   This transformation maps `ou=east,o=sample` in the `Sample Corporation` schema `dc=example,dc=com` in the `Example.com` schema.
5. To enable the transformation by default, select `True`.
6. Specify the source DN as it appears in client requests.

   Example:

```
>>>> Configuring the 'source-dn' property

     Specifies the source DN that may appear in client
     requests which should be remapped to the target DN.
     Note that the source DN must not be equal to the target DN.

     Syntax: DN

Enter a value for the 'source-dn' property:
ou=east,o=sample
```

7. Specify the target DN, where requests for the source DN should be routed.

   Example:

```
>>>> Configuring the 'target-dn' property

    Specifies the DN to which the source DN should be mapped.
    Note that the target DN must not be equal to the source
    DN.

    Syntax: DN

Enter a value for the 'target-dn' property: dc=example,dc=com
```

8. To create the new DN mapping proxy transformation, enter `f`.
9. Repeat the previous steps to create a new DN mapping proxy transformation that maps `ou=west,o=sample` in the `Sample Corporation` schema to `dc=example,dc=com` in the `Example.com` schema, and name it `sample_west-to-example`.
10. Create a DN mapping proxy transformation for the base DN of the `Sample Corporation` database.

Creating a request processor to manage the proxy transformations

Create a new proxying request processor that includes your new attribute and distinguished name (DN) mapping proxy transformations.

About this task

Use the existing `dc_example_dc_com` request processor as a template.

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Request Processor`.
2. On the `Request Processor` menu, enter the number corresponding to `Create a new Request Processor`.
3. Select the option to use the current request processor as a template.
4. Enter a name for the new proxying request processor, such as `o_sample-req-processor`.
5. Review the properties and enter the number corresponding to the `Transformation` property.

> **Note**
>
> The load-balancing algorithm is the same as for the previous request processor, but you must change the transformation property.

6. Enter the number corresponding to the proxy transformations that were previously created.
7. Select the attribute mapping proxy transformations, then select the DN mapping proxy transformations.

> **Note**
>
> The order of the selection is important because you have related DNs. Begin with the DNs that are lower in the tree, and finish with the base DN transformation.

Example:

```
Select the Proxy Transformations you wish to add:

    1)  sample-to-example       5)  sampleLinkedAccounts-to-
                                    exSampleLinkedAccounts
    2)  sample_east-to-example  6)  sampleRegion-to-
                                    exSampleRegion
    3)  sample_west-to-example  7)  Create a new Proxy
                                    Transformation
    4)  sampleID-to-uid         8)  Add all Proxy Transformations

    ?)  help
    b)  back
    q)  quit

Enter one or more choices separated by commas [b]: 4,5,6,2,3,1
```

8. Confirm that the proxy transformations are listed in the correct order and press Enter to accept and use the values.
9. To save your changes, enter `f`.

Creating subtree views

About this task

To configure subtree views for the PingDirectoryProxy server:

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Subtree View`.
2. In the `Subtree View` menu, enter the number corresponding to `Create a new Subtree View`.
3. Enter the option to create the new subtree view from an existing subtree.
4. Select the `dc_example_dc_com-view` subtree view.
5. Enter a descriptive name for the subtree view configuration.
6. Configure the base distinguished name (DN) property of the `Sample Corporation` data set.
7. Enter the request processor created in Creating a request processor to manage the proxy transformations.
8. To save the changes, press `f`.

   Example:

```
>>>> Configure the properties of the Subtree View

        Property           Value(s)
        -----------------------------------------------
    1)  description        -
    2)  base-dn            "o=sample"
    3)  request-processor  o_sample-req-processor

    ?)  help
    f)  finish - create the new Subtree View
    d)  display the equivalent dsconfig arguments to create this
        object
    b)  back
    q) quit
```

Editing the client connection policy

Edit the client connection policy.

About this task

To add the new `o=sample` subtree view:

Steps

1. In the `Configuration` main menu, enter the number corresponding to `Client Connection Policy`.
2. In the `Client Connection` menu, enter the number corresponding to `Create a new Client Connection`.
3. In the configuration properties, select the `subtree-view` property and enter the number corresponding to "Add one or more values" to add the new subtree view created for the previous example.
4. Select the subtree view that you created in Creating subtree views.

   Example:

   ```
   Select the Subtree Views you wish to add:

       1)  o_sample-view
       2)  Create a new Subtree View
   ```

5. Review the subtree views now referenced by the property and press Enter to use these values.
6. Review the configuration properties of the client connection policy and enter `f` to save changes.

Testing proxy transformations

You can test the proxy transformation service by imitating example client requests to search and modify users.

About this task

After setting up the deployment scenario, the PingDirectoryProxy server will respond to requests to the `dc=example,dc=com` and `o=sample` base distinguished names (DNs).

Steps

1. To view a Sample Corporation entry, run `ldapsearch`.

   Example:

   The following example fetches the user with `sampleID=scase` under the `ou=east,o=sample` base DN.

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "ou=east,o=sample" "(sampleID=scase)"
   ```

   Result:

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   objectClass: exampleAccount
   objectClass: top
   description: A customer account migrated from Sample merger
   sampleID: scase
   userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXA==
   exAccountNumber: 234098
   givenName: Sterling
   cn: Sterling Case
   sn: Case
   telephoneNumber: +1 804 094 3356
   street: 00468 Second Street
   mail: sterlingcase@maildomain.com
   l: Arlington
   st: VA
   sampleRegion: east
   sampleLinkedAccounts: sampleID=jcase,ou=People,ou=east,o=sample
   ```

2. Modify the `sampleRegion` value by changing it to `west`.

   Example:

   To modify the value, create an `ldapmodify` input file, called `scase-mod.ldif`, with the following contents.

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   changetype: modify
   replace: sampleRegion
   sampleRegion: west
   ```

3. Use the file as an argument in the `ldapmodify` command.

   Example:

```
root@proxy-east-01: bin/ldapmodify --bindDN "cn=Directory Manager" \
--bindPassword password --filename scase-mod.ldif
```

Result:

```
Processing MODIFY request for sampleID=scase,ou=People, ou=east,o=sample
MODIFY operation successful for DN sampleID=scase,ou=People, ou=east,o=sample
```

4. Search for the `scase` `sampleRegion` value under `o=sample`

   Example:

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "o=sample"  "(sampleID=scase)" \
   sampleRegion
   ```

   Result:

   ```
   dn: sampleID=scase,ou=People,ou=east,o=sample
   sampleRegion: west
   ```

5. To search for `scase`, use `uid` instead of `sampleID`, under the `dc=example,dc=com` base DN.

   Example:

   You can see the Example.com schema version of the entry in the following sample.

   ```
   root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
   --bindPassword password --baseDN "dc=example,dc=com"  "(uid=scase)"
   ```

   Result:

   ```
   dn: uid=scase,ou=People,dc=example,dc=com
   objectClass: person
   objectClass: exampleAccount
   objectClass: inetOrgPerson
   objectClass: organizationalPerson
   objectClass: top
   description: A customer account migrated from Sample merger
   uid: scase
   userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXA==
   exAccountNumber: 234098
   givenName: Sterling
   cn: Sterling Case
   sn: Case
   telephoneNumber: +1 804 094 3356
   street: 00468 Second Street
   mail: sterlingcase@maildomain.com
   l: Arlington
   st: VA
   exSampleRegion: west
   exSampleLinkedAccounts: uid=jcase,ou=People,dc=example,dc=com
   ```

Deploying an entry-balancing PingDirectoryProxy server

Depending upon the needs of your enterprise, you can deploy a PingDirectoryProxy server in a variety of ways.

This section describes and illustrates an entry-balancing deployment scenario that involves:

- Deploying an entry-balancing proxy configuration
- Rebalancing your entries
- Managing the global indexes in entry-balancing configurations
- Working with alternate authorization identities

Deploying an entry-balancing proxy configuration

Entry-balancing is a PingDirectoryProxy server configuration that allows the entries within a portion of the directory information tree (DIT) to reside on multiple external servers.

This configuration is useful when the DIT contains many millions of entries, which can be difficult to bring completely into memory for optimal performance. Entry-balancing allows entries under a balancing point base distinguished name (DN) to be divided among any number of separate directory servers, making the PingDirectoryProxy server responsible for intelligently routing requests based on the division.

In this example scenario, the entries in the DIT outside of the balancing point are replicated across all external servers known to the PingDirectoryProxy server. You must properly configure replication on the external directory servers before proceeding through this example. The directory servers are expected to contain two replication domains: the global domain, `dc=example,dc=com`, and the balancing point, `ou=people,dc=example,dc=com`.

In this deployment scenario, an `austin-proxy1` instance of the PingDirectoryProxy server communicates with four external directory servers. The PingDirectoryProxy server is configured to use entry balancing for the `ou=people,dc=example,dc=com` base DN with two sets of user entries split beneath it. The first set of user entries is defined in the replicated pair of external servers, `austin-set1.example.com` and `newyork-set1.example.com`.

The second set of entries is defined in `austin-set2.example.com` and `newyork-set2.example.com`. The entries in the `dc=example,dc=com` DIT outside of the balancing point base DN are replicated among the four external servers.

The following `dsreplication status` output from the PingDirectory external servers describes the replication configuration that exists before creating the PingDirectoryProxy server configuration.

```
--- Replication Status for dc=example,dc=com: Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
--------:---------:--------:--------------------------:-------------
austin-set1.example.com:389  : 10003   : 0   : N/A  : 722087263
austin-set2.example.com:389  : 10003   : 0   : N/A  : 722087263
newyork-set1.example.com:389 : 10003   : 0   : N/A  : 722087263
newyork-set2.example.com:389 : 10003   : 0   : N/A  : 722087263

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset1): Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
--------:---------:---------:--------------------------:-----------------
austin-set1.example.com:389  : 100001  : 0  : N/A               : 178892712
newyork-set1.example.com:389 : 100001  : 0  : N/A               : 178892712

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset2): Enabled ---

Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
---------:---------:---------:--------------------------:-----------------
austin-set2.example.com:389  : 100001  : 0       : N/A        : 1057593890
newyork-set2.example.com:389 : 100001  : 0       : N/A        : 1057593890
```

Determining how to balance your data

If a single PingDirectory server instance can hold all of your data, then you should store your data on a single server and replicate for high availability to simplify your deployment.

If a single server can't hold all of your data, then you can spread it across multiple servers in these ways:

- If the data is already broken up by hierarchy and all of the clients understand how to access it that way, the number of top-level branches is small and a single PingDirectory server instance can hold all of the information within one or more branches. Configure the PingDirectoryProxy server with multiple base distinguished names (DNs) and use simple load-balancing rather than entry balancing to simplify your deployment.
- If simply breaking up the data using the existing hierarchy is not an option, for example if a large number of top-level branches must be configured, then consider using entry balancing. The contents of any single branch still must fit on a given server, because only entries that are immediate subordinates of the entry-balancing base DN might be spread across multiple servers. Any entries that are further subordinates must be placed in the same directory server instance as their parent.
- If one or more branches are so large that any single PingDirectory server instance can't hold all of the data, you need to use entry balancing within that branch to divide the entries among two or more sets of PingDirectory servers. You might also need to change the way that the data is arranged in the server so that it uses as flat a directory information tree (DIT) as possible, which is easier to use in an entry-balancing deployment.

In an entry-balancing deployment, there can be data that is common to all external directory servers outside the balancing point. This data is referred to as the global domain. The PingDirectoryProxy server entry-balancing configuration will contain at least two subtree views and associated request processors, one for the global domain and one for the entry-balancing domain. In our examples, the global domain is `dc=example,dc=com`, and the entry-balancing domain is `ou=people,dc=example,dc=com`.

> **Note**
>
> The entry-balancing base DN, `ou=people,dc=example,dc=com`, is also the balancing point.

Entry balancing and ACIs

In an entry-balancing deployment, access control instructions (ACIs) are still configured in the backend PingDirectory server data.

When defining access controls in an entry-balancing deployment, you must ensure that the data used by the access control rule is available for evaluation on all data sets.

If you use groups for access control and a group contains users from different data sets, then that group must exist on each data set. For a single ACI to apply to entries in all data sets, it must be specified above the entry-balancing point. For example, if an ACI allows access to modify users that are part of group 1, then two things must exist on both data sets:

- Group 1 must exist in the `ou=groups` branch of both data sets.
- The ACI referencing group 1 must exist in the `ou=people` branch or above. The `ou=people` branch entry itself is part of the common data.

The PingDirectoryProxy server ensures that any changes to entries within the scope of the entry-balancing request processor, but outside the balancing point, are applied to all backend server sets. Any ACI stored at the entry-balancing point is kept in sync if changes are made through the PingDirectoryProxy server.

Overview of deployment steps

This deployment scenario takes the following steps.

- Install the PingDirectoryProxy server on `austin-proxy1`.
- Use the `create-initial-proxy-config` tool to provide our initial setup for entry balancing.

  The initial setup includes defining multiple subtree views and global indexes in support of entry balancing.
- Change the placement algorithm of the `austin-proxy-01` server to use an entry-count placement algorithm.

  This algorithm is used to select the backend set to which to forward an add request. It looks at the number of entries in the backend sets and forwards the add request to the backend with either the fewest or the most entries, depending on the configuration. You can also configure the placement algorithm to make the decision based on the on-disk database size rather than the number of entries.

Installing the PingDirectoryProxy server

About this task

The four external servers, `austin-set1.example.com`, `newyork-set1.example.com`, `austin-set2.example.com`, and `newyork-set2.example.com`, are running.

Steps

- Run the `setup` program in non-interactive mode.

  Example:

```
root@austin-proxy1: ./setup --acceptLicense \
--listenAddress austin-proxy1.example.com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --entryBalancing \
--maxHeapSize 2g --no-prompt
```

Configuring the entry-balancing PingDirectoryProxy server

After the PingDirectoryProxy server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool.

About this task

This tool can only be used once for this initial configuration after which you will have to use `dsconfig` to make any changes to the PingDirectoryProxy server configuration.

Steps

1. Run the `create-initial-proxy-config` tool.

   Example:

```
root@austin-proxy1: ./bin/create-initial-proxy-config
```

2. If the topology meets the requirements, press Enter to continue.

   Example:

```
Some assumptions are made about the topology to keep
this tool simple:

1) all servers will be accessible via a single user account
2) all servers support the same communication security type
3) all servers are PingDirectoryProxy Servers

If your topology does not have these characteristics you can
use this tool to define a basic configuration and then use the
'dsconfig' tool or the Administrative Console to fine tune the configuration.

Would you like to continue? (yes / no) [yes]:
```

3. Provide the external server access credentials.

   All of the proxies have identical proxy user accounts and passwords.

   Example:

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:

Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

4. Specify the type of security that the PingDirectoryProxy server will use to communicate with PingDirectory servers.
5. Enter a base distinguished name (DN) of the PingDirectory server instances that will be accessed by the PingDirectoryProxy server.
6. Define the balancing point as a separate base DN, which is entry balanced.

   Example:

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:

    1)Remove dc=example,dc=com

    b)back

    q)quit

Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]: ou=people,dc=example,dc=com

Are entries within 'ou=people,dc=example,dc=com' split across
multiple servers so that each server stores only a subset of
the entries (i.e. is this base DN 'entry balanced')? (yes / no)
[no]: yes
```

7. Because the data in `ou=people,dc=example,dc=com` will be split across two backend sets, enter `2` to specify that the data will be balanced across two sets of servers.

   Example:

```
Across how many sets of servers is the data balanced?

    c) cancel creating ou=people,dc=example,dc=com
    q) quit

Enter a number greater than one or choose a menu item: 2
```

8. Because the balancing point is the same as the base DN, `ou=people,dc=example,dc=com`, use it as the entry balancing base.

   Example:

```
>>>> Entry Balancing Base

The entry balancing base DN specifies the entry below which the
data is balanced. Entries not below this entry must be duplicated
in all the server sets. If all the entries in the base DN are
distributed the entry balancing base DN is the same as the base DN.

    c) cancel creating ou=people,dc=example,dc=com
    b) back
    q) quit

Enter the entry balancing base DN or choose a menu item
[ou=people,dc=example,dc=com]: ou=people,dc=example,dc=com
```

9. To improve the performance for equality search filters referencing the `uid` attribute, create a `uid` global index. Enter `yes` to add a new attribute to the global index.
10. Specify the `uid` attribute.

    Example:

    ```
    Enter attributes that you would like to add to the global index:

        c)cancel creating ou=people,dc=example,dc=com
        b)back
        q)quit

    Enter an attribute name or choose a menu item [Press ENTER when
    finished entering index attributes]: uid
    ```

11. To optimize PingDirectoryProxy server performance from the moment it starts accepting connections, enter the number corresponding to `Yes, and all subsequent attributes`.
12. Press Enter to finish specifying index attributes.
13. Press Enter to enable relative distinguished name (RDN) index priming.

    Example:

    ```
    Would you like to enable RDN index priming for
    'ou=people,dc=example,dc=com'? (yes / no) [yes]:
    ```

14. Press Enter to finish specifying base DNs.

    Example:

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:

    1) Remove dc=example,dc=com
    2) Remove ou=people,dc=example,dc=com (distributed)

    b)  back
    q)  quit

Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]:
```

15. The external servers are spread among two locations, New York and Austin. Define austin as the location of this PingDirectoryProxy server instance.

    Example:

```
A good rule of thumb when naming locations is to use the
name of your data centers or the cities containing them.

    b)  back
    q)  quit

Enter a location name or choose a menu item: austin

    1)  Remove austin

    b)  back
    q)  quit
```

16. Define the newyork location.

    Example:

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]: newyork

    1)  Remove austin
    2)  Remove newyork

    b)  back
    q)  quit

Enter another location name or choose a menu item [Press ENTER
when finished entering locations]:
```

17. Select the austin location for this PingDirectoryProxy server instance.

    Example:

```
Choose the location for this Directory Proxy Server

    1) austin
    2) newyork

    b) back
    q) quit

Enter choice [1]:
```

18. Specify the LDAP external server instances associated with this location.

    Example:

```
Enter the host and port (host:port) of the first directory server
in 'austin'

     b)  back
     q)  quit

Enter a host:port or choose a menu item [localhost:389]:
austin-set1.example.com:389
```

19. Specify that the `austin-set1` server can handle requests from the global domain and from set 1 restricted domain.

    Example:

```
Assign server austin-set1.example.com:389 to handle requests for
one or more of the defined sets of data:

    1) dc=example,dc=com
    2) ou=people,dc=example,dc=com; Server Set 1
    3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,2
```

20. Enter the number corresponding to `Yes, and all subsequent servers` to prepare the server for access by the Directory Proxy Server.

    Example:

```
Would you like to prepare austin-set1.example.com:389 for access
by the Directory Proxy Server?

       1)Yes
       2)No
       3)Yes, and all subsequent servers
       4)No, and all subsequent servers

Enter choice [3]:
```

21. Select the entry-balanced data set that the `austin-set1` server replicates with other servers.

Example:

```
You may choose a single entry-balanced data set with which
austin-set1.example.com:389 will replicate data with other servers

    1) ou=people,dc=example,dc=com; Server Set 1
    2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set1.example.com:389 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ....Denied
```

22. Modify the root user for use by the PingDirectoryProxy server, specifying the directory manager password for the initial creation of the proxy user.

    Example:

```
Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:

Enter the DN of an account on austin-set1.example.com:389
with which to create or manage the 'cn=Proxy User,cn=Root DNs,
cn=config' account and configuration [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':
Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User,cn=Root DNs,cn=config'privileges...Done
Setting replication set name .....
```

23. Because the replication set name has already been configured, you do not need to use the name created automatically by the PingDirectoryProxy server.

    Example:

```
This server is currently configured for replication set 'dataset1'.
Would you like to reconfigure this server for replication set
'set-1'? (yes / no) [no]:

Setting replication set name ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
Verifying backend 'ou=people,dc=example,dc=com' ..... Done
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

24. Define the other Austin and New York servers using the same procedure in steps 17-24.

    Example:

```
Enter another server in 'austin'

    1) Remove austin-set1.example.com:389
    b) back
    q) quit

Enter a host:port or choose a menu item [Press ENTER when
finished entering servers]: austin-set2.example.com:389

Assign server austin-set2.example.com:389 to handle requests
for one or more of the defined sets of data

    1) dc=example,dc=com
    2) ou=people,dc=example,dc=com; Server Set 1
    3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,3

You may choose a single entry-balanced data set with which
austin-set2.example.com:389 will replicate data with other
servers

    1) ou=people,dc=example,dc=com; Server Set 2
    2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set2.example.com:389 ....Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ... Denied

Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:

Would you like to use the previously entered manager credentials
to access all prepared servers? (yes / no) [yes]:

```

Configuring the placement algorithm using a batch file

Configure the placement algorithm using a batch file.

About this task

You want to place new entries added through the proxy using LDAP `ADD` operations into the least used dataset. Do this using an entry-count placement algorithm. To change the placement algorithm from round-robin to entry-count, first create and enable an entry-count placement algorithm configuration object, and then disable the existing round-robin placement algorithm. The batch file, `dsconfig.post-setup`, contains the `dsconfig` commands required to create the entry-count placement algorithm and disable the old round-robin algorithm.

The batch file contains comments to explain each `dsconfig` command.

> **Note**
>
> In this example, line wrapping is used for clarity. The **`dsconfig`** command requires that the full command be provided on a single line.

The batch file itself looks like the following.

```
root@austin-proxy1:more ../dsconfig.post-setup

# This dsconfig operation creates the entry-count placement
# algorithm with the default behavior of adding entries to the
# smallest backend dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

# Note that once the entry-count placement algorithm is created
# and enabled, we can disable the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then disable the
# original round-robin algorithm created during the setup
# procedure.

dsconfig set-placement-algorithm-prop
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false

# At this point, LDAP ADD operations will be forwarded to an external
# server representing the dataset with the least number of entries.
```

Steps

- Run the `dsconfig` command using the batch file.

  Example:

  ```
  root@austin-proxy1: bin/dsconfig --no-prompt \
  --bindDN "cn=directory manager" --bindPassword password \
  --port 389  --batch-file ../dsconfig.post-setup
  ```

  Result:

  After the batch file has executed, a new entry-count placement algorithm, called `entry-count`, has been created and the old round-robin placement algorithm, `round-robin`, has been disabled.

```
Batch file '../dsconfig.post-setup' contains 2 commands

Executing: create-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

Executing: delete-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false
```

Rebalancing your entries

If your deployment distributes entries using an entry counter placement algorithm or third party algorithm, you might need to redistribute your entries.

If you have an environment that distributes entries across three backends using an entry counter placement algorithm, this algorithm distributes entries to the backend that has the most space. If the backends all reach their maximum capacity and you decide to add a new backend to the deployment, you must move the entries from the full backends and distribute them evenly across all the backends, including the new backend.

You might also want to deliberately rebalance your entries to meet the needs of your organization, such as by direct entry balancing based on attributes on the entries themselves. You can write a custom algorithm that looks at the value of an attribute that is being modified on the entry. Based on the attribute, you can then put this entry somewhere specific. You might use this feature if you want to have certain entries closer geographically to the client application using them. The geographical information could be included in the entry. Rebalancing would be used to move these entries to the server in the correct geographical location.

You can redistribute entry-balanced entries in two ways:

Using dynamic rebalancing

With dynamic rebalancing, as existing entries get modified, they get moved. You configure dynamic rebalancing in the entry counter placement algorithm.

Using the `move-subtree` *tool*

This tool can be used to move either small subtrees through a transactional method or to move large subtrees, potentially taking them offline for a short period.

This section describes each of these methods of entry rebalancing in more detail.

About dynamic rebalancing

During dynamic rebalancing, entries get moved as they are modified. You configure dynamic rebalancing in the entry counter placement algorithm or a third-party placement algorithm that supports rebalancing.

This algorithm keeps a count of the number of entries or the size of the backend set. Configure dynamic rebalancing using the following parameters:

`rebalancing-enabled`

Determines whether entry rebalancing is enabled. When rebalancing is enabled, the placement algorithm is consulted after `modify` and `add` operations to determine whether the target entry should be moved to a different backend set. `rebalancing-scope`

Indicates which modified entries are candidates for rebalancing. A value of `top-level` indicates that only entries immediately below the entry-balancing base can be rebalanced. A value of any indicates that entries at any level below the entry-balancing base might be rebalanced. `rebalancing-minimum-percentage`

Specifies the minimum threshold for entries to be migrated from one backend set to a preferred backend set with a smaller size. Entries are not migrated unless the percentage difference between the value of the current backend set and the value of the preferred backend set exceeds this threshold. This parameter prevents unnecessarily migrating entries back and forth between backend sets of similar sizes. `rebalancing-subtree-size-limit`

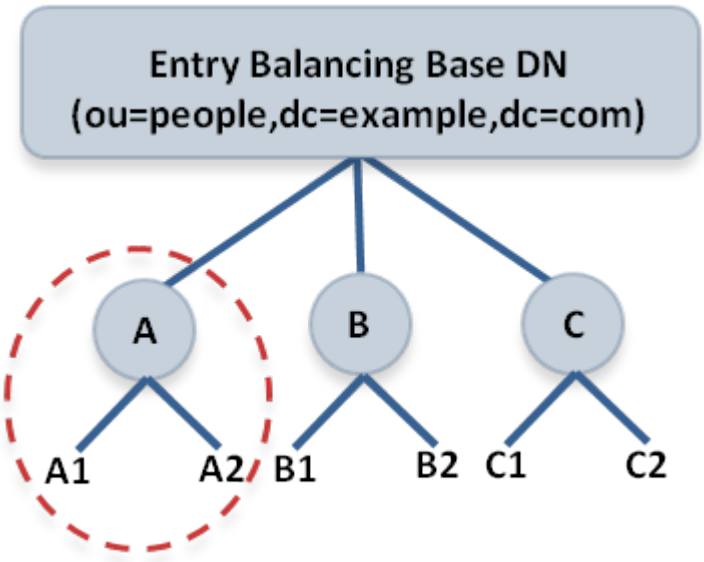
Specifies the maximum size of a subtree that can be rebalanced. `poll-interval`

Specifies how long to wait between polling the size of the backends to determine how to rebalance and works in conjunction with the `rebalancing-minimum-percentage` property. `placement-criteria`

Determines which approach to use to select a destination backend for rebalancing. Possible values are:

- `entry-count`
- `backend-size`
- `custom`

The following figure illustrates an entry-balancing base DN and three subtrees, A, B, and C. If the rebalancing scope is set to `any`, any child entries under the base DN can be rebalanced. For example, if a change is made to entry A1, the entire subtree A might be rebalanced, depending upon how you have configured rebalancing. If the rebalancing scope is set to `top-level`, rebalancing is only triggered when entries at the top level, such as A, are modified. Changes made to subentries, such as A1 or A2, do not trigger rebalancing. Rebalancing is also triggered upon the addition of entries such as `A1`, `A2`, provided the scope is `any`.



If you are writing your own third-party algorithm, you program dynamic rebalancing using the `SelectRebalancingBackendSet` method on the placement algorithm. For more information, see the Server SDK documentation.

Configuring dynamic rebalancing

Configure dynamic rebalancing on an existing entry balancing configuration.

Steps

1. If the current placement algorithm does not support rebalancing, create an entry counter placement algorithm.

   Example:

   You can either do this using `dsconfig` in interactive mode or using the `dsconfig` command line as in this example.

   ```
   $ dsconfig create-placement-algorithm \
     --processor-name dc_example_dc_com-eb-req-processor \
     --algorithm-name rebalancing --type entry-counter \
     --set enabled:true --set rebalancing-enabled:true
   ```

2. Remove any placement algorithm previously configured on this entry-balancing request processor.

3. Throttle how many entries are being moved by the proxy so that the backend servers do not have too heavy a load by setting the `rebalancing-queue-maximum-size` property of the request processor created in the previous step.

   Example:

   By default, the value is 1000. If the load is too high, reduce this value

```
$ dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set rebalancing-queue-maximum-size:50
```

4. Verify that the access logs are configured to display the subtrees being moved by dynamic rebalancing.

   The access logs provide a good way to monitor progress. If the write load on the backend servers is high and you see lots of rebalancing activity in the access log, lower the queue size to lower the rebalancing activity.

   Example:

   This example configures the access log to display entry rebalancing processing information.

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set log-entry-rebalancing-requests:true
```

About the move-subtree tool

The `move-subtree` tool allows you to specify subtrees for rebalancing.

You specify the source server, the target server, and one or more base distinguished names (DNs) identifying the subtrees you want to move. You can move small subtrees using the transactional method or move large subtrees, which does not use this method.

Instead, the large subtree is not fully accessible during the move, so clients might get an `insufficient access rights` error if they try to access the subtree. As entries are moved, clients can read but not write to them. When the transfer is complete, the entries are fully available to client requests.

This tool accepts a file containing a list of the base DNs of the subtrees you want to move.

> **Note**
>
> The **`move-subtree`** tool requires users to have access to the extended operations and controls needed to run the tool. Make sure to apply the following ACIs to your data.
>
> ```
> aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.5 ||
>       1.3.6.1.4.1.30221.2.5.24 || 1.3.6.1.4.1.30221.2.5.13")
>      (version 3.0; acl "Allow admin to submit move-subtree controls";
>       allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
> aci: (extop="1.3.6.1.4.1.30221.2.6.19")
>      (version 3.0; acl "Allow admin to request move-subtree extended
>       operation"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
> ```

About the subtree-accessibility tool

The `subtree-accessibility` tool helps you determine if a subtree has restricted access and helps you fix any problems.

If, during rebalancing, the PingDirectory server issues an alert that a subtree has been unavailable for too long, then you can use this tool to evaluate the problem.

For example, if the `move-subtree` tool is interrupted by a host machine going down unexpectedly, the subtree can't be successfully moved. You can use the `subtree-accessibility` tool to evaluate and correct any problems with the subtrees and then re-run the `move-subtree` tool.

Managing the global indexes in entry-balancing configurations

In an entry-balancing configuration, the PingDirectoryProxy server maintains the default relative distinguished name (RDN) index as well as one or more in-memory global attribute indexes.

The global indexes allow the PingDirectoryProxy server to select the correct backend server set for incoming operations, which avoids broadcasting operations to all backend sets.

The indexes can be preloaded from peer proxies or the backend directory servers when the server starts up and are updated by certain operations that come through the PingDirectoryProxy server. For example, when a new entry is added, the distinguished name (DN) of the new entry is added to the DN index of the PingDirectoryProxy server performing the operation. The indexes are also fault-tolerant and can adapt to changes made in the backend servers without going through the PingDirectoryProxy server. For example, operations are processed directly through the backend server.

This section describes:

- When to create a global attribute index
- How to reload the global index
- How to monitor the global index growth
- How to prime the global index from a peer at startup

Creating a global attribute index

Create a global attribute index for PingDirectoryProxy server to use as a optional index.

About this task

The relative distinguished name (RDN) index is referenced whenever a `modify`, `delete`, or base search is requested. The RDN index is needed when the LDAP request contains the complete distinguished name (DN) of the targeted entry. If the entry-balancing request processor is not configured to prime the RDZ index at startup, then the index is populated over time as LDAP requests are processed.

A global attribute index is an optional index and is referenced when the PingDirectoryProxy server is handling a search request with an equality filter involving an attribute, such as the `telephoneNumber` attribute with the `telephoneNumber=+11234567890` filter.

Because the PingDirectoryProxy server doesn't know what the data within the subtree view looks like or how it is searched, it can't create or recommend default global attribute index definitions. The creation of a global attribute index is based on the range of equality-filtered search requests processed by the PingDirectoryProxy server. The PingDirectory server must also have an equality or ordering index type for the associated attribute Local database (DB) Index.

The common candidates for global attribute indexing are the uniquely-valued equality-indexed attributes on the external servers, such as `uid`, `mail` and `telephoneNumber`. These attributes don't require unique values for use as global attribute indexes by the entry-balancing request processor.

Steps

- Create a global attribute index using the `dsconfig` tool with the `create-global-attribute-index` option.

  Example:

  In this example, a PingDirectoryProxy server deployment expects to process frequent searches of the form `(&(mail=user@example.com)(objectclass=person))`. The `mail` attribute is indexed for equality searches on each of the external servers behind the PingDirectoryProxy server. Because the filter is constructed with an equality match and `&` clause, you can use a global attribute index on the `mail` attribute to avoid forwarding the search request to each entry balanced dataset.

  ```
  $ bin/dsconfig create-global-attribute-index \
    --processor-name ou_people_dc_example_dc_com-eb-req-processor \
    --index-name mail --set prime-index:true \
  ```

Result

The index begins populating as search requests are made to the PingDirectoryProxy server that involve the mail attribute.

> **Tip**
>
> You can use the `reload-index` tool to fully populate the index for optimal performance as described in Reloading the global indexes.

Reloading the global indexes

The `reload-index` tool allows you to manually reload the PingDirectoryProxy server global indexes.

Use the `reload-index` tool to reload all configured indexes in the global index, including the relative distinguished name (RDN) index and all attribute indexes or to reload only the indexes you specify.

You might need to reload the index when:

- The PingDirectoryProxy server fails to successfully load its global indexes on startup.
- Changes are made to the set of indexed attributes.
- Significant changes are made to the content in backend servers.
- The integrity of the index is in question.

The `reload-index` tool schedules an operation to run within the PingDirectoryProxy server's process. You must supply the LDAP connection information so that the tool can communicate with the server through its task interface. You can schedule tasks to run immediately or at a later time. After the tasks are scheduled, manage them using the `manage-tasks` tool.

Reloading all of the indexes

About this task

Reload all the indexes within the scope of the base distinguished name (DN) `dc=example,dc=com`. The task is performed as `cn=Directory Manager` on port 389 of the localhost server.

> **Note**
>
> The existing index contents are erased before reloading.

Steps

- To reload all of the indexes within the scope of the `dc=example,dc=com` base DN, run the **`reload-index`** tool.

  Example:

  ```
  $ bin/reload-index --task --bindPassword password --baseDN "dc=example,dc=com"
  ```

Reloading the RDN and UID index

About this task

To reload the RDN and unique identifier (UID) index in the background so that the existing contents of these indexes can continue to be used:

Steps

- Run the **`reload-index`** tool with the `--index rdn` and `--index uid` options.

  Example:

  ```
  $ bin/reload-index --task --bindPassword password \
    --baseDN "dc=example,dc=com" --index rdn --index uid --background
  ```

Priming the backend server using the --fromDS option

About this task

You can force the PingDirectoryProxy server to prime from the backend directory server using the `--fromDS` option, which overrides the configuration of the `prime-index-source` property.

> **Tip**
>
> You can do this on a one-off basis if the global index appears to be growing too large.

To prime the backend server:

Steps

- Run the **`reload-index`** tool with the `--fromDS` option.

Example:

```
$ bin/reload-index --bindPassword password --baseDN "dc=example,dc=com" --fromDS
```

Monitoring the size of the global indexes

Monitor the size of the global indexes over LDAP and reload the indexes to prevent a build up of stale entries in the global indexes.

About this task

The proxies don't communicate changes to the indexes with one another, which can result in stale entries building up over time in the global indexes. In this situation, the PingDirectoryProxy server continues to operate normally because the global indexes are used only as a hint for where to find entries.

The rate of this growth is typically slow because in most environments the key attributes change infrequently. In addition, the global indexes are compact. However, if the global indexes start to fill up the allocated memory, you might need to flush and reload them.

If the global indexes become full, the PingDirectoryProxy server continues to operate normally, but it needs to start evicting entries from the indexes. Evicting the entries leads to more broadcast searches and reduces the overall performance of the PingDirectoryProxy server.

Steps

- To monitor the size of the global indexes over LDAP, use the `ldapsearch` with the `global-index-current-memory-percent` option.

  Example:

  ```
  $ bin/ldapsearch -b "cn=monitor" -D "uid=admin,dc=example,dc=com" -w password \
    "(objectClass=ds-entry-balancing-request-processor-monitor-entry)" \
    global-index-current-memory-percent
  ```

- To reload the indexes so they no longer hold stale information, run the `reload-index` command with the `--fromDS` option.

  This option ensures that data is loaded from backend directory servers.

  > **Tip**
  >
  > You should reload the indexes during off-peak hours because it might impact the performance while the reload is in progress.

Sizing the global indexes

Use the PingDirectoryProxy server `global-index-size` tool to help you estimate the memory size of your global indexes.

About this task

You can estimate the size of more than one index in a single invocation by providing multiple sets of options.

The `global-index-size` tool creates its estimate using the following information:

Number of keys in the index

For example, for the built-in relative distinguished name (RDN) index, the number of keys is the total number of entries in the PingDirectory server that are immediately below the balancing point. Entries more than one level below the balancing point and entries that are not subordinate to the balancing point aren't contained in the RDN index. For attribute indexes, the number of keys is the number of unique values for that attribute in the entry-balanced portion of the data.

Average size of each key, in bytes

For attributes indexes, the key is the attribute value. For the built-in RDN index, the key is the RDN directly below the balancing base distinguished name (DN). For example, for the DN `uid=user.0,dc=example,dc=com` under the balancing base DN of `dc=example,dc=com`, the key size is 10 bytes (the number of bytes in the RDN `uid=user.0`).

Estimated number of keys

This value corresponds to the maximum number of keys you expect in your PingDirectory server. The number of keys is provided in the index-size configuration property of the `global-attribute-index` object when you configure an attribute index. For the built-in RDN index, the configured number of keys is provided in the `rdn-index-size` property. If you do not provide a value, the tool assumes that the configured number of keys is the same as the actual number of keys.

Steps

- To estimate the size of two separate indexes, run the `global-index-size` tool.

  Example:

  In this example, the two indexes both have 10,000,000 keys but with differing average key sizes. The configured number of keys is assumed to be equal to the actual number of keys.

```
$ bin/global-index-size --numKeys 10000000 \
  --averageKeySize 11 --numKeys 10000000 \
  --averageKeySize 15

Num Keys : Cfg. Num Keys : Avg. Key Size : Est. Memory Size
---------:---------------:---------------:-----------------
10000000 : 10000000      : 11            : 159 mb
10000000 : 10000000      : 15            : 197 mb
```

Priming the global indexes on startup

The PingDirectoryProxy server can prime the global indexes at startup from the backend directory server or from a peer proxy server, preferably one that resides on the same LAN or subnet.

When priming occurs locally, you can avoid WAN bandwidth consumption and reduce the processing load on the directory servers in the topology. You can specify the data sources for the index priming and the order in which priming occurs from these sources. Use the `prime-index-source` property to specify the sources of data, either `ds`, `file` or some combination of the two.

The order you specify is the order in which priming is attempted from these sources. Priming is most efficient if the source server is on the same local network as the PingDirectoryProxy server.

For example, if you specify `prime-index-source:file,ds`, priming is performed from the `global-index` data file created from the previous run of the directory servers. If the entire global index has been primed previously from a startup or reloaded-index directory server's source, the contents of the global index are written to disk periodically with the `file,ds` configuration.

Configuring all indexes at startup

Steps

- To prime all indexes at startup, run the `dsconfig` tool.

  Example:

  The following example configures the entry-balancing request processor so that it primes the global index from the persisted file, if present, or from an external directory server's source, if necessary.

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set prime-all-indexes:true --set prime-index-source:file \
  --set prime-index-source:ds
```

Configuring the global indexes manually

About this task

If you don't want to configure priming during setup, you can configure the index priming manually.

To do this, create an external server, create a global attribute index, and change the entry-balancing request processor to load indexes from the external server.

Steps

1. To create an external server of the PingDirectoryProxy type to represent a peer of the PingDirectoryProxy server, use the `dsconfig` tool with the `create-external-server` subcommand.

   Example:

```
$ bin/dsconfig create-external-server \
  --server-name intra-proxy-host.example.com:3389 \
  --type PingDirectoryProxy-server \
  --set server-host-name:intra-proxy-host \
  --set server-port:338 \
  --set "bind-dn:cn=Directory Manager" \
  --set "password:secret123"
```

2. Create a global attribute index on the `uid` attribute.

   Example:

   ```
   $ bin/dsconfig create-global-attribute-index \
     --processor-name dc_example+dc+com-eb-req-processor \
     --index-name uid \
   ```

3. To load the indexes at startup from the peer PingDirectoryProxy server, change the entry-balancing request processor using `dsconfig set-request-processor-prop`.

Persisting the global index from a file

About this task

The PingDirectoryProxy server supports periodically persisting the global index to a file and priming the global index from the persisted file when the server is restarted.

You can configure an Entry Balancing Request Processor to persist the global index to disk periodically so that when the Entry Balancing Request Processor is reinitialized on startup it can prime the values from disk instead of putting load on the remote servers. Reading the index from disk eliminates the load on backend PingDirectory server instances if many PingDirectoryProxy server instances are starting at the same time.

You can configure an entry-balancing request processor to persist the global index to disk by including `file` as one of the prime index sources with the `prime-index-source` property. The `persist-global-index-frequency` property controls the frequency at which the file is written.

The global index must be primed before it's persisted. It can be primed initially using a peer PingDirectoryProxy server or from a backend PingDirectory server.

When new global attribute indexes are added on a running PingDirectoryProxy, the global index can be primed with those attribute indexes by running the `rebuild-index` tool. The `rebuild-index` tool uses a remote server for priming the global index, even if `file` is configured as a source.

On subsequent restarts of the PingDirectoryProxy server, the global index is primed from the persisted file instead of going over the network to a remote server, which allows it to be primed much faster than if it's using a remote priming source. During server startup, the global index priming works by using each configured `prime-index-source` property in the specified order until it's fully primed to take advantage of what is available locally before contacting one or more remote servers.

Steps

- To prime all indexes at startup from a file, run the `dsconfig` tool.

  Example:

  ```
  dsconfig -n set-request-processor-prop \
    --processor-name entry-balancing \
    --set prime-index-source:file \
    --set prime-index-source:ds \
    --set persist-global-index-frequency:10s \
    --set persist-global-index-directory:/servers/proxy-1/index-files \
    --set prime-all-indexes:true
  ```

Priming or reloading the global indexes from Sun Directory servers

When priming or reloading a global index based on a Sun Directory Server environment, the Sun servers might become overwhelmed and unresponsive because of their method of streaming data.

About this task

To reduce the impact of priming and reloading on these servers, use the `prime-search-entry-per-second` property and the `--searchEntryPerSecond` property of the `reload-index` command. These properties control the rate at which the PingDirectoryProxy server accepts search result entries from the backend directory servers.

The `index-priming-idle-listener-timeout` property specifies the amount of time an extended operation response listener can be idle while the global index priming is in progress. For example, if the global index is priming and a backend server stops returning results but doesn't disconnect, this timeout can be used to force a retry of the operation.

> **Tip**
>
> To find the optimum rate, start low and specify a few thousand search entries per second. Then increase as necessary.

To reduce the impact on server performance:

Steps

- To reduce the impact of priming on servers, use the `prime-search-entry-per-second` property.
- To reduce the impact of reloading these indexes, use the `--searchEntryPerSecond` property of the `reload-index` command.
- To specify the amount of time an extended operation response listener can be idle while the global index priming is in progress, use the `index-priming-idle-listener-timeout`.

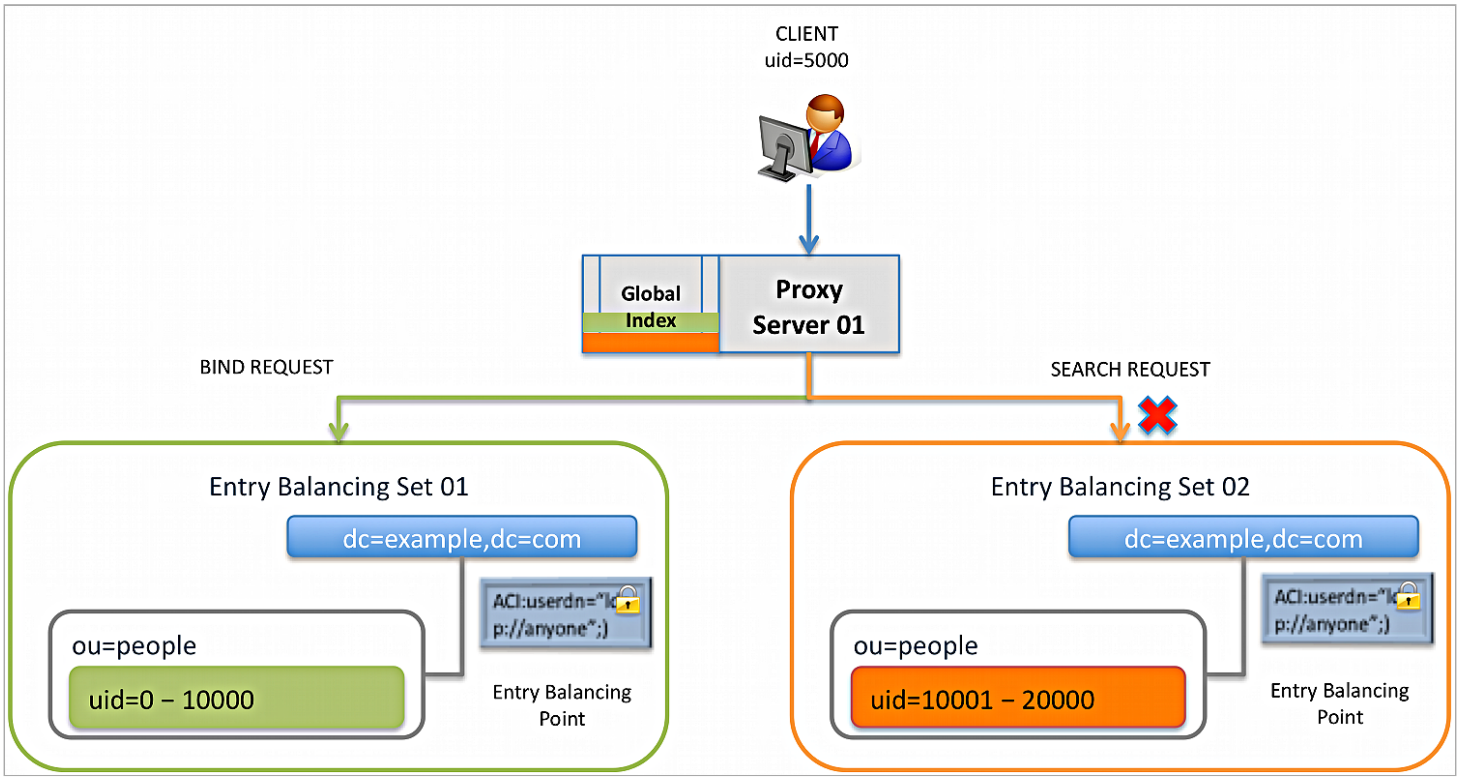
Working with alternate authorization identities

The following sections cover the procedures to configure the alternate authorization identities for the PingDirectoryProxy server.

Access control rules in an entry-balanced deployment are configured in the PingDirectory backend servers and require access to the entry contents of the user issuing the request.

This can introduce a potential issue when clients to the PingDirectoryProxy server authenticate as users whose entries are among the entry-balanced sets. If the server processing a request doesn't contain the issuing user's entry, the access control can't be evaluated. One solution to this problem is to make use of an alternate authorization identity for the user, which references an entry that exists in all PingDirectory server's in all backend sets and has an equivalent set of access control rights as the authenticated user.

For the following example, assume a deployment has two entry-balancing sets: set-01 and set-02. Set-01 has entries in the `uid=0-10000` range, while set-02 has entries for `uid=10001-20000`.



Entry-Balancing Issue with Clients Not Present in the Underlying Data Set

Processing steps

1. The client with `uid=5000` binds to the PingDirectoryProxy server, which sends a `BIND` request to entry-balancing set-01.
2. The client sends a `SEARCH` request with filter `(uid=15000)`.
3. The PingDirectoryProxy server determines that `uid=15000` lives on entry-balancing set-02.
4. The PingDirectoryProxy server determines that the entry for the authenticated user with `uid=5000` doesn't exist in set-02 and that the access control handler has to reject the `SEARCH` request issued by an unknown user.
5. The PingDirectoryProxy server observes that the PingDirectory server processing a request doesn't contain the entry of the user issuing the request and decides to use an alternate authorization identity.

About alternate authorization identities

Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries aren't present within an entry-balanced dataset.

Whenever the PingDirectoryProxy server forwards a request to the backend set containing the user's entry, it forwards the request with an authorization identity that reflects the user's actual identity because the user is known to servers in that set. However, when forwarding a request to a backend set that doesn't contain the user's entry, the PingDirectoryProxy server uses an alternate authorization identity that reflects the generic user with the same set of rights as the actual user issuing the request.

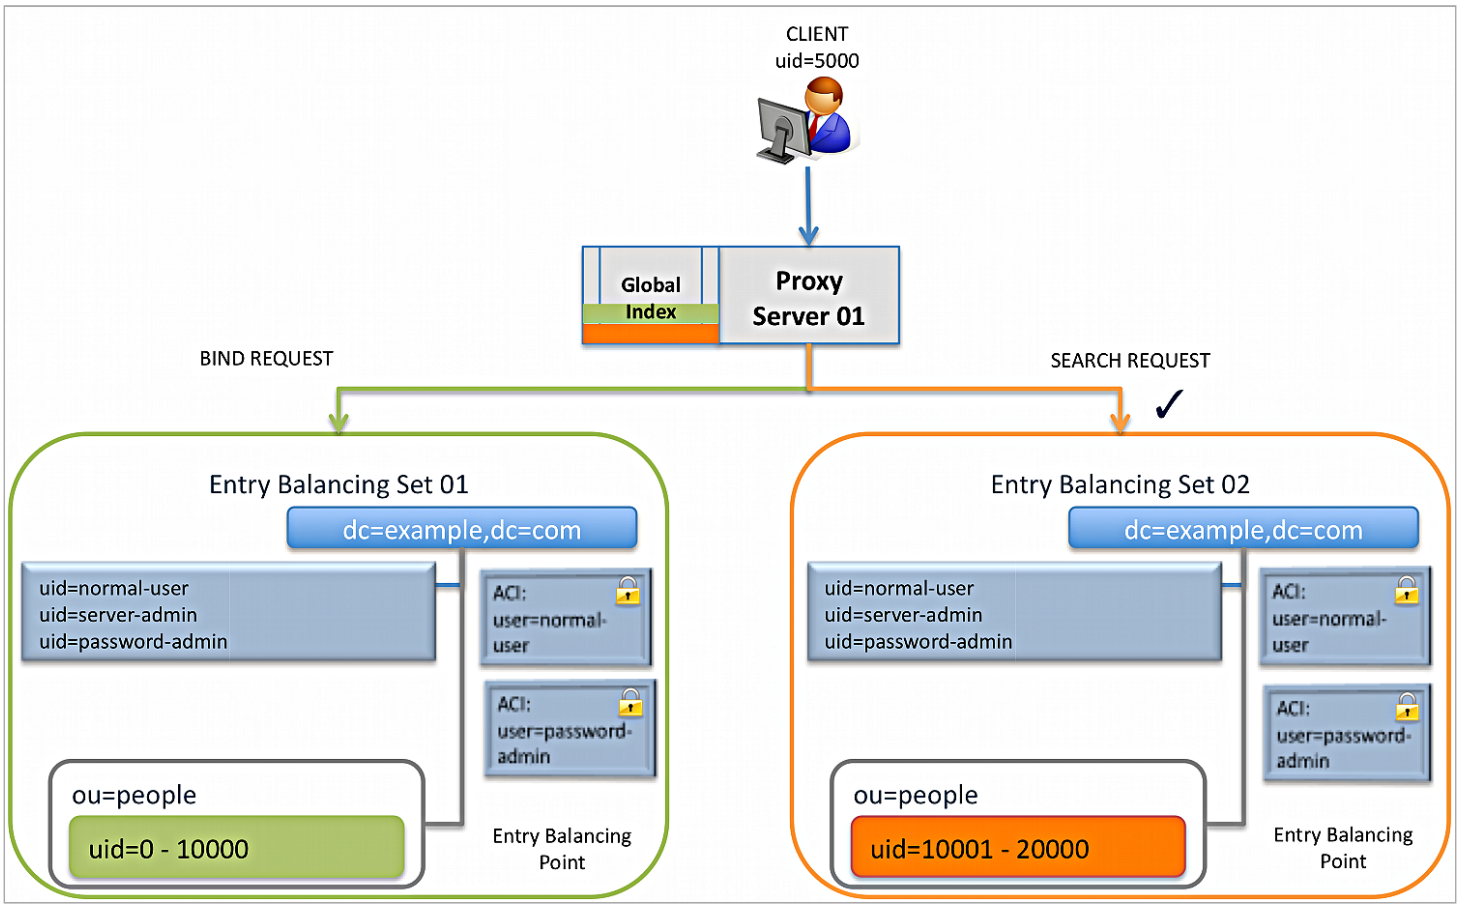
Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries are not present within an entry-balanced dataset.

There are only a few different generic classes of users from an access control perspective. These can be placed in a portion of the directory information tree (DIT) that isn't below the entry-balancing base distinguished name (DN) and is replicated to all servers in the topology.

Whenever a user authenticates to the PingDirectoryProxy server, the server can keep track of which backend set holds that user's entry and determine whether an alternate authorization identity is required. The server can determine which of these generic accounts best describes the rights that the user should have.

For the following example, assume that you have three classes of users: full administrators, password administrators, and normal users. Assume that you create the following entries in the topology and assign them the appropriate access rights:

- `uid=normal user,dc=example,dc=com`
- `uid=server-admin,dc=example,dc=com`
- `uid=password-admin,dc=example,dc=com`



Alternate Authorization Identity Solves Access Control Issues in Entry-Balancing Deployments

Processing steps

1. The client with `uid=5000` binds to the PingDirectoryProxy server, which sends a `BIND` request to entry-balancing set-01.
2. The client sends a `SEARCH` request for `uid=15000`.
3. The PingDirectoryProxy server determines that `uid=15000` lives on entry-balancing set-02.

4. The PingDirectoryProxy server then determines that the client `uid=5000` doesn't have an entry on entry-balancing set-02.
5. The PingDirectoryProxy server uses an alternate authorization identity that reflects the generic user, `uid=normal user`, which has the same set of rights as the client `uid=5000` issuing the request.
6. The access control is accepted and the `SEARCH` request returns a response for `uid=5000`.
7. When an alternate authorization identity is invoked, `authzID='dn:uid=normal user,dc=example,dc=com` records in the server log, which indicates the use of the alternate authorization identity.

