    "input":[
      {
        "name":"IDToken1",
        "value":"jwt"
      }
    ]
  }
]
```

Class to import: `com.sun.identity.authentication.callbacks.HiddenValueCallback`

MetadataCallback

Used to inject key-value meta data into the authentication process. For example:

```
"callbacks":[
  {
    "type":"MetadataCallback",
    "output":[
      {
        "name":"data",
        "value":{"
          "myParameter": "MyValue"
        }
      }
    ]
  }
]
```

Class to import: `com.sun.identity.authentication.spi.MetadataCallback`

PollingWaitCallback

Tells the user the amount of time to wait before responding to the callback.

```
"callbacks":[
  {
    "type":"PollingWaitCallback",
    "output":[
      {
        "name":"waitTime",
        "value":"8000"
      },
      {
        "name":"message",
        "value":"Waiting for response..."
      }
    ]
  }
]
```

Class to import: `org.forgerock.openam.authentication.callbacks.PollingWaitCallback`

RedirectCallback

Used to redirect the user's browser or user-agent.

```
"callbacks":[
  {
    "type":"RedirectCallback",
    "output":[
      {
        "name":"redirectUrl",
        "value":"https://accounts.google.com/o/oauth2/v2/auth?nonce..."
      },
      {
        "name":"redirectMethod",
        "value":"GET"
      },
      {
        "name":"trackingCookie",
        "value":true
      }
    ]
  }
]
```

Class to import: `com.sun.identity.authentication.spi.RedirectCallback`

TextOutputCallback

Used to display a message to the end user.

```
"callbacks":[
  {
    "type":"TextOutputCallback",
    "output":[
      {
        "name":"message",
        "value":"Default message"
      },
      {
        "name":"messageType",
        "value":"0"
      }
    ]
  }
]
```

Class to import: `javax.security.auth.callback.TextOutputCallback`

Backchannel Callbacks

AM uses backchannel callbacks when it needs to recover additional information from the user's request. For example, when it requires a particular header or a certificate.

HttpCallback

Used to access user credentials sent in the Authorization header. For example:

```
Authorization: Basic bXlDbGllbnQ6Zm9yZ2Vybn2Nr
```

Class to import: `com.sun.identity.authentication.spi.HttpCallback`

LanguageCallback

Used to retrieve the locale for localizing text presented to the end user. The locale is sent in the request as a header.

Class to import: `javax.security.auth.callback.LanguageCallback`

ScriptTextOutputCallback

Used to insert a script into the page presented to the end user. The script can, for example, collect data about the user's environment.

Class to import: `com.sun.identity.authentication.callbacks.ScriptTextOutputCallback`

X509CertificateCallback

Used to retrieve the content of an x.509 certificate, for example, from a header.

Class to import: `com.sun.identity.authentication.spi.X509CertificateCallback`

Logging out of AM Using REST

Authenticated users can log out with the token cookie value and an HTTP POST to `/json/sessions/?_action=logout`:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Cache-Control: no-cache" \
--header "iPlanetDirectoryPro: AQIC5wM2...U3MTE4NA..*" \
--header "Accept-API-Version: resource=3.1, protocol=1.0" \
https://openam.example.com:8443/openam/json/realms/root/sessions/?_action=logout
{
  "result": "Successfully logged out"
}
```

Invalidating All Sessions for a Given User

To log out all sessions for a given user, first obtain a list of session handles of their active sessions, by performing an HTTP GET to the `/json/sessions/` endpoint, using the SSO token of an administrative user, such as `amAdmin` as the value of the `iPlanetDirectoryPro` header. You must also specify a `queryFilter` parameter.

The `queryFilter` parameter requires the name of the user, and the realm to search. For example, to obtain a list of session handles for a user named `demo` in the top-level realm, the query filter value would be:

```
username eq "demo" and realm eq "/"
```

Note

The query filter value must be URL encoded when sent over HTTP.