   For example, if the `user.15000` is in a different backend set from `user.5000`, the log shows the following response.

```
% bin/ldapsearch -D "uid=user.5000,ou=people,dc=example,dc=com" -w pasword \
  -b uid=user15000,ou=people,dc=example,dc=com "(objectclass=)"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2
via="app='Directory-Proxy address='127.0.0.1'
authzID='dn:uid=normal user,dc=example,dcom' sessionID='conn=2'
requestID='op=1'" base="uid=user.150000,ou=people,dc=example,dc=com"scope=2
filter="(objectclass=)" attrs="ALL"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2 resultCode=0 etime=2.038
entriesReturned=1 authzDN="uid=normal-user,dc=example,dc=com"
```

Configuring alternate authorization identities

Alternate authorization identities are specified by the `authz-attribute` property of the entry-balancing request processor configuration object.

About this task

By default, the `authz-attribute` property has the default value of `ds-authz-map-to-dn`, which is an attribute reserved for this purpose.

If a user entry has a value for `ds-authz-map-to-dn`, whether it's explicitly contained in the entry or only present with a virtual attribute, that value is used to specify the alternate authorization identity for the user. Otherwise, the default authorization identity, as indicated with the `authz-dn` configuration property, is used to determine the alternate authorization identity.

Steps

1. Set the `authz-dn` property of the entry-balancing request processor configuration using the `dsconfig` tool.

   > **Note**
   >
   > If any user among the balanced entries doesn't have an alternate authorization identity defined, the PingDirectoryProxy server uses the value of the `authz-dn` property of the entry-balancing request processor configuration.

   Example:

```
$ bin/dsconfig set-request-processor-prop \
  --processor-name dc_example_dc_com-eb-req-processor \
  --set "authz-dn:uid=normal user,dc=example,dc=com"
```

2. Create an auxiliary object class containing `ds-authz-map-to-dn` as an allowed attribute.
3. Add the auxiliary object class value to all user entries of interest.
4. Add the following attribute value to a `server-admin` user.

   Example:

   ```
   ds-authz-map-to-dn: uid=server-admin,dc=example,dc=com
   ```

Forwarding authorization identities in requests

By default, the PingDirectoryProxy server tries to ensure that requests it forwards to backend servers get processed with the correct user authorization. To do this, the server relies on a function controlled by the `authorization-method` property, located in the LDAP external server configuration for each of the backend server instances.

Considering proxied authorization scenarios

In environments configured with a PingDirectoryProxy server in front of PingDirectory server instances, the `authorization-method` property is typically set to `intermediate-client-control`. This `authorization-method` value might not be the best option when clients need to authorize a request as a user whose account doesn't exist in the backend server, including the following scenarios:

- Entry-balanced configurations where a user whose account resides in one backend set might need to issue requests targeting entries in a different backend set
- Configurations that have multiple subtree views backed by different sets of backend servers for different parts of the DIT, where a user whose account resides in one part might need to issue requests targeting entries in a different part

However, the `intermediate-client-control` setting can still be appropriate for deployments where some users might need to issue requests that get processed by servers that don't contain their accounts. In these scenarios, there are a small number of roles that any user can assume, such as a regular end user, a password administrator, or a full server administrator. You can create surrogate accounts for each of those roles that reside in all the backend servers.

> **Tip**
>
> To indicate that operations processed in servers that don't contain the requester's user entry should be authorized as the appropriate surrogate account, use the `ds-authz-map-to-dn` operational attribute, whether real or virtual.

Using the `forward-authorization-entry-control`

You can also use the `forward-authorization-entry-control`, which causes the PingDirectoryProxy server to forward a copy of the requester's entry to the backend server. The PingDirectoryProxy server uses that entry to authorize requests as that user in backend servers that don't already contain the entry.

Important

You should prefer the `intermediate-client-control` for proxied authorization.
Reserve the `forward-authorization-entry-control` for scenarios where it's common for users in one entry-balanced backend set to need access to entries in other backend sets—but whose entries can't be reasonably mapped to surrogate entries.
You can only use the `forward-authorization-entry-control` in topologies where all servers are running version 10.3 or later.

Steps

For each PingDirectoryProxy server in the topology, make the following configuration change for every LDAP external server instance:

- **Set the value of `authorization-method` to `forward-authorization-entry-control`.**

  Example:

```
$ bin/dsconfig set-external-server-prop \
  --server-name server.example.com:636 \
  --set authorization-method:forward-authorization-entry-control
```

Managing entry-balancing replication

Replication in the PingDirectoryProxy server synchronizes directory data between all servers in the topology.

However, In a deployment using the entry-balancing feature, directory data under the entry-balancing point is split into multiple data sets. Each data set is replicated to ensure high availability between a subset of the servers in the topology.

Other directory data, such as the schema or data above the entry-balancing point, is replicated between all servers in the topology.

This section about replication in an entry-balancing environment contains the following:

- Overview of replication in an entry-balancing environment
- Replication prerequisites in an entry-balancing deployment
- About the --restricted argument of the dsreplication command-line Tool
- Checking the status of replication in an entry-balancing deployment
- Example of configuring entry-balancing replication

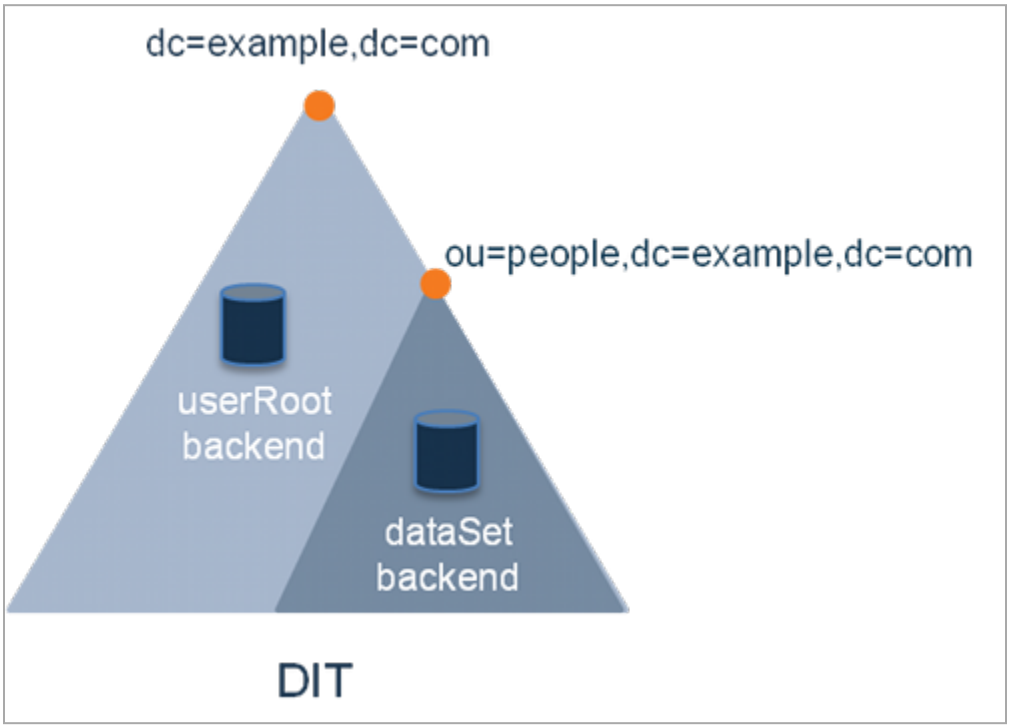
Overview of replication in an entry-balancing environment

In an entry-balanced deployment some data is replicated everywhere, such as the schema, the server registry, and other shared data, and some data is replicated only on certain servers.

A replication domain contains all of the servers in a replicated topology and shares a schema. The replication domain is associated with the base distinguished name (DN) and must be a base DN of a backend.

By default, replication propagates updates to all replication servers in the topology. However, updates to data under the entry-balancing point must be replicated only among server instances in the same data set. Replication requires that in these deployments the PingDirectory server is configured with a `replication-set-name` global configuration property and two backends. One backend has a base DN that is replicated globally, such as `dc=example,dc=com`, and the second backend has a base DN associated with the entry-balancing point, such as `ou=people,dc=example,dc=com`.

The following illustration demonstrates the global and restricted backends in a directory information tree (DIT).



If a data set name is not defined when you set up the PingDirectoryProxy server, one is provided by default. The proper configuration of an entry-balancing environment requires coordination between the PingDirectory server and the PingDirectoryProxy server. After you enable replication, you can designate the replication domain as the domain participating in entry balancing.

You can find more details about replication, managing the replication topology, and working with multiple backends, in the PingDirectory Server Administration Guide.

Replication prerequisites in an entry-balancing deployment

Before you can enable replication in an entry-balancing deployment, you must have the following set up in your server topology:

Multiple local DB backends

When you set up the PingDirectory server instances, you need two backends:

- A global backend for globally replicated data, such as `userRoot`
- A backend for the balancing point base distinguished name (DN), such as `dataSet`

Both backends must be enabled for replication and initialized separately.

Replication set name

Every PingDirectory server in your replicated topology must have a replication set name. This replication set name coordinates the PingDirectoryProxy server and the PingDirectory server.

The restricted domain is only replicated within instances using the same replication set name.

Multiple PingDirectoryProxy server subtree views

The entry-balanced proxy configuration relies on multiple subtree views, one for the globally replicated base DN and one for the entry-balancing point base DN. The globally replicated base DN has a proxying request processor associated with it. The restricted base DN has an entry-balancing request processor associated with it.

> **Tip**
>
> Configure the subtree views after running your setup using the `create-initial-proxy-config` tool.

Homogeneous domains

All servers in a replication topology must have the same domains.

> **Note**
>
> Because the PingDirectory server replication topology assumes that all domains are on all servers, it is not suitable for environments with an inconsistent presence of domains across the server topology.

About the --restricted argument of the dsreplication command-line Tool

The `dsreplication` tool with the `--restricted` argument specifies a base distinguished name (DN) when multiple domains are enabled in an entry balanced environment.

When enabling replication for a server that takes part in an entry-balanced environment, the multiple domains involved are enabled at the same time. There is a global domain and a restricted domain. The restricted domain represents the entry-balancing point. Each base DN is defined in a separate local database (DB) backend. Use the `dsreplication` command-line interface (CLI) tool with the `--restricted` argument to specify which base DN is considered an entry-balancing point.

Using the --restricted argument of the dsreplication command-line tool

About this task

To enable replication between two servers with entry balancing:

Steps

- Choose one of the following ways to run the `dsreplication` command:

  Choose from:

  - Run `dsreplication` in non-interactive mode.

    See the following example.

```
$ bin/dsreplication enable --host1 host1.example.com \
  --port1 1389 --bindDN1 "cn=Directory Manager" \
  --bindPassword1 secret --replicationPort1 8989 \
  --host2 host2.example.com --port2 2389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 secret \
  --replicationPort2 8989 --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --restricted ou=people,dc=example,dc=com
```

- Run `dsreplication` using the interactive command line.

  1. Enter `dsreplication` and the LDAP connection parameters.
  2. Specify that an entry balancing is being used.
  3. Specify the base distinguished name (DN) of the entry-balancing point.

     See the following example.

```
You must choose at least one base DN to be replicated.

Replicate base DN dc=example,dc=com? (yes / no) [yes]: yes

Replicate base DN ou=people,dc=example,dc=com? (yes / no) [yes]: yes

Do you plan to configure entry balancing using the Directory Proxy Server? (yes / no)
[no]: yes

Is dc=example,dc=com an entry-balancing point? (yes / no) [no]: no

Is ou=people,dc=example,dc=com an entry-balancing point? (yes / no) [no]: yes
```

Checking the status of replication in an entry-balancing deployment

You can use the `dsreplication` status tool to check the status of an entry-balancing deployment.

About this task

In this example, the `ou=people,dc=example,dc=com` subtree is entry-balanced.

The data is split into two sets, `set1` and `set2`. The servers `host1` and `host2` are in replication set `set1` and servers `host3` and `host4` are in replication set `set2`.

Steps

- To get a status of replication in the entry-balancing deployment, run the `dsreplication` command.

  Example:

> **Note**
>
> By default, all of the sets are displayed. To view only a specific replication set, use the `--setName` option.

Example:

```
$ bin/dsreplication status --hostname host1.example.com \
  --port 1389 --adminUID admin --adminPassword secret
```

Result:

```
          --- Replication Status for dc=example,dc=com: Enabled ---

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

austin1.example.com:1389 : 1000    : 0            : N/A             : 8989 : Enabled
austin2.example.com:2389 : 1000    : 0            : N/A             : 8989 : Enabled
newyork1.example.com:3389: 1000    : 0            : N/A             : 8989 : Enabled
newyork2.example.com:4389: 1000    : 0            : N/A             : 8989 : Enabled

 -- Replication Status for ou=people,dc= example,dc=com (Set: set1): Enabled --

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

austin1.example.com:1389 : 1000000 : 0            : N/A            : 8989 : Enabled
austin2.example.com:2389 : 1000000 : 0            : N/A            : 8989 : Enabled

---Replication Status for ou=people,dc= example,dc=com (Set: set2): Enabled ---

Server    : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security

----------:--------:------------------:--------------------------:------:--------

newyork1.example.com:3389 : 1000000 : 0            : N/A            : 8989 : Enabled
newyork2.example.com:4389 : 1000000 : 0            : N/A            : 8989 : Enabled
```

Example of configuring entry-balancing replication

This section covers how to set up a four-server replication topology that uses entry balancing to distribute entries across the servers and provides a start-to-finish example to walk you through this process.

Assumptions

The example assumes the following conditions:

- None of the servers have participated in any previous replication topology. This is supported for one or multiple entry balancing domains.
- This example uses the LDAP (389) and replication (8989) ports. It configures the following hosts:
  - austin1.example.com
  - newyork1.example.com
  - austin2.example.com

- newyork2.example.com

- The global domain is `dc=example,dc=com`, which is replicated across all servers.
- The data below the entry-balancing point of `ou=people,dc=example,dc=com` is distributed across two data sets, dataSet1 and dataSet2.
- Each data set is replicated between two directory servers. Each of these servers is associated with one of two locations, Austin or New York.

Configuration summary

To configure replication in an entry-balanced deployment:

1. Install two directory servers in an Austin location and two in a New York location.
2. Create a new backend, called `dataset`, to store the entry-balancing data set.
3. Define entry-balancing set names `dataSet1` and `dataSet2` for assignment to the `replication-set-name` Global Configuration Property of the PingDirectory server instances.
4. Import the data representing the global domain, stored in `userRoot`, into a server. Choose a server for each of the entry-balancing data sets, which are both stored in the backend named `dataset`.
5. Enable replication and initialize remaining servers.
6. Configure the proxies.
7. Check the status of replication.

Installing the PingDirectory server
About this task

Install four PingDirectory server instances, two in the Austin location and two in the New York location:

- austin1.example.com
- newyork1.example.com
- austin2.example.com
- newyork2.example.com

Steps

1. Install the first Austin server, `austin1`.

   Example:

   ```
   root@austin1# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds1 --location Austin
   ```

2. Install the second Austin server, `austin2`.

   Example:

```
root@austin2 # ./setup --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense \
--instanceName ds2 --location Austin
```

3. Install the first New York server, `newyork1`.

   Example:

   ```
   root@newyork1# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds3 --location NewYork
   ```

4. Install the second New York server, `newyork2`.

   Example:

   ```
   root@newyork# ./setup --baseDN dc=example,dc=com \
   --ldapPort 389 --rootUserDN "cn=Directory Manager" \
   --rootUserPassword pass --no-prompt --acceptLicense \
   --instanceName ds4 --location NewYork
   ```

Creating the database backends and defining the replication set name
About this task

To store the entry-balancing data set, create a new backend.

Steps

1. On each server, create a dataset backend named `dataset`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-backend \
   --backend-name dataset --type local-db --set enabled:true \
   --set base-dn:ou=people,dc=example,dc=com
   ```

2. Set the `replication-set-name` for `austin1.example.com` and `newyork1.example.com` to `dataset1`.

   Example:

   ```
   ./bin/dsconfig --no-prompt \
   set-global-configuration-prop \
   --set replication-set-name:dataset1
   ```

3. Set the `replication-set-name` for `austin2.example.com` and `newyork1.example.com` to `dataset2`.

   Example:

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset2
```

Creating and setting the locations
About this task

Create and set the locations of the Austin and New York server instances.

Steps

1. On the Austin servers, create two instance locations, `newyork` and `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-location --location-name austin

   ./bin/dsconfig --no-prompt create-location --location-name newyork \
   --set preferred-failover-location:austin
   ```

2. Set the location of the Austin server instances to `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt set-location-prop --location-name austin \
   --add preferred-failover-location:newyork

   ./bin/dsconfig --no-prompt set-global-configuration-prop \
   --set location:austin
   ```

3. On the New York servers, create two instance locations, `newyork` and `austin`.

   Example:

   ```
   ./bin/dsconfig --no-prompt create-location \
   --location-name austin

   ./bin/dsconfig --no-prompt create-location \
   --location-name newyork \
   --set preferred-failover-location:austin
   ```

4. Set the location of the New York server instances to `newyork`.

   Example:

   ```
   ./bin/dsconfig --no-prompt set-location-prop \
   --location-name austin \
   --add preferred-failover-location:newyork

   ./bin/dsconfig --no-prompt set-global-configuration-prop \
   --set location:newyork
   ```

Importing the entries

Import the `userRoot` data based on data defined in the `userRoot.ldif` file into one server.

About this task

Choose a server for each of the entry-balancing data sets, both stored in the dataset backend.

> **Note**
>
> The `userRoot.ldif` file doesn't contain entries at or within the entry-balancing point, `ou=people,dc=example,dc=com`.

Steps

1. **Import the userRoot data using the `import-ldif` command.**

   Example:

   ```
   root@austin1# ./bin/import-ldif --backendID userRoot \
   --ldifFile /data/userRoot.ldif \
   --includeBranch dc=example,dc=com \
   --rejectFile /data/austin1-import-rejects \
   --port 389
   --hostname austin1.example.com
   ```

2. **Import the `dataSet1` data that is assigned the `replication-set-name` on one server into the dataset backend.**

   Example:

   ```
   root@austin1# ./bin/import-ldif --backendID dataset \
   --ldifFile /data/dataset1.ldif \
   --includeBranch ou=people,dc=example,dc=com \
   --rejectFile /data/austin1-dataset-import-rejects \
   --hostname austin1.example.com --port 389
   ```

3. **Import the `dataSet2` data that is assigned the `replication-set-name` on one server into the dataset backend.**

   Example:

   ```
   root@austin2# ./bin/import-ldif --backendID dataset \
   --ldifFile /data/dataset2.ldif \
   --includeBranch ou=people,dc=example,dc=com \
   --rejectFile /data/austin2-dataset-import-rejects \
   --hostname austin2.example.com --port 389
   ```

Enabling replication in an entry-balancing deployment

Enable replication between the servers and initialize the remaining servers without data.

About this task

> **Note**
>
> In this example, the `--restricted` domain is specified in the **`dsreplication`** command.

To enable replication on the servers in the topology:

Steps

1. Run `dsreplication enable`.

   Example:

   ```
   root@austin1# ./bin/dsreplication enable \
   --host1 austin1.example.com \
   --port1 389 --bindDN1 "cn=directory manager" \
   --bindPassword1 pass --host2 austin2.example.com \
   --port2 389 --bindDN2 "cn=directory manager" \
   --bindPassword2 pass \
   --replicationPort1 8989 \
   --replicationPort2 8989 \
   --baseDN dc=example,dc=com \
   --baseDN ou=people,dc=example,dc=com \
   --restricted ou=people,dc=example,dc=com \
   --adminUID admin --adminPassword pass --trustAll \
   --no-prompt
   ```

   > **Note**
   >
   > Running the **`dsreplication enable`** command for the first time creates the administrator account.

2. Enable replication between `austin1` and `newyork1`.

   Example:

   This procedure automatically also enables replication between `austin2` and `newyork1`.

   ```
   root@austin1# ./bin/dsreplication enable \
   --host1 austin1.example.com \
   --port1 389 --bindDN1 "cn=directory manager" \
   --bindPassword1 pass --host2 newyork1.example.com \
   --port2 389 --bindDN2 "cn=directory manager" \
   --bindPassword2 pass \
   --replicationPort1 8989 \
   --replicationPort2 8989 \
   --baseDN dc=example,dc=com \
   --baseDN ou=people,dc=example,dc=com \
   --restricted ou=people,dc=example,dc=com \
   --adminUID admin --adminPassword pass --trustAll \
   --no-prompt
   ```

3. Enable replication between `austin1` and `newyork2`.

   Example:

```
root@austin1# ./bin/dsreplication enable \
  --host1 austin1.example.com \
  --port1 389 --bindDN1 "cn=directory manager" \
  --bindPassword1 pass --host2 newyork2.example.com \
  --port2 389 --bindDN2 "cn=directory manager" \
  --bindPassword2 pass \
  --replicationPort1 8989 \
  --replicationPort2 8989 \
  --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --restricted ou=people,dc=example,dc=com \
  --adminUID admin --adminPassword pass --trustAll \
  --no-prompt
```

Result:

The entry-balancing replication setup is complete.

4. Initialize the remaining servers without data.

    1. Initialize the global domain, `dc=example,dc=com` on `austin2`, `newyork1`, and `newyork2` servers.

        Example:

        ```
        root@austin1# ./bin/dsreplication initialize \
          --hostSource austin1.example.com --portSource 389 \
          --hostDestination austin2.example.com \
          --portDestination 389 --adminUID admin \
          --adminPassword password \
          --baseDN dc=example,dc=com \
          --no-prompt
        ```

    2. Initialize the entry-balancing domain, `ou=people,dc=example,dc=com`, from `austin1` to `newyork2`.

        Example:

        ```
        root@austin1# ./bin/dsreplication initialize \
          --hostSource austin1.example.com --portSource 389 \
          --hostDestination newyork1.example.com \
          --portDestination 389 --adminUID admin \
          --adminPassword password \
          --baseDN dc=example,dc=com \
          --baseDN ou=people,dc=example,dc=com \
          --no-prompt
        ```

    3. Initialize the entry-balancing domain, `ou=people,dc=example,dc=com`, from `austin2` to `newyork2`.

        Example:

```
root@austin2# ./bin/dsreplication initialize \
  --hostSource austin2.example.com --portSource 389 \
  --hostDestination newyork2.example.com \
  --portDestination 389 --adminUID admin \
  --adminPassword password \
  --baseDN dc=example,dc=com \
  --baseDN ou=people,dc=example,dc=com \
  --no-prompt
```

> **Note**
>
> After `austin2` is initialized with the global domain, you can combine steps 4b and 4c by initializing both domains with one invocation.

Checking the status of replication

After you have configured replication, check the status of the replication topology using the `dsreplication status` command.

Steps

- To check the replication topology status, run the `dsreplication status` command.

  Example:

  ```
  root@austin1# ./bin/dsreplication status \
  --adminPassword pass --no-prompt --port 389
  ```

Managing the PingDirectoryProxy server

After you have configured the PingDirectoryProxy server, you can manage the day-to-day operations of your deployment using the monitoring and logging features.

Managing logs

The PingDirectoryProxy server provides several different log publisher types that provide information about how the server is processing.

About the default logs

You can view all logs in the `PingDirectoryProxy/logs` directory. The following logs are documented in detail:

- Error Log
- server.out Log
- Debug Log

- Config Audit Log and the Configuration Archive
- Access Log
- Setup Log
- Tool Log
- LDAP SDK Debug Log

Error log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. Several messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887 msg="The Directory Server has
started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, and VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- DEBUG – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, because the server provides a separate debug logging facility.
- INFORMATION – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- MILD_WARNING – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- MILD_ERROR – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action.
- NOTICE – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- SEVERE_WARNING – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- SEVERE_ERROR – Used for significant problems that have prevented the server from successfully completing processing and are considered important.

- FATAL_ERROR – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log can be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which can be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE_WARNING, SEVERE_ERROR, and FATAL_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-warning,severe-error,fatal-error
```

Note that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD_WARNING, or MILD_ERROR severities.

The error log configuration can be altered on the fly using tools like `dsconfig`, the admin console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger can be activated with a different set of default severities to debug a short-term problem, and then that logger can be removed after the problem is resolved, so that the normal error log does not contain any of the more verbose information.

server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes several messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- enabled – Indicates whether debug logging is enabled. By default, it is disabled.
- log-file – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- default-debug-level – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.

- default-debug-category – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

> **Note**
>
> Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Audit log

The audit log is a specialized version of the access log used for troubleshooting problems that could occur in the course of processing.

The audit log records all changes to directory data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues.

The audit log is disabled by default because it reduces the server's write performance.

By default, if you enable the audit log on the server, the `userPassword` and `authPassword` attribute values are obscured. Each value of an obscured attribute is replaced in the audit log with a string of the form `"***** OBSCURED VALUE *****"`. You can unobscure these attributes by deleting them from the `obscure-attribute` property.

Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that can be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.

- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages can also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1" to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- origin=replication – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- message – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- additionalInfo – Additional information about the operation that was not included in the response sent back to the client.
- authDN – DN of the user that authenticated to the server (typically only included in bind result messages).
- authzDN – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).

- authFailureID – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- authFailureReason – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- responseOID – OID included in an extended response returned to the client.
- entriesReturned – Number of matching entries returned to the client for a search operation.
- unindexed=true – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here can also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they can contain.

The server provides a second access log implementation called the audit log, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

Setup log

The `setup` command writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log`, although a different name might be used if a file with that name already exists because the `setup` command has already been run. The full path to the setup log file is provided when the `setup` command has completed.

Tool log

Many of the administrative tools provided with the server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, `logs/tools/ import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running using the server tasks interface, log messages generated while the task is running can alternately be written to the server error log file.

LDAP SDK debug log

This log can be used to help examine the communication between the PingDirectory server and the PingDirectoryProxy server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

Types of log publishers

The PingDirectoryProxy server provides different types of loggers that get processing information about the server.

There are three primary types of loggers:

Access loggers

Provide information about operations processed within the server. They can be used for understanding the operations performed by clients, debugging problems with directory-enabled applications, and collecting usage information for performance and capacity planning purposes.

Error loggers

Provide information about warnings, errors, or significant events that occur within the server.

Debug loggers

Provide detailed information about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.

By default, the following log publishers are enabled on the system:

- File-based access logger
- File-based error logger
- Failed-operations access logger

The following log publishers are available for the PingDirectoryProxy server but are disabled by default:

- File-based debug logger
- File-based audit logger
- Expensive operations access logger
- Successful searches with no entries returned access logger

Creating new log publishers

The server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see Configuring Log Rotation and Configuring Log Retention.

Creating a new log publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

   Example:

This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access --publisher-name "Disconnect Logger" \
  --set enabled:true \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set log-connects:false \
  --set log-requests:false --set log-results:false \
  --set log-file:logs/disconnect.log
```

Note

To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.
Because compression can't be disabled or turned off after being configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regard to compressed logs.

2. View log publishers with the following command.

```
$ bin/dsconfig list-log-publishers
```

Creating a log publisher using dsconfig interactive command-line mode

Steps

1. In the command line, enter `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. In the main menu, select the option to configure the log publisher.
4. In the `Log Publisher menu`, select the option to create a new log publisher.
5. Select the Log Publisher type.

   For this example, select File-Based Access Log Publisher.
6. Enter a name for the log publisher.
7. Enable it.
8. Enter the path to the log file relative to the PingDirectory server root.

   For this example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. In the `Log Publisher Properties menu`, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.

12. Enter `f` to apply the changes.

About log compression

The server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The **`summarize-access-log`** tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

About log signing

The server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the **`dsconfig`** tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the **`validate-file-signature`** tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

About encrypting log files

The server lets you encrypt log files as they are written.

The `encrypt-log` configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption can't be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces the overall size of the log file. The `encrypt-file` tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the `encryption-settings-definition-id` property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it can't write an incomplete block of data until the file is closed. This is not an issue for any log file that isn't being actively written.

To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

Configuring log signing

Configure log signing for a log publisher.

Steps

1. To enable log signing for a log publisher, use `dsconfig`.

   Example:

   In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

   ```
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set sign-log:true
   ```

2. Disable and then re-enable the log publisher for the change to take effect.

   Example:

   ```
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set enabled:false
   $ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
     --set enabled:true
   ```

Validating a signed file

The server provides a tool, `validate-file-signature`, that checks if a file hasn't been tampered with in any way.

Steps

- Run the `validate-file-signature` tool to check if a signed file has been tampered with.

  Example:

  For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

  ```
  $ bin/validate-file-signature --file logs/audit
  ```

  Result:

  ```
  All signature information in file 'logs/audit' is valid
  ```

  > **Note**
  >
  > If any validation errors occur, you will see a message similar to the following:
  >
  > ```
  > One or more signature validation errors were encountered
  > while validating the contents of file 'logs/audit':
  > * The end of the input stream was encountered without
  >   encountering the end of an active signature block.
  >   The contents of this signed block cannot be trusted
  >   because the signature cannot be verified
  > ```

Configuring log file encryption

Configure log file encryption for a log publisher.

Steps

1. To enable encryption for a log publisher, use `dsconfig`.

   Example:

   In this example, the File-based Access Log Publisher `"Encrypted Access"` is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

2. Decrypt and decompress the file.

   Example:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...Done

```

Configuring log rotation

The PingDirectory server allows you to configure the log rotation policy for the server.

About this task

When any rotation limit is reached, the server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

Never Rotate Policy

Used in a rare event that does not require log rotation.

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring log rotation listeners

The server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

Steps

- Use the following command to create a new copy log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

> **Note**
>
> The path specified by the **`copy-to-directory`** property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- **Use the following command to create a new summarize log file rotation listener.**

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

> **Note**
>
> The summary output files have the same name as the rotated log file, with an extension of **`.summary`**. If the **`output-directory`** property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.
> As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring log retention

The server allows you to configure the log retention policy for each log on the server.

About this task

When a retention limit is reached, the server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

File Count Retention Policy

Sets the number of log files you want the server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

Custom Retention Policy

Create a new retention policy that meets your server's requirements. This requires developing custom code to implement the desired log retention policy

Never Delete Retention Policy

Used in a rare event that does not require log deletion.

Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Setting resource limits

You can set resource limits for the PingDirectoryProxy server using several global configuration properties as well as setting resource limits on specific client connection policies.

If you configure both global and client connection policy resource limits, the first limit reached is always honored. For example, if the server-wide maximum concurrent connections limit is reached, then all subsequent connections are rejected until existing connections are closed regardless of whether a client connection policy limit has been reached.

Setting global resource limits

You can specify the following types of global resource limits:

`maximum-concurrent-connections`

Specify the maximum number of client connections that can be established at any given time.

If the server already has the maximum number of connections established, then any new connection attempts from any clients are rejected until an existing connection is closed.

The default value of zero indicates that no limit is enforced.

`maximum-concurrent-connections-per-ip-address`

Specify the maximum number of client connections that can be established at any given time from the same client system.

If the server already has the maximum number of connections established from a given client, then any new connection attempts from that client are rejected until an existing connection from that client is closed. The server continues to accept connections from other clients that haven't yet reached this limit.

The default value of zero indicates that no limit is enforced.

`maximum-concurrent-connections-per-bind-dn`

Specify the maximum number of client connections that can be established at any given time while authenticated as a particular user.

This property applies after the connection is established because the bind operation to authenticate the user happens after the connection is established rather than during the course of establishing the connection itself.

If a given user reaches the maximum number of connections, then any new attempt to authenticate as that user causes the connection performing the bind to be terminated.

> **Note**
>
> This limit applies only to authenticated connections and isn't enforced for clients that haven't authenticated or for clients that have authenticated as the anonymous user.

The default value of zero indicates that no limit is enforced.

Any changes to the `maximum-concurrent-connections` and `maximum-concurrent-connections-per-ip-address` properties take effect only for new connections established after the change is made. Any change to the `maximum-concurrent-connections-per-bind-dn` property applies only to connections, including existing connections, that perform authentication after the change is made.

Existing connections are allowed to remain established even if that would cause the new limit to be exceeded.

Setting client connection policy resource limits

Configure resource limits in a client connection policy using the following properties of the client connection policy:

`maximum-concurrent-connections`

This property specifies the maximum number of client connections that can be associated with a specific client connection policy at any given time. After this limit has been reached, any further attempts to associate a connection with this client connection policy result in the termination of the connection.

`maximum-connection-duration`

This property specifies the maximum length of time that a connection associated with a particular client connection policy can persist. After this period, the connection is terminated.

`maximum-idle-connection-duration`

This property specifies the maximum time that a connection associated with a particular client connection policy can persist after the completion of the last operation processed on that connection. Any new operation requested on the connection resets the timer. Connections that are idle for longer than the specified time are terminated.

`maximum-operation-count-per-connection`

This property specifies the maximum number of operations that can be requested by any client connection associated with this client connection policy. Attempts to process more than this number of operations on the connection terminates the connection.

`maximum-concurrent-operations-per-connection`

This property specifies the maximum number of concurrent operations for any connection. This property can be used to prevent a single client connection from monopolizing server processing resources by sending a large number of concurrent asynchronous requests.

`maximum-connection-operation-rate`

This property specifies the maximum rate at which a client associated with a specific client connection policy can issue requests to the PingDirectoryProxy server. If a client attempts to request operations at a rate higher than this limit, then the server behaves as described by the `connection-operation-rate-exceeded-behavior` property.

`connection-operation-rate-exceeded-behavior`

This property describes how the server should behave if a client connection attempts to exceed a rate defined in the `maximum-connection-operation-rate` property.

`maximum-policy-operation-rate`

This property specifies the maximum rate at which all clients associated with a particular client connection policy can issue requests to the PingDirectoryProxy server. If this limit is exceeded, then the server responds as specified in the `policy-operation-rate-exceeded-behavior` property.

`policy-operation-rate-exceeded-behavior`

This property specifies the behavior of the PingDirectoryProxy server if a client connection attempts to exceed the rate defined in the `maximum-policy-operation-rate` property.

Monitoring the PingDirectoryProxy server

While the PingDirectoryProxy server is running, it generates a significant amount of information available through monitor entries.

This section contains information about the following:

- Monitoring server status using the status tool
- About the monitor entries
- Using the monitoring interfaces
- Monitoring with Java Management Extensions (JMX)

Monitoring the server using the status tool

The PingDirectoryProxy server provides a `status` tool that provides basic server status information, including version, connection handlers, a table of LDAP external servers, and the percent of the global index being used.

Steps

1. To view the current state of the server, run the `status` tool.

```
$ bin/status
```

2. Enter the LDAP connection parameters.

```
>>>> Specify LDAP connection parameters

Administrator user bind DN [cn=Directory Manager]:

Password for user 'cn=Directory Manager':
```

Result:

```
          --- Server Status ---
Server Run Status:    Started 07/Jan/2011:10:59:52.000 -0600

```

Monitor entries

> **Note**
>
> This topic applies only to the PingDirectory server.

While the server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- General Monitor Entry (cn=monitor) – Provides a basic set of general information about the server.
- Active Operations Monitor Entry (cn=Active Operations,cn=monitor) – Provides information about all operations currently in progress in the server.
- Backend Monitor Entries (cn={id} Backend,cn=monitor) – Provides information about the backend, including the number of entries, the base DN(s), and whether it's private.
- Client Connections Monitor Entry (cn=Client Connections,cn=monitor) – Provides information about all connections currently established to the server.
- Connection Handler Monitor Entry (cn={name},cn=monitor) – Provides information about the configuration of each connection handler and the client connections established to it.
- Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor) – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor) – Provides information about the amount of usable disk space available to server components.
- JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor) – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor) – Provides a stack trace of all threads in the JVM.
- LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor) – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.

- Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor) – Provides information about the percentage of operations that were completed in various response time categories.
- SSL Context Monitor Entry (cn=SSL Context,cn=monitor) – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- System Information Monitor Entry (cn=System Information,cn=monitor) – Provides information about the underlying JVM and system.
- Version Monitor Entry (cn=Version,cn=monitor) – Provides information about the server version.
- Work Queue Monitor Entry (cn=Work Queue,cn=monitor) – Provides information about the state of the server's work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the `dsconfig` tool and the admin console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

The server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the `status` tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as `server available` or `server unavailable`. Gauges generate alarms when the gauge's severity changes because of changes in the monitored value.

The server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see Profiling server performance using the Stats Logger.

Testing alarms and alerts

Steps

1. Use `dsconfig` to configure a gauge and set the `override-severity` property to critical.

   The following example configures the CPU Usage (Percent) gauge.

   Example:

   ```
   $ dsconfig set-gauge-prop \
     --gauge-name "CPU Usage (Percent)" \
     --set override-severity:critical
   ```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts.

   The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

   Example:

   The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status

```

Indeterminate alarms

The server raises indeterminate alarms for a server condition for which a severity can't be determined.

In most cases, these alarms are benign and don't issue alerts, nor do they appear in the output of the `status` tool or admin console by default.

These alarms are usually caused by an enabled gauge intended to measure an aspect of the server that isn't currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a server isn't currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the `status` tool run with the `–alarmSeverity=indeterminate` option.

```
                        --- Alarms ---
Severity     : Severity Start : Condition      : Resource   : Details
             : Time           :                :            :
-------------:----------------:----------------:------------:-----------------------
Normal       : 26/Aug/2014    : Startup Begun  : cn=config  : The Directory Server
             : 14:16:29 -0500 :                :            : is starting.
             :                :                :            :
Indeterminate: 26/Aug/2014    : Replication    : not        : The value of gauge
             : 14:16:40 -0500 : Latency        : available  : Replication Latency
             :                : (Milliseconds) :            : (Milliseconds) could not
             :                :                :            : be determined. The
             :                :                :            : severity is INDETERMINATE,
             :                :                :            : having assumed this
             :                :                :            : severity Tue Aug 26
             :                :                :            : 14:17:10 CDT 2014.
```

The following is an indeterminate alarm for the Replication Latency (Milliseconds) gauge. A search of the monitor backend for this gauge's entry results in an error message that might explain the indeterminate severity.

```
# ldapsearch -w password --baseDN "cn=monitor"  \

```

Administrative alert handlers

The server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown.

> **Important**
>
> SNMP is deprecated.

The PingDirectory provides several alert handler implementations, including:

Error Log Alert Handler

Sends administrative alerts to the configured server error logger(s).

Exec Alert Handler

Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the PingDirectory. Information about the administrative alert will be made available to the executed application as arguments provided by the command. Learn more in Changing the timeout for an exec alert handler.

Groovy Scripted Alert Handler

Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.

JMX Alert Handler

Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.

SMTP Alert Handler

Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.

SNMP Alert Handler

Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.

SNMP Subagent Alert Handler

Sends SNMP traps to a primary agent in response to administrative alerts generated within the server.

Third Party Alert Handler

Provides alert handler implementations created in third-party code using the Server SDK.

Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the `dsconfig` tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using `dsconfig` in interactive command-line mode, which is visible in the `Standard object menu`.

Configuring the JMX connection handler

About this task

To enable the JMX connection handler:

Steps

1. Run `dsconfig`.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "JMX Connection Handler" \
     --set enabled:true \
     --set listen-port:1689
   ```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the `ldapmodify` tool using an LDIF representation.

   Example:

   ```
   dn: cn=JMX User,cn=Root DNs,cn=config
   changetype: add
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   objectClass: ds-cfg-root-dn-user
   givenName: JMX
   sn: User
   cn: JMX User
   userPassword: password
   ds-cfg-inherit-default-root-privileges: false
   ds-cfg-alternate-bind-dn: cn=JMX User
   ds-privilege-name: jmx-read
   ds-privilege-name: jmx-notify
   ```

Configuring the JMX alert handler

About this task

To configure the Java Management Extensions (JMX) alert handler:

Steps

- Run `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
    --set enabled:true
  ```

Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

About this task

By default, there is no configuration entry for an SMTP alert handler.

Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

  Example:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%\%alert-type\%\%" \
  --set "message-body:Administrative alert:\\n\%\%alert-message\%\%"
```

Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the `dsconfig` tool, which is visible in the `Standard object menu`.

About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see Monitoring using SNMP.

The PingDirectory server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

Steps

- Run `dsconfig`.

  Example:

  In this example:

  - The `server-host-name` is the address of the system running the SNMP subagent.
  - The `server-port` is the port number on which the subagent is running.
  - The `community-name` is the name of the SNMP community that is used for the traps.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

Working with virtual attributes

The PingDirectoryProxy server provides dynamically generated attributes called virtual attributes for local PingDirectoryProxy server data.

The proxy virtual attributes apply to a local proxy backend, such as `cn=config` or the Root DSA-specific entry (DSE).

If you want virtual attributes in entries for proxied requests, they must be configured in the backend servers. Alternately, attributes can be inserted into those entries using proxy transformations. For more information, see Configuring proxy transformations.

For example, you can define a virtual attribute and assign it to the Root DSE using `create-virtual-sttribute`.

```
$ bin/dsconfig create-virtual-attribute \
  --name defineDescriptionOnRootDSE --type user-defined \
  --set enabled:true --set attribute-type:description \
  --set filter:objectclass=ds-root-dse --set value:PrimaryProxy
```

If you search the Root DSE using the following LDAP search, you see that the description attribute now has the value `Primary Proxy`.

```
$ bin/ldapsearch --baseDN "" --searchScope base --bindDN "" \
  --bindPassword "" --port 5389 -- hostname localhost \
  "objectclass=*" description

dn:
description:PrimaryProxy
```

DevOps and infrastructure as code

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- Pets — With the pets service model, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.

- Cattle — With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-primary datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Before server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see Server profiles.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

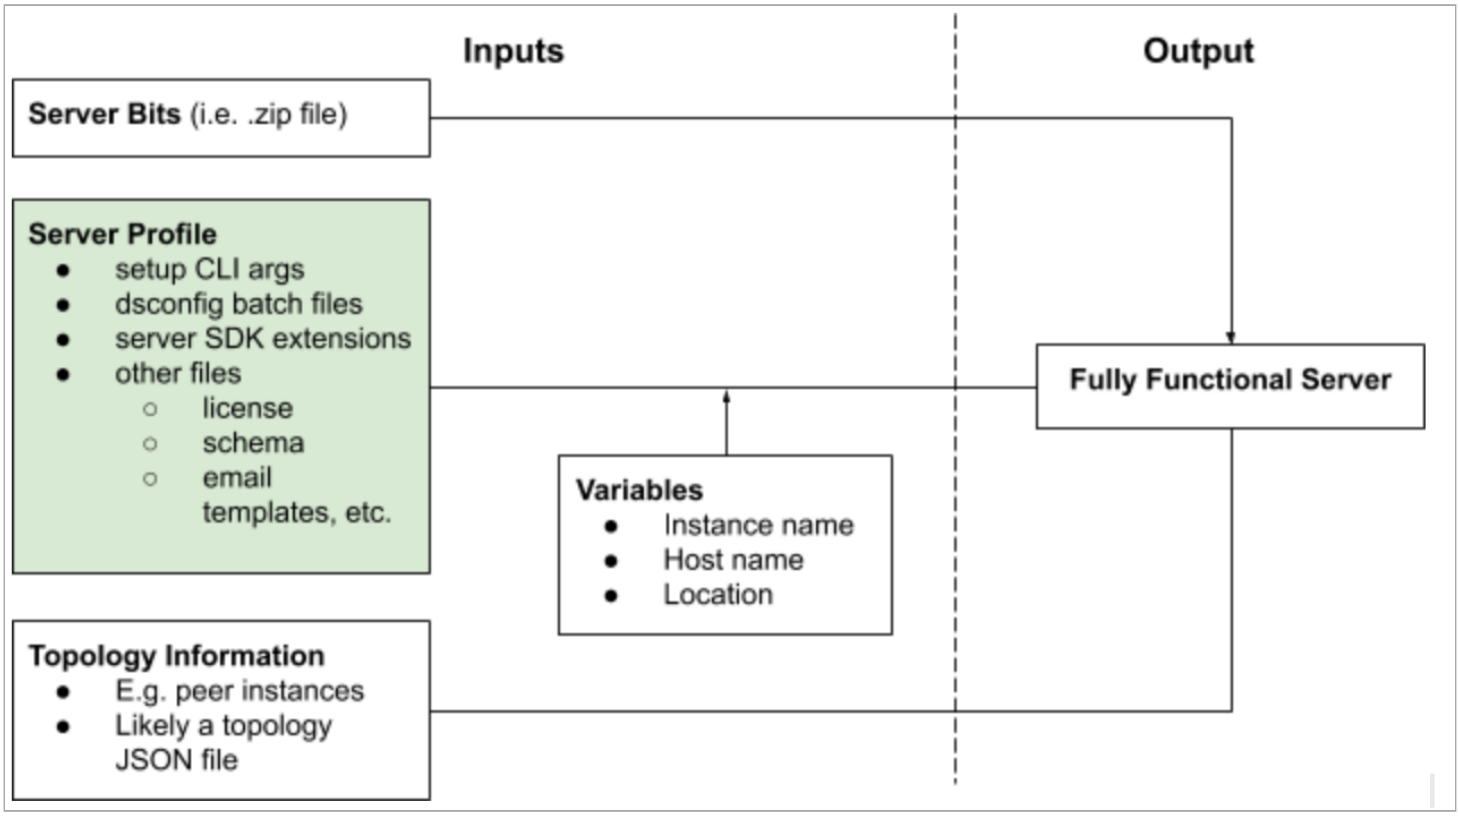
Server profiles

Regardless of the service model that your company follows, server profiles help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDataSync and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.



As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see Variable substitution.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the `manage-profile replace-profile` subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, `manage-profile setup` can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files before its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
`PING_SERVER_ROOT`	Evaluates to the absolute path of the server's root directory
`PING_PROFILE_ROOT`	Evaluates to the individual profile's root directory **Note** Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

For more information about the tool's usage, run the command `bin/manage-profile --help`.

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- ldif/
      |-- userRoot/
  |-- misc-files/
  |-- pre-setup-dsconfig/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
  |-- variables-ignore.txt
```

setup-arguments.txt

When creating a profile, the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/ and pre-setup-dsconfig/

You can include `dsconfig` batch files in the server profile with information about changes to apply to the out-of-box system configuration. Any batch files in the server profile must include a `.dsconfig` extension. `dsconfig` batch files in the server profile can't make changes to any topology configuration, including topology admins and server instances, so you should make topology configuration changes outside of the server profile.

The batch files can be placed in the following server profile directories:

`dsconfig/`

Contains information about changes to apply after the `manage-profile` tool runs `setup`, copies any post-setup files into place, and installs any Server SDK extensions contained in the server profile. The `dsconfig/` directory should be used for most configuration changes applied to the server.

`pre-setup-dsconfig/`

Holds information about changes to apply immediately before the `manage-profile` tool runs `setup`. You should only use the `pre-setup-dsconfig/` directory when setting up the server with a pre-existing encryption settings database and applying the changes required for configuring and activating the cipher stream provider needed to access the encryption settings database.

Note

If multiple batch files are present in the directory that the `manage-profile` tool is using, the files are processed in ascending lexicographic order. For example, `00-base.dsconfig` is processed before `01-second.dsconfig`.

Tip

You can use the `config-diff` tool to create a `dsconfig` batch file that reproduces the current topology configuration.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the server-root/pre-setup directory.

server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

> **Note**
>
> Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

manage-profile generate-profile

To create a server profile from a configured server, use the `generate-profile` subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server

- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by `generate-profile`, and must be provided values when other `manage-profile` subcommands use the generated profile.

The `--excludeSetupArguments` option generates a server profile without a setup-arguments.txt file. This is useful when generating server profiles for use with Docker images.

manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any dsconfig batch files
- Imports any LDIF files
- Starts the server

While manage-profile setup is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

manage-profile replace-profile

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

The `--skipValidation` option which skips the validation step when running on an offline server

> **Important**
>
> When you run the **`manage-profile replace-profile`** tool with an SDK extension included in the new profile, the tool invokes the **`setup`** command.
> The **`manage-profile replace-profile`** tool can update the server version when needed, but will fail if you attempt to downgrade the server to an earlier version. It can also directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to **`dsconfig`** .

Server profiles in a pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Managing Server SDK extensions

The server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your server. Extension bundles are installed from a .zip archive or a file system directory. You can use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

> **Note**
>
> The `manage-extension` tool can only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

Available types of extensions

The Server SDK provides support for creating several different types of extensions for Ping Identity server products, including the PingDirectory server, the PingDirectoryProxy server, and the PingDataSync server. Some of those extensions include:

Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes
- Password Validators
- Plugins

- Tasks
- Virtual Attribute Providers

PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

Command-line tools

The server provides a full suite of command-line tools necessary for administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Available command-line tools

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	`--help`	`dsconfig --help`
A list of subcommands	`--help-subcommands`	`dsconfig --help-subcommands`
More information about a subcommand	`--help` with the subcommand	`dsconfig list-log-publishers --help`

Command-Line Tools

`audit-data-security`	Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data. This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using `dsconfig list-data-security-auditors --advanced --property name`. Either the `--includeAuditor` or the `--excludeAuditor` arguments can be used to limit the scope of the audit. Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`authrate`	Perform repeated authentications against the PingDirectory server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.
`backup`	Back up one or more directory server backends. Each backend backup is stored in a separate backend backup directory. A backend backup directory can contain multiple backups of the backend. Each backend backup directory contains a `backup.info` file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID can be provided to the backup command, or an ID is generated from a current timestamp. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`base64`	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
`check-replication-domains`	Scan the `replicationChanges` database for all known replication domains and identify any obsolete replicas still listed as part of a topology. Run this tool before upgrading replicated topologies to help avoid lockdown mode. Learn more about Discovering obsolete replicas.

`collect-support-data`	Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative. Information collected can include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that might be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive can be encrypted if you desire, you might want to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.
`compare-ldap-schemas`	Compares the schemas of two LDAP servers to identify schema elements that might be present in one but not the other, or elements that might be present in both servers but have differences between them.
`config-diff`	Compares directory server configurations and produces a `dsconfig` batch file needed to bring the source inline with the target. Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration. Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration. Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the `--includeExpectedDifferences` command. Further differences can be excluded with the `--exclude` option. This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a `dsconfig` batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using `dsconfig --offline`.
`create-rc-script`	Create a Run Control (RC) script that you can use to start, stop, and restart the PingDirectory server on UNIX-based systems.
`create-systemd-script`	Create a systemd script to start and stop the PingDirectory server on Linux-based systems.

`dbtest`	Inspect the contents of the PingDirectory server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool. Each local DB backend has a root container, identified by the backend ID. Each root container has an entry container for each base distinguished name (DN) in the backend. Each entry container has several database containers that store entries, attribute indexes and system indexes. The `dbtest` command allows the contents of root containers, entry containers and database containers to be inspected.
`deliver-one-time-password`	Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate using the UNBOUNDID-DELIVERED-OTP SASL mechanism.
`deliver-password-reset-token`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
`dsconfig`	View and edit the PingDirectory server configuration. This utility offers three primary modes of operation, the interactive mode, the non-interactive mode, and the batch mode: • The interactive mode supports viewing and editing the configuration using an intuitive, menu driven environment. Running `dsconfig` in interactive provides a user-friendly, menu-driven interface for accessing and configuring the server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` shell script or batch file without any arguments. • The non-interactive mode provides a simple way to make arbitrary changes to the PingDirectory server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the `dsconfig` command in non-interactive mode. • The batch mode reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each `dsconfig` call. You can view the `logs/config-audit.log` file to review the configuration changes made to the PingDirectory server and to use them in the batch file.

`dsjavaproperties`	Configure the JVM options used to run the PingDirectory server and its associated tools. The options managed by this tool are stored in `config/java.properties`. Typically, you should not edit that file directly. Instead, run the tool specifying `--jvmTuningParameter` arguments to customize JVM options appropriate for this system. Note that the changes will only apply to this PingDirectory server installation. No modifications will be made to your environment variables. Memory and other settings for the JVM tools, including the **`start-server`** tool, can be tuned during initialization by specifying one or more instances of the `--jvmTuningParameter` option when invoking this tool. Supported values are as follows: • `NONE`: Explicitly specify no parameters. • `AGGRESSIVE`: This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly. • `SEMI_AGGRESSIVE`: This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly. If no parameters are specified, the parameters specified by the previous invocation of this tool or setup will be used. Use the `NONE` option to explicitly specify no parameters.
`dsreplication`	Manage data replication between two or more PingDirectory server instances. For replication to work, you must first to enable replication using the **`enable`** subcommand. Then, you initialize the contents of one of the servers with the contents of the other using the **`initialize`** subcommand.
`dump-dns`	Obtain a listing of all of the DNs for all entries below a specified base DN in the PingDirectory server.
`encode-password`	Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.
`encrypt-file`	Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDAP Data Interchange Format (LDIF) exports, and log files generated by the server.
`encryption-settings`	Manage the server encryption settings database. More information about the cipher algorithms and transformations available for use can be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.

`enter-lockdown-mode`	Request that the PingDirectory server enter lockdown mode, during which it only processes operations requested by users holding the `lockdown-mode` privilege. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the `lockdown-mode` privilege.
`export-ldif`	Export data from the PingDirectory server backend in LDIF form. To export data from a remote PingDirectory server, the server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data can be appended to an existing file instead of overwriting it, and the output can be optionally compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`export-reversible-passwords`	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. Include the following arguments to configure the output of the tool: **`--filter`** The export only includes entries matching the specified filter. **`--exportNonReversiblePasswords`** The export includes entries with non-reversible passwords. **`--exportEntriesWithoutPasswords`** The export includes entries that don't have passwords. **`--includeAdditionalAttribute`** The exported entries include the specified attribute(s) in addition to the user's DN and password. You can use `"*"` to include all user attributes and [.codeph]`"+"` to include all operational attributes. **`--includeVirtualAttributes`** The exported entries include the values of virtual attributes in addition to real attributes. This tool can only be used over a secure connection and when authenticated as a user with the `permit-export-reversible-passwords` privilege. The server encrypts the output using a key generated from either a user-supplied passphrase or an encryption settings definition.

`extract-data-recovery-log-changes`	Extracts changes matching a given set of criteria from a PingDirectory server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error). This tool is designed to be used in conjunction with the server's data recovery log files (in the `logs/data-recovery` directory). It can be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that might have been provided in the request. This tool must not be used with a log file that the server can update while the tool is running, or that can have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, use the **`rotate-log`** tool to force the current active file to be rotated. To use this tool to revert an inappropriate set of changes, run it with `--direction revert` and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.). To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with `--direction replay` and an appropriate set of arguments to select the desired set of changes. Also, make sure to use **`dsreplication pre-external-initialization`** before performing the restore or import and applying the changes, and then use **`dsreplication post-external-initialization`** after the changes have been applied. See the PingDirectory Server Administration Guide for additional information. This tool will extract changes from the selected log file (and any previously rotated files, unless the `--doNotFollowRotationChain` argument is provided) and output them in LDIF change format. If the `--outputFile` argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the `--doNotCompressOutput` argument was provided), and the output will be encrypted if the input files were encrypted (unless the `--doNotEncryptOutput` argument was provided). You might want to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, you can use a tool like **`ldapmodify`** or **`parallel-update`** to apply those changes to the server.
`generate-totp-shared-secret`	Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.
`identify-references-to-missing-entries`	Identify entries containing one or more attributes which reference entries that do not exist. This might require the ability to perform unindexed searches and/or the ability to use the simple paged results control.

`identify-unique-attribute-conflicts`	Identify unique attribute conflicts. That is, it can identify values of one or more attributes that are supposed to exist only in a single entry but are found in multiple entries.
`import-ldif`	Import LDIF data into a PingDirectory server backend. Connection parameters are not required when importing to a local PingDirectory server that is not running. However, connection parameters are required if the server is remote, or if it is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file can be compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`indent-ldap-filter`	Parse a provided LDAP filter string and display it a multi-line form that makes it easier to understand its hierarchy and embedded components. If possible, the tool might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
`ldap-debugger`	Intercept and decode LDAP communication.

`ldap-diff`	**Compare the contents of two LDAP servers.** **The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted. For example: `"^attrToExclude"`. When retrieving entries from a PingDirectory server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectClass.** **This command can be used on servers actively being modified, without reporting false positives caused by replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as the requirement that child entries be deleted before parents and parents be added before children.** **The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry** • `ds-cfg-default-root-privilege-name: unindexed-search` • `ds-cfg-default-root-privilege-name: bypass-acl` • `ds-rlim-size-limit: 0` • `ds-rlim-time-limit: 0` • `ds-rlim-idle-time-limit: 0` • `ds-rlim-lookthrough-limit: 0` **For servers from other vendors, consult their documentation for configuring the proper privileges.** **The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` parameter in the `config/java.properties` file and running the `dsjavaproperties` command.**

`ldap-result-code`	Display and query LDAP result codes. This tool can be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring. At most, one of the `--list`, `--int-value`, and `--search` arguments can be provided. If none of them is provided, then the `--list` option will be chosen by default.
`ldapcompare`	Perform compare operations in an LDAP directory server. Compare operations can be used to efficiently determine whether a specified entry has a given value. The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the `--useCompareResultCodeAsExitCode` argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered. The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID can be followed by two colons and the base64-encoded representation of the assertion value, or it can be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value). The DNs of the entries to compare can either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they can be read from a file whose path is provided using the `--dnFile` argument. If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you can use the `--assertionFile` argument to specify the path to a file containing both attribute-value assertions and entry DNs.
`ldapdelete`	Delete one or more entries from an LDAP directory server. You can provide the DNs of the entries to delete using named arguments, trailing arguments, a file, or standard input. Alternatively, you can identify entries to delete using a search base DN and filter.
`ldapmodify`	Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.

`ldappasswordmodify`	Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the `--passwordChangeMethod` argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password-change method will be selected, using a regular LDAP modify operation to update the `unicodePwd` attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. The new password to be set for the user can be specified in one of several ways. It can be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank so that the server generates a new password for the user and includes it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error. The current password for the user can also be specified. This is optional, although some servers might require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a deletion of the current value and an addition of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.
`ldapsearch`	Process one or more searches in an LDAP directory server. The criteria for the search request can be specified in several different ways, including providing all of the details directly using command-line arguments, providing all of the arguments except the filter using command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.

`ldif-diff`	Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file. This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out-of-memory error while running the tool, you might need to increase the amount of memory available to the JVM used to invoke it. The amount of memory available to the JVM can be customized by invoking the JVM with the `-Xms` and `-Xmx` arguments, which specify the initial and maximum amounts of memory that it can use, respectively. These arguments should be immediately followed, without any intervening space, by an integer and a unit to specify the amount of memory to be used. The unit can be either `m` to indicate that the size is in megabytes, or `g` to indicate that it is in gigabytes. For example, `-Xms512m` indicates that the JVM should be given an initial heap size of 512 megabytes, while `-Xmx2g` indicates that it should be given a maximum heap size of two gigabytes. When invoking the **`ldif-diff`** tool included in the installation of a Ping Identity server product, you can edit the `config/java.properties` file to specify the arguments to use when invoking the JVM. After modifying the file, run the **`dsjavaproperties`** tool to ensure that those changes will be used for subsequent tool invocations.
`ldifmodify`	Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike **`ldapmodify`**, the **`ldifmodify`** command cannot read the changes to apply from standard input. All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires. Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete. Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record). Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.
`ldifsearch`	Search one or more LDIF files to identify entries matching a given set of criteria.

`leave-lockdown-mode`	Request that the PingDirectory server leave lockdown mode and resume normal operation. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the lockdown-mode privilege. Note that the PingDirectory server can place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that might have otherwise resulted in exposure of sensitive data).
`list-backends`	List the backends and base DNs configured in the PingDirectory server.
`load-ldap-schema-file`	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool can only be used in conjunction with a server instance running on the local system.
`make-ldif`	Generate LDIF data based on a definition in a template file. See the server's `config/MakeLDIF` directory for example template files. In particular, the `examples-of-all-tags.template` file shows how to use all of the tags for generating values.
`manage-account`	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the `password-reset` privilege to use this extended operation.
`manage-certificates`	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
`manage-extension`	Install or update PingDirectory server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectory server. Extension bundles are installed from a zip archive or file system directory. The server will be restarted if running to activate the extension(s).
`manage-profile`	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including `dsconfig`, initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
`manage-tasks`	Access information about pending, running, and completed tasks scheduled in the PingDirectory server.

`manage-topology`	Manage the topology registry. The topology registry is a branch of the configuration DIT (`cn=Topology,cn=config`). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The **`dsconfig`** tool, configuration API, or the management console can be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
`migrate-ldap-schema`	Migrate schema information from an existing LDAP server into a PingDirectory server instance. This tool can be used to migrate schema information from an existing LDAP server into this PingDirectory server instance. The source server can be any standards-compliant LDAPv3 server. All attribute type and object class definitions, which are contained in the source LDAP server but not in the target PingDirectory server instance, will be either added to the target instance or written to a schema file.
`migrate-sun-ds-config`	Update an instance of the PingDirectory server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x. This tool can be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory server instances in order to identify any differences and update the PingDirectory server configuration to more closely match that of the Sun server instance.
`modrate`	Perform repeated modifications against an LDAP directory server.
`move-subtree`	Move all entries in a specified subtree from one server to another.
`oid-lookup`	Search the OID registry to retrieve information about items that match a given OID or name. The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.

`parallel-update`	Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file. As with other tools like **`ldapmodify`**, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes. This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent can be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.
`populate-composed-attribute-values`	Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins. This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It can be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`profile-viewer`	View information in data files captured by the PingDirectory server profiler. Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the `profile-action` attribute to `stop` to end collection and have the plugin write the file to `logs/profile`.{timestamp}.

`re-encode-entries`	Re-encode all or a specified portion of the entries in a local DB backend. This tool can be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled). This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`rebuild-index`	Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches might behave differently while a rebuild is active than when it is not. An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include attribute indexes, VLV indexes, and JSON field indexes. **Note** PingDirectory does not support the rebuilding of system indexes, regardless of whether the rebuild is attempted online or offline. If you need to rebuild a system index, you must export the backend to LDIF and re-import it. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`register-yubikey-otp-device`	Registers a YubiKey OTP device with the PingDirectory server for a specified user so that the device can be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it can be used to deregister one or more YubiKey OTP devices for a user so that they can no longer be used to authenticate that user.

`reload-http-connection-handler-certificates`	Reload HTTPS Connection Handler certificates. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-attribute-type-from-schema`	Safely remove an attribute type definition from the server schema. The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type can be removed. • The requester must have the update-schema privilege. • The attribute type must not be referenced by any other schema element. • The attribute type must not be defined in any schema file that is included with the PingDirectory server. Only custom attribute types can be removed from the schema. • The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). • The attribute type must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-backup`	Safely remove a backup from the specified PingDirectory server backend. This tool deletes the specified backup archive and updates the backup descriptor accordingly. As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The `--retainFullBackupCount` argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed. The `--retainFullBackupAge` argument can be used to indicate that any full backups older than the specified age are eligible to be removed.
`remove-defunct-server`	Remove a server from this server's topology. This tool will remove the specified server from the topology. In general, the `uninstall` tool should be used to remove a server from the topology. The `remove-defunct-server` tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running remove-defunct-server from it will cleanly remove it from the topology. If it cannot reach the other servers, then remove-defunct-server must also be run from one of the online servers.

`remove-object-class-from-schema`	Safely remove an object class definition from the server schema. The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class can be removed. • The requester must have the update-schema privilege. • The object class must not be referenced by any other schema element. • The object class must not be defined in any schema file that is included with the PingDirectory server. Only custom object classes can be removed from the schema. • The object class must not be referenced in the server configuration. • The object class must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`replace-certificate`	Replace the listener certificate for this PingDirectory server instance.
`restore`	Restore a backup of a PingDirectory server backend. Only one backend can be restored at a time by the restore command. The PingDirectory server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`revert-update`	Revert this server package's most recent update.
`review-license`	Review and/or indicate your acceptance of the license agreement defined in `legal/LICENSE.txt`.

`rotate-log`	Trigger the rotation of one or more log files. If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files. You must have the `config-read` and `config-write` privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`sanitize-log`	Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the **`scramble-ldif`** tool.
`schedule-exec-task`	Schedule an exec task to run a specified command in the server. To run an exec task, several conditions must be satisfied: • The server's global configuration must have been updated to include `com.unboundid.directory.server.tasks.ExecTask` in the set of allowed-task values • The requester must have the `exec-task` privilege • The command to execute must be listed in the `exec-command-whitelist.txt` file in the server's `config` directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.
`search-and-mod-rate`	Perform repeated searches against an LDAP directory server and modify each entry returned.
`search-logs`	Search across log files to extract lines matching the provided patterns, like the **`grep`** command-line tool. The benefits of using the **`search-logs`** tool over **`grep`** are its ability to handle multi-line log messages, extract log messages within a given time range, and the inclusion of rotated log files.
`searchrate`	Perform repeated searches against an LDAP directory server.

`server-state`	View information about the current state of the PingDirectory server process.
`set-delegated-admin-aci`	Request that the PingDirectory server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.
`setup`	Perform the initial setup for a server instance. This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.
`start-server`	Start the PingDirectory server.
`status`	Display basic server information. This tool prints information about the server, such as version, connection handlers, and data sources. Some information might not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.
`stop-server`	Stop or restart the server. This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.
`subtree-accessibility`	List or update the set of subtree accessibility restrictions defined in the PingDirectory server.
`sum-file-sizes`	Calculate the sum of the sizes for a set of files. This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.
`summarize-access-log`	Examine one or more access log files to display several metrics about operations processed within the server.
`sync-pipe-view`	PingDataSync only: Display the detailed configuration of a sync pipe or pipes in PingDataSync and all commands necessary to replicate a specified sync pipe. You can use the `sync-pipe-view` tool online with the PingDataSync server connection credentials or you can use the tool offline. The sync pipe information can be output in a text, CSV, JSON, or tab-delimited format and can be output to a file. The `sync-pipe-view` tool features both an interactive mode and a non-interactive mode.
`transform-ldif`	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.

`uninstall`	Uninstall the PingDirectory server. This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the `dsreplication disable` command.
`update`	Update a deployed server so its version matches the version of this package.
`validate-acis`	Validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
`validate-file-signature`	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
`validate-ldap-schema`	Validate an LDAP schema read from one or more LDIF files.
`validate-ldif`	Validate the contents of an LDIF file against the server schema.
`verify-index`	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be verified include system indexes, attribute indexes and VLV indexes. Any errors found during verification are written to the output. The verification process is exhaustive and can take a long time.
`watch-entry`	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

Saving options in a file

The PingDirectory server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing the PingDirectory server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

The PingDirectory server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Server uses ...
No command-line options	The options in the default `<server-root>/config/tools.properties` file.
Command-line options other than the `--propertiesFilePath <my-properties-file>` option	The command-line options, which take priority if the options are also in the `<server-root>/config/tools.properties` file. The file options for options that are only in the default `<server-root>/config/tools.properties` file.
Only the `--propertiesFilePath <my-properties-file>` option	The options in `<my-properties-file>`.
The `--propertiesFilePath <my-properties-file>` option and other command-line options	The command-line options, which take priority if the options are also in `<my-properties-file>`. The file options for options that are only in `<my-properties-file>`.
The `--noPropertiesFile` option and other command-line options	Only the options you specify on the command line, ignoring the default properties file.

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

  In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

  ```
  $ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
    --propertiesFilePath bin/tools.properties "(objectclass=*)"
  ```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If you do not specify any command-line options, the server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command:

```
$ bin/ldapsearch "(objectclass=*)"
```

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

> **Note**
>
> If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

   Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of Lightweight Directory Access Protocol (LDAP) connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

> **Note**
>
> Properties files do not allow quotation marks of any kind around values.
> Escape spaces and special characters.
> Whenever you specify a path, do not use `~` to refer to the home directory. The server does not expand the `~` value when read from a properties file.

3. Set or change properties that apply to specific tools.

   Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

   ```
   hostname=server1.example.com
   port=1389
   ldapsearch.port=2389
   bindDN=cn=Directory\ Manager
   ```

4. Save your changes and close the file.

dsconfig batch files">

Sample `dsconfig` batch files

The `config/sample-dsconfig-batch-files` directory contains `dsconfig` batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the `dsconfig` tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-request.dsconfig \
  --no-prompt
```

Running task-based tools

The PingDirectory server has a Tasks subsystem that allows you to schedule basic operations, such as `backup`, `restore`, `rotate-log`, `schedule-exec-task`, `stop-server`, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Options for task-based operations

Option	Description
`--task`	Indicates that the tool is invoked as a task. The `--task` option is required. If you invoke a tool as a task without this `--task` option, then a warning message is displayed stating that it must be used. If the `--task` option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
`--start <startTime>`	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
`--dependency <taskID>`	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
`--failedDependencyAction <action>`	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: • `CANCEL` (the default) Cancels the task. * `DISABLE` Disables the task so that it is not eligible to run until you manually enable it again. * `PROCESS` Runs the task.
`--startAlert`	Generates an administrative alert when the task starts running.
`--errorAlert`	Generates an administrative alert when the task fails to complete successfully.
`--successAlert`	Generates an administrative alert when the task completes successfully.
`--startNotify <emailAddress>`	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
`--completionNotify <emailAddress>`	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.

Option	Description
`--errorNotify <emailAddress>`	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
`--successNotify <emailAddress>`	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

Delegated Admin Application Guide

Delegated Admin is an add-on to PingDirectory that enables the delegation of user and group management.

Introduction to Delegated Admin

Delegated Admin is an add-on to PingDirectory that enables the delegation of user and group management.

Delegated Admin lets organizations assign responsibilities associated with the management of identities in the PingDirectory server to a subset of administrators.

These delegated administrators can be any user outside the organization's IT department, including a customer.

The following employees typically fulfill roles that involve at least a basic level of identity management and represent strong candidates for inclusion in a group of delegated administrators:

- Help desk or customer service representatives who unlock and reset passwords
- Managers and Human Resources administrators who update employee profiles
- Application administrators who update identity attributes and manage access to applications

Delegated Admin Features

Delegated Admin lets delegated administrators complete tasks across groups, subtrees, and entire organizations.

Tasks include:

- Create, view, and search user profiles.
- View user account information, including account status, last login time, and password expiration date.
- Update user attributes.
- Implement constructed attributes.
- Set attributes to `read-only`.
- Enable and disable accounts.
- Reset locked accounts.
- Create and edit groups.
- Manage the membership of groups and subgroups.
- Manage the roles of users and groups.
- Delete users, groups, and generic resource types.
- Implement custom UI form fields.
- Select user entries based on their distinguished names (DNs) without displaying the actual values of the DNs.
- Preview and download reports about user profiles. Reporting provides the following features:
    - Capability to report for resources of a given type or limited to members of a group

    - Ability to display multiple values per attribute for each user
    - Protection against spreadsheet formula injection
- Upload CSV files to add user, group membership, or organizational unit (OU) records.
- Trigger a password reset process for a user that invokes the self-service password reset process defined by the business.
- Configure REST Resource Types to correlate to other resource types to create one-to-many relationships without schema changes. Edit or delete linked entries from the edit page of the primary entry.

Configuring Delegated Admin

This section describes the necessary configuration to support Delegated Admin after the application is installed successfully.

At a minimum, you must configure the following properties on the PingDirectory server:

- Delegated administrator rights
- REST resource type
- Attributes and attribute searching

Configuration overview

Delegated Admin must have a PingDirectory server and PingFederate server installed.

For installation instructions, see the documentation for each product.

The process of configuring support for Delegated Admin on a PingDirectory server includes the following tasks:

- Configure users as Delegated Admin administrators.
- Configure attributes and attribute searching.
- Configure groups whose management requires delegation.

The process of configuring a PingFederate server includes the following tasks:

- Configure PingFederate as the identity provider for Delegated Admin.
- Configure PingFederate as the OAuth server for Delegated Admin.
- Register Delegated Admin as a client.
- Register the PingDirectory server as an OAuth token validator client.

Authentication configuration

The delegated administrator signs on to Delegated Admin through the PingFederate server, which is configured as the authentication server and OpenID Connect (OIDC) provider.

PingFederate validates the user's credentials against the PingDirectory server, encapsulates information `claims` about the user's identity, and issues an access token to Delegated Admin, which presents the token to the PingDirectory server in the HTTP Authorization request header.

Interaction with the PingDirectory server

The PingDirectory server is configured to accept access tokens by using access token validators. The values that the PingFederate server sets for the access token `sub` claim must be mappable to a distinguished name (DN) in the PingDirectory server. Setting up an access token validator for use with Delegated Admin requires some coordination with the server configuration. In the suggested default configuration, the access token contains the entryUUID of the administrator user entry in the `sub` claim. This value is mapped back to a PingDirectory server entry by using an Exact Match Identity Mapper.

Authorization by the PingDirectory server

After validation, the PingDirectory server checks the Delegated Admin configuration for authorization of the delegated administrator. Users or groups of users are authorized as delegated administrators in the PingDirectory server admin console,or with the `dsconfig` tool.

Configure authentication

One of the prerequisites to installing Delegated Admin is to configure the following OAuth clients within PingFederate:

- Delegated Admin, which obtains an OIDC token that describes the authenticated user. For more information, see Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin).
- The PingDirectory server itself, which calls PingFederate to validate the OIDC token that Delegated Admin passes to it. For more information, see Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory).

Configuring delegated administrator rights on the PingDirectory server

To delegate users or groups as administrators, use the PingDirectory admin console (Delegated Admin rights and resource rights) or the `dsconfig create-delegated-admin-rights` and `create-delegated-admin-resource-rights` commands.

About this task

To use Delegated Admin, an administrator must possess rights that are designated through the PingDirectory server configuration in addition to valid credentials and an access token that the PingDirectory server can validate.

Admin Permissions

`create`

The administrator can create new resources of this type.

`read`

The administrator can read resources of this type.

> **Note**
>
> The `create`, `delete`, `update`, `update-profile`, `reset-password`, and `manage-group-membership`, `update` permissions require the `read` permission.

`update`

The administrator can edit resources of this type.

`delete`

The administrator can delete resources of this type.

`update-profile`

The administrator can update user profiles but isn't allowed password- change-related privileges.

For group and generic type resources, the `update-profile` permission gives the same rights as the `update` permission.

`reset-password`

The administrator can reset passwords without the ability to change other user attributes.

`manage-group-membership`

The administrator can manage the membership of a group resource by adding or removing members. This permission is only applicable to group resource types.

`reference`

The administrator can reference resources when selecting a parent during the creation of another resource. With the reference permission specified, the administrator can use a parent REST resource type without seeing the option to manage the parent resource type. For example, if the parent type for users is Organizational Unit, the administrator can have reference rights to the Organizational Unit resource type only. The administrator can create users without seeing the Manage Organizational Unit navigation option.

The administrator can reference resource types in Delegated Admin attributes. For example, the administrator can select user entries from a list based on their distinguished name (DN) without displaying the actual values of the DNs.

`download`

The administrator can download reports for resources of this type. With this permission, the Download Report button shows on the Reporting page for the administrator.

`upload`

The administrator can upload a `.csv` file to import resources of this type. With this permission, the Upload File button shows on the Reporting page for the administrator.

> **Note**
>
> For the parent resource type to be available for the creation of new entries under the parent, the `read` or `reference` permission must be specified.

To prevent changes that might break the configuration of the app, the app does not allow changes to RDN attributes of a resource entry DN, for resources referenced in the Delegated Admin server configuration. This includes the following configuration elements:

- `admin-user-DN` **and** `admin-group-DN` **of Admin Rights**
- `resource-subtree` **and** `resources-in-group` **of Admin Resource Rights**

For example, if an Admin Rights configuration contains `admin-group-DN: cn=Admin Group,dc=example,dc=com` and some administrator has rights to modify that particular group through the app, then the `cn` attribute of that group can't be changed without invalidating the configuration. The attribute label has a lock icon and a message indicating that the value can only be changed by a server administrator.

The example commands that follow illustrate the configuration options for delegated administration and are performed on the PingDirectory server.

> **Note**
>
> Administrators who manage only specific subtrees can't create users in an organization that does not reside under, or at the same level as, one of the subtrees.

Steps

- **Restrict an administrator to manage users in specified subtrees.**

  Example:

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com" \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=org1,dc=example,dc=com" \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

- **Restrict an administrator to managing the member users of one or more specified groups.**

  Example:

  In the following example, assume the existence of a static or dynamic group entry whose members include the users to be managed.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
  --set enabled:true
$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-groups \
  --set "resources-in-group:cn=User Group,dc=example,dc=com" \
  --set admin-permission:read \
  --set admin-permission:update \
  --set enabled:true
```

- Assign the delegated admin rights to a group REST resource type that matches the specified group.

  For more information, see Manage groups.

- Rather than delegate a single user as an administrator, delegate an entire group of users as administrators.

  For more information about the PingDirectory server administrators and configuring dynamic and static groups, see the PingDirectory Server Administration Guide.

  Example:

  In this example, groups can be configured to manage specific subtrees or groups with the `resources-in-specific-subtrees` or `resources-in-group` setting for the `admin-scope`.

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name admin-group1 \
  --set "admin-group-dn:cn=Admin Group,ou=people,dc=example,dc=com"
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name admin-group1 \
  --rest-resource-type users \
  --set admin-scope:all-resources-in-base \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true
```

Parameterized Delegated Administrator Rights

Delegated Admin rights can be parameterized so that a single definition provides a pattern for new administrators.

This allows a privileged administrator for a hosting company to use Delegated Admin to onboard a new tenant administrator to manage resources for the tenant's own organization. Using parameterized rights eliminates the need for the PingDirectory server configuration changes to create a new administrator.

In the following example, it's assumed that there are three REST resource types configured:

- `orgs`

- `groups`
- `users`

The users resource type has the parent resource type orgs.

```
$ bin/dsconfig create-delegated-admin-rights \
--rights-name "Tenant Admin" \
--set enabled:true \
--set 'admin-group-dn:cn=($1),ou=groups,dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name "Tenant Admin" \
--rest-resource-type users --set enabled:true \
--set admin-permission:create \
--set admin-permission:read --set admin-permission:update \
--set 'resource-subtree:ou=($1),dc=example,dc=com'

$ bin/dsconfig create-delegated-admin-resource-rights \
--rights-name "Tenant Admin" \
--rest-resource-type orgs --set enabled:true \
--set admin-permission:reference \
--set 'resource-subtree:ou=($1),dc=example,dc=com'
```

A privileged admin can perform the following steps to onboard a new tenant in Delegated Admin:

- Add a new `org` for the tenant.
- Add a new `group` with the same name as the new `org`, representing the tenant admins.
- Add a new `user` representing an initial tenant admin.
- Add the new tenant admin user to the tenant admin group.

The tenant admin user can now sign on to the app and manage users for their own organization.

Configuring user self-service

The PingFederate server provides end users with the ability to self-service their own profiles.

About this task

To enable users created by delegated administrators to manage their own profiles through the PingFederate local identity profile-management feature, you need to perform additional configuration steps in both PingDirectory and PingFederate.

> **Note**
>
> Import the PingFederate LDAP Data Interchange Format (LDIF) first in PingDirectoryProxy and then in PingDirectory. Constructed attributes need to be created only in PingDirectoryProxy. Creating and rebuilding indexes (part of the self-service configuration) is done on PingDirectory.

Steps

1. Configure PingFederate for profile management.

To allow users to change their passwords, enable Allow Password Changes in the HTML Form Adapter. You must make this change if you want to create passwords that the user must change on the first use. For example PingFederate configuration steps, see Customer IAM configuration in the PingFederate documentation.

Setting up PingDirectory for customer identities in the PingFederate documentation includes some of the following required steps on the PingDirectory server.

2. To create passwords that the user must change on the first use after account creation or a password reset, configure a PingDirectory password policy to force users to change their passwords.

   Example:

   This policy requires that you enable Allow Password Changes as mentioned above.

   ```
   dsconfig set-password-policy-prop --policy-name "Default Password Policy" \
   --set force-change-on-add:true --set force-change-on-reset:true
   ```

   Result:

   With these changes, when a user signs on to the PingFederate self-service page, the page prompts the user to change their password.

3. Import the required additional Lightweight Directory Access Protocol (LDAP) schema provided by PingFederate into PingDirectory.

   1. On the PingFederate server, copy the LDIF file `local-identity-pingdirectory.ldif` from the following location: `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.
   2. Use the `scopy` command to securely copy the LDIF file to your local machine.

4. Update the LDAP schema.

   1. Sign on to the PingDirectory admin console.
   2. Go to LDAP Schema → Schema Utilities.
   3. Click Import Schema Element.
   4. Copy the schema changes from the file `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.
   5. Paste the schema changes into the text area.
   6. Click Import.

5. Create an equality index for the pf-connected-identity attribute.

   ```
   $ bin/dsconfig create-local-db-index \
     --backend-name userRoot \
     --index-name pf-connected-identity \
     --set index-type:equality
   ```

6. After adding the index, use the rebuild-index utility to build the indexes.

Example:

The following sample builds the required index.

```
$ bin/rebuild-index \
  --baseDN "dc=example,dc=com" \
  --index pf-connected-identity
```

7. Configure PingDirectory Server Composed Attributes.

   In previous versions of Delegated Admin, the remaining configuration was achieved by setting a constructed attribute on the user REST resource type. In the latest version, composed attribute plugins should be used instead as they provide the following advantages:

   - The populate-composed-attribute-values tool can be used to enable self-service for any existing users.
   - Self-service is enabled for any users not created through the Delegated Admin app.

   Configure two Composed Attribute Plugins as follows:

   > **Note**
   >
   > *<users-base-dn>* and *<users-object-class>* must be replaced with the search base distinguished name (DN) and structural object class of your REST Resource Type.

   ```
   $ bin/dsconfig create-plugin \
     --plugin-name pf-connected-identities \
     --type composed-attribute \
     --set enabled:true \
     --set attribute-type:objectClass \
     --set value-pattern:pf-connected-identities \
     --set target-attribute-exists-during-initial-population-behavior:merge-existing-and-composed-values \
     --set "include-base-dn:<users-base-dn>" \
     --set "include-filter:(objectClass=<users-object-class>)"

   $ bin/dsconfig create-plugin \
     --plugin-name pf-connected-identity \
     --type composed-attribute \
     --set enabled:true \
     --set attribute-type:pf-connected-identity \
     --set "value-pattern:auth-source=pf-local-identity:user-id={entryUUID}" \
     --set "include-base-dn:<users-base-dn>" \
     --set "include-filter:(objectClass=<users-object-class>)"
   ```

   If you configure composed attribute plugins as described after upgrading an existing deployment, then you should remove the old constructed attribute configuration as follows.

   ```
   $ bin/dsconfig set-rest-resource-type-prop --type-name users \
     --remove auxiliary-ldap-objectclass:pf-connected-identities \
     --remove post-create-constructed-attribute:pf-connected-identity \
     --remove update-constructed-attribute:pf-connected-identity
   ```

8. (Optional) Enable self-service for any existing users not already linked to PingFederate.

```
$ bin/populate-composed-attribute-values -h  <host>  -p  <port>  -D "cn=Directory Manager" -w  <password>
```

Configuring attributes and attribute search on the PingDirectory server

Use the Delegated Admin installation file to configure attributes and attribute search.

About this task

The file that installs Delegated Admin specifies the following values:

- Object class of user entries through `structural-ldap-objectclass:inetOrgPerson`
- Number of user attributes to expose

> **Note**
>
> Delegated Admin supports the following attribute types:
> - `Boolean`
> - `Integer`
> - `String`
> - `DateTime`
> - distinguished name (DN)
> - Custom attributes
> - Constructed attributes
> - Multivalued attributes

Steps

1. If necessary, change the attribute that is designated as the primary attribute.

   Example:

   ```
   $ bin/dsconfig set-rest-resource-type-prop \
     --type-name users \
     --set primary-display-attribute-type:mail
   ```

2. Configure any additional user attributes to appear in Delegated Admin by specifying the Lightweight Directory Access Protocol (LDAP) attribute type to expose and by providing a display name for it.

   Example:

   ```
   $ bin/dsconfig create-delegated-admin-attribute \
     --type-name users \
     --attribute-type customAttr \
     --set "display-name:My custom attribute"
   ```

3. Configure attributes with distinguished name (DN) syntax on resource types to provide a reference from one resource to another.

   Such an attribute is the standard LDAP `manager` attribute.

   The referencing resource doesn't have to be the same type of resource as the referenced resource. Delegated Admin allows the referenced resource to be selected without displaying the actual value of the DN.

   Example:

   In this example, the `manager` attribute is included in the users resource type, and its value is constrained to reference only resources of type `managers`. The `managers` REST Resource Type is assumed to have already been defined.

   ```
   $ bin/dsconfig create-delegated-admin-attribute \
     --type-name users \
     --attribute-type manager \
     --set display-name:Manager \
     --set reference-resource-type:managers
   ```

   Example:

   Additionally, the Delegated Admin resource rights for the administrator must provide either read or reference permission to `managers`.

   ```
   $ bin/dsconfig create-delegated-admin-resource-rights \
     --rights-name Admin \
     --rest-resource-type managers \
     --set enabled:true \
     --set admin-permission:reference \
     --set admin-scope:all-resources-in-base
   ```

   For more information about resource rights and permissions, see Configuring delegated administrator rights on the PingDirectory server.

4. Use the following command to set the search filter, where `%%` represents the search text entered in the web application.

   Example:

   ```
   $ bin/dsconfig set-rest-resource-type-prop \
     --type-name users \
     --set 'search-filter-pattern:(|(cn=*%%*)(mail=%%*)(uid=%%*))'
   ```

   When search text is entered in Delegated Admin, the property `search-filter-pattern` specifies which attributes to search in the PingDirectory server. To satisfy the query, define the appropriate attribute indexes for the PingDirectory server. For more information, see the PingDirectory Server Administration Guide.

5. To manage users whose profiles feature a large number of attributes, place the attributes in logical groupings, called attribute categories, and give them a specific display order.

   Example:

The following commands create attribute categories and specify their display order.

```
$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Basic Information" \
  --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Contact Information" \
  --set display-order-index:2

$ bin/dsconfig create-delegated-admin-attribute-category \
  --display-name "Other Attributes" \
  --set display-order-index:3
```

6. The following example commands assign attributes to a category and specify the display order of each attribute within its category.

   Example:

   ```
   $ bin/dsconfig set-delegated-admin-attribute-prop \
     --type-name users \
     --attribute-type cn \
     --set "attribute-category:Basic Information" \
     --set display-order-index:1

   $ bin/dsconfig set-delegated-admin-attribute-prop \
     --type-name users \
     --attribute-type sn \
     --set "attribute-category:Basic Information" \
     --set display-order-index:2
   ```

   Unassigned attributes are displayed in a miscellaneous category.

7. For multivalued LDAP attributes, indicate whether the application should present them as multivalued.

   If not specified, the attributes are presented in the application as single-valued, even if the LDAP schema definition for the attribute allows multiple values.

   > **Note**
   >
   > This setting does not apply to attributes that are handled by custom UI form fields.

   Example:

   ```
   $ bin/dsconfig set-delegated-admin-attribute-prop \
    --type-name users \
    --attribute-type mail \
    --set multi-valued:true
   ```

Constructed attributes

A constructed attribute is an attribute whose value is computed from values that are assigned to other attributes. For example, the system might construct a full- or common-name attribute, `cn`, from values that are assigned to the standard `givenName` and `sn` attributes, as follows:

```
dsconfig create-constructed-attribute \
  --attribute-name ReqConstructedCN --set attribute-type:cn \
  --set 'value-pattern:{givenName} {sn}'
```

Beginning with Delegated Admin 3.5.0 and PingDirectory server 7.3.0.1, the value of a constructed attribute can be updated automatically whenever the value of a source attribute is created or when it is edited.

```
dsconfig set-rest-resource-type-prop \
  --type-name users  \
  --set post-create-constructed-attribute:ReqConstructedCN  \
  --set update-constructed-attribute:ReqConstructedCN
```

In these examples, a change to the value of `givenName` or `sn` forces a corresponding change to the value of `cn`. Attributes that contribute to a required constructed attribute are identified in the UI as Required even if they were not originally designated as such. Because `cn` is a required attribute in this example, `givenName` and `sn` are also required.

> **Note**
>
> An attribute's capability of being changed after its creation is called its mutability.

As with standard attributes, constructed attributes are stored as LDAP attributes in a database like the PingDirectory server.

Setting an attribute to read-only

About this task

Beginning with Delegated Admin 3.5.0 and PingDirectory 7.3.0.1, you can set user access to standard and constructed attributes to `read-only` and `read/write`. You should restrict access to constructed attributes to `read-only`. Read-only attributes do not appear on the UI pages that are associated with the creation of users groups and other objects.

Steps

- Use the `dsconfig` tool to set a standard or constructed attribute as `read-only`.

  Example:

  ```
  dsconfig set-delegated-admin-attribute \
    --type-name users  \
    --attribute-type modifyTimestamp  \
    --set mutability:read-only
  ```

  Example:

  The following example resets a standard or constructed attribute from `read-only` to `read/write`:

```
dsconfig set-delegated-admin-attribute \
  --type-name users  \
  --attribute-type modifyTimestamp  \
  --reset mutability
```

Users and groups

You can configure delegated administrators to manage users and groups in the PingDirectory server.

Configuring delegated administrators involves the following:

- Create new entries.
- Read, view, and search existing entries.
- Edit and update existing entries.
- Edit referenced items.

  For example, if a delegated administrator is viewing an item that references a user, the delegated administrator can edit that user's information inline.

The following sections describe users and groups in more detail.

Enabling user creation

Enable the creation of new users and resources by configuring either a parent entry distinguished name (DN) or parent resource type where new users will be located.

If you configure a parent DN, the entry that it references must exist in the PingDirectory server. All new users are created in this single location. If necessary, use `ldapmodify` to create the parent entry. For more information about the `ldapmodify` tool or about command-line help, see the PingDirectory Server Administration Guide. Alternatively, if a parent resource type is configured, the administrator can choose the specific resource where the new user is created.

> **Note**
>
> Delegated Admin cannot list organizations in which the delegated administrator is unable to manage user entries. Administrators who manage only specific subtrees cannot create users in an organization that does not reside under, or at the same level as, one of the subtrees.

The following example specifies a single location for new users on the PingDirectory server:

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set "parent-dn:ou=people,dc=example,dc=com" \
  --reset parent-resource-type
```

The setup script creates a resource type named `orgs`, which works with entries that feature the `organization objectClass`.

The following example shows that any organization resource can function as the location for new users on the PingDirectory server:

```
$ bin/dsconfig set-rest-resource-type-prop \
   --type-name users \
   --reset parent-dn \
   --set parent-resource-type:orgs
```

A different resource type can be created for `organizationalUnit objectClass` entries, as follows.

```
$ bin/dsconfig create-rest-resource-type \
  --type-name orgUnits \
  --set "display-name:Organizational Units" \
  --set primary-display-attribute-type:ou \
  --set "search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set enabled:false

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name orgUnits \
  --attribute-type ou \
  --set "display-name:Organizational Unit"

$ bin/dsconfig set-rest-resource-type-prop \
  --type-name orgUnits \
  --set enabled:true
```

The new resource type can be referenced as a `parent-resource-type`.

By default, new entries are named by their server-generated `entryUUID` values. To change this behavior, configure the LDAP `RDN` attribute.

> **Note**
>
> The `RDN` attribute type must also be configured as a Delegated Admin attribute. For more information, see Configuring attributes and attribute search on the PingDirectory server. Do not set read-only attributes as the `RDN` attribute.

In the following example, `uid` names new entries and becomes a required attribute.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set create-rdn-attribute-type:uid
```

New users are always created with their configured structural LDAP `objectclass`. One or more auxiliary Lightweight Directory Access Protocol (LDAP) `objectclasses` can be specified, as the following example shows.

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name users \
  --set auxiliary-ldap-objectclass:ubidPersonAux
```

When existing users without all of the specified auxiliary `objectclasses` are edited, the missing `objectclasses` are updated automatically.

By default, the password field appears at the top of the Create User form outside any category. The next example adds the password field to the Required fields category and sets the location of the field to 2.

```
dsconfig set-rest-resource-type-prop \
    --type-name users \
    --set "password-attribute-category:Required fields" \
    --set password-display-order-index:2
```

> **Note**
>
> If the server does not require a password, you can leave the password field blank when you create a user. Without a password, the user can't sign on to Configuring user self-service.

Enabling Account Information tab content

The Delegated Admin GUI's Account Information tab provides information about a user account. For Delegated Admin to display the user account information, you must enable the `Password Policy State JSON` virtual attribute for the users object class. You can then configure the information that displays.

Steps

1. For each PingDirectory instance that contains users, enable the `Password Policy State JSON` virtual attribute for the users object class.

   > **Note**
   >
   > You don't need to enable this virtual attribute on PingDirectoryProxy instances.

   For example, the following command enables the virtual attribute for users with the `person` object class, which includes users whose REST resource type structural object class is derived from `person`, such as `inetOrgPerson`.

   ```
   $ bin/dsconfig set-virtual-attribute-prop \
        --name "Password Policy State JSON" \
        --set enabled:true \
        --set require-explicit-request-by-name:true \
        --set "filter:(objectClass=person)" \
        --no-prompt --applyChangeTo server-group
   ```

   After you enable the virtual attribute, delegated administrative users can access account information for a user in the Delegated Admin GUI.

The Account Information tab provides account status by default. To display the last login time and the password expiration date, you must set their properties. You configure these items per password policy.

When not configured, these entries appear as follows:

LAST LOGIN

`Last login time not available.` (This entry also displays when the user hasn't logged in.)

PASSWORD EXPIRATION

`Password expiration date has not been enabled.`

You can configure these items in the admin console or by using the `dsconfig` tool interactively or non-interactively. The following steps use the non-interactive approach:

2. Select the password policy for which you want to enable the last login time and password expiration date.

   Learn more about Managing password policies.

   ```
   dsconfig list-password-policies
   ```

3. (Optional) Include the last login time.

   To include the last login time, choose which property to set. You can set either of the following properties:

   - `maximum-recent-login-history-successful-authentication-count`
   - `last-login-time-format`

     If you use this property, make sure the `last-login-time-attribute` has its default value `ds-pwp-last-login-time`.

     Values for `last-login-time-format` include:

     - `yyyyMMddHHmmss'Z'` for second-level accuracy
     - `yyyyMMdd` for day-level accuracy

   Learn more about last login time options.

4. (Optional) Include the password expiration date.

   To include this information, set the property `max-password-age`.

5. Set the desired password policy properties.

   Example:

   ```
   $ bin/dsconfig set-password-policy-prop \
        --policy-name "<password_policy_name>" \
        --set maximum-recent-login-history-successful-authentication-count:<count_value>  \
        --set "max-password-age:<password_age_value>" \
        --no-prompt --applyChangeTo server-group
   ```

Setting up initiate password reset for REST resource types

To initiate a password reset, a given REST resource type must have the `ds-pwp-modifiable-state-json` delegated admin attribute.

About this task

> **Note**
>
> The `ds-pwp-modifiable-state-json` delegated admin attribute is not visible on the **View/Edit** and **Reporting** pages. It's for internal use only, similar to the `ds-pwp-account-disabled` attribute.

To enable initiate password reset functionality for a specified REST resource type:

Steps

- Run `dsconfig` with the `create-delegated-admin-attribute` option.

  Example:

  The following example grants `"Tenant Users"` the initiate password reset functionality through the `ds-pwp-modifiable-state-json` delegated admin attribute:

  ```
  dsconfig create-delegated-admin-attribute \
      --type-name "Tenant Users"  \
      --attribute-type ds-pwp-modifiable-state-json  \
      --set "display-name:Modifiable Password Policy State"
  ```

Managing groups

The administrative scope for users determines which users are visible to the group administrator.

You can use `dsconfig` to delegate a user as a group administrator. An administrator can be configured to edit users and manage group memberships. When configuring an administrator, consider the following:

- The group administrator can view, add, and remove any of the users within their administrative scope to the membership of groups within the groups' administrative scope.
- Static groups can be nested.
- Users who belong indirectly to a group through nesting are visible as group members but cannot be removed.
- Users can be removed only from the groups of which they are a member. For example, an Employees group might include a Developers group as a nested member. In this scenario, a user in the Developers group is a direct member of that group and an indirect member of Employees. This member can be removed only when viewing the Developers group, not when viewing the Employees group.
- If a group is configured as a dynamic or virtual static group rather than a static group, then the group and its members are visible, but the group membership cannot be modified.

Example

In the following example, all users in the subtree `ou=org1,dc=example,dc=com` are visible:

```
$ bin/dsconfig create-delegated-admin-rights \
  --rights-name group-admin1 \
  --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name group-admin1 \
  --rest-resource-type groups \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=Groups,dc=example,dc=com" \
  --set admin-permission:manage-group-membership \
  --set admin-permission:create \
  --set admin-permission:read \
  --set admin-permission:update \
  --set admin-permission:delete \
  --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
  --rights-name group-admin1 \
  --rest-resource-type users \
  --set admin-scope:resources-in-specific-subtrees \
  --set "resource-subtree:ou=org1,dc=example,dc=com" \
  --set admin-permission:read \
  --set enabled:true
```

Set group attributes

The default settings for group attributes specify `cn` and `description` as group attributes, with `cn` used for the group title in Delegated Admin. To create the default settings, use the following commands with a search DN and parent DN (`"dc=example,dc=com"`):

```
$ bin/dsconfig create-rest-resource-type \
  --type group \
  --type-name groups \
  --set "display-name:Groups" \
  --set enabled:false \
  --set "search-base-dn:dc=example,dc=com" \
  --set primary-display-attribute-type:cn \
  --set resource-endpoint:groups \
  --set "search-filter-pattern:(cn=%%)" \
  --set structural-ldap-objectclass:groupOfUniqueNames
  --set parent-dn:dc=example,dc=com

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name groups \
  --attribute-type cn \
  --set "display-name:Name"

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name groups \
  --attribute-type description \
  --set "display-name:Description"

$ bin/dsconfig set-rest-resource-type-prop \
  --type-name groups \
  --set enabled:true
```

Set group search filter

When entering text to search for groups, the groups' `search-filter-pattern` property specifies the attributes to be searched in PingDirectory server.

To satisfy the query, define the appropriate attribute indexes for PingDirectory server. The default setting searches the attribute `cn` for the search text, which is represented by `%%`.

Use the following command to set the group search filter:

```
$ bin/dsconfig set-rest-resource-type-prop \
  --type-name groups \
  --set 'search-filter-pattern:(cn=%%)'
```

Rename the Members and Nonmembers columns

An administrator can assign custom names for Members and Nonmembers columns in the Delegated Admin application for the following rest resource types:

- Groups
- Users
- Generic rest resource types

To set these column titles, run `dsconfig set-rest-resource-type-prop`:

```
dsconfig set-rest-resource-type-prop \
    --type-name users \
    --set "members-column-name:<custom member label>" \
    --set "nonmembers-column-name:<custom non member label>"
```

Viewing groups

Use the group `reference` right to grant delegated admins the right to see what groups a user is a member of without granting group resource management rights.

About this task

To grant a delegated admin the group `reference` right:

Steps

- Run `dsconfig` with the `create-delegated-admin-resource-rights` option.

```
dsconfig create-delegated-admin-resource-rights \
    --rights-name DArights  \
    --rest-resource-type groups  \
    --set enabled:true  \
    --set admin-permission:reference  \
    --set admin-scope:all-resources-in-base
```

Result

The admin can see the user's group memberships on the entry preview's Group Membership tab.

Creating a group

You can add users as members to groups that delegated administrators create and manage. You can also add subgroups as members to a group.

The configuration for each delegated group type consists of the following elements:

Group REST resource type

Defines the attributes to locate groups in the directory information tree (DIT).

Parent DN or Parent resource type

Specifies the location in which to create groups in the DIT.

- To specify a parent distinguished name (DN) for a resource type, enter the value in the Parent DN text box in the Resource Creation section. The parent DN is often identical to the search base DN, such as `ou=customers,ou=Groups, dc=example,dc=com`.

- To specify a parent resource type, select a value from the Parent Resource Type list in the Resource Creation section. Delegated administrators are subsequently presented with a list box that lets them select a resource, and the group is created under the selected parent resource. If you specify a parent resource type, set a value for the Primary Display Attribute Type in the Delegated Admin section. This setting determines the values that are displayed in the Delegated Admin GUI. For example, a primary display attribute type of `ou` displays the `ou` value in the list box for each resource within the parent resource type.

Attributes

These attributes are presented to the delegated administrators.

To configure a group REST resource type, go to Configuration > REST Resource Types page in the PingDirectory admin console.

When creating or editing a REST resource type, the Search Base DN field in the General Configuration section determines the data structure that is searched in Delegated Admin, and the Display Name field in the Delegated Admin section specifies the label of the REST resource in the Delegated Admin GUI.

PingDirectory Attributes

PingDirectory admin console		Delegated Admin GUI
UI field	Window and section	UI field onNew Group page
`Display Name`	Configuration > REST Resource Types. Create or edit a REST resource type, and then go to the Delegated Admin section.	`Select a Type` label
`REST Resource Type`	Configuration > Delegated Admin Rights. Create or edit Delegated Admin rights, and then click New Delegated Admin Resource Rights.	`Select a Type` option
`Parent Resource Type`	Configuration > REST Resource Types. Create or edit a REST resource type, and then go to the Resource Creation section.	Display name for parent resource type
`Display Name`	Configuration > REST Resource Types. Create or edit a REST resource type, and then go to the Delegated Admin Attributes section. Click New Delegated Admin Attribute.	Additional fields such as `CN`, `Description`, `Business Category`, and `Organization`

Adding a user to a group

You can add users to groups from the Manage Users page and from the Manage Groups page in the Delegated Admin GUI.

Adding a new user to a configured group

About this task

When the delegated admin rights for a user REST resource type have the `resources-in-specific-groups` admin scope, a user is added to one of the configured groups when you create the user:

- For admins with rights to only one group, the new user is automatically added to that group. No field for `Select Group` displays.
- For admins with rights to more than one group, the admin selects a group to add the user to in the `Select Group` list.
- Admins can select from both static and dynamic groups.
- For dynamic groups, in addition to selecting the group, the new entry must also match criteria for membership of that group.

  For example, in a dynamic group of members with `uid=user.111*`, the `uid` starts with `user.111`.

To create a new user in that group, an administrator must:

Steps

1. In the `Select Group` list, select the group name.
2. Enter the value for `uid` that starts with `user.111`.

Adding a user from the Manage Users window

You can add users to groups using the Manage Users window in the Delegated Admin GUI.

Steps

1. In the Delegated Admin GUI, go to the Manage Users window.
2. Use to search field to search for the user to add to a group.
3. Click the Expand icon on the appropriate user profile.
4. To edit the user profile, click the Pencil icon.
5. Click the Group Membership tab.
6. Use the search field to search for the appropriate group.
7. To add the user to the respective group, in the Nonmember Groups list, click +.

   Result:

   The group moves to the Member Groups list.

Adding a user from the Manage Groups window

You can add users to groups using the Manage Groups window in the Delegated Admin GUI.

Steps

1. In the Delegated Admin GUI, go to the Manage Groups window.
2. To filter by group resource type, make a selection from the drop-down list for the group resource type you want to search within.
3. (Optional) To narrow your results, use the search field to search for the appropriate group.
4. Click the Expand icon on your chosen group.
5. To edit the group profile, click the Pencil icon.
6. Under the group name, click Group Membership.
7. (Optional) To filter entries by resource type, make a selection from the Select a Type drop-down list.

   > **Note**
   >
   > If there is a parent resource type, a second drop-down list appears. Make an additional selection, or leave it to **All** to see all entries in that resource type.

8. Use the search field to search for the appropriate entry.
9. To add an entry to the group, from the Nonmembers list, click +.

   Result:

   The user moves to the Members list.

Unlocking user accounts

To unlock a user account without requiring a password reset, use the Delegated Admin application.

About this task

> **Note**
>
> To require a password reset when unlocking a user, use the **Reset Password** or **Set Password** options in the Delegated Admin application.

To use Delegated Admin to unlock a user account without requiring a password reset:

Steps

1. In the Delegated Admin application, go to Manage Users.
2. In the Search box, enter the user ID of the user you need to unlock and press Enter.
3. (Optional) Click the Expand icon to expand the user entry.
4. Click the Locked toggle.

   Result:

   The toggle turns green and changes to Enabled.

Result

The user can access their account without resetting their password.

Enabling the Delegated Admin user REST resource type photo upload feature

In Delegated Admin 4.10.0 and later, you can add a photo to a user REST resource type profile in the Delegated Admin application.

To use the Delegated Admin photo upload feature, you must first enable the feature. You can use the PingDirectory admin console or `dsconfig` to perform this task.

After you have enabled the feature, it's ready to use when creating a new user or when editing an existing user. To use the enabled photo upload feature, see Uploading a photo to a user REST resource type profile in Delegated Admin.

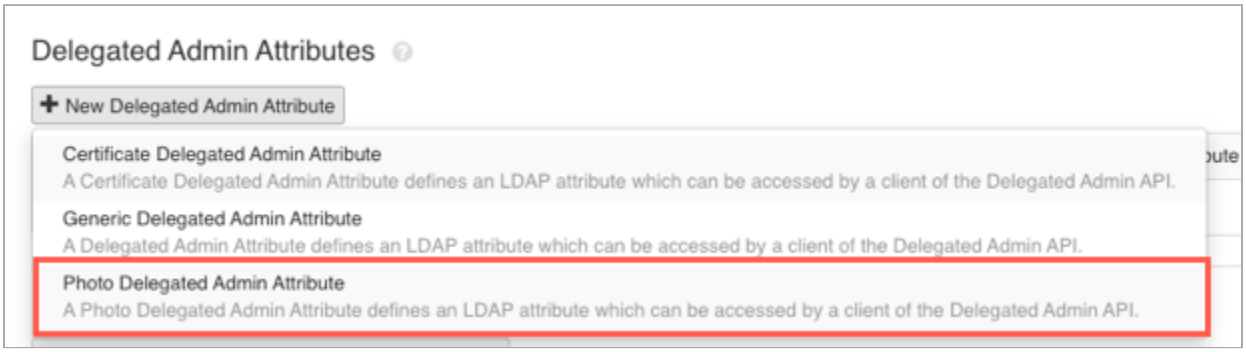
Enabling the user profile photo upload feature using the admin console

About this task

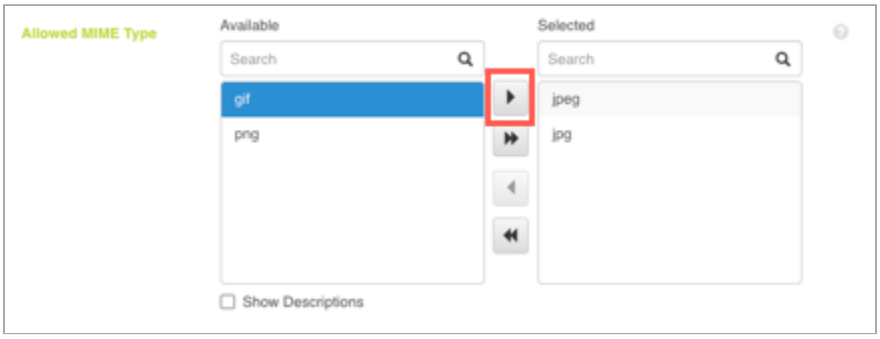
To enable the Delegated Admin user REST resource type photo upload feature using the PingDirectory admin console:

Steps

1. In the Web Services and Applications list, select REST Resource Types.
2. In the REST Resource Types list, select your user REST resource type.
3. Go to Delegated Admin Attributes and click New Delegated Admin Attribute.
4. In the New Delegated Admin Attribute list, select Photo Delegated Admin Attribute.



5. In the Attribute Type field, enter the attribute type, such as `jpegPhoto`.
6. Enter a Display Name for the attribute.
7. Keep the default value for Mutability.
8. (Optional) To allow multiple files to be uploaded for one user, enable Multi Valued.
9. Enter a Display Order Index or keep the default, `0`.
10. In the Allowed MIME Type list, select your desired allowed MIME file types from the Available column and use the arrows to add your selections to the Selected column.



11. Click Save.

Enabling the user profile photo upload feature using `dsconfig`

About this task

> **Tip**
>
> To allow multiple files to be uploaded for one user, set `multi-valued` to `true`, as in the second example.

To enable the Delegated Admin user REST resource type photo upload feature using `dsconfig`:

Steps

- Run `dsconfig create-delegated-admin-attribute`.