For more information on query filter parameters, see "Query" in the *Authentication and Single Sign-On Guide*.

In the following example, there are two active sessions:

```
$ curl \
--request GET \
--header "Content-Type: application/json" \
--header "Cache-Control: no-cache" \
--header "iPlanetDirectoryPro: AQICS...NzEz*" \
--header "Accept-API-Version: resource=3.1, protocol=1.0" \
https://openam.example.com:8443/openam/json/realms/root/sessions?_queryFilter=username%20eq%20%22demo%22%20and%20realm%20eq%20%22%2F%22
{
  "result": [
    {
      "username": "demo",
      "universalId": "id=demo,ou=user,dc=openam,dc=forgerock,dc=org",
      "realm": "/",
      "sessionHandle": "shandle:SJ80.*AA...JT.*",
    }
  ]
}
```

```

    "latestAccessTime": "2018-10-23T09:37:54.387Z",
    "maxIdleExpirationTime": "2018-10-23T10:07:54Z",
    "maxSessionExpirationTime": "2018-10-23T11:37:54Z"
  },
  {
    "username": "demo",
    "universalId": "id=demo,ou=user,dc=openam,dc=forgerock,dc=org",
    "realm": "/",
    "sessionHandle": "shandle:H4CV.*DV...FM.*",
    "latestAccessTime": "2018-10-23T09:37:43.780Z",
    "maxIdleExpirationTime": "2018-10-23T10:07:43Z",
    "maxSessionExpirationTime": "2018-10-23T11:37:43Z"
  }
],
"resultCount": 2,
"pagedResultsCookie": null,
"totalPagedResultsPolicy": "NONE",
"totalPagedResults": -1,
"remainingPagedResults": -1
}

```

To log out all sessions for the specific user, perform an HTTP POST to the `/json/sessions/` endpoint, using the SSO token of an administrative user, such as `amAdmin` as the value of the `iPlanetDirectoryPro` header. You must also specify the `logoutByHandle` action, and include an array of the session handles to invalidate in the POST body, in a property named `sessionHandles`, as shown below:

```

$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Cache-Control: no-cache" \
--header "iPlanetDirectoryPro: AQIC5w...NTcy*" \
--header "Accept-API-Version: resource=3.1, protocol=1.0" \
--data '{
  "sessionHandles": [
    "shandle:SJ80.*AA...JT.*",
    "shandle:H4CV.*DV...FM.*"
  ]
}' \
https://openam.example.com:8443/openam/json/realms/root/sessions/?_action=logoutByHandle
{
  "result": {
    "shandle:SJ80.*AA...JT.*": true,
    "shandle:H4CV.*DV...FM.*": true
  }
}

```

Load Balancer and Proxy Layer Requirements

When authentication depends on the client IP address and AM lies behind a load balancer or proxy layer, configure the load balancer or proxy to send the address by using the `X-Forwarded-For` header, and configure AM to consume and forward the header as necessary. For details, see "Handling HTTP Request Headers" in the *Installation Guide*.

Windows Desktop SSO Requirements

When authenticating with Windows Desktop SSO, add an **Authorization** header containing the string **Basic**, followed by a base64-encoded string of the username, a colon character, and the password. In the following example, the credentials **demo:changeit** are base64-encoded into the string **ZGVtbzpjajGFuZ2VpdA==**:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header "Authorization: Basic ZGVtbzpjajGFuZ2VpdA==" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
{
  "tokenId": "AQIC5w...NTcy*",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

Using the Session Token After Authentication

The following is a common scenario when accessing AM by using REST API calls:

- First, call the **/json/authenticate** endpoint to log a user in to AM. This REST API call returns a **tokenId** value, which is used in subsequent REST API calls to identify the user:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "X-OpenAM-Username: demo" \
--header "X-OpenAM-Password: changeit" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
'https://openam.example.com:8443/openam/json/realms/root/authenticate'
{
  "tokenId": "AQIC5wM...TU30Q*",
  "successUrl": "/openam/console",
  "realm": "/"
}
```

The returned **tokenId** is known as a session token (also referred to as an SSO token). REST API calls made after successful authentication to AM must present the session token in the HTTP header as proof of authentication.

- Next, call one or more additional REST APIs on behalf of the logged-in user. Each REST API call passes the user's **tokenId** back to AM in the HTTP header as proof of previous authentication.

The following is a *partial* example of a **curl** command that inserts the token ID returned from a prior successful AM authentication attempt into the HTTP header:

```
$ curl \
--request POST \
--header "Content-Type: application/json" \
--header "iPlanetDirectoryPro: AQIC5w...NTcy*" \
--header "Accept-API-Version: resource=2.0, protocol=1.0" \
--data '{
...

```

Observe that the session token is inserted into a header field named `iPlanetDirectoryPro`. This header field name must correspond to the name of the AM session cookie—by default, `iPlanetDirectoryPro`. You can find the cookie name in the AM console by navigating to `Deployment > Servers > Server Name > Security > Cookie`, in the `Cookie Name` field of the AM console.

Once a user has authenticated, it is *not* necessary to insert login credentials in the HTTP header in subsequent REST API calls. Note the absence of `X-OpenAM-Username` and `X-OpenAM-Password` headers in the preceding example.

Users are required to have appropriate privileges in order to access AM functionality using the REST API. For example, users who lack administrative privileges cannot create AM realms. For more information on the AM privilege model, see "Delegating Realm Administration Privileges".

- Finally, call the REST API to log the user out of AM as described in "Authentication and Logout using REST". As with other REST API calls made after a user has authenticated, the REST API call to log out of AM requires the user's `tokenID` in the HTTP header.

Server Information

You can retrieve AM server information by using HTTP GET on `/json/serverinfo/*` as follows:

```
$ curl \
--request GET \
--header "Content-Type: application/json" \
--header "Accept-API-Version: resource=1.1, protocol=1.0" \
https://openam.example.com:8443/openam/json/serverinfo/*
{
  "domains": [
    ".example.com"
  ],
  "protectedUserAttributes": [],
  "cookieName": "iPlanetDirectoryPro",
  "secureCookie": false,
  "forgotPassword": "false",
  "forgotUsername": "false",
  "kbaEnabled": "false",
  "selfRegistration": "false",
  "lang": "en-US",
  "successfulUserRegistrationDestination": "default",
  "socialImplementations": [
    {
      "iconPath": "XUI/images/logos/facebook.png",
      "authnChain": "FacebookSocialAuthenticationService",
      "displayName": "Facebook",

```

```
    "valid": true
  }
],
"referralsEnabled": "false",
"zeroPageLogin": {
  "enabled": false,
  "referrerWhitelist": [
    ""
  ],
  "allowedWithoutReferer": true
},
"realm": "/",
"xuiUserSessionValidationEnabled": true,
"FQDN": "openam.example.com"
}
```

Token Encoding

Valid tokens in AM require configuration either in percent encoding or in *C66Encode* format. C66Encode format is encouraged. It is the default token format for AM, and is used in this section. The following is an example token that has not been encoded:

```
AQIC5wM2LY4SfzczntBbXvEA0uECbqMY3J4NW3byH6xwGkGE=@AAJTSQACMDE=#
```

This token includes reserved characters such as `+`, `/`, and `=` (The `@`, `#`, and `*` are not reserved characters per se, but substitutions are still required). To c66encode this token, you would substitute certain characters for others, as follows:

- `+` is replaced with `-`
- `/` is replaced with `_`
- `=` is replaced with `.`
- `@` is replaced with `*`
- `#` is replaced with `*`
- `*` (first instance) is replaced with `@`
- `*` (subsequent instances) is replaced with `#`

In this case, the translated token would appear as shown here:

```
AQIC5wM2LY4SfzczntBbXvEA0uECbqMY3J4NW3byH6xwGkGE.*AAJTSQACMDE.*
```

Logging

AM supports two Audit Logging Services: a new common REST-based Audit Logging Service, and the legacy Logging Service, which is based on a Java SDK and is available in AM versions prior to OpenAM 13. The legacy Logging Service is deprecated.

Both audit facilities log AM REST API calls.

Common Audit Logging of REST API Calls

AM logs information about all REST API calls to the `access` topic. For more information about AM audit topics, see "Audit Log Topics".

Locate specific REST endpoints in the `http.path` log file property.

Legacy Logging of REST API Calls

AM logs information about REST API calls to two files:

- **amRest.access**. Records accesses to a CREST endpoint, regardless of whether the request successfully reached the endpoint through policy authorization.

An `amRest.access` example is as follows:

```
$ cat openam/openam/Log/amRest.access
#Version: 1.0
#Fields: time Data LoginID ContextID IPAddr LogLevel Domain LoggedBy MessageID ModuleName
NameID HostName
"2011-09-14 16:38:17" /home/user/openam/openam/log/ "cn=dsameuser,ou=DSAME Users,o=openam"
aa307b2dcb721d4201 "Not Available" INFO o=openam "cn=dsameuser,ou=DSAME Users,o=openam"
LOG-1 amRest.access "Not Available" 192.168.56.2
"2011-09-14 16:38:17" "Hello World" id=bjensen,ou=user,o=openam 8a4025a2b3af291d01 "Not Available"
INFO o=openam id=amadmin,ou=user,o=openam "Not Available" amRest.access "Not Available"
192.168.56.2
```

- **amRest.authz**. Records all CREST authorization results regardless of success. If a request has an entry in the `amRest.access` log, but no corresponding entry in `amRest.authz`, then that endpoint was not protected by an authorization filter and therefore the request was granted access to the resource.

The `amRest.authz` file contains the `Data` field, which specifies the authorization decision, resource, and type of action performed on that resource. The `Data` field has the following syntax:

```
("GRANT"|"DENY") > "RESOURCE | ACTION"
```

where

```
"GRANT > " is prepended to the entry if the request was allowed
"DENY > " is prepended to the entry if the request was not allowed
"RESOURCE" is "ResourceLocation | ResourceParameter"
  where
    "ResourceLocation" is the endpoint location (e.g., subrealm/applicationtypes)
    "ResourceParameter" is the ID of the resource being touched
    (e.g., myApplicationType) if applicable. Otherwise, this field is empty
    if touching the resource itself, such as in a query.
```

```
"ACTION" is "ActionType | ActionParameter"
```

where

```
"ActionType" is "CREATE||READ||UPDATE||DELETE||PATCH||ACTION||QUERY"
"ActionParameter" is one of the following depending on the ActionType:
  For CREATE: the new resource ID
  For READ: empty
  For UPDATE: the revision of the resource to update
  For DELETE: the revision of the resource to delete
  For PATCH: the revision of the resource to patch
  For ACTION: the actual action performed (e.g., "forgotPassword")
  For QUERY: the query ID if any
```