  Example:

  The following example creates a `jpegPhoto` Delegated Admin attribute with `.png` and `.jpg` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type jpegPhoto  \
      --type photo \
      --set display-name:Photo  \
      --set display-order-index:3  \
      --set allowed-mime-type:png  \
      --set allowed-mime-type:jpg  -n
  ```

  Example:

  The following example creates a multivalued `jpegPhoto` Delegated Admin attribute with `.png` and `.jpg` set as accepted file types:

```
bin/dsconfig create-delegated-admin-attribute \
    --type-name users  \
    --attribute-type jpegPhoto  \
    --type photo \
    --set display-name:Photo  \
    --set multi-valued:true  \
    --set display-order-index:3  \
    --set allowed-mime-type:png  \
    --set allowed-mime-type:jpg  -n
```

Uploading a photo to a user REST resource type profile in Delegated Admin

After you have enabled the photo upload feature, you can use it to add a photo to a new or existing user REST resource type profile in Delegated Admin.

> **Important**
>
> You must enable the photo upload feature before you can use it in the Delegated Admin application. For more information and to enable the feature, see Enabling the Delegated Admin user REST resource type photo upload feature.

Uploading a photo to a new user profile in Delegated Admin

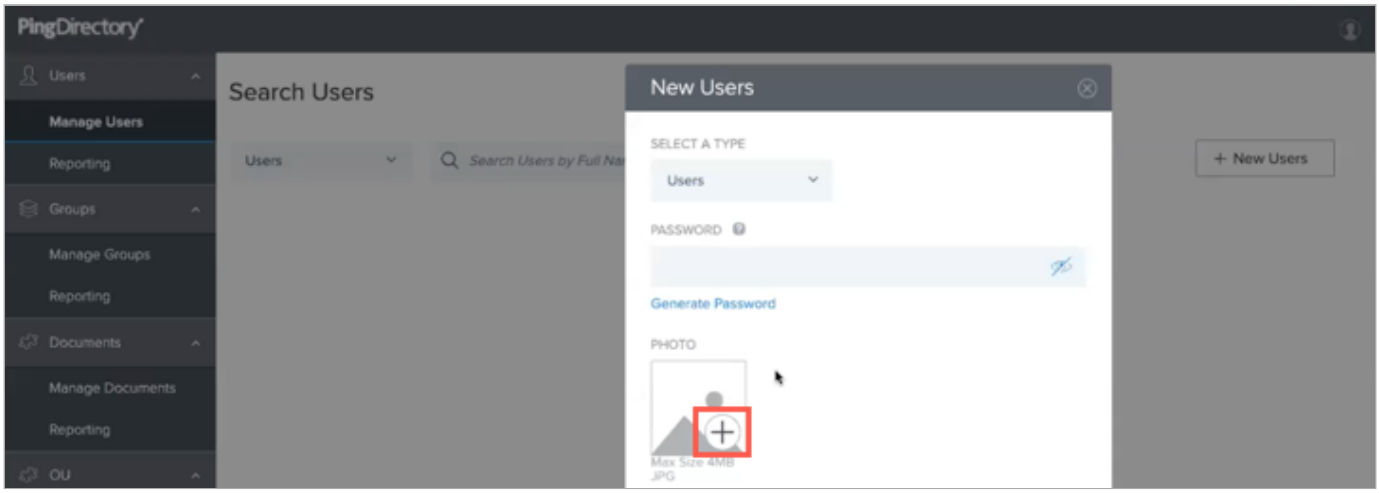
About this task

To add a photo to a new user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. Click New Users.

3. To add a photo, click the + icon and select a photo.



> **Note**
>
> Because of a server limitation, only a thumbnail of the photo and not the file name is displayed after the upload.
> The maximum photo size is 4MB.

4. Complete all other required fields for the new user.
5. Click Save.

Uploading a photo to an existing user profile in Delegated Admin

About this task

To add a photo to an existing user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. To locate the user, enter the user information in the search field.
3. Click the Expand icon on the user profile.
4. To edit the profile, click the Pencil icon.
5. (Optional) If you already have a photo and want to replace it, click Remove to remove the original photo.
6. To add a photo, click the + icon and select a photo.

> **Note**
>
> Because of a server limitation, only a thumbnail of the photo and not the file name is displayed after the upload.
> The maximum photo size is 4MB.

7. Click Save.

Enabling the Delegated Admin user REST resource type certificate upload feature

In Delegated Admin 4.10.0 and later, you can add a certificate to a user REST resource type profile in the Delegated Admin application.

To use the Delegated Admin certificate upload feature, you must first enable the feature. You can use the PingDirectory admin console or `dsconfig` to perform this task.

After you've enabled the feature, it's ready to use when creating a new user or when editing an existing user. To use the enabled certificate upload feature, see Uploading a certificate to a user REST resource type profile in Delegated Admin.

Enabling the user profile certificate upload feature using the admin console

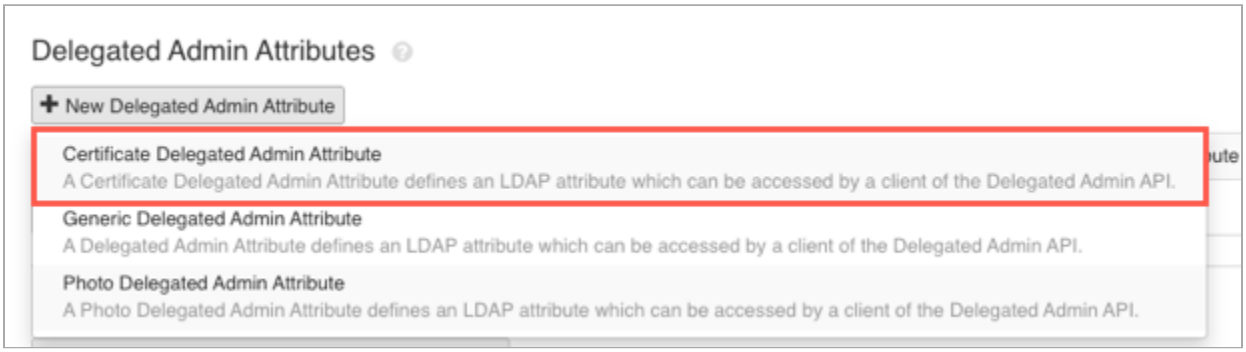
In Delegated Admin 4.10.0 and later, the user profile certificate upload feature can be enabled using the PingDirectory admin console.

About this task

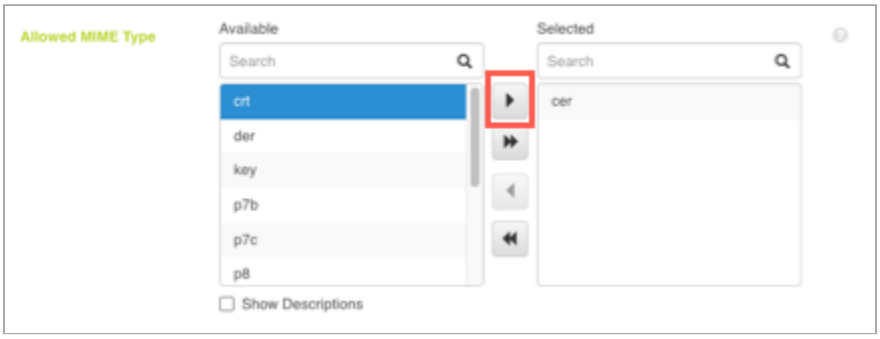
To enable the Delegated Admin user REST resource type certificate upload feature using the PingDirectory admin console:

Steps

1. In the Web Services and Applications list, select REST Resource Types.
2. In the REST Resource Types list, select your user REST resource type.
3. Go to Delegated Admin Attributes and click New Delegated Admin Attribute.
4. In the New Delegated Admin Attribute list, select Certificate Delegated Admin Attribute.



5. In the Attribute Type field, enter the attribute type, such as `userCertificate`.
6. Enter a Display Name for the attribute.
7. Keep the default values for Mutability.
8. (Optional) To allow multiple files to be uploaded for one user, enable Multi Valued.
9. Enter a Display Order Index or keep the default, `0`.
10. In the Allowed MIME Type list, select your desired allowed MIME file types in the Available column, and use the arrows to add your selections to the Selected column.



11. Click Save.

Enabling the user profile certificate upload feature using `dsconfig`

In Delegated Admin 4.10.0 and later, the user profile certificate upload feature can also be enabled using `dsconfig`.

About this task

> **Tip**
>
> To allow multiple files to be uploaded for one user, set `multi-valued` to `true`, as in the second example.

To enable the Delegated Admin user REST resource type profile certificate upload feature using `dsconfig`:

Steps

- Run `dsconfig create-delegated-admin-attribute`.

  Example:

  The following example creates a `userCertificate` attribute with `.cer` and `.crt` set as accepted file types:

  ```
  bin/dsconfig create-delegated-admin-attribute \
      --type-name users  \
      --attribute-type userCertificate  \
      --type certificate  \
      --set "display-name:user certificate"  \
      --set display-order-index:3  \
      --set allowed-mime-type:cer  \
      --set allowed-mime-type:crt -n
  ```

  Example:

  The following example creates a multivalued `userCertificate` attribute with `.cer` and `.crt` set as accepted file types:

```
bin/dsconfig create-delegated-admin-attribute \
    --type-name users  \
    --attribute-type userCertificate  \
    --type certificate  \
    --set "display-name:user certificate"  \
    --set multi-valued:true  \
    --set display-order-index:3  \
    --set allowed-mime-type:cer  \
    --set allowed-mime-type:crt -n
```

Uploading a certificate to a user REST resource type profile in Delegated Admin

After you have enabled the certificate upload feature, you can use it to add a certificate to a new or existing user REST Resource type profile in Delegated Admin.

> **Important**
>
> You must enable the certificate upload feature before you can use it in the Delegated Admin application. For more information and to enable the feature, see Enabling the Delegated Admin user REST resource type certificate upload feature.

Uploading a certificate to a new user profile in Delegated Admin

You can upload a certificate to a new user profile in the Delegated Admin application.

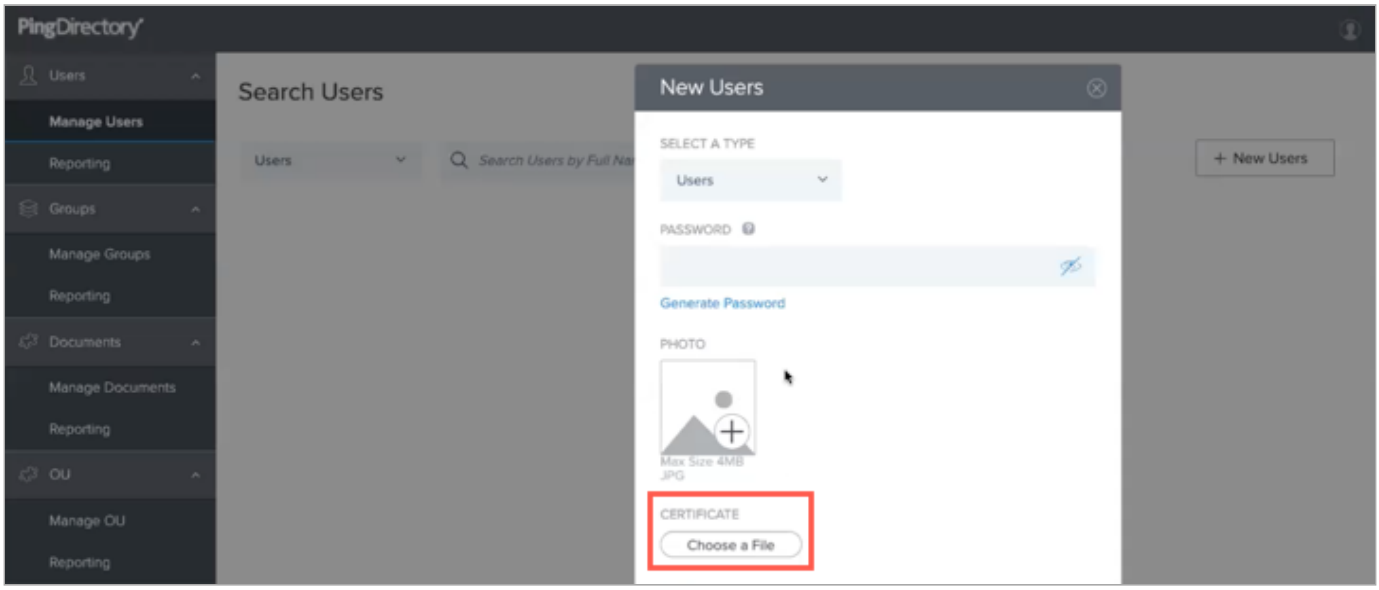
About this task

To add a certificate to a new user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. Click New Users.

3. To add a certificate, click Choose a File.



4. Complete all other required fields for the new user.
5. Click Save.

Uploading a certificate to an existing user profile in Delegated Admin

You can upload a certificate to an existing user profile in the Delegated Admin application.

About this task

To add a certificate to an existing user profile in the Delegated Admin application:

Steps

1. Click Users → Manage Users.
2. To locate the user, enter the user information in the search field.
3. Click the Expand icon on the user profile.
4. To edit the profile, click the Pencil icon.
5. To add a certificate, click Choose a File and select a certificate file.
6. Click Save.

Generic resource types

Use generic resource types to manage Lightweight Directory Access Protocol (LDAP) entries that are neither users nor groups.

You can perform the following actions with generic resource types:

- Create new entries.
- Read, view, and search existing entries.

- Edit and update existing entries.
- Edit referenced items.

For example, a generic resource type can represent a device or used for organizational unit branch entries that are parents of other resources.

Defining a generic resource type

You can define generic resources for any structural LDAP object class and they can function as members of a group.

Steps

1. Define a generic resource type.

   The following example enables the management of device entries:

   Example:

```
$ bin/dsconfig create-rest-resource-type \
  --type-name device \
  --set enabled:true \
  --set resource-endpoint:device \
  --set "display-name:Device" \
  --set structural-ldap-objectclass:device \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(cn=*%%*)' \
  --set primary-display-attribute-type:cn

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name device \
  --attribute-type cn \
  --set "display-name:Device Name" \
  --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute \
  --type-name device \
  --attribute-type serialNumber \
  --set "display-name:Serial Number" \
  --set display-order-index:2
```

2. Create Delegated Admin resource rights for the generic resource type.

   Generic resource administrators must have read access to the user resource. Learn more about Configuring delegated administrator rights on the PingDirectory server.

Working with correlated REST resources

You can link resource types based on a common attribute value. When two or more resources are linked this way, they are known as correlated resources.

Correlated REST resources

When you retrieve a resource configured with correlated resources, any correlated resource with matching attribute values is included with the resource.

You can view, update, and delete a resource's correlated resources. You can also link them to and unlink them from a resource.

Configuration

The following example shows how to create a correlated resource by linking a `documents` resource type to a `users` resource type. When a user resource is retrieved, any document resources with the user's `entryUUID` in their `documentPublisher` attribute are included.

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name Documents  \
    --set display-name:Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:entryUUID  \
    --set secondary-rest-resource-correlation-attribute:documentPublisher
```

Linking and unlinking

You can link resources to correlated resources by taking an attribute value from either the primary resource or the correlated resource and assigning it to the other. To control the direction that the linking value is assigned, use the `use-secondary-value-for-linking` property. If `use-secondary-value-for-linking` is `false` or isn't set, the primary correlation attribute's value is assigned to the secondary correlation attribute to create the link. If `use-secondary-value-for-linking` is `true`, the secondary correlation attribute's value is assigned to the primary correlation attribute.

The following is an example of a `users` resource type linked to a `documents` resource type by assigning the document's `entryUUID` value to the user's `description` attribute. The secondary correlation attribute's value is assigned to the primary correlation attribute, so `use-secondary-value-for-linking` is `true`.

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name ownedDocuments  \
    --set display-name:Owned Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:description  \
    --set secondary-rest-resource-correlation-attribute:entryUUID  \
    --set use-secondary-value-for-linking:true
```

If you inspected a user's `description` attribute with this setup, you see a list of all of the documents owned by the user.

The next example links the attributes in the other direction. Here, the user's `entryUUID` value is assigned to the `documentAuthor` attribute on the document.

```
dsconfig create-delegated-admin-correlated-rest-resource \
    --type-name users  \
    --resource-name authoredDocuments  \
    --set display-name:Authored Documents  \
    --set correlated-rest-resource:Documents  \
    --set primary-rest-resource-correlation-attribute:entryUUID  \
    --set secondary-rest-resource-correlation-attribute:documentAuthor  \
    --set use-secondary-value-for-linking:false
```

If you inspect a document's `documentAuthor` attribute with this setup, you see a list of all of the users who authored the document.

You can also unlink correlated resources from the primary resource. Resources are unlinked by removing the common attribute value using the logic based on the `use-secondary-value-for-linking` property described above.

Unlinking correlated resources differs from deleting correlated resources. When correlated resources are unlinked, the common attribute value is removed, but the correlated resource still exists in the directory. When a correlated resource is deleted, it is removed from the directory.

The attribute that the linking value is assigned to must be a writable attribute because the value must be updated to link and unlink correlated resources. The attributes should also have the same syntax so that the value of one can be assigned to the other successfully.

> **Note**
>
> When `use-secondary-value-for-linking` is enabled and a linked object is deleted, the linking value is not removed from the primary correlation attribute. This means that if a secondary object is recreated with the same value in the secondary correlation attribute, the secondary object is automatically linked to the primary object.

Permissions

The following table describes the permissions required to perform the specified actions.

Action	Permissions required
View	The `read` permission on the secondary resource type.
Update	The `update` or `update-profile` permission on the secondary resource type.
Delete	The `delete` permission on the secondary resource type.

Action	Permissions required
Link or unlink	The `update` or `update-profile` permission. **Important** The required permission is dependent on the `use-secondary-value-for-linking` setting. If `use-secondary-value-for-linking` is set to `false`, the permission is required on the correlated resource type. If `use-secondary-value-for-linking` is set to `true`, the permission is required on the primary resource type.

Setting up a DN reference attribute

A REST resource type can reference or edit other REST resource types based on a distinguished name (DN) without the full DN value. The following task, performed by the system administrator, grants the Delegated Admin administrator this ability.

About this task

In this task, the Delegated Admin attribute used for reference must be in DN syntax, such as `manager`, `entryDN`, or `seeAlso`.

Steps

1. To use a resource type for DN reference:

   Choose from:

   - Use an existing REST resource type.
   - Create a new REST resource type.

2. To add a `reference` Delegated Admin attribute, run `dsconfig` with the `create-delegated-admin-attribute` option using the following syntax.

   Example:

   ```
   dsconfig create-delegated-admin-attribute \
       --type-name users \
       --attribute-type <attribute of DN syntax> \
       --set "display-name:<display name>" \
       --set display-order-index: <index number> \
       --set reference-resource-type:<rest-resource-type>
   ```

   Example:

   The following example uses the values from Creating and configuring a new REST resource type:

```
dsconfig create-delegated-admin-attribute \
    --type-name users \
    --attribute-type manager \
    --set "display-name:Select Manager" \
    --set display-order-index:4 \
    --set reference-resource-type:Managers
```

Creating and configuring a new REST resource type

You can create and configure a new REST resource type in order to set up a reference delegated admin attribute.

About this task

To set up a reference delegated admin attribute, you must have a REST resource type defined and configured.

This example task creates a new REST resource type called `Managers`.

Steps

1. To create the new REST resource type, run `dsconfig` with the `create-rest-resource-type` option.

   Example:

   In the following example, the new resource type of `Managers` is created:

   ```
   dsconfig create-rest-resource-type \
       --type-name Managers \
       --type user \
       --set 'description:Rest type for users who are managers\n\It is used as reference type for the
   field Manager.' \
       --set enabled:true \
       --set resource-endpoint:managers \
       --set structural-ldap-objectclass:inetOrgPerson \
       --set search-base-dn:dc=example,dc=com \
       --set "include-filter:(employeeType=manager)" \
       --set parent-dn:ou=people,dc=example,dc=com \
       --set create-rdn-attribute-type:uid \
       --set display-name:Managers \
       --set 'search-filter-pattern:(|(cn=*%%*)(mail=%%*)(uid=%%*)(sn=*%%*))' \
       --set primary-display-attribute-type:cn
   ```

2. To add Delegated Admin attributes for the resource type, run `dsconfig` with the `create-delegated-admin-attribute` option.

   Example:

   The following example adds Delegated Admin attributes for the `Managers` resource type:

```
dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type cn \
    --set "display-name:Full Name"

dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type uid \
    --set "display-name:Manager ID"

dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type mail \
    --set display-name:Email

dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type employeeType \
    --set "display-name:Employee Type (must be manager)"

dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type sn \
    --set "display-name:Last name"

dsconfig create-delegated-admin-attribute \
    --type-name Managers \
    --attribute-type givenName \
    --set "display-name:First Name"
```

3. To distinguish your resource type from other resources, run `dsconfig` with the `create-delegated-admin-attribute`.

   Example:

   In the following example, `Managers` are distinguished from other users using the `employeeType` attribute:

   ```
   dsconfig create-delegated-admin-attribute \
       --type-name users \
       --attribute-type employeeType \
       --set "display-name:Employee type (manager, other)" \
       --set display-order-index:4
   ```

4. To add Delegated Admin resource rights to your set of existing Delegated Admin rights, run `dsconfig` with the `create-delegated-admin-resource-rights` option.

   Example:

   In the following example, Delegated Admin are granted `reference` Admin Permission for the `Managers` REST resource type to allow viewing access:

```
dsconfig create-delegated-admin-resource-rights \
    --rights-name <existing-rights-name> \
    --rest-resource-type Managers \
    --set enabled:true \
    --set admin-permission:reference \
    --set admin-scope:all-resources-in-base
```

Example:

In the following example, Delegated Admin administrators are granted `read` and `update` Admin Permissions for `Managers` REST resource type to allow edit access:

```
dsconfig create-delegated-admin-resource-rights \
    --rights-name DArights \
    --rest-resource-type Managers \
    --set enabled:true \
    --set admin-permission:read \
    --set admin-permission:update \
    --set admin-scope:all-resources-in-base
```

Next steps

After you have created and configured a new REST resource type, add a reference Delegated Admin attribute. For more information, see step 2 in Setting up a DN reference attribute.

Differentiating resource types within the same subtree

If you have resource types with the same object class and whose subtrees overlap, you can differentiate them through include filters.

About this task

An entry is categorized as a given resource type only if the entry's attributes match the resource type's include filters.

You can only create a new resource if the resource attributes match the include filters for the type of resource being created.

For example, to differentiate between two kinds of `organizationalUnit` resources stored in the same subtree, run the following commands.

```
$ bin/dsconfig create-constructed-attribute \
  --attribute-name businessCategoryHotel \
  --set attribute-type:businessCategory \
  --set value-pattern:Hotel

$ bin/dsconfig create-constructed-attribute \
  --attribute-name businessCategoryCruiseLine \
  --set attribute-type:businessCategory \
  --set value-pattern:CruiseLine

$ bin/dsconfig create-rest-resource-type \
  --type-name Hotel \
  --set enabled:true \
  --set resource-endpoint:hotels \
  --set "display-name:Hotel" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))' \
  --set primary-display-attribute-type:ou \
  --set include-filter:(businessCategory=Hotel) \
  --set post-create-constructed-attribute:businessCategoryHotel

$ bin/dsconfig create-rest-resource-type \
  --type-name "Cruise Line" \
  --set enabled:true \
  --set resource-endpoint:cruiselines \
  --set "display-name:Cruise Line" \
  --set structural-ldap-objectclass:organizationalUnit \
  --set search-base-dn:dc=example,dc=com \
  --set parent-dn:dc=example,dc=com \
  --set 'search-filter-pattern:(&(objectClass=organizationalUnit)(ou=%%))' \
  --set primary-display-attribute-type:ou \
  --set include-filter:(businessCategory=CruiseLine) \
  --set post-create-constructed-attribute:businessCategoryCruiseLine
```

Configuring a resource's summary display in the Delegated Admin GUI

The Delegated Admin GUI provides a summary of attributes for a resource. For example, the user and group resource profiles show a summary.

About this task

By default, a resource's summary shows all required attributes and all search attributes for the resource. However, you can explicitly set the items to include in the summary.

If you configure any attributes to appear in the summary, the default selection does not appear.

To configure an attribute to appear in the summary, either use `dsconfig` to set the `include-in-summary` property or use the PingDirectory admin console to select the Include In Summary checkbox.

Steps

- For a given resource, configure each attribute to include in the summary.

Choose from:

- Use `dsconfig`.

  Use the `set-delegated-admin-attribute-prop` subcommand, where *<name_of_type>* is the resource type and *<type_of_attribute>* is the name of an existing attribute for the given resource.

  ```
  $ bin/dsconfig set-delegated-admin-attribute-prop \
    --type-name  <name_of_type>  \
    --attribute-type  <type_of_attribute>  \
    --set include-in-summary:true
  ```

  The following example includes the `cn` attribute in the summary for the `users` resource type:

  ```
  $ bin/dsconfig set-delegated-admin-attribute-prop \
    --type-name users \
    --attribute-type cn \
    --set include-in-summary:true
  ```

  > **Note**
  >
  > To remove an attribute from the summary, use the same command but change `true` to `false`.

- Use the PingDirectory admin console.

  1. Sign on to the PingDirectory admin console.
  2. From the Configuration page, click REST Resource Types.
  3. To edit a resource type, select it from the Name column.
  4. Go to the Delegated Admin Attributes section.
  5. To edit an attribute, click the Pencil icon.
  6. Select the Include In Summary checkbox.

     > **Note**
     >
     > To remove an attribute from the summary, clear its **Include In Summary** checkbox.

Customizing UI form fields

You can customize the form field for a given attribute.

About this task

Although you can customize the presentation completely, Delegated Admin provides example files to demonstrate the functionality and capabilities.

> **Note**
>
> Because the example files most likely require modifications to address your specific needs, you should have a basic level of familiarity with HTML, CSS, and JavaScript when dealing with custom UI form fields.

The example files cover the following scenarios:

- Single-selection lists, which allow users to select one item from multiple options
- Check boxes, which can be customized so that one check box is dependent on the other
- String fields with validation and error messages
- Custom, user-friendly display of a JSON attribute, such as `ubidEmailJSON`
- Multivalue string field, which allows users to enter multiple, comma-separated values

To set up Delegated Admin to use the custom HTML files and to display custom UI form fields:

Steps

1. Go to `PingDirectory/webapps/delegator/app/customAttributes`.
2. Use a text editor to open the relevant example HTML file, as shown in the following table.

UI Form Field	Example File
Single selection list	`example-select.html`
Dependent check boxes	`example-dependent.html`
String field	`example-basic.html`
Custom display of a JSON attribute	`example-json.html`
Multivalue string field	`example-multivalue.html`

3. Make the appropriate modifications to the example file.

   For information about resizing and other custom capabilities, see the comments in `PingDirectory/webapps/delegator/app/assets/iframe-v1.js`.

4. Save the example file as a new file named `attributeName.html`.

   Example:

   For example, if you are setting up a custom attribute presentation for `cn`, name the file `cn.html`.

5. (Optional) For further clarity, create a directory under the `customAttributes` directory with the name of the resource endpoint of the REST resource types.

   Example:

   For example, because a `users` type exists with the endpoint `usersEndpoint`, you might place `cn.html` in a `customAttributes/usersEndpoint/` directory.

When locating the appropriate HTML file, Delegated Admin searches for the attribute name under the endpoint folder if one exists, and then searches under the `customAttributes` folder.

6. In the PingDirectory server, set the `attribute-presentation` field for the `Delegated Admin` attribute to `custom`.

   Example:

   ```
   dsconfig set-delegated-admin-attribute-prop \
     --type-name users  \
     --attribute-type cn  \
     --set attribute-presentation:custom
   ```

Next steps

Browsers that attempt to aggressively cache HTML files often save and reuse outdated versions of those files. Because such browsers might not display changes that are made to an example HTML file, include the following `<meta>` tag in the head of each custom HTML file.

```
<meta http-equiv="Cache-Control" content="no-cache"/>
```

If your browser still doesn't display the updated HTML file, try the following:

- Clear the browser's cache.
- Use a private browsing window.
- Try a different browser.

Setting up email invitations for a new user

You can set up email invitations for new users.

About this task

To set up email invitations for a new user:

Steps

1. Set up PingFederate for local identity profile management.

   Learn more in Configuring user self-service.

   When you complete this task, the PingFederate configuration has a local identity profile.

2. Configure Delegated Admin profile management by users.

   Learn more in Configuring user self-service.

   When you complete this task, users whom the Delegated Admin creates have the `pf-connected-identities` auxiliary object class and a `pf-connected-identity` attribute value, which provide integration with PingFederate's user self-service.

3. Instruct users to copy the email template to PingDirectory Server.

4. Create request criteria to match Delegated Admin user `ADD` requests.
5. Edit the provided email template and insert the URL to the PingFederate self-service profile management endpoint.
6. Create an SMTP external server.
7. Create a multi-part email account status notification handler for Delegated Admin user `ADD` requests.

Editing and copying the email template to the PingDirectory server

You can edit and copy the email template to the PingDirectory server using the example email template provided.

About this task

An example email template is provided in the Delegated Admin package at the top level in the file `delegated-admin-account-created.template`. This template provides a multi-part text and HTML email to the user with their user name and initial password along with a self-service link they can use to sign on to PingFederate and change their password and profile information.

Steps

1. Edit the template:
    1. Uncomment the line that sets the value for `profile_management_url`.
    2. Change the value of `profile_management_url` to the externally accessible URL of the profile management endpoint of your PingFederate local identity profile.
2. Copy the template file to the `config/account-status-notification-email-templates` folder of each instance of the PingDirectory server.

    By default, the email is sent to the address within the user's Lightweight Directory Access Protocol (LDAP) `mail` attribute.

    > **Note**
    >
    > You must provide a mail value for each user. For more information, see `common-header-fields.vm` in the email templates folder.

Next steps

For more information about the email format and further customization, see the `README` file in the templates folder.

Creating request criteria to match Delegated Admin user ADD requests

You can create request criteria to match Delegated Admin user ADD requests.

Steps

- For each user resource type for which new user email invites will be sent, create simple request criteria to match the parent distinguished name (DN) and object classes for the resource type.

    > **Note**
    >
    > The setup script includes a request criteria for the user resource type that it creates.

Example:

```
$ dsconfig create-request-criteria --criteria-name \
"Delegated Admin User Creation Request Criteria" --type simple \
--set operation-type:add --set \
"included-target-entry-dn:ou=people,dc=example,dc=com" \
--set "any-included-target-entry-filter:(objectClass=inetOrgPerson)" \
--set "included-application-name:PingDirectory Delegated Admin"
```

The `included-application-name` property ensures that the criteria matches users whom the Delegated Admin created, but not users created through another interface, such as the Directory REST API. This application name value is visible in the LDAP access log for operations that the Delegated Admin HTTP servlet invokes.

Creating an SMTP external server

You can create an SMTP external server to send emails.

About this task

To send emails:

Steps

- Configure a PingDirectory server with an SMTP server in the global configuration.

  Example:

```
$ dsconfig create-external-server --server-name \
"SMTP Server" --type smtp --set server-host-name:smtp.example.com \
--set user-name:example-smtp-user --set password:example-smtp-password

$ dsconfig set-global-configuration-prop --set \
"smtp-server:SMTP Server"
```

Creating a multi-part Email Account Status notification handler for Delegated Admin user ADD requests

You must set an Email Account Status notification handler in the password policy in force for new users. This handler is typically the default password policy.

About this task

The notification handler references the email template in the `config/account-status-notification-email-templates` folder.

> **Note**
>
> The setup script creates an example notification handler in a disabled state. This handler cannot be enabled until an SMTP server becomes available in the global configuration.

Steps

1. Create or enable the handler:

Choose from:

- To create the handler from scratch, use the `dsconfig create-account-status-notification-handler` command.

```
$ dsconfig create-account-status-notification-handler \
--handler-name "Delegated Admin Email Account Status \
Notification Handler" --type multi-part-email --set \
enabled:true --set \
"account-creation-notification-request-criteria:Delegated \
Admin User Creation Request Criteria" --set \
account-created-message-template:config/account-status-\
notification-email-templates/delegated-admin-account-created.template
```

- To enable the handler that is provided with the setup script, use the `dsconfig set-account-status-notification-handler-prop` command.

```
$ dsconfig set-account-status-notification-handler-prop \
--handler-name "Delegated Admin Email Account Status Notification \
Handler" --set enabled:true
```

2. Set the handler in the password policy.

Example:

```
$ dsconfig set-password-policy-prop \
--policy-name "Default Password Policy" --set \
"account-status-notification-handler:Delegated Admin Email Account \
Status Notification Handler"
```

Enabling the referential integrity plugin

When a REST resource type is set to create new entries using a relative distinguished name (RDN) attribute other than `entryUUID`, referential integrity issues can result when the entry's RDN attribute is edited.

About this task

To preserve the referential integrity of group memberships in such a scenario, enable the referential identity plugin.

Steps

- Enable the referential integrity plugin with the following command.

```
bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

Result

After you enable the plugin, group memberships are preserved.

Enabling log tracing

You can enable log tracing for token processing, HTTP request and response actions, and API debugging.

Steps

- To view OAuth token processing and full HTTP request and response tracing, enable the debug trace logger with the following command.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name 'Debug Trace Logger' \
  --set enabled:true
```

- To enable `dadmin` API debug logging, use the following commands:

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.server.http \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.server.extensions.dadmin \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name 'File-Based Debug Logger' \
  --target-name com.unboundid.directory.broker.api \
  --set debug-level:VERBOSE
```

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name 'File-Based Debug Logger' \
  --set enabled:true
```

Specifying a custom hostname and port for your PingDirectory server

If an application is installed on a separate server from your PingDirectory server instance, you must specify where the PingDirectory server instance is found within the Delegated Admin application's `config.js` file.

The `DS_HOST` configuration variable should match your PingDirectory server's hostname. The `DS_PORT` configuration variable should match your PingDirectory server's HTTPS port.

> **Note**
>
> You don't need to specify these variables if you're hosting the Delegated Admin application alongside your PingDirectory server instance, as described in previous sections.

Changing the application logo

You can change the Ping Identity logo to your corporate logo.

About this task

Support for corporate logos includes, but is not limited to, the following file types:

- `JPG`
- `PNG`
- `SVG`

To maintain an appropriate aspect ratio, logo images are resized in Delegated Admin to a height of 22px and a maximum width of 150px.

Steps

1. To change the Ping Identity logo to your corporate logo, add the following line to the `config.js` configuration file:

```
window.HEADER_BAR_LOGO = '<filename>';
```

2. Add the logo to the build directory.

> **Note**
>
> Make sure to use the same file name specified in step 1.

Result

The corporate logo appears in the header, and the Ping Identity logo relegates to the sidebar in grayscale, preceded by "Powered by".

Configuring the session timeout

By default, Delegated Admin has an idle session timeout value of 30 minutes. To adjust this value, perform the following steps.

Steps

1. Open the `config.js` configuration file in a text editor.
2. Add the following line to the configuration file:

```
window.TIMEOUT_LENGTH_MINS=<TimeoutValue>;
```

<*TimeoutValue*> is an integer that represents the session timeout value in minutes.

To view an example outline that features this setting, see `example.config.js`.

3. Save your changes to `config.js`.

Reporting

Reports provide information about users and group membership. You can preview a report and search, filter, and sort the content. When the preview meets your needs, you can download the resulting report.

About this task

In the Delegated Admin GUI, the left navigation pane provides a Reporting tab under the top-level sections, such as Users and Groups.

Administrators can also use the Reporting page to upload users and group members in bulk with a `.csv` file. The `.csv` file should contain headers with the exact attribute names of the users resource type. Users can be uploaded with missing info for some of the attributes but the required attributes must be present and specified. For a group administrator, uploading users will also add them to the appropriate group. Click `Upload` on the Reporting page and select a `.csv` file to upload.

On each Reporting tab, you can:

- Filter the columns or attributes to display.
- Filter the users returned, such as all users with the first name John. Only exact matches are returned.
- Sort columns by clicking the column name.

Steps

- To apply filters to the report, click Run.
- To download the report as currently filtered and sorted, click Download Report.
- To clear any filtering and sorting, click Reset.

Compatibility matrix

The following matrix identifies the minimum versions of the PingDirectory server required to access the full functionality provided by each release of Delegated Admin.

> **Note**
>
> All versions of Delegated Admin require PingFederate 9.0.0 or later.

Delegated Admin	PingDirectory server
5.0.0	9.3.0.0
4.10.0	9.1.0.0
4.9.0	9.1.0.0 EA
4.8.0	9.0.0.0
4.7.0	9.0.0.0 EA
4.6.0	8.3.0.0
4.5.0	8.3.0.0 EA
4.4.1	8.2.0.0
4.4.0	8.2.0.0
4.3.0	8.2.0.0 EA

Configuring the PingFederate server

PingFederate offers many configuration options. This section provides an example PingFederate configuration that supports Delegated Admin.

> **Note**
>
> The PingFederate information in this section is based on the PingFederate 10.1 interface.

Configuring the PingFederate server includes the following:

- Configuring PingFederate as the identity provider
- Configuring the OAuth server
- Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory)
- Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin)
- Setting cross-origin resource sharing (CORS) settings

Configuring PingFederate as the identity provider

The following task configures the PingFederate server as the identity provider (IdP) for the PingDirectory server.

Before you begin

Download the LDAPS certificate from the PingDirectory server. For more information, see Exporting certificates.

Steps

1. Sign on to the PingFederate admin console.
2. Import the PingDirectory server LDAPS certificate:
    1. Go to Security → Certificate & Key Management → Trusted CAs.
    2. Click Import, click Choose File to browse to the certificate, click Next, and then click Save.
3. Add an Lightweight Directory Access Protocol (LDAP) datastore:
    1. Go to System → Data Stores.
    2. Click Add New Data Store.
    3. Specify a Name for the data store.
    4. Set Type to Directory (LDAP).
    5. Click Next.
    6. In the Hostname(s) field, enter the PingDirectory server host name and LDAPS port, separated by a colon (for example, 10.101.113.75:1636) and click Add.
    7. Select the Use LDAPS check box.
    8. Set LDAP Type to PingDirectory.
    9. In the User DN field, enter one of the following values based on your PingDirectory configuration:
        - `cn=dmanager`
        - `cn=Directory Manager`

        > **Note**
        >
        > These values are based on the assumption that Delegated Admin will run as the directory manager.

    10. In the Password field, specify the root password.
    11. Click Advanced and then Advanced LDAP Options.
        1. Select the Create New Connections If Necessary check box.
        2. Clear the Verify LDAPS Hostname check box.
        3. Click Done.
    12. Click Test Connection.
    13. Click Next.
    14. Click Save.
4. Create the HTML form IdP Adapter.

The adapter authenticates users against the PingDirectory server.

1. Go to Authentication → IdP Adapters → Create New Instance
2. In the Instance Name field, enter a name such as `PingDirectoryIdP`.
3. Specify an Instance ID.
4. Set Type to HTML Form IdP Adapter.
5. Click Next.
6. Go to the bottom of the page and click Manage Password Credential Validators.
7. Create a validator to authenticate users against the PingDirectory server:
    1. Click Create New Instance.
    2. Specify an Instance Name.
    3. Specify an Instance ID.
    4. Set Type to LDAP User Name Password Credential Validator.
    5. Click Next.
    6. Specify an LDAP Datastore.
    7. Specify an Search Base.
    8. Enter the following text in the Search Filter field to use the email address or user name to sign on to the system.

        ```
        (|(uid=${username})(mail=${username}))
        ```

    9. Click Next and extend the contract with `entryUUID` and `cn`.

        > **Note**
        >
        > These values are used later.

    10. Click Next, Done, or Save until you reach the Create Adapter Instance screen.
8. Add a new row to Password Credential Validators, choose the new LDAP Password Credential Validator, and click Update.
9. Go to the Extended Contract tab and extend the adapter contract with `entryUUID` and `cn`.
10. Go to the Adapter Attributes tab, select `entryUUID` for a pseudonym, and then click Next, Next, Done, and Save.

    Learn more about Configuring the LDAP Username Password Credential Validator in the PingFederate documentation.

5. Enable session tracking:
    1. Go to Authentication → Sessions

2. Select the Track Adapter Sessions For Logout check box.
3. Select the Track Revoked Sessions On Logout check box.
4. Select the Enable Authentication Sessions For All Sources check box.
5. Click Save.

Configuring the OAuth server

The following task configures the PingFederate server for OAuth and OpenID Connect (OIDC) authentication.

Steps

1. Sign on to the PingFederate admin console.
2. Set the identity provider (IdP) adapter mapping:
    1. Go to Authentication > OAuth > IdP Adapter Grant Mapping.
    2. From the Source Adapter Instance list, select the IdP adapter you created in Configuring PingFederate as the identity provider and click Add Mapping.
    3. Click Next.

    > **Note**
    > No attribute source is needed.

    4. On the Contract Fulfillment tab, set the contracts as shown in the following table:

Contract	Source	Value
USER_KEY	Adapter	entryUUID
USER_NAME	Adapter	cn

    5. Click Next and then click Next again.
    6. Click Save.
3. Set up Access Token Management.

    Select an existing instance or click Applications > OAuth > Access Token Management > Create New Instance.

    Choose from:

    - If selecting an existing instance, click the Instance Configuration tab.

    > **Note**
    > With an existing instance, a JSON Web Token (JWT) is configured automatically.

    - If creating a new instance, specify the required fields and set Type to JSON Web Tokens.

> **Note**
>
> Take note of your new instance name. You'll need that information later.

1. Use symmetric encryption for the JWT by adding a row in the Symmetric Keys section using 32 bytes or 64 characters of hex.

   > **Note**
   >
   > This encryption only requires a symmetric key, not a certificate and private key. This step requires the client to validate the token by hitting the validation endpoint on the server.

2. Set JWS Algorithm to HMAC Using SHA-256.
3. Set Active Symmetric Key ID to your symmetric key and click Next.
4. On the Session Validation tab, select all options and click Next.
5. On the Access Token Attribute Contract tab, list at least one attribute to be defined in the access token, add `sub`, click Next until you reach the last section, and then click Save.

4. Set up access token mapping:
   1. Go to Applications > OAuth > Access Token Mappings.
   2. Set Context to Default, set Access Token Manager to the access token manager you created in the last step, and click Add Mapping.
   3. Click Next in the Attribute Source & User Lookup section to go to the Contract Fulfillment section.
   4. In the sub row, make the following selections:
      - In the Source list, select Persistent Grant.
      - In the Value list, select USER_KEY.
   5. Click Next until you reach the Summary section. Click Save.
5. Set up the OpenID Connect policy:
   1. Go to Applications > OAuth > OpenID Connect Policy Management.
   2. Click Add Policy.
   3. Specify a Policy ID.
   4. Specify a Name.
   5. Choose the previously created access token manager and click Next.
   6. Delete all extended contract attributes except `sub`.

      Other scopes are defined, if configured.
   7. Click Next to reach the Contract Fulfillment section.
   8. Fulfill the OpenID Connect (OIDC) contract sub with the access token attribute `sub`.

9. Click Next and then click Done.
10. If a default OIDC policy is not already defined, set this new policy as the default and click Save.

6. Add scopes for PingDirectory server APIs:
    1. Go to System > OAuth Settings > Scope Management.
    2. Click the Exclusive Scopes tab.
    3. Add a scope with a Scope Value of `urn:pingidentity:directory-delegated-admin` and a Scope Description of `DAScope`.
    4. Click Save.

Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory)

When creating a PingFederate access token validator in the PingDirectory server, use the `pingdirectory` client ID and secret.

About this task

The PingDirectory server uses an identity mapper to match the `sub` claim against the `entryUUID` attribute.

To configure the PingDirectory server as the token validator:

Steps

1. Sign on to the PingFederate admin console.
2. Go to Applications → OAuth → Clients.
3. Click Add Client.
4. For both the Client ID and Name, specify `pingdirectory`.
5. In the Client Authentication section, select Client Secret.
6. In the Client Secret section, select Change Secret and then enter or generate a secret.
7. Copy the secret key.
8. In the Allowed Grant Types section, select Access Token Validation (Client is a Resource Server).
9. Set the Default Access Token Manager to the access token manager you created in step 3 of Configuring the OAuth server.
10. Click Save.

Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin)

The following task configures Delegated Admin as a new client and outlines how to create an OAuth client for Delegated Admin.

About this task

To configure Delegated Admin as a new client:

Steps

1. Sign on to the PingFederate admin console.
2. Go to Applications → OAuth → Clients.
3. Click Add Client.
4. For both the Client ID and Name, specify `dadmin`.
5. Set Client Authentication to None.

> **Important**
>
> Do not set a client secret.

6. For Redirect URIS, enter the appropriate URI for your environment based on the following table and then click Add.

For Delegated Admin on a PingDirectory server or a PingDirectoryProxy server	`https://<server-host>:<server-port>/delegator/*`
For Delegated Admin on a web server hosted locally	`http://localhost:<server-port>/*`

7. Make the following selections:
    1. In the Bypass Authorization Approval section, select Bypass.
    2. In the Exclusive Scopes section, select Allow Exclusive Scopes and then select urn:pingidentity:directory-delegated-admin.
    3. In the Allowed Grant Types section, select Authorization Code.
    4. In the Default Access Token Manager list, select the token manager that you created in step 3 of Configuring the OAuth server.
    5. Select the check box for Require Proof Key for Code Exchange (PKCE).
    6. In the OpenID Connect section, select the OpenID Connect (OIDC) policy that you created in step 5 of Configuring the OAuth server.
8. Click Save.

Next steps

After completing the previous steps, configure the following settings to display the name of the administrator who is signed on to the client application:

1. Add the `profile` scope and ensure it is available to the OAuth client used for the Delegated Admin application.
2. Add and fulfill the `name` attribute as part of the contract for both the access token and the ID token supplied to the Delegated Admin application.

3. Set the `PROFILE_SCOPE_ENABLED` configuration variable for Delegated Admin in the `config.js` file to `true`.

```
/**
 * Configuration wrapper object for Delegated Admin
 */
window.PD_DADMIN_CONFIG = {
  /**
   * Set to true if the "profile" scope is supported for the Delegated Admin OIDC client on
   * PingFederate and you wish to use it to show the current user's name in the navigation.
   * DEFAULT: false
   */
  PROFILE_SCOPE_ENABLED: true,
};
```

Setting cross-origin resource sharing (CORS) settings

The CORS settings can be set through the PingFederate admin console.

Steps

1. Sign on to the PingFederate admin console.
2. Click SYSTEM → OAuth Settings → Authorization Server Settings.
3. Go to the Cross-Origin Resource Sharing Settings section.
4. Add `https://${directoryServer:httpPort}` to Allowed Origin, using the host name and HTTPS listener port for the PingDirectory server.

> **Important**
>
> Don't include `/delegator` in the **Allowed Origin** field. Doing so causes Delegated Admin to throw a token validation error when you attempt to sign on.

For example, consider the following table:

For Delegated Admin on a PingDirectory server or a PingDirectoryProxy server	`https://<server-host>:<server-port>`
For Delegated Admin on a web server hosted locally	`http://localhost:5000/*`

5. Click Save.

Changing the default OIDC grant type

To change the Delegated Admin application's default OpenID Connect (OIDC) grant type, use the PingFederate admin console and the Delegated Admin `config.js` file.

About this task

To improve authentication security, switch your default OIDC grant type to Authorization Code with Require Proof Key for Code Exchange (PKCE). The Authorization Code with PKCE grant type hides access tokens during authentication with JavaScript applications, in comparison to the Implicit grant type that displays access tokens in the URL redirect during OIDC authentication.

> **Note**
>
> For more information, see OAuth Grant Types.

The following example changes the default OIDC grant type from Implicit to Authorization Code with Require Proof Key for Code Exchange (PKCE).

Steps

1. In the PingFederate admin console, go to Applications > OAuth > Clients.
2. From the Clients list, select the dadmin client.
3. In the Allowed Grant Types section:
    1. Select the Authorization Code check box.
    2. Clear the Implicit check box.
    3. Select the Require Proof Key for Code Exchange (PKCE) check box.
    4. Click Save.
4. From your `<server-root>` directory, open the Delegated Admin application's `config.js` file and set the `AUTHENTICATE_WITH_PKCE` variable to `true`.

    Example:

    ```
    /*
     * Indicates if this app should authenticate using the 'Authorization Code with PKCE' OAuth grant.
     * If true, the 'Authorization Code with PKCE grant will be used. If false, the 'Implicit' grant
     * will be used. * DEFAULT: window.AUTHENTICATE_WITH_PKCE = true;
     */
    window.AUTHENTICATE_WITH_PKCE = true;
    ```

    > **Note**
    >
    > If you don't already have the `AUTHENTICATE_WITH_PKCE` variable in your `config.js` file, you must add it.

PingDataSync Server Administration Guide

The PingDataSync server is an efficient, Java-based server that provides high throughput, low latency, and bidirectional real-time synchronization between two endpoint topologies, such as PingDirectory servers, PingDirectoryProxy servers, PingOne, or relational database management systems (RDBMS).

PingDirectory product documentation

Support

https://support.pingidentity.com

Overview of the PingDataSync server process

The following topics present a general overview of the PingDataSync process and examples for use:

Data synchronization process

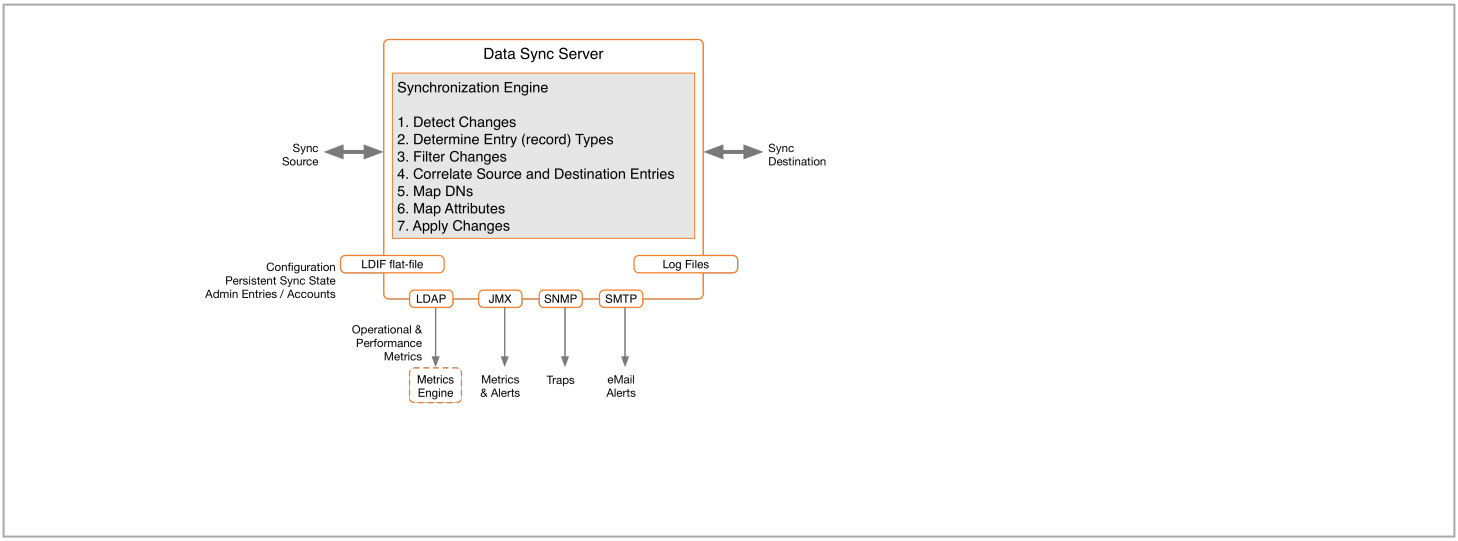
PingDataSync performs point-to-point synchronization between a source endpoint and a destination endpoint. An endpoint is defined as any source or destination topology of directory or database servers.

PingDataSync synchronizes data in one direction or bidirectionally between endpoints. For example, in a migration phase from Sun Directory server to a PingDirectory server, synchronization can occur in one direction from the source server to a staging server. With one-way synchronization, the source server is the authoritative endpoint for changes in the system. Bidirectional synchronization allows for parallel active installations between the source and the destination endpoints. With bidirectional synchronization, both endpoints are authoritative for the same set of attributes or for different sets of data.

PingDataSync also contains no single point of failure, either for detecting changes or for applying changes. PingDataSync instances themselves are redundant. There can be multiple instances running at a time, but only the server with the highest priority is actively synchronizing changes. The stand-by servers are constantly polling the active server instance to update their persistent state. This state contains the minimum amount of information needed to begin synchronization where the primary server left off, which logically is the last processed change number for the source server. In the case of a network partition, multiple servers can synchronize simultaneously without causing problems, because they each verify the full entry before making changes.

Synchronization architecture

PingDataSync uses a virtualized, dataless approach that does not store directory data locally. The log files, administrator entries, configuration, and sync state information are stored as flat files (LDIF format) within the system. No additional database is required.



Change tracking, monitoring, and logging

PingDataSync tracks and manages processes and server health with the following tools:

Change Tracking

Each directory instance stores a separate entry under `cn=changelog` for every modification made to the directory. PingDataSync provides full control over the synchronization process by determining which entries are synchronized, how they are correlated to the entries at the destination endpoint, and how they are transformed into the destination schema.

- For PingDirectory server topologies, PingDataSync uses the server's LDAP Change Log for modification detection.
- For Oracle/Sun Directory Server, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, PingDataSync uses the server's Retro Change Log, which provides a detailed summary of each change.

- For Active Directory (AD), PingDataSync uses the DirSync control, which polls for object attribute changes.
- For RDBMS systems, PingDataSync uses a Ping Identity Server SDK plugin to interface with a customized RDBMS change log table. The database triggers on each table record all INSERT, UPDATE, and DELETE operations to the change log table.

Monitoring, Alerts, and Alarms

PingDataSync supports several industry-standard administrative protocols for monitoring alarms and alerts. System alarms and gauges can be configured to determine healthy performance thresholds and the server actions taken when performance values are outside the threshold. All administrative alarms are exposed over LDAP as entries under base DN `cn=alarms`. An administrative alert framework sends warnings, errors, or other server events through log messages, email, or JMX notifications. Administrative alerts are also exposed over LDAP as entries below base DN `cn=alerts`. Typical alert events are startup or shutdown, applied configuration changes, or synchronized resources unavailable.

Logging

PingDataSync provides standard logs (`sync`, `access`, `error`, `failed-operations`, `config-audit.log`, and `debug`). The server can also be configured for multiple active sync logs. For example, each detected change, each dropped change, each applied change, or each failed change can be logged.

Synchronization modes

PingDataSync runs as a standalone Java process with two synchronization modes: standard and notification.

Standard synchronization

In standard synchronization mode, PingDataSync polls the directory server change log for create, modify, and delete operations on any entry. The server fetches the full entries from both the source and destination endpoints, and compares them to produce the minimal set of changes required to synchronize the destination with the source.

Notification synchronization

In notification synchronization mode, PingDataSync skips the fetch and compare phases of processing, notifies the destination that a change has happened, and provides the details of the change. Notification mode is currently available for the PingDirectory and Alcatel-Lucent 8661 directory and proxy servers only.

PingDataSync operations

PingDataSync provides seamless integration between disparate systems to transform data using attribute and DN mappings. A bulk resynchronization operation can be run to verify mappings and test synchronization settings.

Real-time synchronization

Real-time synchronization is performed with the `realtime-sync` utility. The `realtime-sync` utility polls the source server for changes and synchronizes the destination entries immediately. After the server determines that a change should be synchronized, it fetches the full entry from the source. It then searches for the corresponding entry in the destination endpoint using correlation rules and applies the minimum set of changes to synchronize the attributes. The server fetches and compares the full entries to make sure it does not synchronize any old data from the change log.

After a synchronization topology is configured, run `resync` to synchronize the endpoints, and then run `realtime-sync` to start global synchronization.

The `realtime-sync` tool is used for the following tasks:

- Start or stop synchronization globally or for specific sync pipes only.
- Set a start point at which synchronization should begin such as the beginning or end of the change log, at a specified change number, at a specified change sequence number, or at a specified time frame in the change log.

Data transformations

Data transformations alter the contents of synchronized entries between the source and destination directory server to handle variances in attribute names, attribute values, or DN structures. When entries are synchronized between a source and a destination server, the contents of these entries can be changed using attribute and DN mappings, so that neither server needs be aware of the transformations.

- Attribute Mapping – Any attribute in the entry can be renamed to fit the schema definitions from the source endpoint to the destination endpoint. This attribute mapping makes it possible to synchronize information stored in one directory's attribute to an attribute with a different name in another directory server, or to construct an attribute using portions of the source attribute values.
- DN Mapping – Any DNs referenced in the entries can be transparently altered. This mapping makes it possible to synchronize data from a topology that uses one DIT structure to a system that uses a different DIT structure.

Bulk resync

The `resync` tool performs a bulk comparison of entries on source topologies and destination topologies. PingDataSync streams entries from the source, and either updates the corresponding destination entries or reports those that are different. The `resync` utility resides in the `/bin` folder (UNIX or LINUX) or `\bat` folder (Windows), and can be used for the following tasks:

- Verify that the two endpoints are synchronized after an initial configuration.
- Initially populate a newly configured target endpoint.
- Validate that the server is behaving as expected. The `resync` tool has a `--dry-run` option that validates that synchronization is operating properly, without updating any entries. This option also can be used to check attribute or DN mappings.
- Perform scheduled synchronization.
- Recover from a failover by resynchronizing entries that were modified since the last backup was taken.

The `resync` tool also enables control over what can be synchronized, such as:

- Include or exclude any source and destination attributes.
- Apply an LDAP filter to only sync entries created since the last time the tool ran.
- Synchronize only creations or only modifications.
- Change the logging verbosity.
- Set a limit on `resync` operations (such as 2000 operations per second) to reduce impact on endpoint servers.

The sync retry mechanism

PingDataSync is designed to quickly synchronize data and attempt a retry should an operation fail for any reason. The retry mechanism involves two possible retry levels, which are configurable on the Sync Pipe configuration using advanced Sync Pipe properties.

First Level Retry

If an operation fails to synchronize, the server will attempt a configurable number of retries. The total number of retry attempts is set in the `max-operation-attempts` property on the Sync Pipe. The property indicates how many times a worker thread should retry the operation before putting the operation into the second level of retry, or failing the operation altogether.

Second Level Retry

Once the `max-operation-attempts` property has been exceeded, the retry is sent to the second level, called the delayed-retry queue. The delayed-retry queue uses two advanced Sync Pipe properties to determine the number of times an operation should be retried in the background after a specified delay.

Operations that make it to this level will be retried after the `failed-op-background-retrydelay` property (default: 1 minute). Next, PingDataSync checks the `max-failedop-background-retries` property to determine the number of times a failed operation should be retried in the background. By default, this property is set to 0, which indicates that no background retry should be attempted, and that the operation should be logged as failed.

> **Note**
>
> Background operations can hold up processing other changes, since PingDataSync will only process up to the next 5000 changes while waiting for a retried operation to complete.

Retry can be controlled by the custom endpoint based on the type of error exception. When throwing an exception, the endpoint code can signal that a change should be aborted, retried a limited number of times, or retried an unlimited number of times. Some errors, such as endpoint server down, should be retried indefinitely.

If the `max-failed-op-background-retries` property has been exceeded, the retry is logged as a failure and appears in the sync and the sync-failed-ops logs.

Configuration components

PingDataSync supports the following configuration parameters that determine how synchronization takes place between directories or databases:

Sync Pipe

Defines a single synchronization path between the source and destination topologies. Every Sync Pipe has one or more Sync Classes that control how and what is synchronized. Multiple Sync Pipes can run in a single server instance.

Sync Source

Defines the directory topology that is the source of the data to be synchronized. A Sync Source can reference one or more supported external servers.

Sync Destination

Defines the topology of directory servers where changes detected at the Sync Source are applied. A Sync Destination can reference one or more external servers.

External Server

Defines a single server in a topology of identical, replicated servers to be synchronized. A single external server configuration object can be referenced by multiple Sync Sources and Sync Destinations

Sync Class

Defines the operation types and attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated. A source entry is in one Sync Class and is determined by a base DN and LDAP filters. A Sync Class can reference zero or more Attribute Maps and DN Maps, respectively. Within a Sync Pipe, a Sync Class is defined for each type of entry that needs to be treated differently, such as entries that define attribute mappings, or entries that should not be synchronized at all. A Sync Pipe must have at least one Sync Class but can refer to multiple Sync Class objects.

DN Map

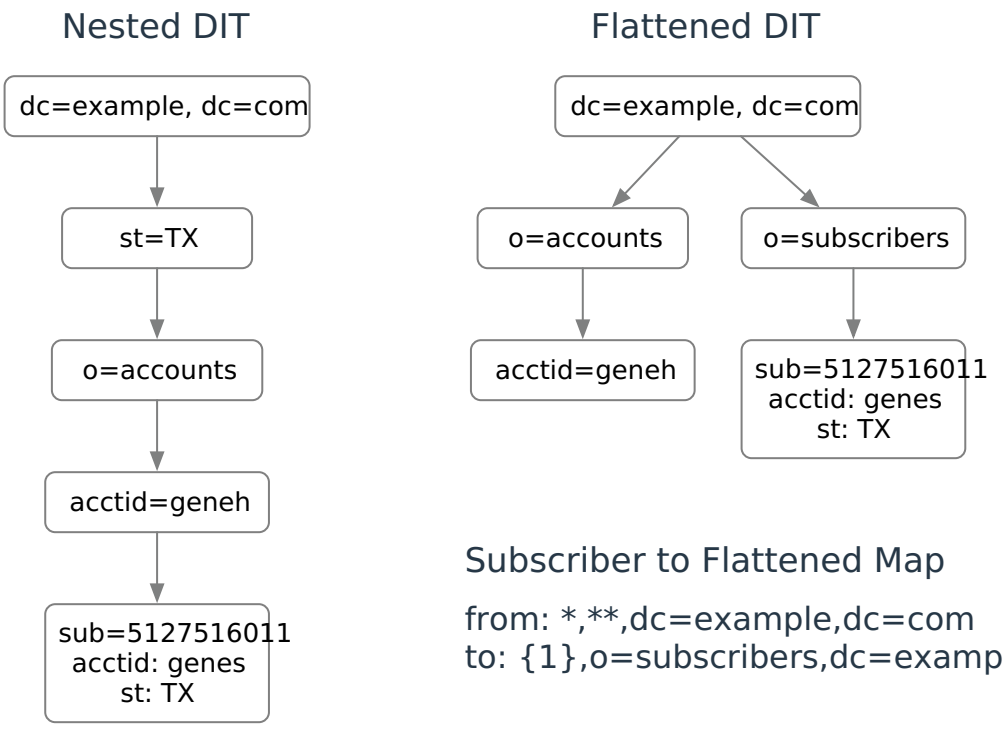
Defines mappings for use when destination DNs differ from source DNs. These mappings allow the use of wild cards for DN transformations. A single wild card ("*") matches a single RDN component and can be used any number of times. The double wild card ("**") matches zero or more RDN components and can be used only once. The wild card values can be used in the `to-dn-pattern` attribute using `{1}` and their original index position in the pattern, or `{attr}` to match an attribute value. For example:

```
**,dc=myexample,dc=com->{1},o=example
```

Regular expressions and attributes from the user entry can also be used. For example, the following mapping constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of `givenname` and `sn`) and the employee ID (`eid` attribute).

```
uid={givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid},{2},o=example
```

The following figure illustrates how a nested DIT can be mapped to a flattened structure.



Attribute Map and Attribute Mappings

Defines a mapping for use when destination attributes differ from source attributes. A Sync Class can reference multiple attribute maps. Multiple Sync Classes can share the same attribute map. There are three types of attribute mappings:

- **Direct Mapping – Attributes are directly mapped to another attribute: For example:**

```
employeenumber->employeeid
```

- **Constructed Mapping – Destination attribute values are derived from source attribute values and static text. For example:**

```
{givenname}.{sn}@example.com->mail
```

- **DN Mapping – Attributes are mapped for DN attributes. The same DN mappings that map entry DNs can be referenced. For example:**

```
uid=jdoe,ou=People,dc=example,dc=com.
```

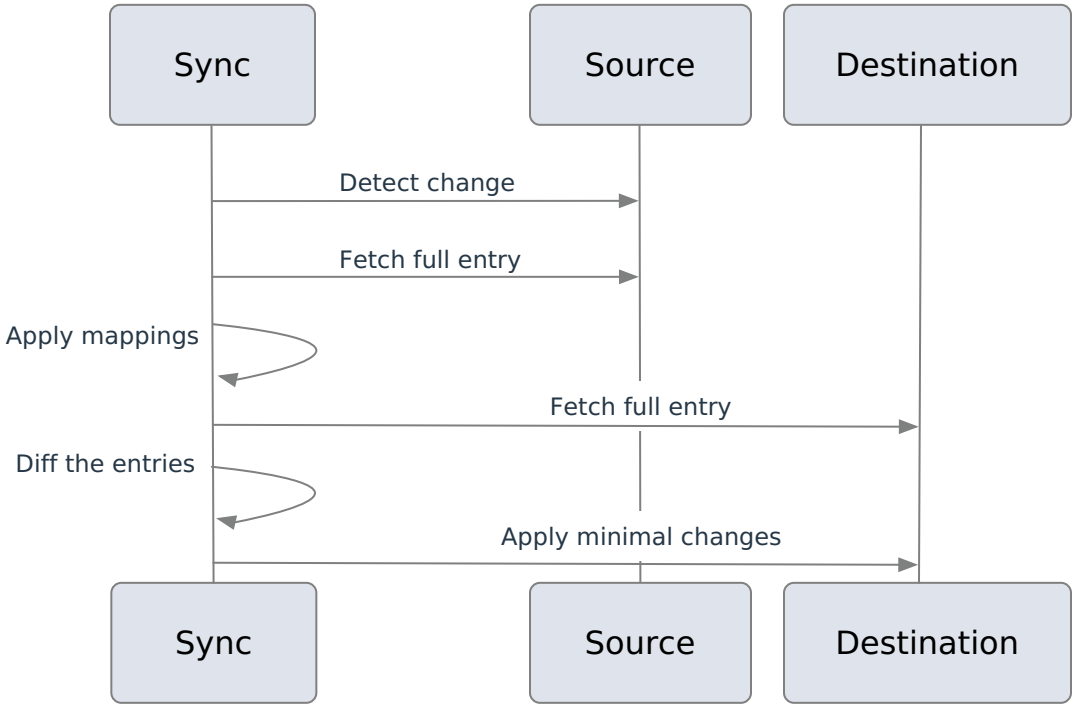
Sync flow examples

PingDataSync processes changes by fetching the most up-to-date, full entries from both sides and then comparing them. This process flow is called standard synchronization mode.

The processing flow differs depending on the type of PingDataSync change (`ADD, MODIFY, DELETE, MODDN`) that is requested. The following examples show the control flow diagrams for the sync operations, especially for those cases when a `MODIFY` or a `DELETE` operation is dropped. The sync log records all completed and failed operations.

Modify operation example

About this task

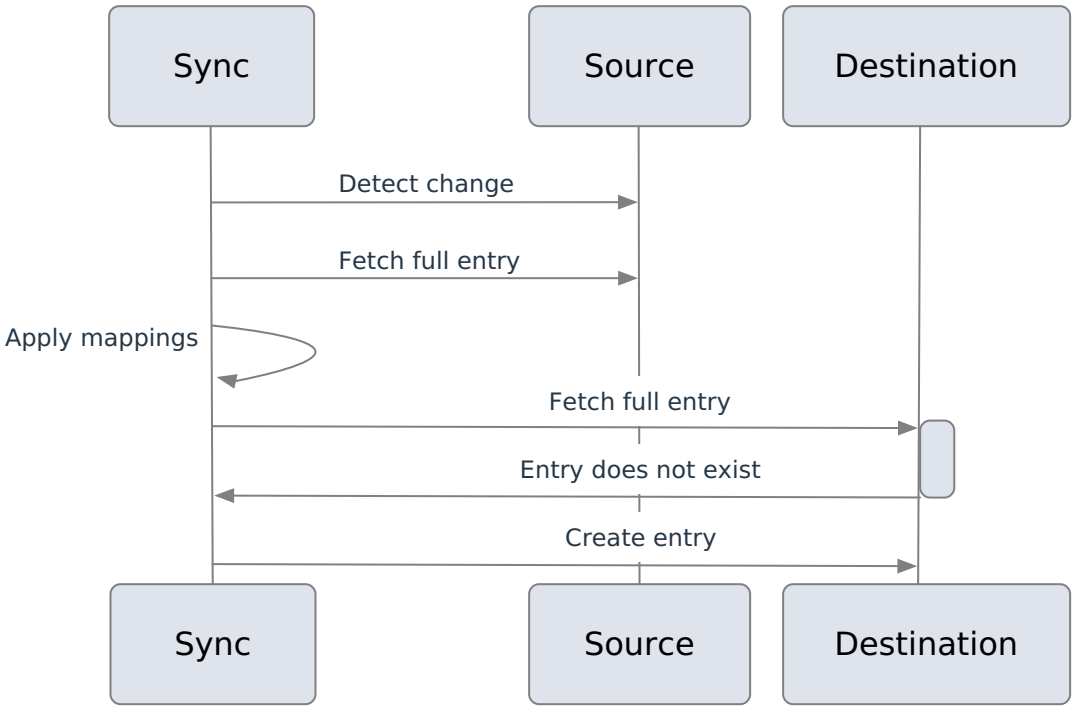


Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
4. Fetch the entry or table rows from affected tables on the destination.
5. Diff the computed destination entry and actual destination entry.
6. Apply the changes to the destination.

Add operation example

About this task

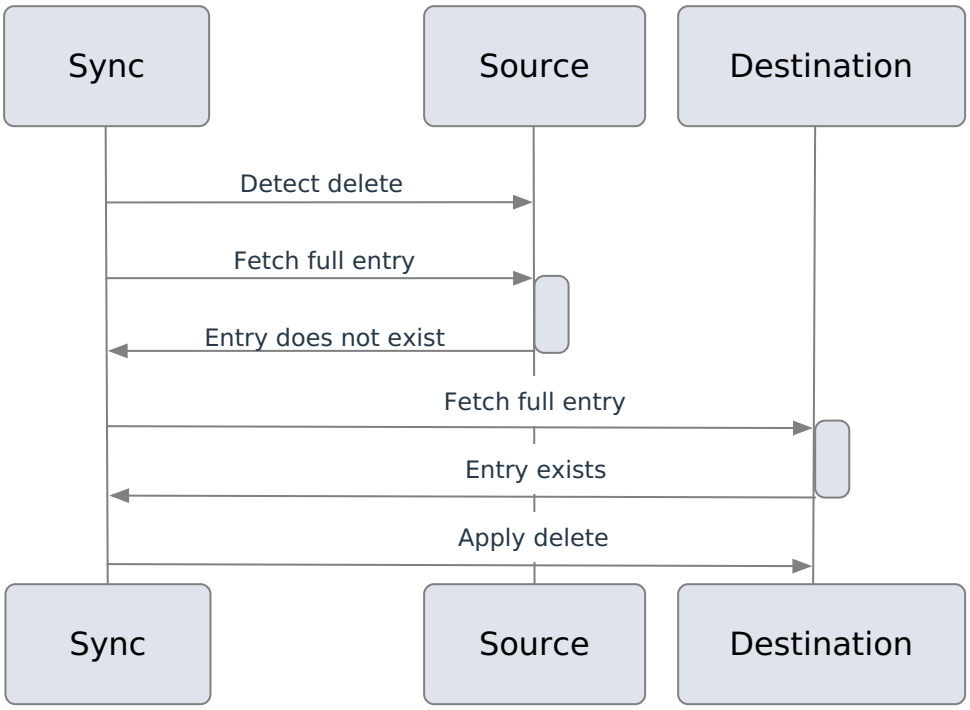


Steps

1. **Detect change from the change log table on the source.**
2. **Fetch the entry or table rows from affected tables on the source.**
3. **Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.**
4. **Fetch the entry or table rows from affected tables on the destination.**
5. **The entry or table row does not exist on the destination.**
6. **Create the entry or table row.**

Delete operation example

About this task

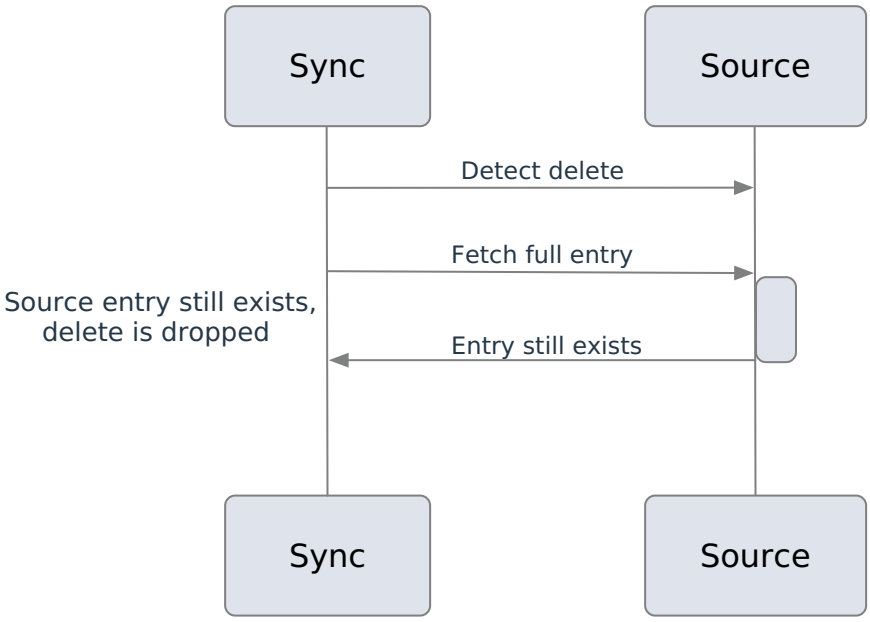


Steps

1. **Detect delete from the change log table on the source.**
2. **Fetch the entry or table rows from affected tables on the source.**
3. **Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.**
4. **Fetch the entry or table rows from affected tables on the destination.**
5. **The entry or table row exists on the destination.**
6. **Apply the delete on the destination.**

Delete after source entry is re-added

About this task

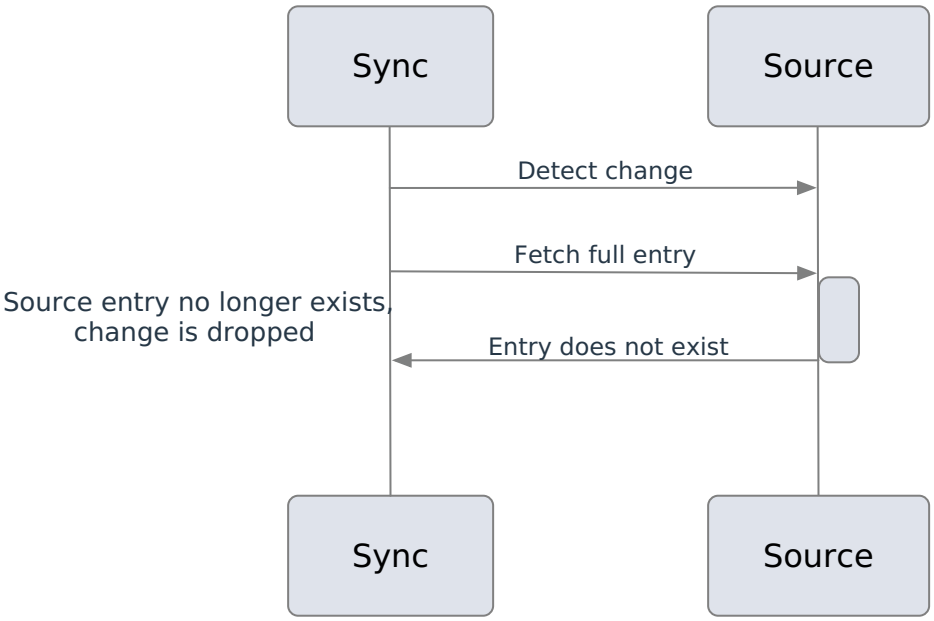


Steps

1. Detect delete from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. The entry or table row exists on the source.
4. Delete request is dropped.

Standard modify after source entry is deleted

About this task



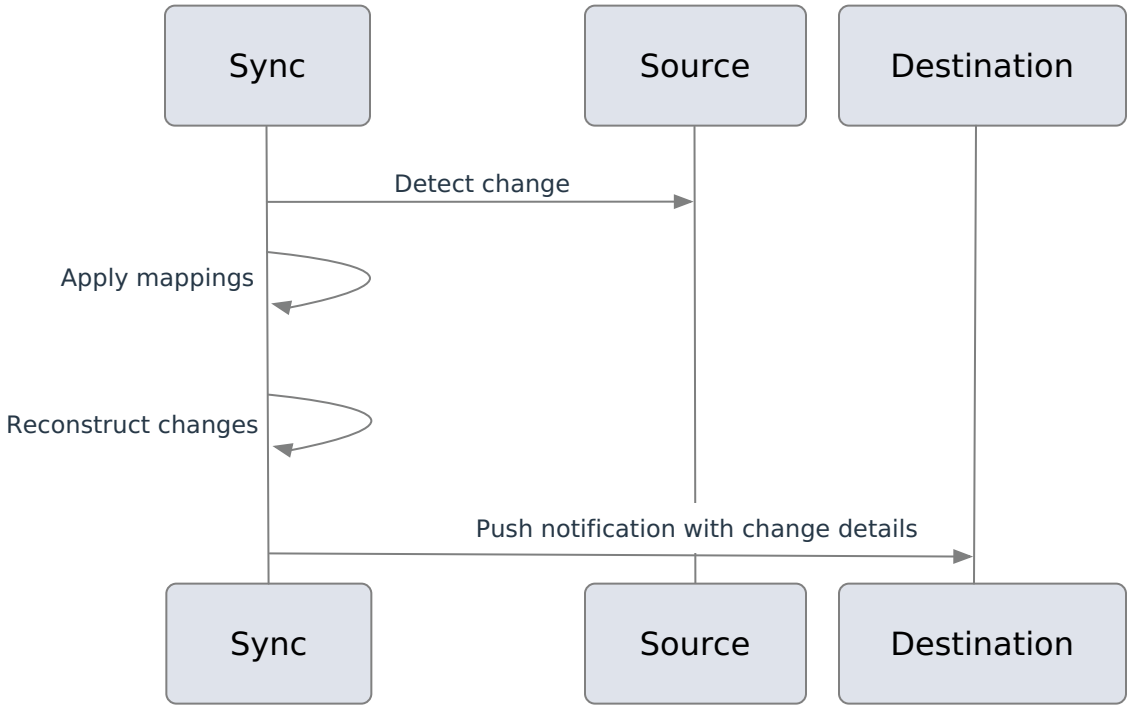
Steps

1. Detect change from the change log table on the source.

2. Fetch the entry or table rows from affected tables on the source.
3. The entry does not exist.
4. Change request is dropped because the source entry no longer exists.

Notification add, modify, modifyDN, and delete

About this task



Steps

1. Detect change from the change log table on the source.
2. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
3. Reconstruct changed entries.
4. Push notification with change details to the destination.

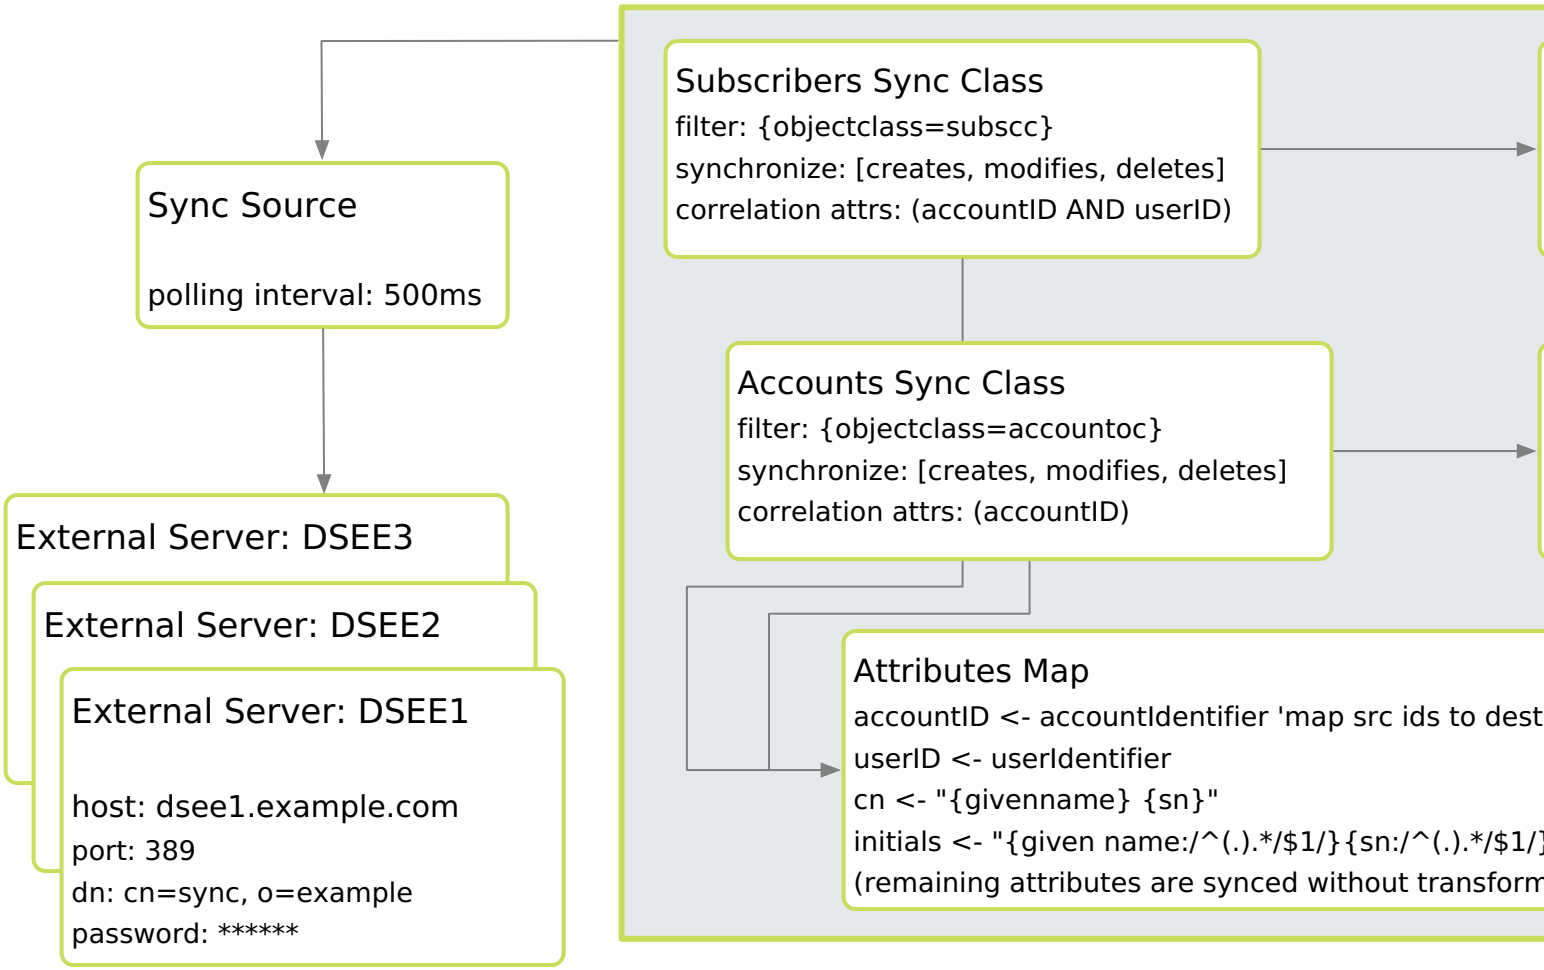
Sample synchronization

The following is a synchronization migration example from a Sun Directory Server Enterprise Edition (DSEE) topology to the PingDirectory server topology, including a change in the DIT structure to a flattened directory structure. The Sync Pipe connects the Sun Directory Server topology as the Sync Source and the PingDirectory server topology as the Sync Destination. Each endpoint is defined with three external servers in their respective topology. The Sync Pipe destination has its base DN set to `o=example`, which is used when performing LDAP searches for entries.

Two Sync Classes are defined: one for Subscribers, and one for Accounts. Each Sync Class uses a single "Sun DS to PingData Attribute Map" that has four attribute mappings defined. Each Sync Class also defines its own DN maps. For example, the Accounts Sync Class uses a DN map, called PingData Account Map, that is used to flatten a hierarchical DIT, so that the Account entries appear directly under `ou=accounts` as follows:

```
*,**,o=example ->{1},ou=accounts,o=example
```

With this mapping, if an entry DN has `uid=jsmith,ou=people,o=example`, then "*" matches `uid=jsmith`, "**" matches `ou=people`, and `{1}` matches `uid=jsmith`. Therefore, `uid=jsmith,ou=people,o=example` gets mapped to `uid=jsmith,ou=accounts,o=example`. A similar map is configured for the Subscribers Sync Class.



Server folders and files

After the distribution file is unzipped, the following folders and command-line utilities are available.

Directories/Files/Tools	Description
ldif	Stores any LDIF files that you might have created or imported.
import-tmp	Stores temporary imported items.
classes	Stores any external classes for server extensions.
bak	Stores the physical backup files used with the backup command-line tool.
velocity	Stores Velocity templates that define the server's application pages.
update.bat, and update	The update tool for UNIX/Linux systems and Windows systems.
uninstall.bat, and uninstall	The uninstall tool for UNIX/Linux systems and Windows systems.
ping_logo.png	The image file for the Ping Identity logo.
setup.bat, and setup	The setup tool for UNIX/Linux systems and Windows systems.
revert-update.bat, and revert-update	The revert-update tool for UNIX/Linux systems and Windows systems.
README	README file that describes the steps to set up and start the server.
License.txt	Licensing agreement for the product.
legal-notices	Stores any legal notices for dependent software used with the product.
docs	Provides the release notes, Configuration Reference (HTML), API Reference, and all other product documentation.
bin	Stores UNIX/Linux-based command-line tools.
bat	Stores Windows-based command-line tools.
lib	Stores any scripts, jar files, and library files needed for the server and its extensions.
locks	Stores any lock files in the backends.
tmp	Stores temporary files.
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.

Directories/Files/Tools	Description
config	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.
logs	Stores log files.
AD-Password-Sync-Agent.zip	The Active Directory Sync Agent package.

Changing the administrative password

Users that authenticate to the Configuration API or the admin console are stored in `cn=RootDNs,cn=config`. The `setup` tool automatically creates one administrative account when performing an installation. Accounts can be added or changed with the `dsconfig` tool.

About this task

Root users are governed by the Root Password Policy and by default, their passwords never expire. However, if a root user's password must be changed, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password. In this example, name the file rootuser.txt.

```
$ echo password > rootuser.txt
```

2. Use `ldappasswordmodify` to change the root user's password.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager" \
--bindPassword secret --newPasswordFile rootuser.txt
```

3. Remove the text file.

```
$ rm rootuser.txt
```

Running the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2016, 2019, and 2022. This enables logging out of a machine without the server being stopped.

Register the service

Steps

1. Stop the server using the `bin\stop-server` command. A server cannot be registered while it is running.
2. Register the server as a service. From a Windows command prompt, run `bat\register-windows-service.bat`.
3. After a server is registered, start the server from the Windows Services Control Panel or with the `bat\start-server.bat` command.

> **Note**
>
> Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Run multiple service instances

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>\config\wrapper-product.conf` file. To run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

Deregister and uninstall

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat\deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

Log files

The log files are stored in `<server-root>\logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or because of file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>\config\wrapper.conf` file.

Configuring the PingDataSync server

PingDataSync provides a suite of tools to configure a single server instance or a group of servers. All configuration changes to the server are recorded in the `config-audit.log`. Before configuring PingDataSync, review Configuration components.

Topics include:

- Configuration checklist
- Sync user account
- Configure PingDataSync in standard mode
- Using the Configuration API
- Configuration with the `dsconfig` tool

- Topology configuration
- Domain Name Service (DNS) caching
- IP address reverse name lookups
- Configure the synchronization environment with `dsconfig`
- Prepare external server communication
- HTTP connection handlers
- The `resync` command
- The `realtime-sync` tool
- Configure the PingDirectory server backend for synchronizing deletes
- Configure DN maps
- Configure synchronization with JSON attribute values
- Configure fractional replication
- Configure failover behavior
- Configure traffic through a load balancer
- Configure authentication with a SASL external certificate
- Configure an LDAPv3 Sync Source
- Server SDK extensions

Configuration checklist

Before any deployment, determine the configuration parameters necessary for the synchronization topology.

For a better configuration experience, gather the following information before you start your configuration.

External servers

> **Warning**
>
> As a best practice, external server definitions should not point at load balancers. Instead, direct connections should be made to the required systems.

External server type

Determine the type of external servers included in the synchronization topology. Supported servers include:

- **PingDirectory server**
- **PingDirectoryProxy server**
- **Sun Directory Server Enterprise Edition**

- Sun Directory Server
- Oracle Unified Directory
- OpenDJ
- Microsoft Active Directory (AD)
- Generic LDAP directories

LDAP connection settings

Determine the following for each external server instance included in the synchronization topology:

- Host
- Port
- Bind distinguished name (DN)
- Bind password

Security and authentication settings

Determine the following:

- The secure connection types for each external server, such as SSL or StartTLS
- The authentication methods for external servers, such as simple authentication or external SASL mechanisms

> **Important**
>
> If you are synchronizing encoded passwords or clear-text passwords in particular, the connection should be secure. To synchronize to or from a Microsoft AD system, establish an SSL or StartTLS connection to PingDataSync. You should also enable password encryption for synchronization from AD or when synchronizing clear-text passwords. For more information, see Configuring password encryption.

Sync Pipes

A `Sync Pipe` defines a single synchronization path between the source and destination targets. One `Sync Pipe` is needed for each point-to-point synchronization path defined for a topology.

`Sync Source`

Determine which external server is the `Sync Source` for the synchronization topology. You can define a prioritized list of external servers for failover purposes.

`Sync Destination`

Determine which external server is the `Sync Destination` for the synchronization topology. You can define a prioritized list of external servers for failover purposes.

Sync Classes

A `Sync Class` defines how attributes and DNs are mapped and how source and destination entries are correlated. For each `Sync Pipe` defined, define one or more `Sync Classes` with the following information:

Evaluation order

If you are defining more than one `Sync Class`, the evaluation order of each `Sync Class` must be determined with the `evaluation-order-index` property. If there is an overlap between criteria used to identify a `Sync Class`, the `Sync Class` with the most specific criteria is used first.

Base DNs

Determine which base DNs contain entries needed in the `Sync Class`.

Include filters

Determine the filters to be used to search for entries in the `Sync Source`.

Synchronized entry operations

Determine which operations to synchronize:

- `create`
- `modify`
- `delete`

DNs

Determine the differences between the DNs from the `Sync Source` topology to the `Sync Destination` topology. For example, if there are structural differences in each directory information tree (DIT).

Destination correlation attributes

Determine the correlation attributes used to associate a source entry to a destination entry during synchronization. During the configuration setup, one or more comma-separated lists of destination correlation attributes are defined and used to search for corresponding source entries. PingDataSync maps all attributes in a detected change from source to destination attributes using the attribute maps defined in the `Sync Class`.

The correlation attributes are flexible enough that several destination searches with different combinations of attributes can be performed until an entry matches. For LDAP server endpoints, use the DN to correlate entries.

For example, to correlate entries in LDAP deployments, specify the attribute lists `dn,uid`, `uid,employeeNumber` and `cn,employeeNumber`. PingDataSync searches for a corresponding entry that has the same `dn` and `uid` values. If the search fails, it then searches for `uid` and `employeeNumber`. If that search fails, it searches for `cn` and `employeeNumber`. If none of these searches are successful, the synchronization change is aborted and a message is logged.

> **Note**
>
> To prevent incorrect matches, the most restrictive attribute lists (those that will never match the wrong entry) should be first in the list, followed by less restrictive attribute lists, which are used when the earlier lists fail. For LDAP-to-LDAP deployments, use the DN with a combination of other unique identifiers in the entry to guarantee correlation. For non-LDAP deployments, determine the attributes that can be synchronized across the network.

Attributes

Determine the differences between the attributes from the `Sync Source` to the `Sync Destination`.

Attribute consideration	Description
Attribute mappings	Determine how attributes are mapped from the `Sync Source` to the `Sync Destination`. For example, if they're mapped directly, mapped based on attribute values, or mapped based on attributes that store DN values.
Automatically mapped source attributes	Determine if there are attributes that can be automatically synchronized with the same name at the `Sync Source` to `Sync Destination`. For example, if you can set direct mappings for `cn`, `uid`, `telephoneNumber`, or for all attributes.
Non-auto mapped source attributes	Determine if there are attributes that shouldn't be automatically mapped. For example, the `Sync Source` might have an attribute, `employee`, while the `Sync Destination` has a corresponding attribute, `employeeNumber`. If an attribute isn't automatically mapped, you must provide a map to synchronize it.
Conditional value mapping	Determine if some mappings should only be applied some of the time as a function of the source attributes. **Note** You can use conditional value mappings with the `conditional-value-pattern` property, which conditionalizes the attribute mapping based on the subtype of the entry, or on the value of the attribute. For example, this might apply if the `adminName` attribute on the destination should be a copy of the `name` attribute on the source, but only if the `isAdmin` attribute on the source is set to `true`. Conditional mappings are multivalued. Each value is evaluated until one is matched (the condition is `true`). If none of the conditional mappings are matched, the ordinary mappings is used. If there isn't an ordinary mapping, the attribute is not created on the destination.

Sync user account

PingDataSync creates a Sync User account DN on each external server. The account (by default, `cn=Sync User`) is used exclusively by PingDataSync to communicate with external servers. The entry is important in that it contains the credentials (DN and password) used by PingDataSync to access the source and target servers. The Sync User account resides in different entries depending on the targeted system:

- For the PingDirectory server and PingDirectoryProxy servers, the Sync User account resides in the configuration entry (`cn=Sync User,cn=Root DNs,cn=config`).
- For Sun Directory Server, Sun DSEE, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, the Sync User account resides under the base DN in the `userRoot` backend (`cn=Sync User,dc=example,dc=com`). The Sync User account should not reside in the `cn=config` branch for Sun Directory Server and DSEE machines.
- For Microsoft Active Directory (AD) servers, the Sync User account resides in the Users container (`cn=Sync User,cn=Users,DC=adsync,DC=unboundid,DC=com`).

- For Oracle and Microsoft SQL Servers, the Sync User account is a login account (`SyncUser`) with sufficient privileges to access the tables to be synchronized.

In most cases, modifications to this account are rare. Make sure that the entry is not synchronized by setting up an optional Sync Class if the account resides in the `userRoot` backend (Sun Directory Server or Sun DSEE) or Users container (Microsoft Active Directory). For example, a Sync Class can be configured to have all CREATE, MODIFY, and DELETE operations set to `false` .

Configure PingDataSync in standard mode

The `create-sync-pipe-config` tool is used to configure Sync Pipes and Sync Classes. For bidirectional deployments, configure two Sync Pipes, one for each directional path.

`xref:pd_sync_use_create_sync_pipe_tool.adoc[] illustrates a bidirectional synchronization deployment in standard mode. The example assumes that two replicated topologies are configured:`

- The first endpoint topology consists of two Sun LDAP servers: the main server and one failover. Both servers have Retro change logs enabled and contain the full DIT that will be synchronized to the second endpoint.
- The second endpoint topology consists of two PingDirectory servers: the main server and one failover. Both servers have change logs enabled and contain entries similar to the first endpoint servers, except that they use a `mail` attribute, instead of an `email` attribute.

A specific `mail` to `email` mapping must also be created to exclude the source attribute on the Sync Pipe going the other direction.

> **Note**
>
> If the source attribute is not excluded, PingDataSync will attempt to create an `email` attribute on the second endpoint, which could fail if the attribute is not present in the destination server's schema.

Then, two Sync Classes are defined:

- One to handle the customized `email` to `mail` attribute mapping.
- Another to handle all other cases (the default Sync Class).

The `dsconfig` command is used to create the specific attribute mappings. The `resync` command is used to test the mappings. Synchronization can start using the `realtime-sync` command.

Using the create-sync-pipe tool to configure synchronization

You can use the `create-sync-pipe-config` utility to configure a Sync Pipe. After the configuration is completed, you can adjust settings using the `dsconfig` tool.

About this task

> **Important**
>
> If servers have no base entries or data, the `cn=Sync User,cn=Root DNs,cn=config` account needed to communicate cannot be created. Make sure that base entries are created on the destination servers.

If synchronizing pre-encoded passwords to a PingDirectory server destination, you must allow pre-encoded passwords in the default password policy. You must also configure password encryption on the destination. Make sure that the password encryption algorithm is supported by both source and destination servers with the following command:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set allow-pre-encoded-passwords:true
```

Encrypted and clear-text passwords can be synchronized by configuring the sync destination `password-synchronization-format` and `require-secure-connection-for-clear-text-passwords` properties.

> **Note**
>
> You can set the `require-secure-connection-for-clear-text-passwords` property to `false` when working in a test environment.
> If the `password-synchronization-format` property is set to `clear-text`, and the `require-secure-connection-for-clear-text-passwords` property is set to `true`, the connection must be secure. If a secure connection is not available, an error is generated and the password is not synchronized.

To configure PingDataSync with the `create-sync-pipe-config` command:

Steps

1. Start PingDataSync:

   ```
   $  <server-root>/bin/start-server
   ```

2. From the `bin` directory, run the `create-sync-pipe-config` tool:

   ```
   $bin/create-sync-pipe-config
   ```

3. In the Initial Synchronization Configuration Tool menu, press Enter (yes) to continue the configuration.
4. In the Synchronization Mode menu, press Enter to select Standard Mode.
5. In the Synchronization Directory menu, select oneway(1) or bidirectional(2) for the synchronization topology.

   This example assumes bidirectional synchronization.

6. In the Source Endpoint Type menu, select the directory or database server for the first endpoint.
7. In the Source Endpoint Name menu, enter a name for the endpoint server, or press Enter to accept the default.
8. In the Base DNs menu, enter the base distinguished name (DN) on the first endpoint topology where the entries will be searched.

   For example, `dc=example,dc=com`.

9. Select an option for the server security.

10. Enter the host name and listener port number for the source server, or accept the default.

    Make sure that the endpoint servers are online and running.

11. Enter another server host and port, or press Enter to continue.

12. Enter the SyncUser account DN for the endpoint servers, or press Enter to accept the default (`cn=Sync User,cn=RootDNs,cn=config`).

13. Enter and confirm a password for this account.

    Result:

    You can now configure the servers in the destination endpoint topology.

14. Repeat steps 6– 13 to configure the second server.

15. Define the maximum age of changelog log entries, or press Enter to accept the default.

    After you configure the source and destination topologies, PingDataSync prepares each external server by testing the connection to each server. Step 15 determines if each account has the necessary privileges (root privileges are required) to communicate with and transfer data to each endpoint during synchronization.

16. In the Sync Pipe Name menu, create a name for the Sync Pipe, or press Enter to accept the default.

    Because this configuration is bidirectional, the following step is setting up a Sync Pipe path from the source endpoint to the destination endpoint. A later step will define another Sync Pipe from the PingDirectory server to another server.

17. In the SyncClass Definitions menu, enter `Yes` to create a custom Sync Class.

    A Sync Class defines the operation types (creates, modifies, or deletes), attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated.

18. Enter a name for the new Sync Class, such as `server1_to_server2` .

19. In the Base DNs for Sync Class menu, enter one or more base DNs to synchronize specific subtrees of a directory information tree (DIT).

    > **Note**
    >
    > Entries outside of the specified base DNs are excluded from synchronization. Make sure the base DNs do not overlap.

20. In the Filters for Sync Class menu, define one or more LDAP search filters to restrict specific entries for synchronization, or press Enter to accept the default (no).

    Entries that do not match the filters are excluded from synchronization.

21. In the Synchronized Attributes for Sync Class menu, specify which user attributes will be automatically mapped from one system to another.

    This example will exclude the source attribute (`email`) from being auto-mapped to the target servers. Operational attributes are not included in any attribute mapping.

22. In the Operations for Sync Class menu, select the operations to synchronize for the Sync Class, or press Enter to accept the default (`1,2,3`).

23. Define a default Sync Class that specifies how the other entries are processed, or press Enter to create a Sync Class called `Default Sync Class`.
24. In the Default Sync Class Operations menu, specify the operations that the default Sync Class will handle during synchronization, or press Enter to accept the default.
25. Define a Sync Pipe going from the PingDirectory server to the Sun Directory Server and exclude the `mail` attribute from being synchronized to the other endpoint servers.
26. Review the Sync Pipe Configuration Summary, and press Enter to accept the default (write configuration), which records the commands in a batch file (`<server-root>/sync-pipe-cfg.txt`).

    You can reuse the batch file to set up other topologies.

Next steps

Apply the configuration changes to the local PingDataSync instance by using a `dsconfig` batch file. Any Server SDK extensions should be saved to the `<server-root>/lib/extensions` directory.

The next step is to configure the attribute mappings using the `dsconfig` command.

Configuring attribute mapping

About this task

The following procedure defines an attribute map from the `email` attribute in the source servers to a `mail` attribute in the target servers. Both attributes must be valid in the target servers and must be present in their respective schemas.

> **Note**
>
> The following can also be done with `dsconfig` in interactive mode. The attribute mapping options are available from the PingDataSync main menu.

Steps

1. On PingDataSync, run the `dsconfig` command to create an attribute map for the "SunDS>DS" Sync Class for the "Sun DS to Ping Identity DS" Sync Pipe, and then run the second `dsconfig` command to apply the new attribute map to the Sync Pipe and Sync Class.

```
$ bin/dsconfig --no-prompt create-attribute-map \
  --map-name "SunDS>DS Attr Map" \
  --set "description:Attribute Map for SunDS>Ping Identity Sync Class" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name "Sun DS to DS" \
  --class-name "SunDS>DS" \
  --set "attribute-map:SunDS>DS Attr Map" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. Create an attribute mapping (from `email` to `mail`) for the new attribute map.

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
  --map-name "SunDS>DS Attr Map" \
  --mapping-name mail --type direct \
  --set "description:Email>Mail Mapping" \
  --set from-attribute:email \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

3. For a bidirectional deployment, repeat steps 1–2 to create an attribute map for the DS>SunDS Sync Class for the Ping Identity DS to Sun DS Sync Pipe, and create an attribute mapping that maps `mail` to `email`.

```
$ bin/dsconfig --no-prompt create-attribute-map \
  --map-name "DS>SunDS Attr Map" \
  --set "description:Attribute Map for DS>SunDS Sync Class" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name "Ping Identity DS to Sun DS" \
  --class-name "DS>SunDS" \
  --set "attribute-map:DS>SunDS Attr Map" \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
  --map-name "DS>SunDS Attr Map" \
  --mapping-name email \
  --type direct \
  --set "description:Mail>Email Mapping" \
  --set from-attribute:mail \
  --port 7389 \
  --bindDN "cn=admin,dc=example,dc=com" \
  --bindPassword secret
```

Configuring server locations

About this task

PingDataSync supports endpoint failover, which is configurable using the `location` property on the external servers. By default, the server prefers to connect to, and failover to, endpoints in the same location as itself. If there are no location settings configured, PingDataSync will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

> **Note**
>
> Location-based failover is only applicable for LDAP endpoint servers.

Steps

1. On PingDataSync, run the `dsconfig` command to set the location for each external server in the Sync Source and Sync Destination. For example, the following command sets the location for six servers in two data centers, `austin` and `dallas`.

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:1389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:2389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:3389 \
  --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:4389 \
  --set location:dallas
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:5389 \
  --set location:dallas
```

```
$ bin/dsconfig set-external-server-prop \
  --server-name example.com:6389 \
  --set location:dallas
```

2. Run `dsconfig` to set the location on the Global Configuration. This is the location of PingDataSync itself. In this example, set the location to `austin`.

```
$ bin/dsconfig set-global-configuration-prop \
  --set location:austin
```

Using the Configuration API

PingDataSync servers provide a Configuration API, which can be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's `host:port` in the `/config` context. Because of the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used, for hosting the Configuration extension.

Authentication and authorization

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

dsconfig tool">

Relationship between the Configuration API and the `dsconfig` tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes can be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes can be excluded from responses by specifying the `excludedAttributes` parameter. See Sorting and filtering configuration objects for more information on query parameters.

Operations supported by the API are those typically found in REST APIs:

HTTP Method	Description	Related dsconfig Example

GET	Lists the attributes of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	`get-backend-prop`
		`list-backends`
		`get-global-configuration-prop`

POST	Creates a new instance of an object when used with a relation parent path, such as `config/backends`.	`create-backend`
PUT	Replaces the existing attributes of an object. A PUT operation is similar to a PATCH operation, except that the PATCH is determined by determining the difference between an existing target object and a supplied source object. Only those attributes in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	`set-backend-prop` `set-global-configuration-prop`
PATCH	Updates the attributes of an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	`set-backend-prop` `set-global-configuration-prop`
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	`delete-backend`

The OPTIONS method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded in the `path` segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. So the URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

```

GET list example

The following is a sample GET request for all local backends:

```
GET /config/backends
Host: example.com:5033
Accept: application/scim+json
```

The response (which has been shortened):

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 24,
  "Resources": [
    {
      "schemas": [
        "urn:unboundid:schemas:configuration:2.0:backend:ldif"
      ],
      "id": "adminRoot",
      "meta": {
        "resourceType": "LDIF Backend",
        "location": "http://localhost:5033/config/backends/adminRoot"
      },
      "backendID": "adminRoot",

      ],
      "id": "alarms",
```

```
        "meta": {
          "resourceType": "Alarm Backend",
          "location": "http://localhost:5033/config/backends/alarms"
        },
    ...
```

PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API supports a subset of possible values for the `path` attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

  ```
  {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }
  ```

  is analogous to:

  ```
  $ dsconfig set-backend-prop --backend-name userRoot \
    --set "description:A new backend"
  ```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

  ```
  {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }
  ```

  is analogous to:

  ```
  $ dsconfig set-backend-prop --backend-name userRoot \
    --add je-property:je.env.backgroundReadLimit=0
  ```

- An operation to remove a value from a multi-valued property. In this case, `path` specifies a SCIM filter identifying the value to remove:

```
{
  "op" : "remove",
  "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.cleaner.adjustUtilization=false
```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is `value`:

```
{
  "op" : "remove",
  "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.nodeMaxEntries=32
```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
  "op" : "remove",
  "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --reset id2childrenIndexEntryLimit
```

The following is the full example request. The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

Example request:

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

Example response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"

           that had already hit the previous limit."
        }
      ]
    }
  }
```

API paths

The Configuration API is available under the `/config` path. A full listing of root sub-paths can be obtained from the `/config/ResourceTypes` endpoint:

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Sample response (abbreviated):

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
         Handler provides an implementation that uses syntax
         compatible with the Sun Java System Directory Server
         Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-
access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
         application-wide access control. The server's access
         control handler is defined through an extensible
         interface, so that alternate implementations can be created.
         Only one access control handler may be active in the server
         at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
      }
    },
    {
    ...
```

The response's `endpoint` elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name like `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

Sorting and filtering configuration objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters or paging parameters, and attributes to include or exclude in both `get` and `list` operations.

GET Parameters for sorting and filtering

GET Parameter	Description
`filter`	Values can be simple SCIM filters such as `id eq "userRoot"` or compound filters like `meta.resourceType eq "Local DB Backend"` and `baseDn co"dc=example,dc=com"`.
`sortBy`	Specifies a property value to sort by.
`sortOrder`	Specifies either `ascending` or `descending` alphabetical order.
`startIndex`	1-based index of the first result to return.
`count`	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",
    "location": "http://example.com:5033/config/backends/userRoot"
  },
  "backendID": "userRoot",
  "backgroundPrime": "false",
  "backupFilePermissions": "700",

    "primeMethod": [
      "none"
    ],
    "primeThreadCount": "2",
    "primeTimeLimit": "0 ms",
    "processFiltersWithUndefinedAttributeTypes": "false",
    "returnUnavailableForUntrustedIndex": "true",
    "returnUnavailableWhenDisabled": "true",
    "setDegradedAlertForUntrustedIndex": "true",
    "setDegradedAlertWhenDisabled": "true",
    "subtreeDeleteBatchSize": "5000",
    "subtreeDeleteSizeLimit": "100000",
    "uncachedId2entryCacheMode": "cache-keys-only",
    "writabilityMode": "enabled"
  }
```

Administrative actions

Updating a property might require an administrative action before the change can take effect. If so, the server will return `200 Success`, and any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
  "requiredActions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to
         take effect, the component must be restarted,
         either by disabling and re-enabling it, or by
         restarting the server"
    },
    {
      "property": "id2childrenIndexEntryLimit",
      "type": "other",
      "synopsis": "If this limit is increased, then the
         contents of the backend must be exported to LDIF
         and re-imported to allow the new limit to be used
         for any id2children keys that had already hit the
         previous limit."
    }
  ]
}
...
```

Update servers and server groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query parameter. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `singleServer` or `serverGroup` can be specified. For example:

```
https://example.com:5033/config/Backends/userRoot?applyChangeTo=singleServer
```

> **Note**
>
> This does not apply to mirrored subtree objects, which include Topology and Cluster level objects. Changes made to mirrored objects are applied to all objects in the subtree.

Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request. The following table lists response codes and their meanings:

Response code	Description	Response body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the `urn:unboundid:schemas:configuration:messages:2.0` object.	List of objects, or object properties, administrative actions.
204 No Content	The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.	None.
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message.
401 Unauthorized	User authentication is required. Some user agents such as browsers might respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.	None.
403 Forbidden	The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None.
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message.

Response code	Description	Response body
409 Conflict	The requested operation could not be performed because of the current state of the configuration. For example, an attempt was made to create an object that already exists or an attempt was made to delete an object that is referred to by another object.	Error summary and optional message.
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None.
500 Server Error	The server encountered an unexpected error. Report server errors to customer support.	Error Summary and optional message.

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence might depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

dsconfig tool">

Configuration with the `dsconfig` tool

The Ping Identity servers provide several command-line tools for management and administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and in the `bat` directory for Microsoft Windows systems.

The `dsconfig` tool is the text-based management tool used to configure the underlying server configuration. The tool has three operational modes:

- Interactive mode
- Non-interactive mode
- Batch mode

The `dsconfig` tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

Each command-line utility provides a description of the subcommands, arguments, and usage examples needed to run the tool. View detailed argument options and examples by typing `-- help` with the command.

```
$ bin/dsconfig --help
```

To list the subcommands for each command:

```
$ bin/dsconfig --help-subcommands
```

To list more detailed subcommand information:

```
$ bin/dsconfig list-log-publishers --help
```

dsconfig in interactive mode">

Using `dsconfig` in interactive mode

Running `dsconfig` in interactive command-line mode provides a menu-driven interface for accessing and configuring the PingDataSync server. To start `dsconfig` in interactive mode, run the tool without any arguments:

```
$ bin/dsconfig
```

Running the tool requires server connection and authentication information. After connection information is confirmed, a menu of the available operation types is displayed.

dsconfig in non-interactive mode">

Using `dsconfig` in non-interactive mode

Non-interactive command-line mode provides a simple way to make arbitrary changes to the server, and to use administrative scripts to automate configuration changes. To make changes to multiple configuration objects at the same time, use batch mode.

The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` option specifies non-interactive mode. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on the implementation. The `{subcommand}` argument specifies which general action to perform. The following example uses standard LDAP connections:

```
$ bin/dsconfig --no-prompt list-backends \
  --hostname server.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password
```

The following example uses SASL GSSAPI (Kerberos) parameters:

```
$ bin/dsconfig --no-prompt list-backends \
  --saslOption mech=GSSAPI \
  --saslOption authid=admin@example.com \
  --saslOption ticketcache=/tmp/krb5cc_1313 \
  --saslOption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular task. To always list the advanced properties, use the `--advanced` command-line option.

> **Note**
>
> Global arguments can appear anywhere on the command line. The subcommand-specific arguments can appear anywhere after the subcommand.

dsconfig batch mode">

Using `dsconfig` batch mode

The `dsconfig` tool provides a batching mechanism that reads multiple invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

```
$ bin/dsconfig --no-prompt \
  --hostname host1 \
  --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --batch-file /path/to/sync-pipe-config.txt
```

If a `dsconfig` command has a missing or incorrect argument, the command will fail and stop the batch process without applying any changes to the server. A `--batch-continue-on-error` option is available, which instructs `dsconfig` to apply all changes and skip any errors.

View the `logs/config-audit.log` file to review the configuration changes made to the server, and use them in the batch file. The batch file can have blank lines for spacing, and lines starting with a pound sign (#) for comments. The batch file also supports a "\" line continuation character for long commands that require multiple lines.

PingDataSync also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to PingDataSync machines.

Topology configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a primary/secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group.

> **Note**
>
> To remove a server from the topology, it must be uninstalled with the `uninstall` tool.

Topology primary requirements and selection

A topology primary server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers when they poll the primary. The primary always sends a digest of its subtree contents on each update. If the node has a different digest than the primary, it knows it's not synchronized. The servers will pull the entire subtree from the primary if they detect that they are not synchronized. A server can detect it is not synchronized with the primary under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its primary, then it knows it's not synchronized.
- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The primary of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a primary, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the primary. If a new server can be the primary, it will communicate that to the other servers, if no other server has advertised that it should be the primary. This ensures that all servers accept the same primary at approximately the same time (within a few milliseconds of each other). If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary. (The primary server itself is considered while determining this majority.)
- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration configuration object, a `mirrored-subtree-manager-forced-as-master-warning` alarm is raised. If multiple servers have been forced as primaries, then a `mirrored-subtree-manager-forced-as-master-error` critical alarm will be raised.

Topology components

When a server is installed, it can be added to an existing topology, which will clone the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a primary because a majority of servers is not available. A server with this setting enabled will be assigned the role of primary if no suitable primary can be determined. Learn more in Topology primary requirements and selection.

The Config File Handler Backend defines three topology (`mirrored-subtree`) settings:

- `mirrored-subtree-peer-polling-interval` – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that might warrant a new primary selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable primary is found, the polling frequency is adjusted to 100 milliseconds until a new primary is selected.
- `mirrored-subtree-entry-update-timeout` – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the primary on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if primary selection is in progress at the time the update operation was received.
- `mirrored-subtree-search-timeout` – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology meta-data is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology. Topology data includes the following:

- The server ID of the current primary, if the primary is not known.
- The instance name of the current primary, or if a primary is not set, a description stating why a primary is not set.
- A flag indicating if this server thinks that it should be the primary.
- A flag indicating if this server is the current primary.
- A flag indicating if this server was forced as primary.
- The total number of configured peers in the topology group.

- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its primary, or another node in the topology if the primary is unknown.
- The amount of time in milliseconds where multiple primaries were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as primary.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary.
- The number of operations processed by this server as primary that were successful.
- The number of operations processed by this server as primary that failed to validate.
- The number of operations processed by this server as primary that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the primary.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the primary.

Domain Name Service (DNS) caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

network-address-cache-ttl

Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.

network-address-outage-cache-enabled

Caches host name-to-IP address results in the event of a DNS outage. This is set to `true` by default, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays because of unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` or `options single-request` in `/etc/resolv.conf`.

- If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

IP address reverse name lookups

Ping Identity servers perform some numeric IP address-to-host name lookups, including the following:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- JMX: Creating a server socket
- Key Management: Generating a truststore
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- SASL Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Address masks configured in Access Control Lists (ACIs), Connection Handlers, Connection Criteria, and Certificate handshake processing might trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- ACI dns: bind rules under *Managing Access Control*(PingDirectory server and PingDirectoryProxy servers)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication*(PingDirectory server)
- Connection Criteria: *Restricting Server Access Based on Client IP Address*(PingDirectory server and PingDirectoryProxy servers)
- Connection Handlers: *Restrict Server Access Using Connection Handlers* (Configuration Reference Guide for all PingData servers)

dsconfig">

Configure the synchronization environment with `dsconfig`

The `dsconfig` tool can be used to configure any part of PingDataSync, but will likely be used for more fine-grained adjustments. If configuring a Sync Pipe for the first time, use the `create-sync-pipe-config` tool to guide through the necessary Sync Pipes creation steps.

Configure server groups with `dsconfig` interactive

In a typical deployment, one PingDataSync server and one or more redundant failover servers are configured. Primary and secondary servers must have the same configuration settings to ensure proper operation. To enable this, assign all servers to a server group using the `dsconfig` tool. Any change to one server will automatically be applied to the other servers in the group.

Run the `dsconfig` command and set the global configuration property for server groups to `all-servers`. On the primary PingDataSync server, run the following command:

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:all-servers
```

Updates to servers in the group are made using the `--applyChangeTo server-group` option of the `dsconfig` command. To apply the change to one server in the group, use the `--applyChangeTo single-server` option. If additional servers are added to the topology, the `setup` tool will copy the configuration from the primary server to the new servers.

Start the Global Sync configuration with `dsconfig` interactive

About this task

After the Synchronization topology is configured, perform the following steps to start the Global Sync configuration, which will use only those Sync Pipes that have been started:

Steps

1. On the `dsconfig` main menu, type the number corresponding to the Global Sync Configuration.
2. On the Global Sync Configuration menu, type the number corresponding to view and edit the configuration.
3. On the GlobalSync Configuration Properties menu, type the number corresponding to setting the started property, and then follow the prompts to set the value to `TRUE`.
4. On the GlobalSync Configuration Properties menu, type `f` to save and apply the changes.

Prepare external server communication

About this task

The `prepare-endpoint-server` tool sets up any communication variances that can occur between PingDataSync and the external servers. Typically, directory servers can have different security settings, privileges, and passwords configured on the Sync Source that might reject the import of entries in the Sync Destination.

The `prepare-endpoint-server` tool also creates a Sync User Account and its privileges on all of the external servers (see Sync user account for more detailed information). The `prepare-endpoint-server` tool verifies that the account has the proper privileges to access the `firstChangeNumber` and `lastChangeNumber` attributes in the root DSE entry so that it can access the latest changes. If the Sync User does not have the proper privileges, PingDataSync displays a warning message, which is saved in the `logs/prepare-endpoint-server.log` file.

> **Note**
>
> If the synchronization topology was created using the `create-sync-pipe-config` tool, this command does not need to be run. It is already part of the `create-sync-pipe-config` process.

Perform the following steps to prepare PingDataSync for external server communication:

Steps

1. Use the `prepare-endpoint-server` tool to prepare the directory server instances on the remote host for synchronization as a data source for the subtree, `dc=example,dc=com`. If the user account is not present on the external server, it will be created if a parent entry exists.

```
$ bin/prepare-endpoint-server \
  --hostname sun-ds1.example.com \
  --port 21389 \
  --syncServerBindDN "cn=Sync User,dc=example,dc=com" \
  --syncServerBindPassword secret \
  --baseDN "dc=example,dc=com" \
  --isSource
```

2. When prompted,enter the bind DN and password to create the user account. This step enables the change log database and sets the `changelog-maximum-age` property.
3. Repeat steps 1–2 for any other external source servers.
4. For the destination servers, repeat steps 2–3 and include the `--isDestination` option. If destination servers do not have any entries, a "Denied" message will display when creating the `cn=Sync User` entry.

```
$ bin/prepare-endpoint-server \
  --hostname PingIdentity-ds1.example.com \
  --port 33389 \
  --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
  --syncServerBindPassword sync \
  --baseDN "dc=example,dc=com" \
  --isDestination
```

5. Repeat step 4 for any other destination servers.

HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP connection handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire directory server from starting. The server's `start-server` tool will output any errors to the error log. This allows the server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include:

listen-address

Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler will listen for requests from clients. Required.

use-ssl

Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

http-servlet-extension

Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers, listening on different address/port combinations, with identical or different sets of servlet extensions. At least one servlet extension must be configured.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.

key-manager-provider

Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.

web-application-extension

Specifies the Web applications to be hosted by the server.

Configure an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, an HTTP log publisher. The HTTP servlet extension and log publisher must be configured before configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the ExampleHTTPServletExtension in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set
"extensionclass:com.unboundid.directory.sdk.examples.ExampleHTTPServletEx
tension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like listen-port, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. By default, the HTTP Connection Handler has an advanced monitor entry property, `keep- stats`, that is set to `TRUE` by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which might be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be challenging, because log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID can also be passed to the LDAP subsystem. For the SCIM 1, Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy server. The correlation ID header is also added to requests forwarded by the PingAuthorize gateway.

For Server SDK extensions that have access to the current HttpServletRequest, the current correlation ID can be retrieved as a string through the HttpServletRequest's `com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configuring HTTP correlation ID support

Correlation ID support is enabled by default for each HTTP connection handler.

- To enable correlation ID support for the HTTPS connection handler:

```
$ bin/dsconfig set-connection-handler-prop \
                   --handler-name "HTTPS Connection Handler" \
                   --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS connection handler:

```
$ bin/dsconfig set-connection-handler-prop \
                   --handler-name "HTTPS Connection Handler" \
                   --set use-correlation-id-header:false
```

Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to"X-Request-Id."

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set correlation-id-response-header:X-Request-Id
```

Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that can be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every server using correlation IDs.

```
$ bin/dsconfig set-connection-handler-prop \
                    --handler-name "HTTPS Connection Handler" \
                    --set correlation-id-request-header:X-Request-Id \
                    --set correlation-id-request-header:X-Correlation-Id \
                    --set correlation-id-request-header:Correlation-Id \
                    --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
                Accept: /
                Accept-Encoding: gzip, deflate
                Authorization: Bearer ...
                Connection: keep-alive
                Host: localhost:1443
                User-Agent: HTTPie/0.9.9
                HTTP/1.1 200 OK
                Content-Length: 266
                Content-Type: application/hal+json
                Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
                Date: Fri, 02 Nov 2018 15:16:50 GMT
                Request-Id: 369
                {
                "_dn": "uid=user.86,ou=People,dc=example,dc=com",
                "_links": {
                "schemas": [
                {
                "href": "https://localhost:1443/directory/v1/schemas/
                inetOrgPerson"
                }
                ],
                "self": {
                "href": "https://localhost:1443/directory/v1/
                uid=user.86,ou=People,dc=example,dc=com"
                }
                },
                "mail": [
                "user.86@example.com"
                ]
                }
```

This correlation ID can be used to search the HTTP trace log for matching log records, as follows:

```
$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'
                        {pingdir}/logs/debug-trace

Configuring the PingDataSync server to use an HTTP proxy server

Some organizations configure their network so that internal systems cannot directly access the Internet, but instead must use an HTTP proxy server to access external services.

The PingDataSync server now supports using an HTTP proxy server in conjunction with the following components:

- The Amazon Key Management Service cipher stream provider
- The Amazon Secrets Manager cipher stream provider
- The Amazon Secrets Manager passphrase provider
- The Amazon Secrets Manager password storage scheme
- The Azure Key Vault cipher stream provider
- The Azure Key Vault passphrase provider

- The Azure Key Vault password storage scheme
- The PingOne pass-through authentication plugin
- The PingOne sync source and destination
- The Pwned Passwords password validator
- The SCIMv1 sync destination
- The SCIMv2 sync destination
- The Twilio alert handler
- The Twilio OTP delivery mechanism
- The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler

Setting up the server to use an HTTP proxy server involves two steps, which are described in the following sections.

1. Creating an HTTP proxy external server in the configuration.
2. Configuring the appropriate component(s) to use the HTTP proxy server.

Creating an HTTP proxy external server

An HTTP proxy external server configuration object provides information about a proxy server that should be used. At present, we only support HTTP proxy servers (which can handle both unencrypted HTTP and encrypted HTTPS connections), with or without authentication.

HTTP proxy external server definitions support the following configuration properties:

`server-host-name`

The resolvable name or IP address of the HTTP proxy server to use. This is required.

`server-port`

The port on which the HTTP proxy server is listening for connections. This is required.

`basic-authentication-username`

The username to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

`basic-authentication-passphrase-provider`

The passphrase provider to use to obtain the password to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

For example, you can use a configuration change like the following to create an HTTP proxy external server that does not require authentication:

```
dsconfig create-external-server \
     --server-name "Example HTTP Proxy Server" \
     --type http-proxy \
     --set server-host-name:proxy.example.com \
     --set server-port:3128
```

Configuring server components to use the HTTP proxy external server

Merely defining an HTTP proxy external server in the configuration does not cause the server to use that proxy server for anything. Instead, you must indicate which components should use that proxy server.

This is necessary because you might only need to use an HTTP proxy server for certain components (for example, it might be necessary when accessing external web services, but not for services on the internal private network).

All of the components that support the use of an HTTP proxy server offer an `http-proxy-external-server` configuration property whose value should be the name of the appropriate HTTP proxy external server definition in the configuration. For example, to update the Pwned Passwords password validator to use the HTTP proxy server defined in the "Example HTTP Proxy Server" configuration object, use a configuration change like the following:

```
dsconfig set-password-validator-prop \
     --validator-name "Pwned Passwords" \
     --set "http-proxy-external-server:Example HTTP Proxy Server"
```

resync command">

The `resync` command

The `resync` command provides bulk synchronization that can be used to verify the synchronization setup. The command operates on a single Sync Pipe at a time, retrieves entries from the Sync Source in bulk, and compares the source entries with the corresponding destination entries. If destination entries are missing or attributes are changed, they are updated.

The command provides a `--dry-run` option that can be used to test the matches between the Sync Source and Destination, without committing any changes to the target topology. The `resync` command also provides options to write debugging output to a log.

> **Note**
>
> The **`resync`** command should be used for relatively small datasets. For large deployments, export entries from the Sync Source into an LDIF file, run the **`bin/translate-ldif`** command to translate and filter the entries into the destination format, and then import the result LDIF file into the Sync Destination.

Use the **`resync --help`** command for more information and examples. Logging is located in `logs/tools/resync.log` and in `logs/tools/resync-errors.log`. If necessary, the logging location can be changed with the `--logFilePath` option.

Test attribute and DN maps

The `resync` command can be used to test how attribute maps and DN maps are configured by synchronizing a single entry. If the `--logFilePath` and `--logLevel` options are specified, the `resync` command generates a log file with details.

Use the `--dry-run` option and specify a single entry, such as `uid=user.0`. Any logging performed during the operation appears in `logs/tools/resync.log`.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --sourceSearchFilter "(uid=user.0)" \
  --dry-run \
  --logLevel debug
```

Verify the synchronization configuration

The most common use for the `resync` command is to test that the Sync Pipe configuration has been set up correctly. For example, the following procedure assumes that the configuration was set up with the Sync Source topology (two replicated Sun Directory servers) with 2003 entries. The Sync Destination topology (two replicated PingDirectory servers) has only the base entry and the `cn=Sync User` entry. Both source and destination topologies have their LDAP Change Logs enabled. Because both topologies are not actively being updated, the `resync` command can be run with one pass through the entries.

Use the `resync` command with the `--dry-run` option to check the synchronization configuration. The output displays a timestamp that can be tracked in the logs.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --numPasses 1 \
  --dry-run
Starting Pass 1
Status after completing all passes[20/Mar/2010:10:20:07 -0500]
---------------------------------
Source entries retrieved 2003
Entries missing 2002
Entries out-of-sync 1
Duration (seconds) 4
Resync completed in 4 s.
0 entries were in-sync, 0 entries were modified, 0 entries were created,
1 entries are still out-of-sync, 2002 entries are still missing, and
0 entries could not be processed due to an error
```

Populate an empty sync destination topology

About this task

The following procedure uses the `resync` command to populate an empty Sync Destination topology for small datasets. For large deployments, use the `bin/translate-ldif` command.

In this example, assume that the Sync Destination topology has only the base entry (`dc=example,dc=com`) and the `cn=Sync User` entry. Perform the following steps to populate an empty Sync Destination:

Steps

1. Run the `resync` command with the log file path and with the log level `debug`. Logging is located in `logs/tools/resync.log` and in `logs/tools/resync-errors.log`.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
  --numPasses 1 \
  --logLevel debug
```

2. Open the `logs/resync-failed-DNs.log` file in a text editor to locate the error and fix it. An entry cannot be created because the parent entry does not exist.

```
# Entry '(see below)' was dropped because there was a failure at the
resource:
Failed to create entry uid=mlott,ou=People,dc=example,dc=com. Cause:
LDAPException(resultCode=no such object, errorMessage='Entry
uid=user.38,ou=People,dc=example,dc=com cannot be added because its parent
entry ou=People,dc=example,dc=com does not exist in the server',
matchedDN='dc=example,dc=com')
(id=1893859385ResourceOperationFailedException.java:126 Build
revision=4881)
dn: uid=user.38,ou=People,dc=example,dc=com
```

3. Rerun the `resync` command. The command creates the entries in the Sync Destination topology that are present in the Sync Source topology.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe
```

```
...(output from each pass)...
Status after completing all passes[20/Mar/2016:14:23:33 -0500]
----------------------------
Source entries retrieved 160
Entries in-sync 156
Entries created 4
Duration (seconds) 11

Resync completed in 12 s.

156 entries were in-sync, 0 entries were modified, 4 entries were created,
0 entries are still out-of-sync, 0 entries are still missing, and 0
entries could not be processed due to an error
```

> **Note**
>
> If importing a large amount of data into a PingDirectory server, run **`export-ldif`** and **`import-ldif`** on the newly populated backend for most efficient disk space use. If needed, run **`dsreplication initialize`** to propagate the efficient layout to additional replicas.

Set the synchronization rate

About this task

The `resync` command has a `--ratePerSecondFile` option that enables a specific synchronization rate. The option can be used to adjust the rate during off-peak hours, or adjust the rate based on measured loads for very long operations.

> **Note**
>
> The `resync` command also has a `--ratePerSecond` option. If this option is not provided, the command operates at the maximum rate.

Run the `resync` command first at 100 operations per second, measure the impact on the source servers, then adjust as needed. The file must contain a single positive integer number surrounded by white space. If the file is updated with an invalid number, the rate is not updated.

Steps

1. Create a text file containing the rate. The number must be a positive integer surrounded by white space.

```
$ echo '100 ' >rate.txt
```

2. Run the `resync` command with the `--ratePerSecondFile` option.

```
$ bin/resync --pipe-name "sun-to-ds-sync-pipe" \
  --ratePerSecondPath rate.txt
```

Synchronize a specific list of DNs

About this task

The `resync` command enables synchronizing a specific set of DNs that are read from a file using the `--sourceInputFile` option. This option is useful for large datasets that require faster processing by targeting individual base-level searches for each source DN in the file. If any DN fails (parsing, search, or process errors), the command creates an output file of the skipped entries (`resync-failed-DNs.log`), which can be run again.

The file must contain only a list of DNs in LDIF format with `dn:` or `dn::`. The file can include comment lines. All DNs can be wrapped and are assumed to be wrapped on any lines that begin with a space followed by text. Empty lines are ignored.

Small files can be created manually. For large files, use the `ldapsearch` command to create an LDIF file, as follows:

Steps

1. Run an `ldapsearch` command using the special OID "1.1" extension, which only returns the DNs in the DIT. For example, on the Sync Source directory server, run the following command:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com \
  --baseDN dc=example,dc=com \
  --searchScope sub "(objectclass=*)" "1.1" > dn.ldif
```

2. Run the `resync` command with the file.

```
$ bin/resync --pipe-name "sun-to-ds-pipe" \
  --sourceInputFile dn.ldif
```

```
Starting pass 1
[20/Mar/2016:10:32:11 -0500]
-----------------------------------
Resync pass 1
Source entries retrieved 1999
Entries created 981
Current pass, entries processed 981
Duration (seconds) 10
Average ops/second 98
Status after completing all passes[20/Mar/2016:10:32:18 -0500]
---------------------------------
Source entries retrieved 2003
Entries created 2003
Duration (seconds) 16
Average ops/second 98
Resync completed in 16 s.
0 entries were in-sync, 0 entries were modified, 2003 entries were
created, 0 entries are still out-of-sync, 0 entries are still missing, and
0 entries could not be processed due to an error
```

3. View the `logs/tools/resync-failed-DNs.log` to determine skipped DNs. Correct the source DNs file, and rerun the `resync` command.

realtime-sync tool">

The `realtime-sync` tool

The `bin/realtime-sync` tool controls starting and stopping synchronization globally or for individual Sync Pipes. The tool also provides features to set a specific starting point for real-time synchronization.

To see the current status of real-time synchronization, view the monitor properties: `num-sync-ops-in-flight`, `num-ops-in-queue`, and `source-unretrieved-changes`. For example, use `ldapsearch` to view a specific Sync Pipe's monitor information:

```
$ bin/ldapsearch --baseDN cn=monitor \
--searchScope sub "(cn=Sync Pipe Monitor: PIPE_NAME)"
```

The Stats Logger can also be used to view status. See the PingDirectory Server Administration Guide for details.

Start real-time synchronization globally

About this task

The `realtime-sync` command assumes that the synchronization topology is configured correctly.

Perform the following steps to start real-time synchronization globally:

Steps

1. Run the command from the `<server-root>/bin` directory. This example assumes that a single Sync Pipe called "dsee-to-ds-sync-pipe" exists.

```
$ bin/realtime-sync start --pipe-name "dsee-to-ds-sync-pipe" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. If more than one Sync Pipe is configured, specify each using the `--pipe-name` option. The following example starts synchronization for a bidirectional synchronization topology.

```
$ bin/realtime-sync start --pipe-name "Sun DS to DS" \
  --pipe-name "DS to Sun DS" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

Start or Pause synchronization

Pause or start synchronization by using the `start` and `stop` subcommands. If synchronization is stopped and then restarted, changes made at the Sync Source while synchronization was stopped will still be detected and applied. Synchronization for individual Sync Pipes can be started or stopped using the `--pipe-name` option. If the `--pipe-name` option is omitted, then synchronization is started or stopped globally.

The following command stops all Sync Pipes:

```
$ bin/realtime-sync stop --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

If a topology has two Sync Pipes, Sync Pipe1 and Sync Pipe2, the following command stops Sync Pipe1.

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret --no-prompt
```

Set startpoints

About this task

Startpoints instruct the Sync Pipe to ignore all changes made before the current time. Once synchronization is started, only changes made after this command is run will be detected at the Sync Source and applied at the Sync Destination.

The `set-startpoint` subcommand is often run during the initial setup before starting real-time synchronization. It should be run before initializing the data in the Sync Destination.

The `set-startpoint` subcommand can start synchronization at a specific change log number, or back at a state that occurred at a specific time. For example, synchronization can start 10 minutes before the current time.

Perform the following steps to set a synchronization startpoint:

Steps

1. If started, stop the synchronization topology globally with the following command:

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

2. Set the startpoint for the synchronization topology. Any changes made before setting this command will be ignored.

```
$ bin/realtime-sync set-startpoint --pipe-name "Sync Pipe1" \
  --port 389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \

  --no-prompt \
  --beginning-of-changelog
```

```
Set StartPoint task 2011072109564107 scheduled to start immediately
[21/Jul/2016:09:56:41 -0500] severity="INFORMATION" msgCount=0
msgID=1889535170
message="The startpoint has been set for Sync Pipe 'Sync Pipe1'.
Synchronization will resume from the last change number in the Sync
Source"
Set StartPoint task 2011072109564107 has been successfully completed
```

Restart synchronization at a specific change log event

About this task

Perform the following steps to restart synchronization at a specific event:

Steps

1. Search for a specific change log event from which to restart the synchronization state. On one of the endpoint servers, run the `ldapsearch` command to search the change log.

```
$ bin/ldapsearch -p 1389
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret \
--baseDN cn=changelog \
--dontWrap
```

```
"(objectclass=*)"
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog
dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.13,ou=People,dc=example,dc=com
changeType: modify
changes::
cmVwbGFjZTogcm9vbU51bWJlcgpyb29tTnVtYmVyOiAwMTM4Ci0KcmVwbGFjZTogbW9kaW
ZpZXJzTmFtZQptb2RpZmllcnNOYW1lOiBjbj1EaXJlY3RvcnkgTWFuYWdlcixjbj1Sb290

ltZTo6IEFBQUJKZ25OWlUwPQotCgA=
changenumber: 1
          ... (more output)
dn: changeNumber=2329,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.49,ou=People,dc=example,dc=com
changeType: modify
changes::
cmVwbGFjZTogcm9vbU51bWJlcgpyb29tTnVtYmVyOiAwNDMzCi0KcmVwbGFjZTogbW9kaW
ZpZXJzTmFtZQptb2RpZmllcnNOYW1lOiBjbj1EaXJlY3RvcnkgTWFuYWdlcixjbj1Sb290
IEROcyxjbj1jb25maWcKLQpyZXBsYWNlOiBkcy11cGRhdGUtdGltZQpkcy11cGRhdGUtdG
ltZTo6IEFBQUJKZ25OTUM4PQotCgA=
changenumber: 2329
```

2. Restart synchronization from change number 2329 using the `realtime-sync` command. Any event before this change number will not be synchronized to the target endpoint.

```
$ bin/realtime-sync set-startpoint \
  --change-number 2329 \
  --pipe-name "Sync Pipe 1" \
  --bindPassword secret \
  --no-prompt
```

Change the synchronization state by a specific time duration

The following command will start synchronizing data at the state that occurred 2 hours and 30 minutes before the current time on External Server 1 for Sync Pipe 1. Any changes made before this time will not be synchronized. Specify days (d), hours (h), minutes (m), seconds (s), or milliseconds (ms).

Use `realtime-sync` with the `--startpoint-rewind` option to set the synchronization state and begin synchronizing at the specified time.

```
$ bin/realtime-sync set-startpoint \
  --startpoint-rewind 2h30m \
  --pipe-name "Sync Pipe 1" \
  --bindPassword secret \
  --no-prompt
```

Schedule a real-time sync as a task

About this task

The `realtime-sync` command features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDataSync server's process. To schedule an operation, supply LDAP connection options that allow this command to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` command.

Perform the following steps to schedule a synchronization task:

Steps

1. Use the `--start` option with the `realtime-sync` command to schedule a start for the synchronization topology. The following command will set the start time at July 21, 2016 at 12:01:00 AM. The scheduled task can be stopped with the `--stop` option.

   ```
   $ bin/realtime-sync set-startpoint \
     --pipe-name "sun-to-ds-sync-pipe" \
     --port 389 \
     --bindDN "uid=admin,dc=example,dc=com" \
     --bindPassword secret \
     --start 20160721000100 \
     --no-prompt
   ```

   ```
   Set StartPoint task 2009072016103807 scheduled to start Jul 21, 2016
   12:01:00 AM CDT
   ```

2. Run the `manage-tasks` command to manage or cancel the task.

   ```
   $ bin/manage-tasks --port 7389 \
     --bindDN "uid=admin,dc=example,dc=com" \
     --bindPassword secret
   ```

Configure the PingDirectory server backend for synchronizing deletes

About this task

The PingDirectory server's change log backend's `changelog-deleted-entry-include-attribute` property specifies which attributes should be recorded in the change log entry during a DELETE operation. Normally, PingDataSync cannot correlate a deleted entry to the entry on the destination. If a Sync Class is configured with a filter, such as "`include-filter: objectClass=person`," the `objectClass` attribute must be recorded in the change log entry. Special correlation attributes (other than DN), will also need to be recorded on the change log entry to be properly synchronized at the endpoint server.

On each PingDirectory server backend, use the `dsconfig` command to set the property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set changelog-deleted-entry-include-attribute:objectClass
```

If the destination endpoint is an Oracle/Sun DSEE (or Sun DS) server, the Sun DSEE server does not store the value of the user deleting the entry, specified in the modifiers name attribute. It only stores the value of the user who last modified the entry while it still existed.

To set up a Sun DSEE destination endpoint to record the user who deleted the entry, use the Ping Identity Server SDK to create a plugin, as follows:

Steps

1. Update the Sun DSEE schema to include a `deleted-by-syncauxiliary` objectclass. It will only be used as a marker objectclass, and not require or allow additional attributes to be present on an entry.
2. Update the Sun DSEE Retro Change Log plugin to include the `deleted-by-sync auxiliary` objectclass as a value for the `deletedEntryAttrs` attribute.
3. Write an `LDAPSyncDestinationPlugin` script that in the `preDelete()` method modifies the entry that is being deleted to include the `deleted-by-sync` objectclass.
4. Update the Sync Class filter that is excluding changes by the Sync User to also include `(!(objectclass=deleted-by-sync))`.

Configure DN maps

Similar to attribute maps, DN maps define mappings when destination DNs differ from source DNs. These differences must be resolved using DN maps in order for synchronization to successfully take place. For example, the Sync Source could have a DN in the following format:

```
uid=jdoe,ou=People,dc=example,dc=com
```

The Sync Destination could have the standard X.500 DN format.

DN mappings allow the use of wildcards for DN transformations. A single wildcard (`*`) matches a single RDN component and can be used any number of times. The double wildcard (`**`) matches zero or more RDN components and can be used only once.

> **Note**
>
> If a literal '*' is required in a DN, it must be escaped as `'\2A'`.

The wildcard values can be used in the `to-dn-pattern` attribute using {1} to replace their original index position in the pattern, or {attr} to match an attribute value. For example:

```
*,**,dc=com->{1},ou=012,o=example,c=us
```

For example, using the DN, `uid=johndoe,ou=People,dc=example,dc=com`, and mapping to the target DN, `uid=johndoe,ou=012,o=example,c=us`:

- `"*"` matches one RDN component, `uid=johndoe`
- `"**"` matches zero or more RDN components, `ou=People,dc=example`
- `"dc=com"` matches `dc=com` in the DN.

The DN is mapped to the `{1},ou=012,o=example,c=us`. `"{1}"` substitutes the first wildcard element `"uid=johndoe"`, so that the DN is successfully mapped to:

```
uid=johndoe,ou=012,o=example,c=us
```

Regular expressions and attributes from the user entry can also be used in the `to-dn-pattern` attribute. For example, the following expression constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of given name and `sn`) and the employee ID (the `eid` attribute) of a user.

```
uid={givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid},{2},o=example
```

> **Note**
>
> PingDataSync automatically validates any DN mapping before applying the configuration.

Configuring a DN map by using `dsconfig`

About this task

You can configure a DN map by using `dsconfig`, either with the interactive DN Map menu, or from the command line.

Perform the following to configure a DN map:

Steps

1. Use `dsconfig` to create a DN map for PingDataSync.

```
$ bin/dsconfig --no-prompt create-dn-map \
  --map-name nested-to-flattened \
  --set "from-dn-pattern:*,**,dc=example,dc=com" \
  --set "to-dn-pattern:uid={1},{2},dc=example,dc=com" \
  --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

2. After DN mappings are configured, add the new DN map to a new Sync Class or modify an existing Sync Class.

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
  --pipe-name test-sync-pipe \
  --class-name test-sync-class \
  --set dn-map:test-dn-map \
  --port 389 --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

About attribute mappings

Attribute mappings define how the values of a single destination attribute are determined.

The destination attribute in an attribute mapping can be derived from a direct mapping with a source attribute, constructed from a combination of hard-coded strings and elements of other attributes, or generated using custom Java class code. All attribute mapping types support the following properties:

Property	Description
`to-attribute`	Specifies the name of the attribute whose values are constructed by the mapping. This property is required.
`description`	Describes the attribute mapping. This property is optional.
`exclude-value`	Specifies a list of values to exclude from the destination attribute after applying the mapping. This property is optional.
`also-depends-on-src-attribute`	Specifies the source attributes that trigger an update to the relevant destination attributes when changed, regardless of changes to attributes the mapping directly depends on. This property is optional.
`sync-on-every-update`	Synchronizes the value of `to-attribute` on any detected change of any attribute. This property is optional. **Note** The attribute mapping of `to-attribute` is always evaluated during sync, even if the value didn't change.

Note

Use the **`dsconfig list-attribute-mappings`** command to view configured attribute mappings.

The PingDataSync server supports the following attribute mappings:

JSON attribute mapping

Use for a destination JSON attribute whose JSON field values are constructed by defining JSON attribute mapping field configuration objects. If any field value cannot be constructed, either because of the required source attributes not being present or the resulting value being invalid, that field is omitted from the constructed JSON attribute. The following example creates a JSON attribute mapping with the field `formatted` from the `cn` attribute:

```
$ bin/dsconfig create-attribute-map \
  --map-name PingDirectory_to_PingOne_User_Map
```

```
$ bin/dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --type json
```

```
$ bin/dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name formatted \
  --set from-attribute:cn \
  --set json-type:string
```

> **Note**
>
> If any existing JSON fields of the destination attribute must be preserved, a JSON attribute configuration object must be created for the sync class.

Constructed attribute mapping

Use when a destination attribute's values are constructed from static text and multiple source attribute values. The source attribute values can be modified using regular expressions and replacement values. You can use a constructed attribute mapping to provide a fixed set of attribute values or to augment existing attribute values with additional fixed values. Constructed attribute mappings support the following properties:

Property	Description
`value-pattern`	**Specifies a pattern for constructing the destination attribute value using fixed text and attribute values from the source entry.** **Note** You can't have more than one multivalued attribute. If an attribute is multivalued, the destination value takes the same number of values minus duplicates. For example, a mapping of `{givenName}{sn}` produces values of `'Jim Smith'`, `'James Smith'` if `givenName` has values of `'Jim'`, `'James'` and `sn` has a value of `'Smith'`. **This property is optional.**
`conditional-value-pattern`	**Specifies a pattern for conditionally constructing the destination attribute value using fixed text and attribute values from the source entry. The pattern constructs the destination attribute only if the specified LDAP filter matches the source entry. The value of this property has the form `LDAP-filter : pattern`.** **Note** The LDAP filter is similar to what you can pass to the **`ldapsearch`** command. For example, if you want to select the `admin-user-name` attribute from the source only if the `is-admin` attribute has a value of `true`, you can use a value pattern of `(is-admin=true) : {admin-user-name}`. **This property is optional.**

Direct attribute mapping

Use when a destination attribute receives its values directly from a source attribute. To use a direct attribute mapping, the attribute values must not change in format from the source to the destination. Direct attribute mappings support the following properties:

Property	Description
`from-attribute`	**Specifies the name of the source attribute whose values are used to provide the values of the destination attribute.** **This property is required.**

Property	Description
`base64-encode-value`	Encodes the source attribute with base-64 before synchronizing it to the destination. This property is optional.
`base-64-decode-value`	Decodes the source attribute from base-64 before synchronizing it to the destination. This property is optional.

DN attribute mapping

Use when a destination attribute receives its values directly from a source attribute whose distinguished name (DN) values require translation. This translation can be performed either by an existing DN map or a map configured within the attribute mapping itself. DN attribute mappings support the following properties:

Property	Description
`from-attribute`	Specifies the name of the source attribute whose values are used to directly provide the values of the destination attribute. This property is required.
`dn-map`	Constructs the destination DN value using components of the source DN and attributes from the source entry. If source DNs match different DN patterns, you can specify multiple DN maps. This property is optional.

Configure synchronization with JSON attribute values

PingDataSync supports synchronization of attributes that hold JSON objects. The following scenarios are supported:

- Synchronizing a JSON attribute to another JSON attribute - A subset of fields can be synchronized, optionally retaining fields that appear at the destination but not at the source.
- Synchronizing a JSON attribute to a non-JSON attribute - A single field of the JSON value can be extracted with a constructed attribute mapping.
- Synchronizing a non-JSON attribute to a JSON attribute - The source value can be escaped so that it ensures the JSON value is properly formatted.
- Attribute correlation - A JSON field can be used when correlating a destination entry with a source entry.

The following examples show configuration scenarios based on the LDAP `ubidEmailJSON` attribute, which has fields of `value`, `type`, `primary`, and `verified`:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "primary" : true,
                "verified" : true}
```

ubidEmailJSON fully">

Synchronizing `ubidEmailJSON` fully

If a source JSON attribute value should be fully synchronized to a destination JSON attribute value, no special configuration is required.

Synchronizing a subset of fields from the source attribute

The following configuration can be used to synchronize the `value` and `type` fields of `ubidEmailJSON` from the source to a destination. To synchronize this source value:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "primary" : true}
```

to this value at the destination:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home"}
```

You can filter JSON field values in the `value-pattern` and `conditional-value-pattern` constructed attribute mapping properties. This enables a given field value to only be mapped for values that match a given filter.

For example, if `ubidEmailJSON` is a JSON attribute and the `value` field is to be extracted only for values where the `type` field is equal to `work`, the value pattern specifying this would be as follows:

```
{ubidEmailJSON.value({{"filterType":"equals","field":"type","value":"work"}})}
```

A JSON Attribute configuration object must be created and associated with the Sync Class. This can be done by either explicitly including the fields to synchronize:

```
$ bin/dsconfig create-json-attribute --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set include-field:type \
  --set include-field:value
```

Or by excluding the fields that should not be synchronized:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set exclude-field:preferred \
  --set exclude-field:verified
```

If the destination is prepared to only handle a specific subset of fields, then list the fields to include. However, if only a small, known subset of fields from the source should be excluded, then `exclude-field` could be used. In this example, the destination data for the `ubidEmailJSON` attribute will always be a subset of the full data.

> **Note**
>
> A Sync Class can be configured to exclude certain attributes from synchronization. Creating a regular attribute mapping will override this setting, and the attribute will be synchronized. Creating a JSON attribute mapping does not override this setting, and the JSON attribute will not be synchronized. A JSON attribute is not a traditional attribute mapping. It only includes information on the destination attribute name. To work around this, the attribute either needs to be mapped from a source attribute, or have its value constructed.

The following scenario illustrates how the destination can include additional fields that are not present at the source.

Retaining destination-only fields

To synchronize changes to the source fields while preserving the value of the `verified` field of the `ubidEmailJSON` attribute at the destination, configure the JSON Attribute as follows:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set id-field:value \
  --set exclude-field:verified
```

The `verified` field is excluded and `value` is chosen to correlate destination values with source values. For example, given that the source and destination `value` fields match, if the source initially contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home"}
```

and the destination contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "home",
                "verified" : true},
```

if the source changed to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "other"}
```

then the destination would change to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
                "type" : "other",
                "verified" : true}
```

However, if the source changed to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
                "type" : "home"}
```

then the destination would be updated to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
                "type" : "home"}
```

The `verified` field has been dropped because this logically represents a new JSON object rather than an update of an existing one.

Synchronizing a field of a JSON attribute into a non-JSON attribute

If the source stores:

```
ubidEmailJSON: {"value" : "jsmith@example.com", "type" : "home"}
```

but the destination stores:

```
mail: jsmith@example.com
```

To synchronize changes between these systems, a constructed attribute mapping must be configured:

```
$ bin/dsconfig create-attribute-mapping \
  --map-name "Attribute Map" \
  --mapping-name mail \
  --type constructed \
  --set "value-pattern:{ubidEmailJSON.value}"
```

The `value-pattern` syntax allows attributes to be referenced by placing them in `{}`. JSON fields within the attribute can be referenced by using the syntax `{attribute.field}`. See this property in the Configuration Reference guide, or `dsconfig` tool command help for more information.

After the "Attribute Map" is created, it can be referenced from the Sync Class:

```
$ bin/dsconfig set-sync-class-prop
  --pipe-name "A to B" \
  --class-name Users \
  --set "attribute-map:Attribute Map"
```

Note

While LDAP attribute names are not case sensitive, the JSON field names are. By default, errors related to attribute mapping are not logged. To enable error logging, configure the Debug Logger with the following:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true
```

```
$ bin/dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.sync.mapping \
  --set debug-level:warning
```

Synchronizing a non-JSON attribute into a field of a JSON attribute

This scenario provides a reversal of the previous example. The source stores the following information:

```
mail: jsmith@example.com
```

but the destination stores the following information:

```
ubidEmailJSON: {"value" : "jsmith@example.com"}
```

To construct an attribute value that functions as a JSON object, use *JSON attribute mapping* and *JSON attribute mapping field* configuration objects. The following code provides an example:

```
bin/dsconfig create-attribute-mapping --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --type json

bin/dsconfig create-json-attribute-mapping-field --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --field-name "value" \
  --from-attribute mail
```

For more information about these configuration object types, see the configuration reference guide.

You can also use a constructed attribute mapping to construct a JSON attribute value as a raw string, as follows:

```
$ bin/dsconfig create-attribute-mapping \
  --map-name "Attr Map" \
  --mapping-name ubidEmailJSON \
  --type constructed \
  --set 'value-pattern:{{"value" : "{mail:jsonEscape}"}}'
```

When constructing a value, be aware of the following points:

- Double curly brackets ({{ }}) are necessary to represent a single curly bracket ({ }) in the output. These brackets are typically used to reference attribute values.
- Use the `:jsonEscape` modifier to escape attribute values that appear within a JSON attribute. This step prevents values that include quotes like '`"John Smith" <jsmith@example.com>`' from producing invalid JSON.

In the following example, a JSON Attribute object must be created because the destination value is likely to be augmented with additional information:

```
$ bin/dsconfig create-json-attribute \
  --pipe-name "A to B" \
  --class-name Users \
  --attribute-name ubidEmailJSON \
  --set id-field:value \
  --set include-field:value
```

Synchronizing multiple non-JSON attributes into fields of a JSON attribute

Multiple JSON fields can be defined within a single JSON attribute. For any source attribute that does not exist, the corresponding JSON field is omitted from the JSON attribute. The following code demonstrates the mapping of a standard LDAP schema into the standard PingOne user schema.

```
dsconfig create-attribute-map \
  --map-name PingDirectory_to_PingOne_User_Map

...

dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map \
  -mapping-name name \
  --type json

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name formatted \
  --set from-attribute:cn \
  --json-type string

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name given \
  --set from-attribute:givenName \
  --json-type string

dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name family \
  --set from-attribute:sn \
  --json-type string
```

Correlating attributes based on JSON fields

When the destination of a Sync Pipe is a PingDirectory server or a PingDirectoryProxy server, source and destination entries can be correlated by referencing a field within a JSON attribute. In the following example, source entries will be matched with destination entries that have the same `value` field within the `ubidEmailJSON` value.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name "A to B" \
  --class-name Users \
  --set destination-correlation-attributes:ubidEmailJSON.value
```

This could also be used with the previous example, which does not store `ubidEmailJSON.value` at the source but maps into it before correlating at the destination.

Configure fractional replication

PingDataSync supports fractional replication to any server type. For example, if a replica only performs user authentications, PingDataSync can be configured to propagate only the `uid` and `userpassword` password policy attributes, reducing the database size at the replica and the network traffic needed to keep the servers synchronized.

About this task

The following example configures a fractional replication, where the `uid` and `userPassword` attributes of all entries in the source topology are synchronized to the destination topology. Because the `uid` and `userPassword` attributes are present, the `objectclass` attribute must also be synchronized. The example assumes that PingDataSync and the external servers are configured and a Sync Pipe and Sync Class are defined, but real-time synchronization or bulk resync have not been performed.

Perform the following steps to configure fractional replication from the `dsconfig` interactive menu:

Steps

1. On the main menu, type the number corresponding to Sync Classes.
2. On the Sync Class menu, type the number corresponding to viewing and editing an existing Sync Class. Assume that only one Sync Class has been defined.
3. Verify that the Sync Pipe and Sync Class exist.
4. On the Sync Class Properties menu, type the number specifying the source LDAP filter (`include-filter` property) that defines which source entries are to be included in the Sync Class.
5. On the Include-Filter Property menu, type the number corresponding to adding a filter value. For this example, type (`objectclass=person`). When prompted, enter another filter. Press Enter to continue. On the menu, enter 1 to use the value when specifying it.
6. On the Sync Class Properties menu, type the number corresponding to the `auto-mapped-source-attribute` property. Change the value from " `-all-` " to a specific attribute, so that only the specified attribute is automatically mapped from the source topology to the destination topology.
7. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to adding the source attributes that will be automatically mapped to the destination attributes of the same name. When prompted, enter each attribute, and then press Enter.

   ```
   Enter another value for the 'auto-mapped-source-attribute' property
   [continue]: uid
   Enter another value for the 'auto-mapped-source-attribute' property
   [continue]: userPassword
   Enter another value for the 'auto-mapped-source-attribute' property
   [continue]: objectclass
   Enter another value for the 'auto-mapped-source-attribute' property
   [continue]:
   ```

8. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to removing one or more values. In this example, remove the " `-all-` " value, so that only the `objectclass` , `uid` , and `userPassword` attributes are synchronized.

9. On the Auto-Mapped-Source-Attribute Property menu, press Enter to accept the values.

10. On the Sync Class Properties menu, type the number corresponding to excluding some attributes from the synchronization process. When using the `objectclass=person` filter, the `cn`, `givenName`, and `sn` attributes must be excluded. Enter the option to add one or more attributes, and then add each attribute to exclude on the `excluded-auto-mapped-source-attributes` Property menu. For this example, exclude the `cn` and `sn` attributes, which are required attributes of the `Person` objectclass. Also exclude the `givenName` attribute, which is an optional attribute of the `inetOrgPerson` objectclass.

```
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: givenName
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: sn
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]:
```

11. On the Excluded-Auto-Mapped-Source-Attributes Property menu, press Enter to accept the changes.

> **Note**
>
> If using `entryUUID` as a correlation attribute, some attribute uniqueness errors might occur while using the `resync` tool. Either set the `excluded-auto-mapped-source-attributes` property value to `entryUUID` on the Sync Class configuration menu, or run `resync` with the `--excludeDestinationAttr` entryUUID argument.

12. On the Sync Class Properties menu, review the configuration and accept the changes.

13. On the server instances in the destination topology, turn off schema checking to avoid a schema error that occurs when the required attributes in the `Person` objectclass are not present. Make sure that the global configuration property for the `server-group` is set to `all-servers`. Use the following command to turn off schema checking on all of the servers in the group.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
  --set check-schema:false \
  --applyChangeTo server-group \
  --port 3389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret
```

14. Run `bin/resync` to load the filtered data from the source endpoint to the target endpoint.

```
$ bin/resync --pipe-name "test-sync-pipe" \
  --numPasses 3
```

15. Run `bin/realtime-sync` to start synchronization.

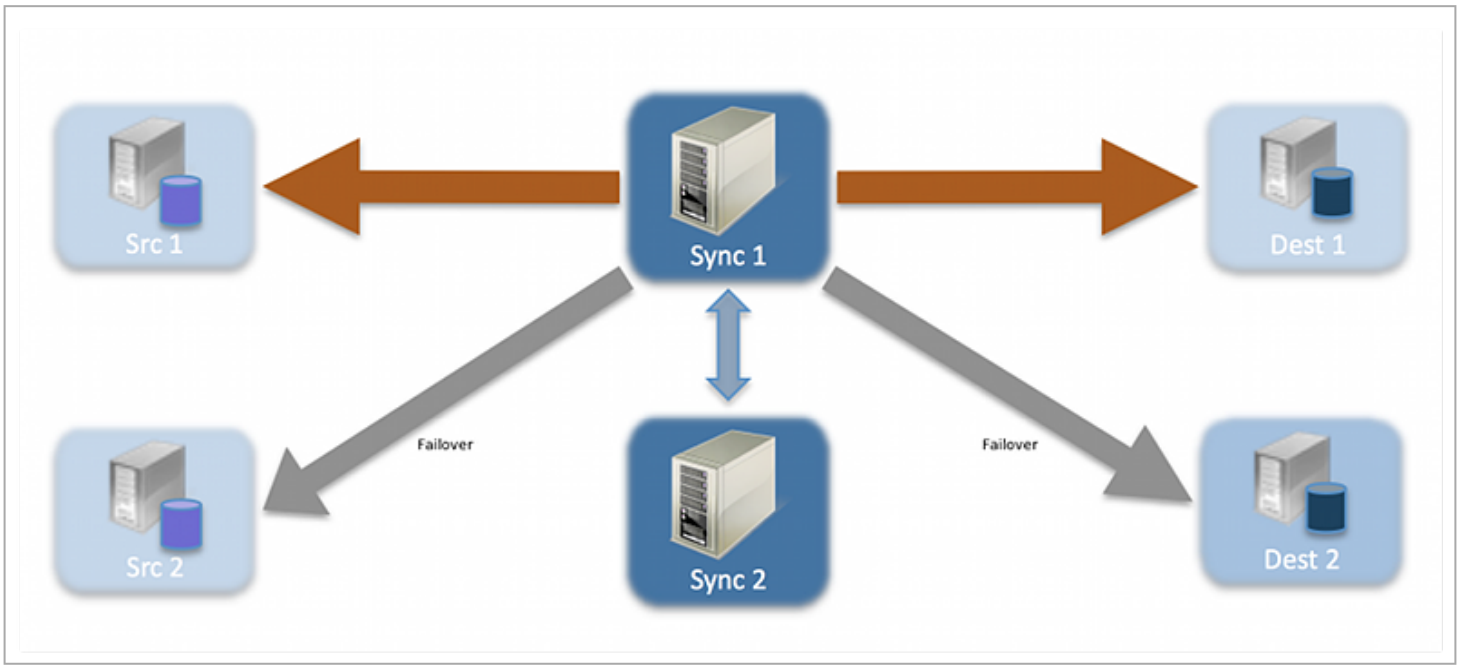
```
$ bin/realtime-sync start --pipe-name "test-sync-pipe" \
  --port 7389 \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPassword secret \
  --no-prompt
```

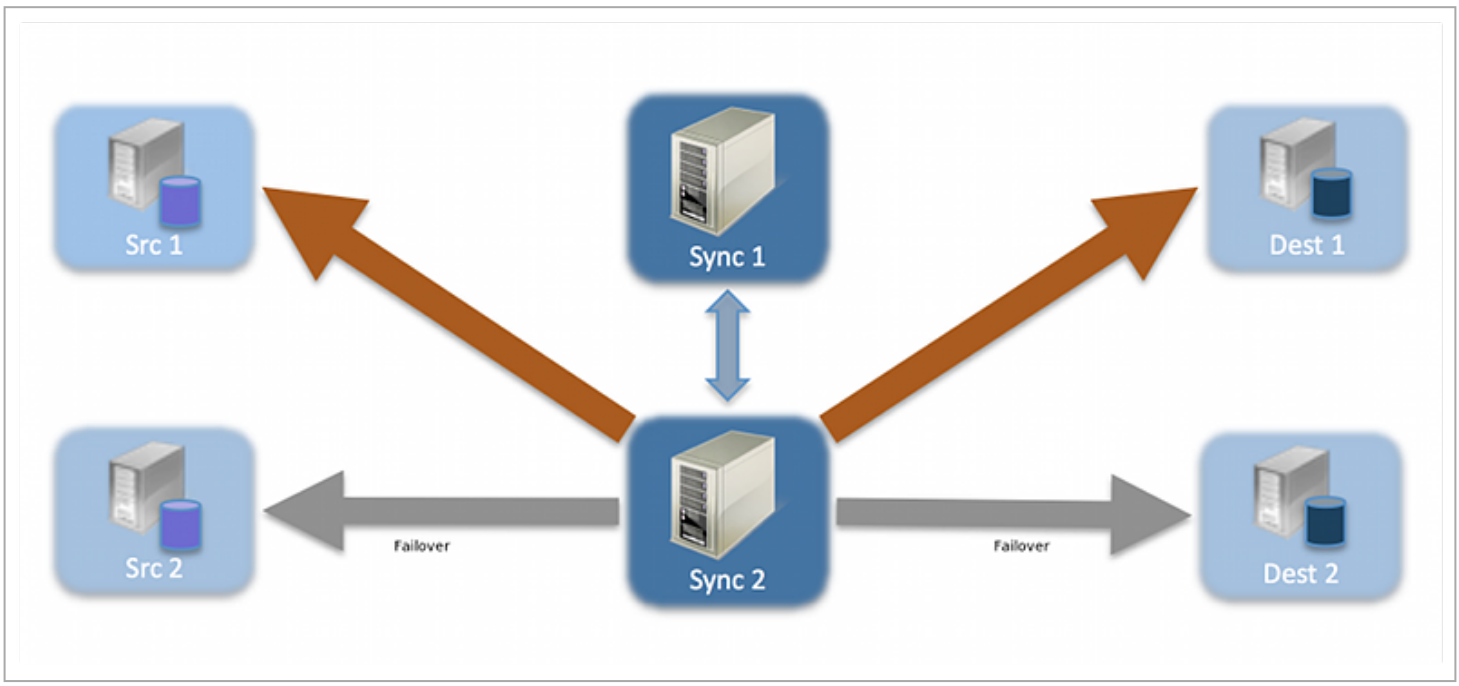
Configure failover behavior

The following figure illustrates a simplified synchronization topology with a single failover server on the source, destination, and PingDataSync server, respectively. The gray lines represent possible failover connections in the event the server is down. The external servers are prioritized so that src1 has higher priority than src2; dest1 has higher priority than dest2.

The main PingDataSync server and its redundant failover instance communicate with each other over LDAP and bind using `cn=IntraSync User,cn=Root DNs,cn=config`. The servers run periodic health checks on each other and share information on all changes that have been processed. Whenever the failover server loses connection to the main server, it assumes that the main server is down and begins processing changes from the last known change. Control reverts back to the main server after it is back online.

Unlike the PingDataSync servers, the external servers and their corresponding failover server(s) do not run periodic health checks. If an external server goes offline, the failover server will receive transactions and remain connected to PingDataSync until the sync pipe is restarted, regardless of whether the main external server comes back online.





Triggering failover in a topology

For PingDataSync servers in a topology, you can trigger a failover to another server instance if the active server isn't operating as expected.

Steps

- Trigger a failover to another PingDataSync server instance:

  Choose from:

  - Stop the active server instance by running the `stop-server` command.
  - Increase the value of the `sync-server-priority-index` property to lower the priority of the active server instance.

    Example:

    ```
    $ bin/dsconfig set-external-server-prop \
        --server-name intra-sync-<server:port> \
        --set sync-server-priority-index:3 \
        --no-prompt --applyChangeTo server-group
    ```

    > **Note**
    >
    > Learn more about the `sync-server-priority-index` property in the PingDataSync configuration documentation.

Conditions that trigger immediate failover

Immediate failover occurs when PingDataSync receives one of the following error codes from an external server:

- BUSY (51)
- UNAVAILABLE (52)
- SERVER CONNECTION CLOSED (81)
- CONNECT ERROR (91)

If PingDataSync attempts a write operation to a target server that returns one of these error codes, PingDataSync will automatically fail over to the server instance with the next-highest priority in the target topology, issue an alert, and then reissue the retry attempt. If the operation is unsuccessful for any reason, the server logs an error.

Failover server preference

PingDataSync supports endpoint failover, which is configurable using the `location` property on the external servers. By default, PingDataSync prefers to connect to and failover to endpoint servers in the same location as itself. If no location settings are configured, PingDataSync will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

PingDataSync does not perform periodic health checks of external servers, and does not failover automatically to a preferred external server. Because of the cost of sync failover, PingDataSync remains connected to a given server until the server stops responding or until the Sync Pipe is restarted. When a failover occurs, PingDataSync returns to the most preferred server, optionally using location settings to identify it, and works its way down the list. Here is an example configuration of external servers:

```
austin1.server.com:1389
london1.server.com:2389
boston1.server.com:3389
austin2.server.com:4389
boston2.server.com:5389
london2.server.com:6389
```

If the austin1 server were to become unavailable, PingDataSync will automatically pick up changes on the next server on the list, london1. If london1 is also down, then the next server, boston1, will be picked up. After PingDataSync iterates through the list, it returns to the top of the list. If PingDataSync is connected to london2 and it goes down, it will fail over to austin1.

To minimize WAN traffic, configure the `location` property for each external server using the `dsconfig` command on PingDataSync. Assume that PingDataSync has its own `location` property (set in the Global Configuration) set to "austin."

```
austin1.server.com:1389 location=austin
london1.server.com:2389 location=london
boston1.server.com:3389 location=boston
austin2.server.com:4389 location=austin
boston2.server.com:5389 location=boston
london2.server.com:6389 location=london
```

With the `location` property set for each server, PingDataSync gets its changes from server austin1. If austin1 goes down, PingDataSync will pick up changes from austin2. If austin2 goes down, the server will iterate through the rest of the list in the order it is configured.

The `location` property has another sub-property, `preferred-failover-location` that specifies a set of alternate locations if no servers in this location are available. If multiple values are provided, servers are tried in the order in which the locations are listed. The `preferred-failover-location` property provides more control over the failover process and allows the failover process to jump to a specified location. Care must be used so that circular failover reference does not take place. Here is an example configuration:

```
austin1.server.com:1389 location=austin preferred-failover-location=boston
london1.server.com:2389 location=london preferred-failover-location=austin
boston1.server.com:3389 location=boston preferred-failover-location=london
austin2.server.com:4389 location=austin preferred-failover-location=boston
boston2.server.com:5389 location=boston preferred-failover-location=austin
london2.server.com:6389 location=london preferred-failover-location=london
```

PingDataSync will respect the `preferred-failover-location`. If it cannot find any external servers in the same location as itself, it will look for any external servers in its own `preferred-failover-location`. In this example, when austin1 becomes unavailable, it will fail over to austin2 because they are in the same location. If austin2 is unavailable, it will fail over to boston1, which is in the `preferred-failover-location` of PingDataSync. If boston1 is unavailable, PingDataSync will fail over to boston2, and finally, it will try the london1 and london2 servers.

Configuration properties that control failover behavior

There are four important advanced properties to fine tune the failover mechanism:

- `max-operation-attempts` (Sync Pipe)
- `response-timeout` (source and destination endpoints)
- `max-failover-error-code-frequency` (source and destination endpoints)
- `max-backtrack-replication-latency` (source endpoints only)

These properties apply to the following LDAP error codes:

LDAP Error Codes

Error Code	Description
ADMIN_LIMIT_EXCEEDED(11)	Indicates that processing on the requested operation could not continue, because an administrative limit was exceeded.
ALIAS_DEREFERENCING_PROBLEM(36)	Indicates that a problem was encountered while attempting to dereference an alias for a search operation.
CANCELED(118)	Indicates that a cancel request was successful, or that the specified operation was canceled.

Error Code	Description
CLIENT_SIDE_LOCAL_ERROR(82)	Indicates that a local (client-side) error occurred.
CLIENT_SIDE_ENCODING_ERROR(83)	Indicates that an error occurred while encoding a request.
CLIENT_SIDE_DECODING_ERROR(84)	Indicates that an error occurred while decoding a request.
CLIENT_SIDE_TIMEOUT(85)	Indicates that a client-side timeout occurred.
CLIENT_SIDE_USER_CANCELLED(88)	Indicates that a user canceled a client-side operation.
CLIENT_SIDE_NO_MEMORY(90)	Indicates that the client could not obtain enough memory to perform the requested operation.
CLIENT_SIDE_CLIENT_LOOP(96)	Indicates that a referral loop was detected.
CLIENT_SIDE_REFERRAL_LIMIT_EXCEEDED(97)	Indicates that the referral hop limit was exceeded.
DECODING_ERROR(84)	Indicates that an error occurred while decoding a response.
ENCODING_ERROR(83)	Indicates that an error occurred while encoding a response.
INTERACTIVE_TRANSACTION_ ABORTED(30221001)	Indicates that an interactive transaction was aborted.
LOCAL_ERROR(82)	Indicates that a local error occurred.
LOOP_DETECT(54)	Indicates that a referral or chaining loop was detected while processing a request.
NO_MEMORY(90)	Indicates that not enough memory could be obtained to perform the requested operation.
OPERATIONS_ERROR(1)	Indicates that an internal error prevented the operation from being processed properly.
OTHER(80)	Indicates that an error occurred that does not fall into any of the other categories.
PROTOCOL_ERROR(2)	Indicates that the client sent a malformed or illegal request to the server.
TIME_LIMIT_EXCEEDED(3)	Indicates that a time limit was exceeded while attempting to process the request.
TIMEOUT(85)	Indicates that a timeout occurred.
UNWILLING_TO_PERFORM(53)	Indicates that the server is unwilling to perform the requested operation.

max-operation-attempts property">

The `max-operation-attempts` property

The `max-operation-attempts` property (part of the Sync Pipe configuration) specifies the maximum number of times to retry a synchronization operation that fails for reasons other than the Sync Destination being busy, unavailable, server connection closed, or connect error.

To change the default number of retries, use `dsconfig` in non-interactive mode to change the `max-operation-attempts` value on the Sync Pipe object. The following command changes the number of maximum attempts from five (default) to four.

```
$ bin/dsconfig set-sync-pipe-prop \
  --pipe-name "Test Sync Pipe" \
  --set max-operation-attempts:4
```

response-timeout property">

The `response-timeout` property

The `response-timeout` property specifies how long PingDataSync should wait for a response from a search request to a source server before failing with LDAP result code 85 (client-side timeout). When a client-side timeout occurs, the Sync Source will retry the request according to the `max-failover-error-code-frequency` property before failing over to a different source server and performing the retry. The total number of retries will not exceed the `max-operation-attempts` property defined in the Sync Pipe configuration. A value of zero indicates that there should be no client-side timeout. The default value is one minute.

Assuming a bidirectional topology, the property can be set with `dsconfig` on the Sync Source and Sync Destination, respectively.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name src \
  --set "response-timeout:8 s"
```

```
$ bin/dsconfig set-sync-destination-prop \
  --destination-name U4389 \
  --set "response-timeout:9 s"
```

max-failover-error-code-frequency property">

The `max-failover-error-code-frequency` property

The `max-failover-error-code-frequency` property (part of the Sync Source configuration) specifies the maximum time period that an error code can re-appear until it fails over to another server instance. This property allows the retry logic to be tuned, so that retries can be performed once on the same server before giving up and trying another server. The value can be set to zero if there is no acceptable error code frequency and failover should happen immediately. It can also be set to a very small value (such as 10 ms) if a high frequency of error codes is tolerable. The default value is three minutes.

To change the `max-failover-error-code-frequency` property, use `dsconfig` in non-interactive mode to change the property on the Sync Source object. The following command changes the frequency from three minutes to two minutes.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name source1 \
  --set "max-failover-error-code-frequency:2 m"
```

max-backtrack-replication-latency property">

The `max-backtrack-replication-latency` property

The `max-backtrack-replication-latency` property (part of the Sync Source configuration) sets the time period that PingDataSync will look for missed changes in the change log caused by replication delays. The property should be set to a conservative upper-bound of the maximum replication delay between two servers in the topology. A value of zero implies that there is no limit on the replication latency. The default value is two hours. PingDataSync stops looking in the change log after it finds a change that is older than the maximum replication latency.

For example, after failing over to another server, PingDataSync must look through the new server's change log to find the equivalent place to begin synchronizing changes.

Normally, PingDataSync can successfully backtrack with only a few queries of the directory, but in some situations, it might have to look further back through the change log to make sure that no changes were missed. Because the changes can come from a variety of sources (replication, synchronization, and over LDAP), the replicated changes between directory servers are interleaved in each change log. When PingDataSync fails over between servers, it has to backtrack to figure out where synchronization can safely pick up the latest changes.

Backtracking occurs until the following:

- The server determines that there is no previous change log state available for any source servers, so it must start at the beginning of the change log.
- The server finds the last processed replication change sequence number (CSN) from the last time it was connected to that replica, if at all. This process is similar to the `set-startpoint` functionality on the `realtime-sync` command.
- The server finds the last processed replication CSN from every replica that has produced a change so far, and it determines that each change entry in the next-oldest batch of changes has already been processed.
- The server finds a change that is separated by more than a certain duration (specified by the `max-backtrack-replication-latency` property) from the most recently processed change.

The following command changes the maximum backtracking from two hours to three hours.

```
$ bin/dsconfig set-sync-source-prop \
  --source-name source1 \
  --set "max-backtrack-replication-latency:3 h"
```

Configure traffic through a load balancer

If a PingDataSync server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address should be recorded to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingDataSync server. See the product documentation for the device type. For PingDataSync servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP) and set `use-forwarded-headers` to `true`.
- When `use-forwarded-headers` is set to `true`, the server will use the client IP address and port information in the `X-Forwarded-*` headers instead of the address and port of the entity that's actually sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

Configure authentication with a SASL external certificate

About this task

By default, PingDataSync authenticates to the PingDirectory server using LDAP simple authentication (with a bind DN and a password). However, PingDataSync can be configured to use SASL EXTERNAL to authenticate to the PingDirectory server with a client certificate.

> **Note**
>
> This procedure assumes that PingDataSync instances are installed and configured to communicate with the backend PingDirectory server instances using either SSL or StartTLS.

After the servers are configured, perform the following steps to configure SASL EXTERNAL authentication:

Steps

1. Create a JKS keystore that includes a public and private key pair for a certificate that the PingDataSync instance(s) will use to authenticate to the PingDirectory server instance(s). Run the following command in the instance root of one of the PingDataSync instances. When prompted for a keystore password, enter a strong password to protect the certificate. When prompted for the key password, press ENTER to use the keystore password to protect the private key:

```
$ keytool -genkeypair \
  -keystore config/sync-user-keystore \
  -storetype JKS \
  -keyalg RSA \
  -keysize 2048 \
  -alias sync-user-cert \
  -dname "cn=Sync User,cn=Root DNs,cn=config" \
  -validity 7300
```

2. Create a `config/sync-user-keystore.pin` file that contains a single line that is the keystore password provided in the previous step.

3. If there are other PingDataSync instances in the topology, copy the `sync-user-keystore` and `sync-user-keystore.pin` files into the config directory for all instances.

4. Use the following command to export the public component of the user certificate to a text file:

```
$ keytool -export \
  -keystore config/sync-user-keystore \
  -alias sync-user-cert \
  -file config/sync-user-cert.txt
```

5. Copy the `sync-user-cert.txt` file into the `config` directory of all PingDirectory server instances. Import that certificate into each server's primary trust store by running the following command from the server root. When prompted for the keystore password, enter the password contained in the `config/truststore.pin` file. When prompted to trust the certificate, enter `yes`.

```
$ keytool -import \
  -keystore config/truststore \
  -alias sync-user-cert \
  -file config/sync-user-cert.txt
```

6. Update the configuration for each PingDataSync instance to create a new key manager provider that will obtain its certificate from the `config/sync-user-keystore` file. Run the following `dsconfig` command from the server root:

```
$ dsconfig create-key-manager-provider \
  --provider-name "Sync User Certificate" \
  --type file-based \
  --set enabled:true \
  --set key-store-file:config/sync-user-keystore \
  --set key-store-type:JKS \
  --set key-store-pin-file:config/sync-user-keystore.pin
```

7. Update the configuration for each LDAP external server in each PingDataSync server instance to use the newly created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication. Run the following `dsconfig` command:

```
$ dsconfig set-external-server-prop \
  --server-name ds1.example.com:636 \
  --set authentication-method:external \
  --set "key-manager-provider:Sync User Certificate"
```

Next steps

After these changes, PingDataSync should re-establish connections to the LDAP external server and authenticate with SASL EXTERNAL. Verify that PingDataSync is still able to communicate with all backend servers by running the `bin/status` command. All of the servers listed in the "--- LDAP External Servers ---" section should have a status of `Available`. Review the PingDirectory server access log to make sure that the BIND RESULT log messages used to authenticate the connections from PingDataSync include `authType="SASL", saslMechanism="EXTERNAL", resultCode=0`, and `authDN="cn=Sync User,cn=RootDNs,cn=config"`.

Configure an LDAPv3 Sync Source

Synchronization can be performed with an LDAP V3-compliant source, such as IBM SDS (Tivoli Directory Server), Oracle Unified Directory, DSEE, or OpenDJ, by configuring a Generic LDAP Sync Source. PingDataSync relies on the source server having a `cn=changelog` implementation. If the server does not have a `cn=changelog` implementation, a Server SDK Change Detector extension can be configured to define the change detection criteria that PingDataSync should use.

If multiple Generic LDAP Sync Source instances are defined, the order in which they are added is used as a priority order for failover. If server locations are defined, PingDataSync will always fail over to servers that are in the same location. If there are multiple Sync Sources in the same location as PingDataSync, then PingDataSync will fail over to the first local server in the list and proceed down the list.

During synchronization, when a change is detected by PingDataSync, the changed entry is fetched from the source. Initially, the DN of the entry is used to search for the entry. If that search fails, then a second search is performed using the `unique-id-attribute` if it is defined. This is typically an operational attribute that is automatically generated by the server, such as `entryUUID`.

Server SDK extensions

Custom server extensions can be created with the Server SDK. Extension bundles are installed from a .zip archive or a file system directory. Use the **`manage-extension`** command to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

> **Note**
>
> The **`manage-extension`** command must be used with Java extensions packaged using the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation.

The Server SDK enables creating extensions for all PingDirectory servers. Cross-product extensions include:

- Access loggers
- Alert handlers

- Error loggers
- Key Manager providers
- Monitor providers
- Trust Manager providers
- OAuth token handlers
- Manage extension plugins

Synchronize with PingOne

PingDataSync supports PingOne as a synchronization destination and source for newly created or modified accounts with native password changes between directory servers, relational databases, or other PingOne systems.

> **Note**
>
> For PingOne documentation, see PingOne Platform.

The following topics include configuration procedures for synchronization between PingOne and the PingDirectory server, or other LDAP source servers or targets.

- Prerequisites
- Synchronize changes to a PingOne environment
- Synchronize changes from a PingOne environment
- Testing and troubleshooting the sync
- PingOne synchronization limitations

For more information, see Syncing passwords to PingOne.

Prerequisites

Before attempting to synchronize changes to or from a PingOne environment, make certain the prerequisites in this section are satisfied.

Create a worker application

A worker application is an administrator application that can have the same roles as human administrators. Creating a worker application creates a sync destination or source for synchronizing changes to and from PingOne.

Before you begin

Before you create a worker application, have the following information ready:

- The app name and description
- Redirect URLs for authentication (required for interactive applications only)

About this task

You can use worker applications to create a userless service app that can perform administrator functions. Role assignments determine the functions that the app can perform.

Required grant type

By default, worker applications are configured with the required Client Credentials grant type. They can also be configured to support additional grant/response types, similar to the other app types. The worker application can also perform administrator functions with the role of its user. To accomplish this task, give the app one or more additional grant types, which are used instead of the role assignments.

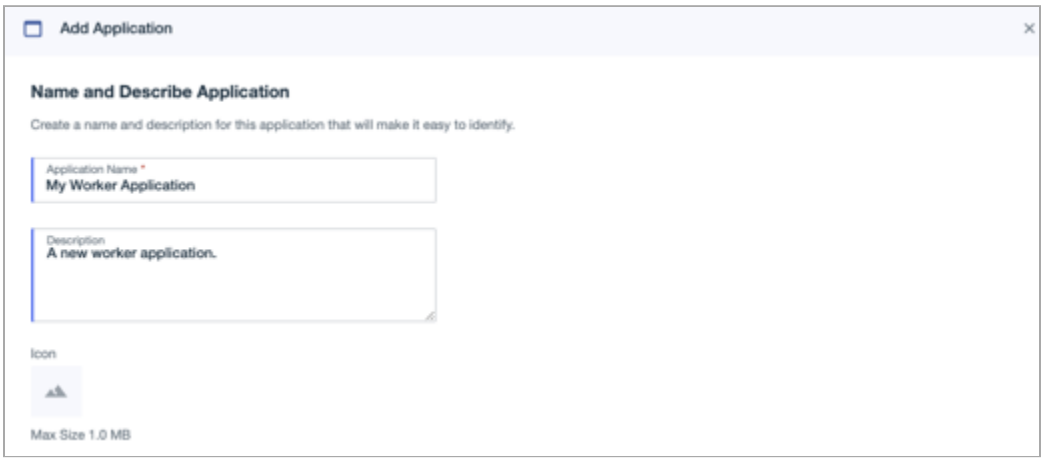
Required roles

A role is a collection of permissions that can be assigned to a user. Of the many roles that PingOne includes by default, only the Identity Data Admin role, which manages identities and identity data, is required for the worker app that you need to create. Permissions center around managing user identities and include functions like creating users, resetting a user's password, and creating, editing, and deleting populations.

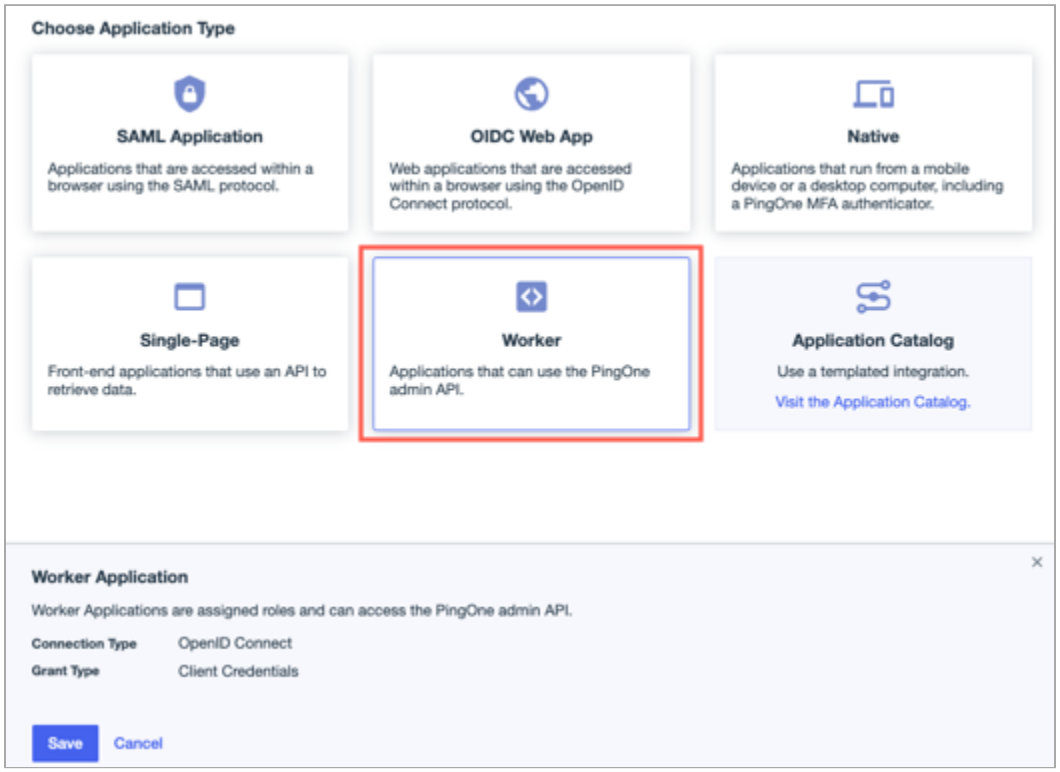
To create and configure a worker app in PingOne:

Steps

1. In the PingOne admin portal, go to Connections → Applications.
2. Click the + icon.
3. Create the application profile by entering the following:
    - Application name: A unique identifier for the application.
    - Description (optional): A brief characterization of the application.
    - Icon (optional): A graphic representation of the application. Use a file up to 1MB in JPG, JPEG, GIF, or PNG format.



4. In the Choose Application Type section, click Worker.



5. Click Save.

   Result:

   The app is displayed on the Applications page.

6. Make note of the OAuth Client ID, which appears directly below the name of the app.

   This value is required when creating a PingOne sync destination or source.

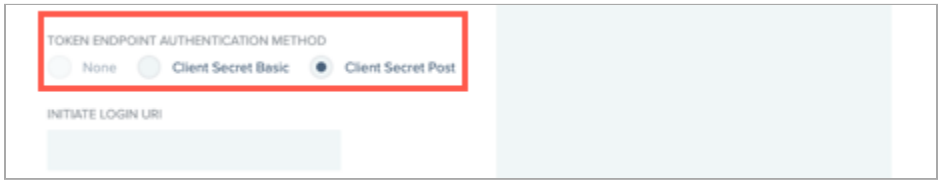
7. Click the Configuration tab, and then click the Pencil icon to edit the configuration:

   1. In the General section, make note of the Client Secret.

      This value is required when creating a PingOne sync destination or source.

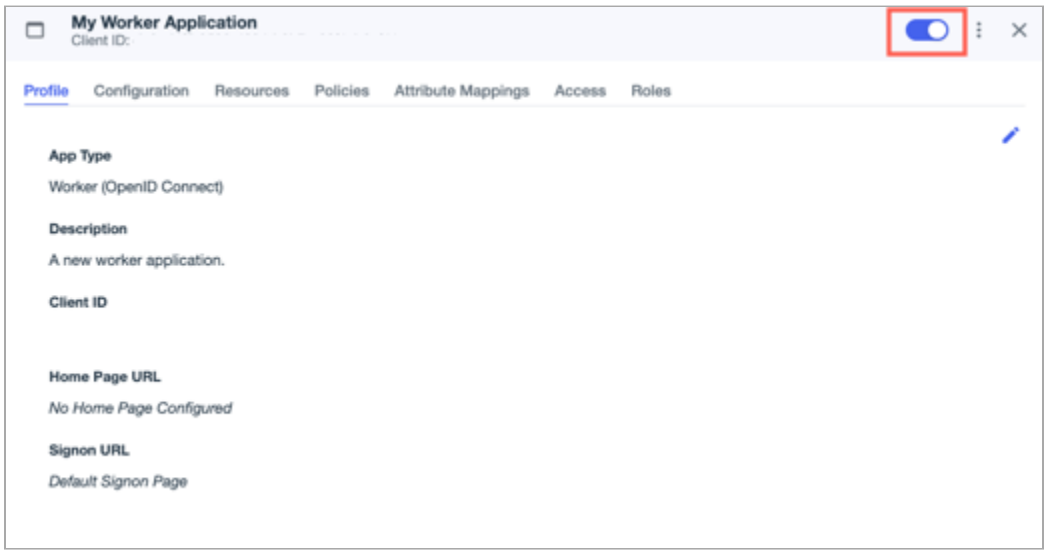
   2. For Grant Type, select the Client Credentials check box.

3. For a token endpoint authentication method, click Client Secret Post.



4. Click Save.

8. Click the toggle to enable the application.



9. In the left navigation pane, click Environment → Properties.

10. Make note of the Environment ID.

    This value is required when creating a PingOne sync destination or source.

Next steps

Use your worker application as a sync source or destination for PingOne:

- Synchronize changes to a PingOne environment.
- Synchronize changes from a PingOne environment.

Review the PingOne user resource model

A user resource is a unique identity within PingOne that interacts with the applications and services in the environment to which the user is assigned.

Users are associated with an environment and a population, and the service implements directory functions to create, read, update, delete, and search for user resources. For more information, see the PingOne Platform API Reference.

The username field is required with the PingOne user resource model. This field is a string that specifies the user name, which must be unique within an environment. Limited to 128 characters in length, the username must be a well-formed email address or a string of any Unicode letter, mark (like an accent or umlaut), dot, underscore, or hyphen.

Synchronize changes to a PingOne environment

This section describes the configuration that is necessary to synchronize changes to a PingOne environment. PingDataSync supports synchronization of single and multivalued attributes to PingOne. To view an example configuration, see the file located at `<server-root>/config/sample-dsconfig-batch-files/reference-ping-one-sync-destination-configuration.dsconfig`.

> **Note**
>
> When configuring a sync pipe in PingDataSync to synchronize users to a PingOne destination, you must include a constructed attribute mapping named `resourceType` with a value-pattern of `user`.

Creating a PingOne sync destination

Before you create a PingOne sync destination, make sure you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

Learn more about obtaining these values in Creating a PingOne worker application.

The following sample creates a PingOne sync destination.

```
dsconfig create-sync-destination  \
  --destination-name PingOne  \
  --type ping-one-customer  \
  --set api-url:https://api.pingone.com/v1 \
  --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
  --set environment-id:[PING_ONE_ENV_ID]  \
  --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID]  \
  --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

Configuring JSON attribute mappings

Add the JSON attribute mapping type with sub-objects (the JSON attribute mapping field) that allow you to map individual fields.

About this task

If a source attribute doesn't have a value, the corresponding field is omitted.

> **Note**
>
> Use JSON attribute mappings rather than constructed attribute mappings.

Steps

1. To create an attribute map, run `dsconfig` with the `create-attribute-map` option.

   Example:

   The following example creates an attribute map titled `PingDirectory_to_PingOne_User_Map`.

   ```
   dsconfig create-attribute-map \
     --map-name PingDirectory_to_PingOne_User_Map
   ```

2. To create the attribute mapping, run `dsconfig` with the `create-attribute-mapping` option.

   Example:

   The following example creates the attribute mapping to `PingDirectory_to_PingOne_User_Map`.

   ```
   dsconfig create-attribute-mapping \
     --map-name PingDirectory_to_PingOne_User_Map \
     --mapping-name name \
     --type json
   ```

3. To map JSON attributes, run `dsconfig` with the `create-json-attribute-mapping-field` option.

   Example:

   The following example creates the JSON attribute mapping field `formatted` from the `cn` attribute.

   ```
   dsconfig create-json-attribute-mapping-field \
     --map-name PingDirectory_to_PingOne_User_Map \
     --mapping-name name \
     --field-name formatted \
     --set from-attribute:cn \
     --set json-type:string
   ```

   The following example creates the JSON attribute mapping field `given` from the `givenName` attribute.

```
dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name given \
  --set from-attribute:givenName \
  --set json-type:string
```

The following example creates the JSON attribute mapping field `family` from the `sn` attribute.

```
dsconfig create-json-attribute-mapping-field \
  --map-name PingDirectory_to_PingOne_User_Map \
  --mapping-name name \
  --field-name family \
  --set from-attribute:sn \
  --set json-type:string
```

Configuring constructed attribute mappings

> **Note**
>
> You should use JSON attribute mappings instead of constructed attribute mappings. Learn more in Configuring JSON attribute mappings.

The PingOne User model contains simple JSON attributes like `"title": "Director"` as well as complex JSON objects like `\{"name": \{"given": "Jane", "family": "Doe"}}`. To ensure accurate processing when you construct attribute mappings that interact with complex objects, construct valid JSON strings and use the command `jsonEscape`, as the following example shows.

```
dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map  \
  --mapping-name name  \
  --type constructed  \
  --set 'value-pattern:{{"given":"{givenname:jsonEscape}","family":"{sn:jsonEscape}"}}'
```

Some attributes in the User resource are operational and cannot be modified by synchronizing data. For more information, see the PingOne Platform API Reference.

Correlating entries

The PingOne User Resource model provides an attribute named `externalId`. To ensure that users correlate to the appropriate entry in PingDirectory, map `entryUUID` to this value and configure `externalId` as a destination-correlation-attribute on the Sync class.

Considerations and limitations

There are limitations and other constraints to consider when synchronizing changes to a PingOne environment.

Renaming entries isn't allowed

As a sync destination, PingOne doesn't allow `moddn` operations to rename an entry. When creating a sync class, set the `allow-destination-renames` option to `false` to prevent PingDataSync from attempting to rename entries and then logging related errors. For example:

```
dsconfig create-sync-class \
  --pipe-name PingDirectory_to_PingOne \
  --class-name "PingDirectory_to_PingOne User Sync Class" \
  --set allow-destination-renames:false \
  --set attribute-map:PingDirectory_to_PingOne_User_Map \
  --set auto-mapped-source-attribute:-none- \
  --set destination-correlation-attributes:externalId \
  --set destination-correlation-attributes:username \
  --set destination-correlation-attributes:email \
  --set destination-create-only-attribute:resourceType \
  --set creates-as-modifies:true \
  --set include-filter:(objectClass=person)
```

Tip

You can find the previous example in the PingDataSync distribution. Learn more in the following file: `config/sample-dsconfig-batch-files/reference-pingone-sync-destination-configuration.dsconfig` .

Populations

Note

All PingOne user resources must exist within a population.

The PingOne synchronization destination provides the following methods for managing a user's population:

- If a single population is in use, set the configuration attribute `default-population-id` on the sync destination.
- If multiple populations are in use, use a constructed attribute mapping.

The following syntax provides an example with a constructed attribute mapping:

```
dsconfig create-attribute-mapping \
  --map-name PingDirectory_to_PingOne_User_Map  \
  --mapping-name population  \
  --type constructed  \
  --set 'value-pattern:{{"id":"[DEFAULT_POPULATION_ID]"}}'
```

To set the population, construct a valid JSON object.

Multivalued attributes

If your incoming data is in JSON format, configure your PingOne multivalued attribute as JSON and use a JSON attribute mapping.

If your incoming data is not in JSON format, you can configure your PingOne multivalued attribute as JSON and use a constructed attribute mapping. Otherwise, you must configure your PingOne multivalued attribute as `DECLARED` and use a direct attribute mapping.

> **Important**
>
> Direct attribute mapping does not work with JSON multivalued PingOne attributes even with an attribute with the same name and value in PingDirectory.

Synchronize changes from a PingOne environment

This section describes the configuration that is necessary to synchronize changes from a PingOne environment. To view an example configuration, see the file located at `<server-root>/config/sample-dsconfig-batch-files/reference-ping-one-sync-source-configuration.dsconfig`.

Create a PingOne sync source

Before you create a PingOne sync source, make certain you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

Learn more about obtaining these values in Creating a PingOne worker application.

The following example creates a PingOne sync source.

```
dsconfig create-sync-source \
  --source-name PingOne \
  --type ping-one-customer \
  --set api-url:https://api.pingone.com/v1 \
  --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
  --set environment-id:[PING_ONE_ENV_ID] \
  --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID] \
  --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

Configuring attribute mapping

The process of synchronizing data uses the concepts and structures associated with LDAP entries. Ping Identity recommends that you conceptualize the PingOne User Resource model as an LDAP entry when configuring an attribute mapping. Additionally, you might need to use JSON pathing when selecting a value for complex JSON attributes within the user.

```
dsconfig create-attribute-mapping \
  --map-name PingOne_to_PingDirectory_User_Map \
  --mapping-name givenname \
  --type constructed \
  --set "value-pattern:{name.given}"
```

Correlating entries

To ensure that users correlate to the appropriate entry in PingDirectory, map the `id` attribute from the user resource to `entryUUID` in PingDirectory.

Synchronizing PingOne account status with PingDirectory

About this task

When configuring a one-way sync from PingOne to PingDirectory, you can enable PingDirectory to synchronize with the `User.Locked` or `User.Unlocked` status of a PingOne account. This synchronization reduces confusion for the administrator and enhances the security posture of the account. For example, if a PingOne account is locked due to multiple failed MFA attempts, it could be risky to leave the corresponding account fully functional.

> **Note**
>
> A PingOne `User.Locked` event disables the destination entry in PingDirectory. A `User.Unlocked` event enables the destination entry.

To enable this synchronization, you must map two account status attributes from PingOne directly to the corresponding PingDirectory attributes. Because the PingDirectory attributes can't be written to directly, PingDataSync uses intermediate attributes to facilitate an extended operation.

The following table shows the relevant source, intermediate, and destination attributes for this mapping:

PingOne attribute	Intermediate attribute	PingDirectory attribute
`account.status`	`ds-pwp-account-disabled-from-pingone`	`ds-pwp-account-disabled`
`account.lockedAt`	`pwdAccountLockedTimeFromPingOne`	`pwdAccountLockedTime`

> **Note**
>
> Intermediate attributes only exist in memory on the PingDataSync server so that they can be consumed for attribute mappings. They don't exist in PingOne or on the PingDirectory server.

Steps

- Map `ds-pwp-account-disabled-from-pingone` to `ds-pwp-account-disabled` using the following command:

```
dsconfig create-attribute-mapping \
  --map-name PingOne_to_PingDirectory_User_Map \
  --mapping-name ds-pwp-account-disabled \
  --type direct \
  --set from-attribute:ds-pwp-account-disabled-from-pingone
```

- Map `pwdAccountLockedTimeFromPingOne` to `pwdAccountLockedTime` using the following command:

```
dsconfig create-attribute-mapping \
  --map-name PingOne_to_PingDirectory_User_Map \
  --mapping-name pwdAccountLockedTime \
  --type direct \
  --set from-attribute:pwdAccountLockedTimeFromPingOne
```

- To have the `pwdAccountLockedTime` attribute appear on the destination entry, set the `lockout-failure-count` attribute to a non-zero value.

  Example:

  ```
  dsconfig set-password-policy-prop \
    --policy-name "Default Password Policy" \
    --set lockout-failure-count:1
  ```

Troubleshooting

By default, the `modifies-as-creates` sync class property is set to `false`.

Active Directory attributes might not be synchronized as expected when all of the following are true:

- You are using the `realtime-sync` tool.
- The `modifies-as-creates` sync class property is set to `true`.
- A modification is detected on the source endpoint to a missing entry on the destination endpoint.
- The modification is to attributes other than the two PingOne attributes previously mentioned.

To avoid this, you can run the `resync` tool instead of the `realtime-sync` tool. Using `resync` will correctly copy all attributes. Learn more about the resync command.

Considerations and limitations

This section describes limitations and other constraints to consider when synchronizing changes from a PingOne environment.

Bidirectional synchronization

If you plan on configuring bidirectional synchronization between PingOne and PingDirectory, make sure that you satisfy the following conditions:

- Use separate worker apps for the source and destination.
- To prevent the unnecessary duplication of changes, add the client ID of the destination worker app to the `actor-id-to-ignore` configuration attribute of the source.
- To ensure that no attribute mappings are mismatched, modify the reference `dsconfig` batch files.

Password synchronization

PingDataSync does not support the synchronizing of passwords from PingOne.

Population management

If your PingOne environment features a large number of populations, or if you want to limit synchronized users to a specific set of populations, provide one or more `population-to-synchronize` configuration attributes to the source. The name or ID of the population can be used.

Synchronization delay

PingDataSync propagates changes throughout PingOne nearly in real time. However, a delay might occur between the time a change occurs in PingOne and the time it becomes available for PingDataSync to synchronize. To help ensure that no changes are missed, a default delay of 5 seconds has been configured within the sync source. For environments of sufficient size or with high rates of change, use the configuration attribute `realtime-sync-polling-offset` on the sync source to increase the delay.

Testing and troubleshooting the sync

Follow these steps to test and troubleshoot your configured sync between PingOne and PingDirectory.

Steps

1. Test the sync:
    1. Run the sync with the following command:

        ```
        /opt/<PingDataSync>/bin/resync -p  <sync_pipe_name>
        ```

    2. (Optional) If the sync results in any errors, see the `/Ping/<PingDataSync>/logs/tools/re-sync-failed-DNs.log`.
    3. (Optional) If you receive an error that includes `Cannot connect because: The connection to server localhost:11389 was closed while waiting for a response to a bind request SimpleBindRequest(dn='cn=dmanager').`:
        1. In the PingDataSync admin console, go to Configuration → External Servers → ServerPD_PDtest.
        2. Update your password.

PingOne synchronization limitations

PingOne can return errors when synchronizing with PingDataSync because of a rate-limiting mechanism in PingOne. A workaround for this issue has been implemented in PingDataSync.

The PingOne API contains a resource-limit mechanism to prevent clients from overwhelming the service and returns HTTP 429 error codes when this limit is reached.

> **Note**
>
> This limit is set to 100 operations per second.

Because PingDataSync sends changes to a destination as quickly as possible, the server might hit this limit, especially if a large number of threads are in use.

If the PingDataSync server receives HTTP 429 errors from PingOne, it waits briefly and retries any failed operations again. An operation is retried up to 15 times to attempt to synchronize a change. This retry mechanism allows the PingDataSync server to process a change without the operation dropping as a failure after initial HTTP 429 errors.

Synchronize with Active Directory and other directory servers

PingDataSync supports full synchronization for newly created or modified accounts with native password changes between directory server, relational databases, and Microsoft Active Directory (AD) systems.

Considerations

There are three key considerations when synchronizing between AD and PingDirectory:

The `realtime-sync` tool

The `realtime-sync` tool uses the AD DirSync control to detect changes on entries, which requires the control to be searched at the top of the directory information tree (DIT). Because of this, you must point your AD Sync Source to the top of the AD tree for `realtime-sync` to work.

Distinguished name (DN) mapping

The AD Sync Source must be pointed at the top of the DIT, but not every branch under the top of the tree can be easily synchronized.

For example, `cn=Users` is a container organizational unit (OU) that doesn't easily convert into a standard OU. Likewise, `cn=Builtin` is a top-level domain that also contains built-in groups without a purpose in PingDirectory and that don't need to be synchronized.

To avoid synchronizing entries that are native and apply only to AD, point your Sync Classes at specific OUs.

Schema and attribute mapping

The schema between AD and PingDirectory is not a 1:1 relationship, which means that not all attributes can be directly synchronized.

The following attributes are among those that can be directly synchronized:

- `cn`
- `sn`
- `mail`

Other attributes, such as the AD attribute `{{samAccountName}}` aren't defined in PingDirectory by default, and if you don't define schema for the attribute, you can map it to a similar attribute such as the PingDirectory `uid` attribute. You should create attribute mappings for each attribute that you want to synchronize between AD and PingDirectory.

Known limitations and workarounds

Tracking group membership changes in AD

The virtual attribute `memberOf` exists in an AD user entry and contains a list of that user's group memberships. When group membership changes, AD updates only the group entry member attribute. Therefore, if PingDataSync monitors only `memberOf` for group membership changes in AD, it won't detect them.

You can try the following workarounds:

- Run the `resync` command periodically.
- Manually sync the groups between AD and PingDirectory.

> **Important**
>
> This requires the ability to map DNs between AD and PingDirectory based on the available information, which is often limited.

Syncing passwords from LDAP servers to AD

You can sync passwords from PingDirectory to AD, but syncing passwords directly from other Lightweight Directory Access Protocol (LDAP) servers to AD isn't supported. You should sync these passwords to PingDirectory first, which allows you to then sync them to AD.

Configuration information

For configuration information and procedures for synchronization between PingDirectory server or other LDAP source servers or targets with Microsoft AD systems, refer to the following:

- Overview of configuration tasks

From PingDirectory to AD

- Active Directory sync user account
- Preparing external servers
- Configuring password encryption
- Password Sync Agent

From AD to PingDirectory

- Configuring one way synchronization from Active Directory to PingDirectory
- Mapping AD password policy state attributes to PingDirectory using `dsconfig`
- Configuring sync pipes and sync classes

Overview of configuration tasks

PingDataSync supports bidirectional synchronization between PingDirectory and Active Directory (AD). This section describes the configuration tasks that are necessary to synchronize changes to Active Directory systems. To view an example configuration, see the file located in the `<server-root>/config/sample-dsconfig-batch-files/reference-bidirectional-sync-activedirectory-pingdirectory.dsconfig` directory.

Enable SSL connections

If you are synchronizing passwords between systems, Active Directory systems require that SSL be enabled on the Active Directory domain controller, so that PingDataSync can securely propagate the `cn=Sync User` account password and other user passwords to the target.

Run the create-sync-pipe-config tool

On the PingDataSync server, use the `create-sync-pipe-config` tool to configure the Sync Pipes to communicate with the Active Directory source or target.

Configure outbound password synchronization on an PingDirectory Server Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from a PingDirectory server Sync Source is required. If so, enable the Password Encryption component on all PingDirectory server sources that receive password modifications. The PingDirectory server uses the Password Encryption component to intercept password modifications and add an encrypted attribute, `ds-changelog-encrypted-password`, to the changelog entry. The component enables passwords to be synchronized securely to the Active Directory system, which uses a different password storage scheme. The encrypted attribute appears in the change log and is synchronized to the other servers, but does not appear in the entries.

Configure outbound password synchronization on an Active Directory Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from an Active Directory Sync Source is required. If so, install the Password Sync Agent (PSA) after configuring PingDataSync.

Run the realtime-sync set-startpoint tool

The `realtime-sync set-startpoint` command can take several minutes to run, because it must issue repeated searches of the Active Directory domain controller until it has paged through all the changes and received a cookie that is up-to-date. NOTE: If the Password Sync Agent is down for any length of time and misses a password change, these changes will not be synced on recovery without either a new password change for the entry or the use of pass-through authentication. The Password Sync Agent cannot be pointed at multiple domain clusters.

Configuring one way synchronization from Active Directory to PingDirectory

Configure a one-way Sync Pipe with the Active Directory (AD) topology as the sync source and a PingDirectory server topology as the Sync Destination.

About this task

Syncing from AD-LDS to PingDirectory is supported for all features except password syncing.

Important

If you are syncing the `lockoutTime`, `userAccountControl & (ACCOUNTDISABLE == 2)`, or `pwdLastSet` AD attributes, or the AD-LDS `ms-DS-User-Account-Disabled` attribute, see Synchronizing Active Directory with PingDirectory.

Note

The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. From the `server-root` directory, start PingDataSync.

```
$ <server-root>/bin/start-server
```

2. To set up the initial synchronization topology, run the `sync` tool.

```
$ bin/create-sync-pipe-config
```

3. In the Create Initial Synchronization Configuration menu, press Enter to continue the configuration.
4. In the Synchronization Mode menu, press Enter to accept the default option `1` for `Standard mode`.
5. In the Synchronization Direction menu, press Enter to accept the default option `1` for `One way`.
6. In the Source Endpoint Type menu, enter option `7` for `Microsoft Active Directory`.
7. In the Source Endpoint Name menu, enter a name for the Microsoft AD source server, or press Enter to accept the default value of `Microsoft Active Directory Source`.
8. In the <*Source Server*> Server Security menu, press Enter to accept the default option `1` for `SSL` security.
9. In the <*Source Server*> Servers menu, enter the host name and listener port for Lightweight Directory Access Protocol (LDAP) communication with the source server in the format of `<host name>:<port number>` and press Enter.

   The Data Sync server attempts a connection to the AD source server. After adding the first server, you can add additional servers for the source endpoints that will be prioritized below the first server.
10. When you have finished adding servers, press Enter to continue to the next configuration step.
11. In the Synchronization User Account for <*Source Server*> menu, enter a user account distinguished name (DN) for the source servers, or press Enter to accept the default value.

    The account is used exclusively by the Data Sync Server to communicate with the source external servers.
12. Enter a password for the synchronization user account and press Enter.

    Note

    The User Account DN password must meet the minimum password requirements for AD domains.

13. In the Destination Endpoint Type menu, press Enter to select the default option `1` for `Ping Identity Directory Server`.
14. In the Destination Endpoint Name menu, enter a name for your destination endpoint, or press Enter to select the default value, `Ping Identity Directory Server Destination`.
15. In the Base DNs for *<Endpoint Server>* menu, enter a base DN where synchronized entries can be found in your endpoint server, or press Enter to accept the default value.

    After your initial entry, you can add additional base DNs by following the prompts.
16. When you have finished entering base DNs for synchronized entries, press Enter to continue the configuration.
17. In the *<Endpoint Server>* Server Security menu, enter the option for the type of security that the Sync Server will use in communication with the endpoint server and press Enter.
18. In the *<Endpoint Server>* Servers menu, enter the host name and port for LDAP communication in the format of `<host name>:<port number>` and press Enter.

    The PingDataSync server attempts a connection to the destination PingDirectory server endpoint. After adding the first server, you can add additional servers for the destination endpoints that will be prioritized below the first server.
19. When you have finished adding servers, press Enter to continue to the next configuration step.
20. In the Synchronization User Account for *<Endpoint Server>* menu, enter a DN for the synchronization user account that will be used in communication with external servers, or press Enter to accept the default value, `[cn=Sync User,cn=Root DNs,cn=config]`.
21. Enter a password for the synchronization user account and press Enter.
22. In the Prepare Server *<Source Server>* menu, press Enter to accept the default option `1` for `Yes` to prepare the source server for synchronization.
23. In the Prepare Server *<Endpoint Server>* menu, press Enter to accept the default option `1` for `Yes` to prepare the endpoint server for synchronization.
24. In the Sync Pipe Name menu, enter a name for the Sync Pipe from the source server (AD) to the endpoint server (PingDirectory server), or press Enter to select the default value, `Microsoft_Active_Directory_Source_to_Ping_Identity_Directory_Server_Destination`.
25. In the Pre-configured Sync Class Configuration for Active Directory Sync Source menu, follow the prompts to create the basic sync classes and attribute mappings needed to synchronize user accounts, user passwords, and groups to and from AD.

    1. To synchronize user **`Create`**, **`Modify`**, and **`Delete`** operations from AD, follow the prompts.
    2. Enter the object class for user entries at the endpoint, or press Enter to accept the default value, `inetOrgPerson`.
    3. To configure which password policy state attributes to synchronize, follow the prompts.

       For more information on the AD to PingDirectory password policy state attribute mappings, see Synchronizing Active Directory with PingDirectory.

> **Note**
>
> For the referenced password policy state attributes, AD is treated as the authoritative source, because synchronization from PingDirectory to AD is not supported for those attributes.

> **Important**
>
> The password policy in PingDirectory must match the password in AD. For example, the `lockout-failure-count` in PingDirectory must match the account lockout threshold in AD.

4. To create a DN map for users in the sync pipe, enter `yes` and press Enter. To not create a DN map, press Enter to accept the default option, `no`.
5. Review the list of basic mappings set up for synchronized user entries and follow the prompts to add any additional attribute mappings. Press Enter to continue.
6. To synchronize group `Create`, `Modify`, and `Delete` operations from AD, follow the prompts.

26. In the Sync Pipe Sync Class Definitions menu, either press Enter to accept the `Microsoft Active Directory Source Users Sync Class`, or enter a value and press Enter to create a new sync class name.
27. Review the Configuration Summary and press Enter to write the configuration file as displayed.

    Result:

    The server writes the configuration file to a `dsconfig` batch file.
28. To apply the configuration changes to the local PingDataSync server, press Enter. (If you don't want to apply the changes, enter `no` and press Enter.)

Synchronizing Active Directory with PingDirectory

When you use the `sync-pipe` tool to configure AD or AD-LDS as a one-way sync with PingDirectory, three AD password policy state attributes require user input to map to a corresponding PingDirectory attribute.

The following table shows these three attributes, the intermediate attribute that is formed between PingDirectory and AD (or AD-LDS), and the extended operation type used by the PingDirectory server to apply the change.

AD and AD-LDS attribute	Intermediate attribute	PingDirectory attribute	PasswordPolicyStateOperation opType
`lockoutTime`	`pwdAccountLockedTimeFromAD`	`pwdAccountLockedTime`	`OP_TYPE_SET_AUTH_FAILURE_TIMES`
`userAccountControl & (ACCOUNTDISABLE == 2)` **Note** In AD-LDS, the corresponding attribute is `msDS-User-Account-Disabled`.	`ds-pwp-account-disabled-from-ad`	`ds-pwp-account-disabled`	`OP_TYPE_SET_ACCOUNT_DISABLED_STATE`

AD and AD-LDS attribute	Intermediate attribute	PingDirectory attribute	PasswordPolicyStateOperation opType
`pwdLastSet`	`pwdChangedTimeFromAD`	`pwdChangedTime`	`OP_TYPE_SET_PW_CHANGED_TIME`

> **Note**
>
> Intermediate attributes only exist in memory on the PingDataSync server so that they can be consumed for attribute mappings. They don't exist on either the AD server or on the PingDirectory server.

`modifies-as-creates`

By default, the `modifies-as-creates` sync class property is set to `false`.

Active Directory attributes might not be synchronized as expected when the following is true:

- **You are using the `realtime-sync` tool.**
- **The `modifies-as-creates` sync class property is set to `true`.**
- **A modification is detected on the source endpoint to a missing entry on the destination endpoint.**
- **The modification is to attributes other than the three AD password policy state attributes previously mentioned.**

To avoid this known issue, you can run the `resync` tool instead of the `realtime-sync` tool. Using `resync` will correctly copy all attributes. For more information, see The `resync` command.

dsconfig">

Mapping AD password policy state attributes to PingDirectory using `dsconfig`

If you have a working sync configuration between PingDirectory and Active Directory (AD) and want to manage password policy state attributes, use the `dsconfig` command to map these attributes instead of re-running the `sync` command.

About this task

To map AD password policy state attributes to PingDirectory attributes:

Steps

- **Run `dsconfig` with the `create-attribute-mapping` option.**

  Example:

  The following example maps the AD attribute `lockoutTime` to the PingDirectory attribute `pwdAccountLockedTime`.

```
dsconfig create-attribute-mapping
        --map-name  "<Microsoft Active Directory Users Attribute Map>"
        --mapping-name pwdAccountLockedTime
        --type direct
        --set from-attribute:pwdAccountLockedTimeFromAD
```

Example:

The following example maps the AD attribute `userAccountControl & (ACCOUNTDISABLE == 2)` to the PingDirectory attribute `ds-pwp-account-disabled`.

```
dsconfig create-attribute-mapping
        --map-name  "<Microsoft Active Directory Users Attribute Map>"
        --mapping-name ds-pwp-account-disabled
        --type direct
        --set from-attribute:ds-pwp-account-disabled-from-ad
```

Example:

The following example maps the AD attribute `pwdLastSet` to the PingDirectory attribute `pwdChangedTime`.

```
dsconfig create-attribute-mapping
        --map-name  "<Microsoft Active Directory Users Attribute Map>"
        --mapping-name pwdChangedTime
        --type direct
        --set from-attribute:pwdChangedTimeFromAD
```

> **Note**
>
> Learn more about synchronizing these AD attributes with PingDirectory in Synchronizing Active Directory with PingDirectory.

Active Directory sync user account

The Sync User created for Active Directory (AD) is added to the `cn=Administrators` branch and is given most of a root user's permissions. If this account cannot be secured and there is a need to configure the permissions required by the Sync User, the following are required to perform synchronization tasks.

As a Sync Source, these permissions are needed:

- List contents
- Read all properties
- Read permissions

Deleted items are a special case. For the PingDataSync server to see deleted entries, the user account must have sufficient access to `cn=Deleted Objects,<domain name>`. Giving access to that distinguished name (DN) requires using the `dsacls` tool, such as:

```
# Take ownership may be required to make the needed changes.
dsacls "CN=Deleted Objects,DC=example,DC=com" /takeOwnership
```

```
# Give the Sync User generic read permission to the domain.
dsacls "CN=Deleted Objects,DC=example,DC=com" /G "example\SyncUser":GR
```

```
# List the permission for the domain.
dsacls "CN=Deleted Objects,DC=example,DC=com"
```

To revoke all permissions from the Sync User, run the following `dsacls` command:

```
dsacls "CN=Deleted Objects,DC=example,DC=com" /R "example\SyncUser"
```

If Active Directory is used as a destination for synchronization, the Sync User account should not be changed.