```
$ cat openam/openam/log/amRest.authz
```

```
#Version: 1.0
#Fields: time Data ContextID LoginID IPAddr LogLevel Domain MessageID LoggedBy NameID

```

AM also provides additional information in its debug notifications for accesses to any endpoint, depending on the message type (error, warning or message) including realm, user, and result of the operation.

Reference

This reference section covers return codes and system settings relating to REST API support in AM.

REST APIs

amster service name: `RestApis`

The following settings are available in this service:

Default Resource Version

The API resource version to use when the REST request does not specify an explicit version. Choose from:

- **Latest**. If an explicit version is not specified, the latest resource version of an API is used.
- **Oldest**. If an explicit version is not specified, the oldest supported resource version of an API is used. Note that since APIs may be deprecated and fall out of support, the oldest *supported* version may not be the first version.
- **None**. If an explicit version is not specified, the request will not be handled and an error status is returned.

The possible values for this property are:

- **Latest**
- **Oldest**
- **None**

Default value: **Latest**

amster attribute: **defaultVersion**

Warning Header

Whether to include a warning header in the response to a request which fails to include the **Accept-API-Version** header.

Default value: **false**

amster attribute: **warningHeader**

API Descriptions

Whether API Explorer and API Docs are enabled in AM and how the documentation for them is generated. Dynamic generation includes descriptions from any custom services and authentication modules you may have added. Static generation only includes services and authentication modules that were present when AM was built. Note that dynamic documentation generation may not work in some application containers.

The possible values for this property are:

- **DYNAMIC**. Enabled with Dynamic Documentation
- **STATIC**. Enabled with Static Documentation

- `DISABLED`

Default value: `STATIC`

amster attribute: `descriptionsState`

Default Protocol Version

The API protocol version to use when a REST request does not specify an explicit version. Choose from:

- `Oldest`. If an explicit version is not specified, the oldest protocol version is used.
- `Latest`. If an explicit version is not specified, the latest protocol version is used.
- `None`. If an explicit version is not specified, the request will not be handled and an error status is returned.

The possible values for this property are:

- `Oldest`
- `Latest`
- `None`

Default value: `Latest`

amster attribute: `defaultProtocolVersion`

Enable CSRF Protection

If enabled, all non-read/query requests will require the X-Requested-With header to be present.

Requiring a non-standard header ensures requests can only be made via methods (XHR) that have stricter same-origin policy protections in Web browsers, preventing Cross-Site Request Forgery (CSRF) attacks. Without this filter, cross-origin requests are prevented by the use of the application/json Content-Type header, which is less robust.

Default value: `true`

amster attribute: `csrfFilterEnabled`

Appendix B. Getting Support

ForgeRock provides support services, professional services, training through ForgeRock University, and partner services to assist you in setting up and maintaining your deployments. For a general overview of these services, see <https://www.forgerock.com>.

ForgeRock has staff members around the globe who support our international customers and partners. For details on ForgeRock's support offering, including support plans and service level agreements (SLAs), visit <https://www.forgerock.com/support>.

ForgeRock publishes comprehensive documentation online:

- The ForgeRock Knowledge Base offers a large and increasing number of up-to-date, practical articles that help you deploy and manage ForgeRock software.

While many articles are visible to community members, ForgeRock customers have access to much more, including advanced information for customers using ForgeRock software in a mission-critical capacity.

- ForgeRock product documentation, such as this document, aims to be technically accurate and complete with respect to the software documented. It is visible to everyone and covers all product features and examples of how to use them.

Glossary

Access control	Control to grant or to deny access to a resource.
Account lockout	The act of making an account temporarily or permanently inactive after successive authentication failures.
Actions	Defined as part of policies, these verbs indicate what authorized identities can do to resources.
Advice	In the context of a policy decision denying access, a hint to the policy enforcement point about remedial action to take that could result in a decision allowing access.
Agent administrator	User having privileges only to read and write agent profile configuration information, typically created to delegate agent profile creation to the user installing a web or Java agent.
Agent authenticator	Entity with read-only access to multiple agent profiles defined in the same realm; allows an agent to read web service profiles.
Application	<p>In general terms, a service exposing protected resources.</p> <p>In the context of AM policies, the application is a template that constrains the policies that govern access to protected resources. An application can have zero or more policies.</p>
Application type	<p>Application types act as templates for creating policy applications.</p> <p>Application types define a preset list of actions and functional logic, such as policy lookup and resource comparator logic.</p>

	Application types also define the internal normalization, indexing logic, and comparator logic for applications.
Attribute-based access control (ABAC)	Access control that is based on attributes of a user, such as how old a user is or whether the user is a paying customer.
Authentication	The act of confirming the identity of a principal.
Authentication chaining	A series of authentication modules configured together which a principal must negotiate as configured in order to authenticate successfully.
Authentication level	Positive integer associated with an authentication module, usually used to require success with more stringent authentication measures when requesting resources requiring special protection.
Authentication module	AM authentication unit that handles one way of obtaining and verifying credentials.
Authorization	The act of determining whether to grant or to deny a principal access to a resource.
Authorization Server	In OAuth 2.0, issues access tokens to the client after authenticating a resource owner and confirming that the owner authorizes the client to access the protected resource. AM can play this role in the OAuth 2.0 authorization framework.
Auto-federation	Arrangement to federate a principal's identity automatically based on a common attribute value shared across the principal's profiles at different providers.
Bulk federation	Batch job permanently federating user profiles between a service provider and an identity provider based on a list of matched user identifiers that exist on both providers.
Circle of trust	Group of providers, including at least one identity provider, who have agreed to trust each other to participate in a SAML v2.0 provider federation.
Client	In OAuth 2.0, requests protected web resources on behalf of the resource owner given the owner's authorization. AM can play this role in the OAuth 2.0 authorization framework.
Client-based OAuth 2.0 tokens	After a successful OAuth 2.0 grant flow, AM returns a token to the client. This differs from CTS-based OAuth 2.0 tokens, where AM returns a <i>reference</i> to token to the client.
Client-based sessions	AM sessions for which AM returns session state to the client after each request, and require it to be passed in with the subsequent

	<p>request. For browser-based clients, AM sets a cookie in the browser that contains the session information.</p> <p>For browser-based clients, AM sets a cookie in the browser that contains the session state. When the browser transmits the cookie back to AM, AM decodes the session state from the cookie.</p>
Conditions	<p>Defined as part of policies, these determine the circumstances under which which a policy applies.</p> <p>Environmental conditions reflect circumstances like the client IP address, time of day, how the subject authenticated, or the authentication level achieved.</p> <p>Subject conditions reflect characteristics of the subject like whether the subject authenticated, the identity of the subject, or claims in the subject's JWT.</p>
Configuration datastore	LDAP directory service holding AM configuration data.
Cross-domain single sign-on (CDSSO)	AM capability allowing single sign-on across different DNS domains.
CTS-based OAuth 2.0 tokens	After a successful OAuth 2.0 grant flow, AM returns a <i>reference</i> to the token to the client, rather than the token itself. This differs from <i>client-based OAuth 2.0 tokens</i> , where AM returns the entire token to the client.
CTS-based sessions	AM sessions that reside in the Core Token Service's token store. CTS-based sessions might also be cached in memory on one or more AM servers. AM tracks these sessions in order to handle events like logout and timeout, to permit session constraints, and to notify applications involved in SSO when a session ends.
Delegation	Granting users administrative privileges with AM.
Entitlement	Decision that defines which resource names can and cannot be accessed for a given identity in the context of a particular application, which actions are allowed and which are denied, and any related advice and attributes.
Extended metadata	Federation configuration information specific to AM.
Extensible Access Control Markup Language (XACML)	Standard, XML-based access control policy language, including a processing model for making authorization decisions based on policies.
Federation	Standardized means for aggregating identities, sharing authentication and authorization data information between trusted providers, and

	allowing principals to access services across different providers without authenticating repeatedly.
Fedlet	Service provider application capable of participating in a circle of trust and allowing federation without installing all of AM on the service provider side; AM lets you create Java Fedlets.
Hot swappable	Refers to configuration properties for which changes can take effect without restarting the container where AM runs.
Identity	Set of data that uniquely describes a person or a thing such as a device or an application.
Identity federation	Linking of a principal's identity across multiple providers.
Identity provider (IdP)	Entity that produces assertions about a principal (such as how and when a principal authenticated, or that the principal's profile has a specified attribute value).
Identity repository	Data store holding user profiles and group information; different identity repositories can be defined for different realms.
Java agent	Java web application installed in a web container that acts as a policy enforcement point, filtering requests to other applications in the container with policies based on application resource URLs.
Metadata	Federation configuration information for a provider.
Policy	Set of rules that define who is granted access to a protected resource when, how, and under what conditions.
Policy agent	Java, web, or custom agent that intercepts requests for resources, directs principals to AM for authentication, and enforces policy decisions from AM.
Policy Administration Point (PAP)	Entity that manages and stores policy definitions.
Policy Decision Point (PDP)	Entity that evaluates access rights and then issues authorization decisions.
Policy Enforcement Point (PEP)	Entity that intercepts a request for a resource and then enforces policy decisions from a PDP.
Policy Information Point (PIP)	Entity that provides extra information, such as user profile attributes that a PDP needs in order to make a decision.
Principal	Represents an entity that has been authenticated (such as a user, a device, or an application), and thus is distinguished from other entities.

	When a Subject successfully authenticates, AM associates the Subject with the Principal.
Privilege	In the context of delegated administration, a set of administrative tasks that can be performed by specified identities in a given realm.
Provider federation	Agreement among providers to participate in a circle of trust.
Realm	AM unit for organizing configuration and identity information. Realms can be used for example when different parts of an organization have different applications and identity stores, and when different organizations use the same AM deployment. Administrators can delegate realm administration. The administrator assigns administrative privileges to users, allowing them to perform administrative tasks within the realm.
Resource	Something a user can access over the network such as a web page. Defined as part of policies, these can include wildcards in order to match multiple actual resources.
Resource owner	In OAuth 2.0, entity who can authorize access to protected web resources, such as an end user.
Resource server	In OAuth 2.0, server hosting protected web resources, capable of handling access tokens to respond to requests for such resources.
Response attributes	Defined as part of policies, these allow AM to return additional information in the form of "attributes" with the response to a policy decision.
Role based access control (RBAC)	Access control that is based on whether a user has been granted a set of permissions (a role).
Security Assertion Markup Language (SAML)	Standard, XML-based language for exchanging authentication and authorization data between identity providers and service providers.
Service provider (SP)	Entity that consumes assertions about a principal (and provides a service that the principal is trying to access).
Authentication Session	The interval while the user or entity is authenticating to AM.
Session	The interval that starts after the user has authenticated and ends when the user logs out, or when their session is terminated. For browser-based clients, AM manages user sessions across one or more applications by setting a session cookie. See also CTS-based sessions and Client-based sessions.

Session high availability	Capability that lets any AM server in a clustered deployment access shared, persistent information about users' sessions from the CTS token store. The user does not need to log in again unless the entire deployment goes down.
Session token	Unique identifier issued by AM after successful authentication. For a CTS-based sessions, the session token is used to track a principal's session.
Single log out (SLO)	Capability allowing a principal to end a session once, thereby ending her session across multiple applications.
Single sign-on (SSO)	Capability allowing a principal to authenticate once and gain access to multiple applications without authenticating again.
Site	<p>Group of AM servers configured the same way, accessed through a load balancer layer. The load balancer handles failover to provide service-level availability.</p> <p>The load balancer can also be used to protect AM services.</p>
Standard metadata	Standard federation configuration information that you can share with other access management software.
Stateless Service	<p>Stateless services do not store any data locally to the service. When the service requires data to perform any action, it requests it from a data store. For example, a stateless authentication service stores session state for logged-in users in a database. This way, any server in the deployment can recover the session from the database and service requests for any user.</p> <p>All AM services are stateless unless otherwise specified. See also Client-based sessions and CTS-based sessions.</p>
Subject	<p>Entity that requests access to a resource</p> <p>When an identity successfully authenticates, AM associates the identity with the Principal that distinguishes it from other identities. An identity can be associated with multiple principals.</p>
Identity store	Data storage service holding principals' profiles; underlying storage can be an LDAP directory service or a custom IdRepo implementation.
Web Agent	Native library installed in a web server that acts as a policy enforcement point with policies based on web page URLs.