Preparing external servers

About this task

Perform the following steps to prepare external servers: NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. After configuring the source and destination endpoints, PingDataSync prompts to "prepare" each external server. The process requires trusting the certificate presented to the server, and then testing the connection. If this step is not performed, the process can be completed after configuring the Sync Pipes using the `prepare-endpoint-server` command.
2. Configuring this server for synchronization requires manager access. Enter the distinguished name (DN) and password of an account capable of managing the external directory server.
3. Enter the maximum age of change log entries. The value is formatted as `[number][time-unit]`, where the time unit format resembles ("8h" for eight hours, "3d" for three days, "1w" for one week). Setting this value caps how long the PingDataSync server can be offline. A smaller value limits how many changes are stored and is necessary to limit excessive changelog growth in high-modification environments.
4. To prepare another server in the topology, follow the prompts. The previously entered manager credentials can be reused to access additional servers. Repeat the process for each server configured in the system.

Configuring sync pipes and sync classes

About this task

Perform the following steps to configure Sync Pipes and Sync Classes:

Steps

1. On the Sync Pipe Name menu, type a unique name to identify the Sync Pipe, or accept the default.
2. On the Pre-Configured Sync Class Configuration for Active Directory Sync Source menu, enter `yes` to synchronize user CREATE operations, and enter the object class for the user entries at the destination server, or accept the default (user). To synchronize user MODIFY and DELETE operations from Active Directory (AD), enter `yes`.

3. To synchronize passwords from Active Directory, press Enter to accept the default (yes). If synchronizing passwords from Active Directory, install the Ping Identity Password Sync Agent component on each domain controller.

4. To create a distinguished name (DN) map for the user entries in the Sync Pipe, enter the base DN for the user entries at the Microsoft Active Directory Sync Source, then enter the base DN for the user entries at the PingDataSync Destination.

   A list of basic attribute mappings from the Microsoft Active Directory Source to the PingDirectory Server destination is displayed. More complex attribute mappings involving constructed or DN attribute mappings must be configured with the `dsconfig` command. The following is a sample mapping.

   ```
   Below is a list of the basic mappings that have been set up for user
   entries synchronized from Microsoft Active Directory ->  {pingdir}
   Server. You can add to or modify this list with any direct attribute
   mappings. To set up more complex mappings (such as constructed or DN
   attribute mappings), use the 'dsconfig' tool.
   1) cn -> cn
   2) sn -> sn
   3) givenName -> givenName
   4) description -> description
   5) sAMAccountName -> uid
   6) unicodePwd -> userPassword
   ```

5. Enter the option to add a new attribute mapping. Enter the source attribute, and then enter the destination attribute. The following example maps the `telephoneNumber` attribute (Active Directory) to the `otherTelephone` attribute (PingDirectory Server).

   ```
   Select an attribute mapping to remove, or choose 'n' to add a new one
   [Press ENTER to continue]: n
   Enter the name of the source attribute: telephoneNumber
   Enter the name of the destination attribute: otherTelephone
   ```

6. If synchronizing group CREATE, MODIFY, and DELETE operations from Active Directory, enter `yes`.

7. Review the basic user group mappings.

8. On the Sync Pipe Sync Class Definitions menu, enter another name for a new Sync Class if required. Repeat steps 2–6 to define this new Sync Class. If no additional Sync Class definitions are required, press Enter to continue.

9. Review the Sync Pipe Configuration Summary, and accept the default ("write configuration"), which records the commands in a batch file (`sync-pipe-cfg.txt`). The batch file can be used to set up other topologies. The following summary shows two Sync Pipes and their associated Sync Classes.

```
>>>> Configuration Summary
  Sync Pipe: AD to  {pingdir}  Server
    Source: Microsoft Active Directory
      Type: Microsoft Active Directory
      Access Account: cn=Sync
User,cn=Users,DC=adsync,DC=PingIdentity,DC=com
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Servers: 10.5.1.149:636
    Destination:  {pingdir}  Server
      Type:  {pingdir}  Server
      Access Account: cn=Sync User,cn=Root DNs,cn=config
      Base DN: dc=example,dc=com
      Servers: localhost:389
    Sync Classes:
      Microsoft Active Directory Users Sync Class
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Filters: (objectClass=user)
      DN Map: **,CN=Users,DC=adsync,DC=PingIdentity,DC=com ->{1},ou=users,
      dc=example,dc=com
      Synchronized Attributes: Custom set of mappings are defined
      Operations: Creates,Deletes,Modifies
  Sync Pipe:  {pingdir}  Server to AD
    Source:  {pingdir}  Server
      Type:  {pingdir}  Server
      Access Account: cn=Sync User,cn=Root DNs,cn=config
      Base DN: dc=example,dc=com
      Servers: localhost:389
    Destination: Microsoft Active Directory
      Type: Microsoft Active Directory
      Access Account: cn=Sync
User,cn=Users,DC=adsync,DC=PingIdentity,DC=com
      Base DN: DC=adsync,DC=PingIdentity,DC=com
      Servers: 10.5.1.149:636
    Sync Classes:
        {pingdir}  Server Users Sync Class
      Base DN: dc=example,dc=com
      Filters: (objectClass=inetOrgPerson)
      DN Map: **,ou=users,dc=example,dc=com ->{1},CN=Users,DC=adsync,
      DC=PingIdentity,DC=com
      Synchronized Attributes: Custom set of mappings are defined
      Operations: Creates,Deletes,Modifies
```

10. To apply the configuration to the local PingDataSync server instance, type `yes`. The configuration is recorded at `<server-root>/logs/tools/createsync-pipe-config.log`.

Configuring password encryption

You must follow this procedure when synchronizing passwords from a PingDirectory server to Active Directory (AD), or when synchronizing clear text passwords.

About this task

These steps aren't required for the following scenarios:

- Synchronizing from AD to a PingDirectory server
- Excluding password synchronization

Steps

1. On the PingDirectory server that will receive the password modifications, enable the Change Log Password Encryption component. The component intercepts password modifications, encrypts the password and adds an encrypted attribute, `ds-changelog- encrypted-password`, to the change log entry. The encryption key can be copied from the output if displayed, or accessed from the `<serverroot>/bin/sync-pipe-cfg.txt` file.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Changelog Password
Encryption" \
  --set enabled:true \
  --set changelog-password-encryption-key:<key>
```

2. On PingDataSync, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

```
$ bin/dsconfig set-global-sync-configuration-prop \
  --set changelog-password-decryption-key:ej5u9e39pqo68
```

Next steps

Test the configuration or populate data in the destination servers using the bulk comparison capability of the resync tool. Then, use the `realtime-sync` tool to start synchronizing the data. If synchronizing passwords, install the Password Sync Agent (PSA) on all of the domain controllers in the topology.

> **Note**
>
> To synchronize passwords from PingDirectory to AD, you must use the **`realtime-sync`** tool. The **`resync`** tool isn't supported for this operation.

Password Sync Agent

When synchronizing passwords with Active Directory (AD) systems, PingDataSync requires that the Ping Identity Password Sync Agent (PSA) be installed on all domain controllers in the synchronization topology. This component provides real-time outbound password synchronization from Microsoft Active Directory to any supported Sync Destinations.

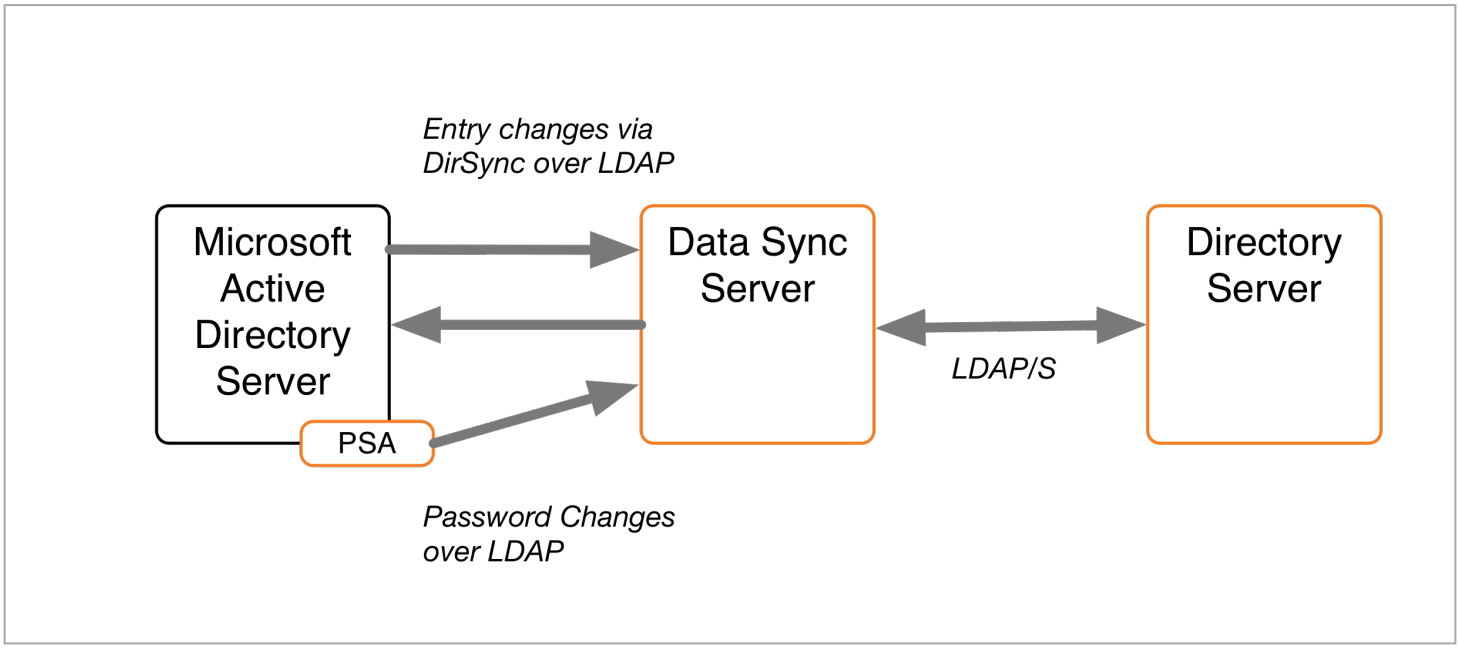
> **Note**
>
> The Password Sync Agent can't be pointed at multiple domain clusters.

The PSA component provides password synchronization between directories that support differing password storage schemes. The PSA immediately hashes the password with a 160-bit salted secure hash algorithm and erases the memory where the clear-text password was stored. The component only transmits data over a secure (SSL) connection, and follows Microsoft's security guidelines when handling clear-text passwords. The PSA also uses Microsoft Windows password filters, which are part of the local security authority (LSA) process. The password filters enable implementing password policy validation and change notification mechanisms. For more information, see Microsoft's product documentation.

The default password hashing algorithm is SSHA256. To change the algorithm, create a registry key in the Windows registry under `HKLM\SOFTWARE\UnboundID\PasswordSync` called `PASSWORD_HASHING_ALGORITHM`. The options are SSHA, SSHA1, SSHA256, SSHA384, and SSHA512.

Note

For outbound password synchronization from a PingDirectory server to AD, enable the Password Encryption component. See Configuring password encryption for more information.



The PSA supports failover between servers. It caches the hashed password changes in a local database until it can be guaranteed that all PingDataSync servers in the topology have received them. The failover features enable any or all of the PingDataSync servers to be taken offline without losing any password changes from Active Directory.

Important

If the Password Sync Agent is down for any length of time and misses a password change, the change won't be synced on recovery without either a new password change for the entry or the use of pass-through authentication.

The PSA is safe to leave running on a domain controller indefinitely. To stop synchronizing passwords, remove the `userPassword` attribute mapping in PingDataSync, or stop the server. The PSA will not allow its local cache of password changes to grow out of control; it automatically cleans out records from its local database as soon as they have been acknowledged. It also purges changes that have been in the database for more than a week.

Before installing the PSA, consider the following:

- The PSA pre-encodes all passwords with a one-way salted SHA-256 hash before uploading them to PingDataSync. Password changes from Active Directory can only be synchronized to destinations that support setting pre-encoded passwords. Currently, pre-encoded password synchronization is limited to PingDirectory, DSEE, Oracle OUD, and OpenDJ. Active Directory explicitly does not allow for the synchronization of pre-encoded passwords.
- Syncing a pre-encoded password to PingDirectory skips password validation.
- Unlike the changelog password encryption plugin, the PSA never has access to a decryptable version of the password, so it cannot sync it to any source that doesn't support pre-encoded passwords, such as Active Directory.
- The Active Directory Sync Destination drops any passwords it can't decrypt without logging anything about the dropped change.
- Make sure that the Active Directory domain controller has SSL enabled and running.
- Make sure the PingDataSync servers are configured to accept SSL connections when communicating with the Active Directory host.
- At least one Active Directory Sync Source (ADSyncSource) needs to be configured on PingDataSync and should point to the domain controller(s) on which the PSA will reside.
- You must add the certificate of the Active Directory Domain Controller (ADDC) to the certificate trust store of the PingDataSync server. To do this, export the certificate from the ADDC and then use the `manage-certificates trust-server-certificate` tool to import it into the trust store of the PingDataSync server.
- At the time of installation, all PingDataSync servers in the sync topology must be online and available.
- The PSA component is for outbound-only password synchronization from the Active Directory Systems. It is not necessary if performing a one-way password synchronization from the PingDirectory server to the Active Directory server.

Installing the Password Sync Agent

About this task

The PingDirectory server distributes the PSA in zip file format with each PingDataSync package. The initial installation of the PSA requires a system restart. NOTE: The Password Sync Agent cannot be pointed at multiple domain clusters.

Steps

1. On the domain controller, double-click the `setup.exe` file to start the installation.
2. Select a folder for the PSA binaries, local database, and log files.
3. Enter the host names (or IP addresses) and SSL ports of the PingDataSyncs, such as `sync.host.com:636`. Do not add any prefixes to the host names.
4. Enter the Directory Manager distinguished name (DN) and password. This creates an ADSync user on PingDataSync.
5. Enter a password (secret key) for the ADSync user that will be used by the PSA when connecting to the PingDataSync instances.

6. Click Next to begin the installation. All of the specified PingDataSync servers are contacted, and any failures will roll back the installation. If everything succeeds, a message displays indicating that a restart is required. The PSA will start when the computer restarts, and the LSA process is loaded into memory. The LSA process cannot be restarted at runtime.

7. If synchronizing pre-encoded passwords from AD to a Ping Identity system, allow pre-encoded passwords in the default password policy.

```
$ bin/dsconfig set-password-policy-prop \
--policy-name "Default Password Policy" \
--set allow-pre-encoded-passwords:true
```

Upgrading the Password Sync Agent

Before you begin

You must know which version of the PSA you're running. To check the version number, go to Control Panel → Programs → Programs and Features and find the row containing the Password Sync Agent item. The version number is displayed on that row.

> **Important**
>
> If you are running a version earlier than 4.7, you must uninstall the Password Sync Agent before upgrading because the installer has trouble locating the registry values from the older version. If you don't uninstall the older version of the PSA in this scenario, the upgraded PSA fails to start after the update.

About this task

You can upgrade the PSA by following these steps:

Steps

1. Extract the new version of the PSA.

   > **Important**
   >
   > Check the `Readme` file included with the PSA. If the header doesn't indicate a version, download version 4.7 or later before upgrading.

2. Follow the instructions for installing the PSA.

   > **Note**
   >
   > You don't need to restart the computer to complete this step. The core password filter DLL is already running under LSA. The update replaces the implementation binaries, which are encapsulated from the password filter DLL and can be updated dynamically.

Next steps

After you complete the installation, a dialog window might indicate that a restart is necessary due to configuration changes:

- If the logging service has restarted, you can safely ignore this message.

- If the logging service has not restarted, you should restart the computer to ensure that the PSA resumes syncing password changes.

Uninstalling the Password Sync Agent

About this task

You can use any of these options to uninstall the PSA from the AD system.

Steps

- Uninstall the PSA.

  Choose from:

  - Go to Control Panel → Programs → Programs and Features and double-click the Password Sync Agent item.
  - Run `setup.exe` for the installed version of the PSA and select Remove Password Sync Agent.

Result

The implementation DLL gets unloaded, and the database and log files are deleted. Only the binaries remain. The core password filter is still running under the LSA process. It imposes zero overhead on the domain controller because the implementation DLL has been unloaded. To remove the password filter itself (located at `C:\WINDOWS\System32\ubidPassFilt.dll`), restart the computer. After restarting the computer, you can delete the password filter and implementation binaries from the install folder.

> **Note**
>
> You must reboot the computer again before reinstalling the PSA.

Manually configure the Password Sync Agent

Configuration settings for the Password Sync Service are stored in the Windows registry in `HKLM\SOFTWARE\UnboundID\PasswordSync`. Configuration values under this registry key can be modified during runtime. The agent automatically reloads and refreshes its settings from the registry. Verify that the agent is working by checking the current log file, located in `<server-root>\logs\password-sync-current.log`.

Synchronize with Relational Databases

PingDataSync supports high-scale, highly-available data synchronization between the directory servers and relational database management systems (RDBMS). Any database with a Java database connectivity (JDBC) 3.0 or later driver can be used.

Use the server SDK

Synchronizing Lightweight Directory Access Protocol (LDAP) data to or from a relational database requires creating a Java database connectivity (JDBC) Sync Source or Destination extension to act as an interface between PingDataSync and the relational database. The Server SDK provides APIs to develop plugins and third-party extensions to the server using Java or Groovy. The Server SDK's documentation is delivered with the Server SDK build in `.zip` format.

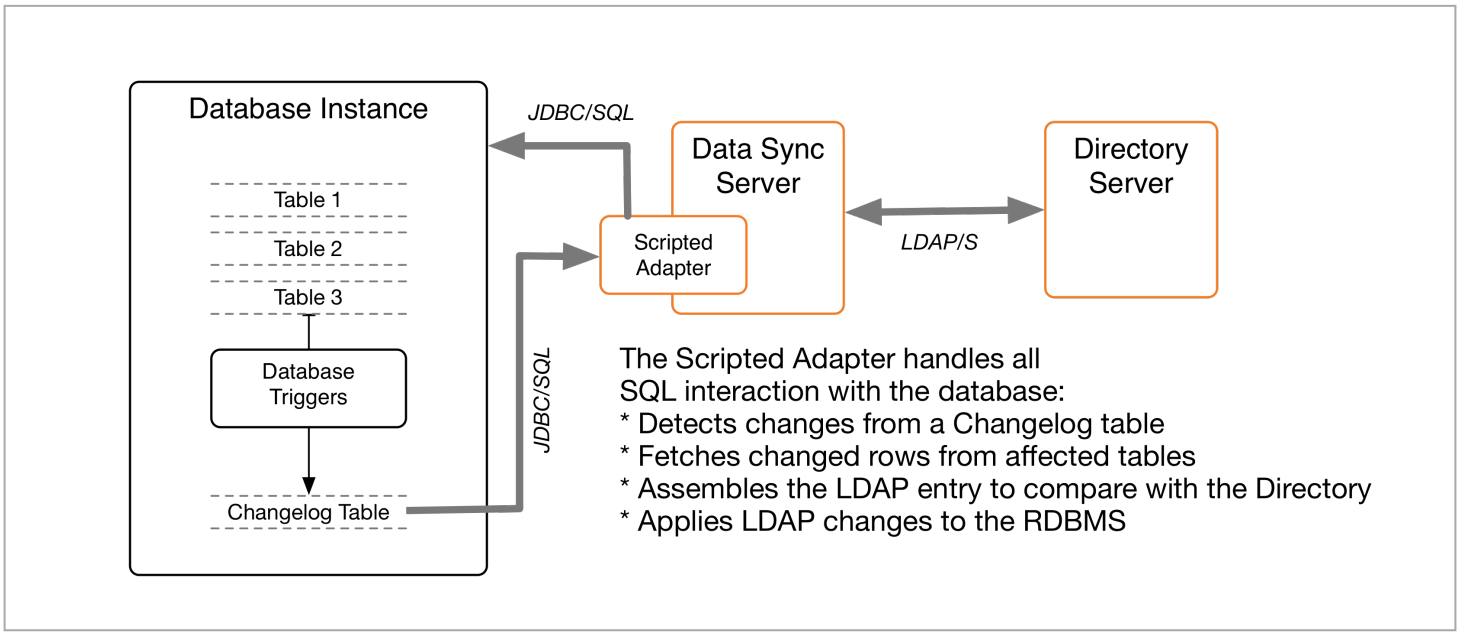
The Server SDK contains two abstract classes that correspond to how the database is used:

```
com.unboundid.directory.sdk.sync.api.JDBCSyncSource

com.unboundid.directory.sdk.sync.api.JDBCSyncDestination
```

The remainder of the SDK contains helper classes and utility functions to facilitate the script implementation. The SDK can use any change tracking mechanism to detect changes in the database. Examples are provided in the `<server-root>/config/jdbc/samples` directory for Oracle Database and Microsoft SQL Server.

PingDataSync uses a scripted adapter layer to convert any database change to an equivalent LDAP entry. The Sync Pipe then processes the data through inclusive (or exclusive) filtering using attribute and DN maps defined in the Sync Classes to update the endpoint servers. For example, a script using Java can be configured by setting the `extension-class` property on a `ThirdPartyJDBCSyncSource` or `ThirdPartyJDBCSyncDestination` configuration object within PingDataSync. The following figure is a sample architecture.



RDBMS synchronization process

PingDataSync synchronizes data between a directory server and a relational database management system (RDBMS) with a Server SDK extension. PingDataSync provides multiple configuration options, such as advanced filtering (fractional and subtree), attribute and distinguished name (DN) mappings, transformations, correlations, and configurable logging.

To support synchronizing changes, the database must be configured with a change tracking mechanism. An approach involving triggers, (one trigger per table) to record all changes to a change log table, is recommended. The database change log table Ping Identity should record the type of change (INSERT, UPDATE, DELETE), the specific table name, the unique identifier for the changed row, the database entry type, the changed columns (from the source table), the modifier's name, and the changetimestamp.

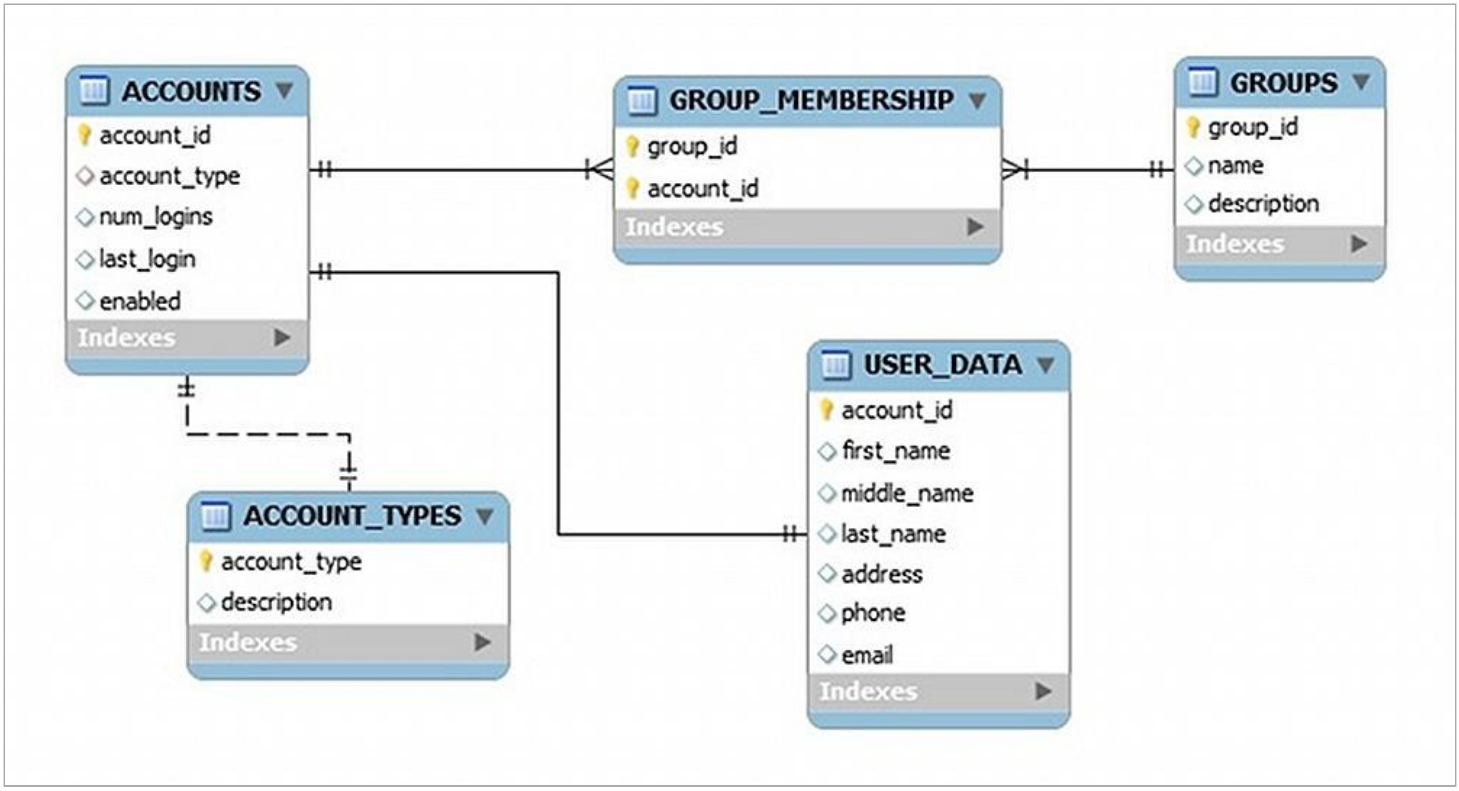
PingDataSync delegates the physical interaction with the database to a user-defined extension, which has full control of the SQL queries. The extension layer provides flexibility in how the mapping semantics between the Lightweight Directory Access Protocol (LDAP) environment and the relational database environment are defined. The connection management, pooling, retry logic, and other boilerplate code are handled internally by PingDataSync.

The RDBMS Synchronization (DBSync) implementation does not support failover between different physical database servers. Most enterprise databases have a built-in failover layer from which PingDataSync can point to a single virtual address and port and still be highly available. A single RDBMS node can scale to multiple directory server endpoints.

DBSync example

PingDataSync provides a DBSync example between two endpoints consisting of a PingDirectory server source and a relational database management system (RDBMS), which will be used in this topic.

The entity-relational diagram for the normalized database schema is available in `<server-root>/config/jdbc/samples/oracle-db/ComplexSchema.jpg`, and is illustrated here:



Five tables are represented with their primary keys in bold. The entity relations and foreign keys are marked by the relationship lines. The illustration shows mapping to a custom object class on the directory server, while the "groups" table maps to a standard Lightweight Directory Access Protocol (LDAP) group entry with `objectclass:groupOfUniqueNames`.

Example directory server entries

The following example assumes that the directory server's schema is configured to handle the mapped attributes. If configuring a database-to-directory Sync Pipe with a newly installed directory server, make sure that the schema has the correct `attributeType` and `objectClass` definitions in place. The definitions can be added in a custom `99-user.ldif` file in the `config/schema` folder of the directory server, if necessary.

The following are the LDAP entries that are used in the synchronization example:

```
dn: accountid=0,ou=People,dc=example,dc=com
objectClass: site-user
firstName: John
lastName: Smith
accountID: 1234
email: jsmith@example.com
phone: +1 556 805 4454
address: 17121 Green Street
numLogins: 4
lastLogin: 20070408182813.196Z
enabled: true

dn: cn=Group 1,ou=Groups,dc=example,dc=com
objectClass: groupOfUniqueNames
description: This is Group 1
uniqueMember: accountID=0,ou=People,dc=example,dc=com
uniqueMember: accountID=1,ou=People,dc=example,dc=com
```

Configure DBSync

About this task

Configuring a DBSync system includes extra tasks to create the extensions and to configure the database. The overall configuration process is provided here:

Steps

1. Download the appropriate Java database connectivity (JDBC) driver to PingDataSync's `/PingDataSync/lib` directory, and restart the server for the driver to load into the runtime.
2. Open the `java.properties` file with a text editor and add the `jdbc.drivers` argument. Save the file. When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file.
3. Run the `dsjavaproperties` command to apply the change. For example, enter the following for `start-sync-server`:

   ```
   start-sync-server.java-args=-d64 -server -Xmx256m -Xms256m -
   XX:+UseConcMarkSweepGC -
   Djdbc.drivers=foo.bah.Driver:wombat.sql.Driver:com.example.OurDriver ...
   etc.
   ```

4. Create one or more JDBC extensions based on the Server SDK. If configuring for bidirectional synchronization, two scripts are needed: one for the JDBC Sync Source and the other for the JDBC Sync Destination. Place the compiled extensions in the `/lib/extensions` directory.
5. Configure the database change log table and triggers (presented later). The vendor's native change tracking mechanism can be used, but a change log table should also be configured. Each table requires one database trigger to detect the changes and loads them into the change log table.
6. Configure the Sync Pipes, Sync Classes, external servers, distinguished name (DN) and attribute maps for one direction.

7. Run the `resync --dry-run` command to test the configuration settings.
8. Run `realtime-sync set-startpoint` to initialize the starting point for synchronization.
9. Run the `resync` command to populate data on the destination endpoint.
10. Start the Sync Pipes using the `realtime-sync start` command.
11. Monitor PingDataSync using the status commands and logs.
12. For bidirectional synchronization, configure another Sync Pipe, and repeat steps 4–8 to test the system.

Create the JDBC extension

The Java database connectivity (JDBC) extension implementation must be written in Java or in the Groovy scripting language. Consult the Server SDK documentation for details on how to build and deploy extensions. The examples in this guide use Java. Java extensions are more strict and will catch programming errors during compile time rather than at runtime. Groovy is more flexible and can accomplish more with less lines of code.

Groovy scripts must reside in the `/lib/groovy-scripted-extensions` directory (Java implementations reside in `/lib/extensions`), which can also contain other plugins built using the Server SDK. If a script declares a package name, it must live under the corresponding folder hierarchy, just like a Java class. For example, to use a script class called `ComplexJDBCSyncSource` whose package is `com.unboundid.examples.oracle`, place it in `/lib/groovy-scripted-extensions/com/unboundid/examples/oracleand` set the `script-class` property on the Sync Source to `com.unboundid.examples.oracle.ComplexJDBCSyncSource`. There are a few reference implementations provided in the `config/jdbc/samples` directory. Use the `manage-extension` tool in the `bin` directory, or `bat` (Windows), to install or update the extension. See the Server SDK extensions section for more information.

When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

> **Note**
>
> Any changes to an existing script require a manual Sync Pipe restart. Any configuration change automatically restarts the affected Sync Pipe.

The default libraries available on the classpath to the script implementation include:

- Groovy
- Lightweight Directory Access Protocol (LDAP) SDK for Java
- JRE

Logging from within a script can be done with the Server SDK's `ServerContext` abstract class. Some of the `ServerContext` methods are not available when the `resync` tool runs, because it runs outside of the PingDataSync process. Any logging during a `resync` operation is saved to the `logs/tools/resync.log` file.

Implement a JDBC sync source

The `JDBCSyncSource` abstract class must be implemented to synchronize data from a relational database. Because PingDataSync is LDAP-centric, this class enables database content to be converted into LDAP entries. For more detailed information on the class, see the Server SDK Javadoc.

When using custom JDBC sources, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK. Depending on the data, implement the following methods:

- `initializeJDBCSyncSource` – Called when a Sync Pipe first starts, or when the `resync` process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncSource` – Called when a Sync Pipe stops, or when the `resync` process stops. Any clean up should be performed here, and all internal resources should be freed.
- `setStartpoint` – Sets the starting point for synchronization by identifying the starting point in the change log. This method should cause all changes previous to the specified start point to be disregarded and only changes after that point to be returned by the `getNextBatchOfChanges` method. There are several different startpoint types (see SetStartpointOptions in the Server SDK), and this implementation is not required to support them all. If the specified startpoint type is unsupported, this method throws an exception (`IllegalArgumentException`). This method can be called from two different contexts: when the `realtime-syncset-startpoint` command is used (the Sync Pipe is required to be stopped) or immediately after a connection is established to the source server.

  > **Note**
  >
  > The `RESUME_AT_SERIALIZABLE` startpoint type must be supported. This method is used when a Sync Pipe first starts and loads its state from disk.

- `getStartpoint` – Gets the current value of the startpoint for change detection.
- `fetchEntry` – Returns a full source entry (in LDAP form) from the database, corresponding to the `DatabaseChangeRecord` object that is passed. The `resync` command also uses this class to retrieve entries.
- `acknowledgeCompletedOps` – Provides a means for PingDataSync to acknowledge to the database which operations have completed processing.

  > **Note**
  >
  > The internal value for the startpoint should only be updated after a synchronization operation is acknowledged in this script (through this method). If not, changes could be missed when PingDataSync is restarted.

- `getNextBatchOfChanges` – Retrieves the next set of changes for processing. The method also provides a generic means to limit the size of the result set.
- `listAllEntries` – Used by the `resync` command to get a listing of all entries.

- `cleanupChangelog` – In general, we recommend implementing a `cleanupChangelog` method, so that PingDataSync can purge old records from the change log table, based on a configurable age.

See the `config/jdbc/samples` directory for example script implementations and the Server SDK Javadoc for more detailed information on each method.

Implement a JDBC sync destination

The `JDBCSyncDestination` abstract class must be implemented to synchronize data into a relational database. The class enables converting LDAP content to database content. The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK, depending on the database configuration.

When using custom JDBC destinations, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties` for the update to the `java.properties` file to take effect.

Implement the following methods in the script:

- `initializeJDBCSyncDestination` – Called when a Sync Pipe starts, or when the `resync` process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncDestination` – Called when a Sync Pipe stops, or when the `resync` process stops. Any clean up should be performed here, and all internal resources should be freed.
- `createEntry` – Creates a full database entry (or row), corresponding to the LDAP entry that is passed in.
- `modifyEntry` – Modifies a database entry, corresponding to the LDAP entry that is passed in.
- `fetchEntry` – Returns a full destination database entry (in LDAP form), corresponding to the source entry that is passed in.
- `deleteEntry` – Deletes a full entry from the database, corresponding to the LDAP entry that is passed in.

For more detailed information on the abstract class, see the Server SDK Javadoc.

Configure the database for synchronization

About this task

Configuring the database for synchronization includes defining:

- A database SyncUser account
- The change tracking mechanism
- The database triggers (one per table) for the application

The following procedure uses the example setup script in `/config/jdbc/samples/oracle-db/OracleSyncSetup.sql.` Items in brackets are user-named labels.

> **Note**
>
> Database change tracking is necessary if synchronizing FROM the database. If synchronizing TO a database, configure the Sync User account and the correct privileges.

Steps

1. Create an Oracle login (`SyncUser`) for PingDataSync, so that it can access the database server. Grant sufficient privileges to the `SyncUser` for any tables to be synchronized, and change the default password.

```
CREATE USER SyncUser IDENTIFIED BY password
DEFAULT TABLESPACE users TEMPORARY TABLESPACE temp;
GRANT "RESOURCE" TO SyncUser;
GRANT "CONNECT" TO SyncUser;
```

2. Create change log tables on the database as follows:

```
CREATE TABLE ubid_changelog (
  --This is the unique number for the change change_number Number NOT NULL
PRIMARY KEY,
  --This is the type of change (insert, update, delete). NOTE: This should
represent
  --the actual type of change that needs to happen on the destination(for
example a
  --database delete might translate to a LDAPmodify, etc.)
    change_type VARCHAR2(10) NOT NULL,
  --This is the name of the table that was changed table_name VARCHAR(50)
NOT NULL,
  --This is the unique identifier for the row that was changed. It is up
to
  --the trigger code to construct this, but it should follow a DN-like
format
  --(e.g. accountID={accountID}) where at least the primary key(s) are
  --present. If multiple primary keys are required, they should be
delimited
  --with a unique string, such as '%%' (e.g. accountID={accountID}%%
  --groupID={groupID})
    identifier VARCHAR2(100) NOT NULL,
  --This is the database entry type. The allowable values for this must be
  --set on the JDBC Sync Source configuration within the Synchronization
  --Server.
    entry_type VARCHAR2(50) NOT NULL,
  --This is a comma-separated list of columns from the source table that
were updated as part of
  --this change.
    changed_columns VARCHAR2(1000) NULL,
  --This is the name of the database user who made the change
    modifiers_name VARCHAR2(50) NOT NULL,
  --This is the timestamp of the change
    change_time TIMESTAMP(3) NOT NULL, CONSTRAINT chk_change_type
    CHECK (change_type IN ('insert','update','delete'))) ORGANIZATION
INDEX;
```

3. Create an Oracle function to get the `SyncUser` name. This is a convenience function for the triggers.

```
CREATE OR REPLACE FUNCTION get_sync_user RETURN VARCHAR2
IS
BEGIN
  RETURN 'SyncUser';
END get_sync_user;
```

4. Create an Oracle sequence object for the change-number column in the change log table.

```
CREATE SEQUENCE ubid_changelog_seq MINVALUE 1 START WITH 1
NOMAXVALUE INCREMENT BY 1 CACHE 100 NOCYCLE;
```

5. Create a database trigger for each table that will participate in synchronization. An example, located in `/config/jdbc/samples/oracle-db/OracleSyncSetup.sql`, shows a trigger for the Accounts table that tracks all changed columns after any INSERT, UPDATE, and DELETE operation. The code generates a list of changed items and then inserts them into the change log table.

Considerations for synchronizing to database destination

When configuring a directory-to-database Sync Pipe, the following are recommended:

Identify the Object Classes

Create a Sync Class per object class, so that they can easily be distinguished and have different mappings and synchronization rules.

For each Sync Class, set the following items in the configuration menus using the `dsconfig` tool.

Set the Include-Filter Property

Make sure the `include-filter` property is set on the Sync Class configuration menu to something that will uniquely identify the source entries, such as `objectClass=customer`.

Create Specific Attribute Mappings

Create an attribute mapping for every Lightweight Directory Access Protocol (LDAP) attribute to be synchronized to a database column, add these to a single attribute map, and set it on the Sync Class. With this configured, the script does not need to know about the schema on the directory side. A constructed attribute mapping that maps a literal value to the `objectClass` attribute can be added to the script to determine the database entry type. For example, `"account" → objectClass` can be added, which would result in the constructed destination LDAP entry always containing an `objectClass` of `"account"`. If needed, a mulit-valued `conditional-value-pattern` property can be used to conditionalize the attribute mapping based on the subtype of the entry or on the value of the attribute.

Create Specific DN Maps (optional)

If necessary, create a distinguished name (DN) map that recognizes the DN's of the source entries and maps them to a desired destination DN. In most cases, the script will use the attributes rather than the DN to figure out which database entry needs to be changed.

Set auto-mapped-source-attribute to "-none-"

Remove the default value of "-all-" from the `auto-mapped-source-attribute` on the Sync Class configuration menu, and replace it with "-none-."

Configure Create-Only Attributes

Any attributes that should be included when created, but never modified (such as `objectclass`) should be specified on the Sync Pipe as a `create-only` attribute. If PingDataSync ever computes a difference in that attribute between the source and destination, it will not try to modify it at the destination. To avoid bidirectional loop-back, set the `ignore-changes-by-[user\|dn]` property on both Sync Sources when configuring for bidirectional synchronization.

Synchronizing DELETE Operations

On the PingDirectory server, configure the `changelog-deleted-entry-include-attribute` property on the changelog backend menu using the `dsconfig` tool. This property allows for the proper synchronization of DELETE operations. For more information, see Configure the PingDirectory server backend for synchronizing deletes.

Attribute-Synchronization-Mode for DBSync

For MODIFY operations, PingDataSync detects any change on the source change log, fetches the source entry, applies mappings, computes the equivalent destination entry, fetches the actual destination entry, and then runs a diff between the two entries to determine the minimal set of changes to synchronize. By default, changes on the destination entry are made only for those attributes that were detected in the original change log entry. This is configurable using the `attribute-synchronization-mode` property, which sets the type of `diff` operation that is performed between the source and destination entries.

If the source endpoint is a database server, set the `attribute-synchronization-mode` property to `all-attributes` on the Sync Class configuration menu. The diff operation will consider all source attributes. Any that have changed will be updated on the destination, even if the change was not originally detected in the change log. This mode is useful when a list of changed columns in the database might not be available. If both endpoints are directory servers, use the default configuration of `modified-attributes-only` to avoid possible replication conflicts.

Handling MODDN Operations

The concept of renaming an entry (modifyDN) does not have a direct equivalent for relational databases. The `JDBCSyncDestination` API does not handle changes of this type. Instead, the `modifyEntry()` method is called as if it is a normal change. The extension can verify if the entry was renamed by looking at the `SyncOperation` that is passed in (`syncOperation.isModifyDN()`). If true, the `fetchedDestEntry` parameter will have the old DN. The new DN can be obtained by calling `syncOperation.getDestinationEntryAfterChange()`.

Configure a directory-to-database sync pipe

The following topics contain procedures that let you configure a one-way Sync Pipe with a PingDirectory Server as the Sync Source and an RDBMS (Oracle) system as the Sync Destination with the `create-sync-pipe-config` tool. You can configure Sync Pipes later using the `dsconfig` command.

Creating the sync pipe

The following procedures configure the Sync Pipe, external servers, and Sync Classes. The examples are based on the Complex JDBC sample in the `config/jdbc/samples/oracle-db` directory. The **`create-sync-pipe-config`** tool can be run with the server offline and the configuration can later be imported.

1. Run the **`create-sync-pipe-config`** tool.

   ```
   $ bin/create-sync-pipe-config
   ```

2. At the `Initial Synchronization Configuration Tool` prompt, press Enter to continue.
3. On the Synchronization Mode menu, select Standard Mode or Notification Mode.
4. On the Synchronization Directory menu, choose one-way or bidirectional synchronization.

Configure the sync source

1. On the Source Endpoint Type menu, enter the number for the sync source corresponding to the type of source external server.
2. Enter a name for the Source Endpoint.
3. Enter the base distinguished name (DN) for the directory server, which is used as the base for Lightweight Directory Access Protocol (LDAP) searches. For example, enter `dc=example,dc=com`, and then press Enter again to return to the menu. If entering more than one base DN, make sure the DNs do not overlap.
4. On the Server Security menu, select the type of communication that PingDataSync will use with the endpoint servers.
5. Enter the host and port of the source endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. The server tests that a connection can be established.
6. Enter the DN of the Sync User account and create a password for this account. The Sync User account enables PingDataSync to access the source endpoint server. By default, the Sync User account is stored as `cn=SyncUser,cn=RootDNs,cn=config`.

Configure the destination endpoint server

1. On the Destination Endpoint Type menu, select the type of datastore on the endpoint server. This example is configuring an Oracle Database.
2. Enter a name for the Destination Endpoint.
3. On the JDBC Endpoint Connection Parameters menu, enter the fully-qualified host name or IP address for the Oracle database server.
4. Enter the listener port for the database server, or press Enter to accept the default (1521).
5. Enter a database name such as `dbsync-test`.
6. The server attempts to locate the JDBC driver in the `lib` directory. If the file is found, a success message is shown.

   ```
   Successfully found and loaded JDBC driver for:
   jdbc:oracle:thin:@//dbsync-w2k8-vm-2:1521/dbsync-test
   ```

If the server cannot find the JDBC driver, add it later, or quit the `create-sync-pipe-config` tool and add the file to the `lib` directory.

7. Add any additional Java database connectivity (JDBC) connection properties for the database server, or press Enter to accept the default (no). Consult the JDBC driver's vendor documentation for supported properties.
8. Enter a name for the database user account with which PingDataSync will communicate, or press Enter to accept the default (SyncUser). Enter the password for the account.
9. On the Standard Setup menu, enter the number for the language (Java or Groovy) that was used to write the server extension.
10. Enter the fully qualified name of the Server SDK extension class that implements the `JDBCSyncDestination` API.

```
Enter the fully qualified name of the Java class that will implement
com.unboundid.directory.sdk.sync.api.JDBCSyncDestination:
com.unboundid.examples.oracle.ComplexJDBCSyncDestination
```

11. Configure any user-defined arguments needed by the server extension. These are defined in the extension itself and the values are specified in the server configuration. If there are user-defined arguments, enter `yes`.
12. To prepare the Source Endpoint server, which tests the connection to the server with the Sync User account, press Enter to accept the default (yes). For the Sync User account, it will return "Denied" as the account has not been written yet to the PingDirectory server at this time.

```
Testing connection to server1.example.com:1389  Done
Testing 'cn=Sync User,cn=Root DNs,cn=config' access     Denied
```

13. To configure the Sync User account on the directory server, press Enter to accept the default (yes). Enter the bind DN (`cn=DirectoryManager`) and the bind DN password of the directory server so that you can configure the `cn=Sync User` account. PingDataSync creates the Sync User account, tests the base DN, and enables the change log.

```
Created 'cn=Sync User,cn=Root DNs,cn=config'
Verifying base DN 'dc=example,dc=com'   Done
Enabling cn=changelog .....
```

14. Enter the maximum age of the change log entries, or press Enter to accept the default.

Configuring the sync pipe and sync classes

The following procedures define a Sync Pipe and two Sync Classes. The first Sync Class is used to match the `accounts` objects. The second Sync Class matches the `group` objects.

1. Continuing from the previous session, enter a name for the Sync Pipe.
2. When prompted to define one or more Sync Classes, enter `yes`.

Configure the accounts Sync Class

1. Enter a name for the Sync Class. For example, type `accounts_sync_class`.

2. If restricting entries to specific subtrees, enter one or more base DNs. If not, press Enter to accept the default (no).
3. To set an LDAP search filter, type `yes` and enter the filter `"(accountid=*)"`. Press Enter again to continue. This property sets the LDAP filters and returns all entries that match the search criteria to be included in the Sync Class. In this example, specify that any entry with an `accountID` attribute be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press Enter to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press Enter to accept the default.

Configure the groups Sync Class

For this example, configure another Sync Class to handle the `groups` object class. The procedures are similar to that of the configuration steps for the `account_sync_class` Sync Class.

1. On the Sync Class menu, enter a name for a new sync class, such as `groups_sync_class`.
2. To restrict entries to specific subtrees, enter one or more base DNs.
3. Set an LDAP search filter. Type `yes` to set up a filter and enter the filter `"(objectClass=groupOfUniqueNames)"`. This property sets the LDAP filters and returns all entries that match the `groupOfUniqueNames` attribute to be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press Enter to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press Enter to accept the default.
6. At the prompt to enter the name of another Sync Class, press Enter to continue.
7. On the Default Sync Class Operations menu, press Enter to accept the default. The Default Sync Class determines how all entries that do not match any other Sync Class are handled.
8. Review the configuration, and press Enter to write the configuration to the server.

Use the `dsconfig` command to make changes to this configuration. Refer to Configuring PingDataSync for configuration options and details.

Considerations for synchronizing from a database source

When synchronizing from a database to a directory or relational database management system (RDBMS) server, the following are recommended:

Identify Database Entry Types

Identify the database entry types that will be synchronized, and:

- Set the `database-entry-type` property on the Java database connectivity (JDBC) Sync Source (this is required), and make sure the entry types are what the triggers are inserting into the change tracking mechanism.
- Create a Sync Class per entry type, and set different mappings and rules for each one.

For each Sync Class, do the following:

- Make sure the `include-filter` property is set to match the entry type.
- Create a specific attribute mapping for every database column to be synchronized to an Lightweight Directory Access Protocol (LDAP) attribute and set it on the Sync Class. If this is done, the script will not have to know about the schema on the directory side.
- Create a distinguished name (DN) map that recognizes the DNs generated by the script and maps them to the correct location at the destination.
- Remove the default value of "-all-" from the `auto-mapped-source-attribute` property on the Sync Class, and replace it with the value `objectClass`. The object class for the fetched source entry is determined by the scripted layer. Values from the database should not be automatically mapped to an attribute with the same name, except the `objectclass` attribute, which should map directly for CREATE operations. If this is not done, an error is generated.
- Change the destination-correlation-attributes property to contain the attributes that uniquely represent the database entries on the directory server destination.

Avoid Bidirectional Loopback

Set the `ignore-changes-by-[user\|dn]` property on both Sync Sources when configuring for bidirectional synchronization, to make sure that changes are not looped back by PingDataSync.

See Using the create-sync-pipe tool to configure synchronization for details about creating the Sync Pipe.

Synchronize a specific list of database elements

About this task

The `resync` command enables synchronizing a specific set of database keys that are read from a Java database connectivity (JDBC) Sync Source file using the `--sourceInputFile` option. The contents of the file are passed line-by-line into the `listAllEntries()` method of the `JDBCSyncSource` extension, which is used for the Sync Pipe. The method processes the input and returns `DatabaseChangeRecord` instances based on the input from the file.

Perform the following steps to synchronize a specific list of database elements using the `resync` command:

Steps

1. Create a file of JDBC Sync Source elements. There is no set format for the file, but it typically contains a list of primary keys or SQL queries. For example, create a file containing a list of primary keys and save it as `sourceSQL.txt`.

   ```
   user.0
   user.1
   user.2
   user.3
   ```

2. Run the `resync` command with the `--sourceInputFile` option to run on individual primary keys in the file.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--sourceInputFile sourceSQL.txt
```

3. If searching for a specific type of database entry, use the `--entryType` option that matches one of the configured entry types in the JDBCSyncSource.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--entryType account \
--sourceInputFile sourceSQL.txt
```

Synchronize with Apache Kafka

Apache Kafka is an open-source streaming platform that communicates state changes in a distributed environment. Changes to a datastore are sent to a Kafka topic, which lets customers update other datastores that contain the same information. Although Kafka persists, orders, and transmits changes, it neither detects changes nor applies them to other datastores.

PingDataSync supports Kafka as a sync destination with a Ping Identity sync source, such as a PingDirectory server. In this scenario, the Kafka sync destination publishes changes in the PingDirectory server to a Kafka topic, and displays the entry in JSON format both before and after each change. This level of indirection enables other systems and services to react to changes in the PingDirectory server by consuming messages from the topic.

Endpoints that use the Server SDK do not require custom sync destinations.

Restrictions

The following restrictions affect the manner in which a Kafka sync destination is used:

- The sync source must be a Ping Identity sync source.
- The `changelog` backend must be enabled on all instances of the PingDirectory server.
- To ensure the availability of an entry's attributes from before and after a change, the configuration property `changelog-include-key-attribute` must include `'*'`.
- The Sync Pipe must be configured in Notification mode (`synchronization-mode:notification`) because a Kafka sync destination cannot retrieve the current version of a destination entry.

Configure a Kafka sync destination

Use the `dsconfig` command or the admin console to configure PingDataSync to synchronize changes to an Apache Kafka environment.

PingDataSync supports synchronization of single and multivalued attributes to Kafka. You can reuse existing Ping Identity sync sources that were created for other Sync Pipes.

> **Tip**
>
> To view an example configuration, see the file located at `<server-root>/config/sample-dsconfig-batch-files/reference-sync-pingdirectory-to-kafka.dsconfig`.
> To configure Kerberos authentication for a Kafka sync destination, supply the `producer-property` attribute with the appropriate values according to the Apache Kafka documentation.

The following objects are required to configure a Kafka sync destination:

- Kafka cluster external server – Defines the procedure for connecting to a Kafka cluster. The Kafka cluster external server can be referenced from multiple Kafka sync destination configuration objects. The only required property is `bootstrap-server`, which identifies some of the Kafka brokers in the environment.

  When `use-ssl` is set to `true`, the following configuration changes are made:

  - A `trust-manager-provider` is configured to validate the Kafka broker's SSL certificate.
  - A `key-manager-provider` is configured to let the Kafka broker authenticate the PingDataSync Kafka producer.

- Kafka sync destination – References the Kafka cluster external server. The Kafka sync destination must specify the name of the topic to use for publishing messages.

  To adjust Kafka messages beyond the mapping, attribute filtering, and other configuration changes that PingDataSync makes, reference one or more of the `KafkaSyncDestinationPlugin` extension points that are implemented by using the Server SDK.

Run the `prepare-endpoint-server` command for the PingDirectory sync source.

Obscuring sensitive producer property values

About this task

When configuring a PingDataSync Kafka producer, you might add producer properties that contain sensitive values such as keys or passwords. To prevent storing these sensitive values in plain text, you can use the `sensitive-kafka-producer-property` configuration property.

You create a `sensitive-kafka-producer-property` using the following required arguments:

`--property-name`

Specifies the name of the sensitive Kafka producer property.

`--set sensitive-producer-key:<key>`

Specifies the name of the valid property key that contains a sensitive value.

`--set sensitive-producer-value:<value>`

Specifies the sensitive value associated with the producer key.

Steps

- Create one or more sensitive Kafka producer properties using `dsconfig create-sensitive-kafka-producer-property`.

  Example:

```
$ bin/dsconfig create-sensitive-kafka-producer-property \
  --property-name saslConfig \
  --set "sensitive-producer-key:sasl.jaas.config" \
  --set "sensitive-producer-value:org.apache.kafka.common.security.scram.ScramLoginModule" \
    required username="username" password="password";
```

Result:

Perform an `ldapsearch` for the sensitive property:

```
ldapsearch --baseDN "cn=saslConfig,cn=Sensitive Kafka Producer Property,cn=config" "(objectclass=*)"
```

The sensitive value is now obscured.

```
dn: cn=saslConfig,cn=Sensitive Kafka Producer Property,cn=config
objectClass: top
objectClass: ds-cfg-sensitive-kafka-producer-property
cn: saslConfig
ds-cfg-sensitive-producer-key: sasl.jaas.config
ds-cfg-sensitive-producer-value: AADu9yRP8DyrLndvqqDzeQEK9aqqLvDBZZhgHAZbh+
+KgovN+kUthhyn9+1o9+AqExDmigO14YQnwakqOpTAB4LnbsvwBJos6PZzYlWMNjFNXsDtOUeBsFhVi/
nErPJT+cmQijC5P1EUsKWPvjDVauBe
```

> **Note**
>
> The `config-audit.log` file that contains the **`dsconfig`** change you made to create the sensitive property also obscures the value.

- (Optional) Delete one or more sensitive Kafka producer properties using **`dsconfig delete-sensitive-kafka-producer-property`**.

  Example:

```
$ bin/dsconfig delete-sensitive-kafka-producer-property \
--property-name saslConfig
```

SSL configuration

The following table identifies the `trust-manager-provider` and `key-manager-provider` properties of the Kafka cluster external server configuration object, as well as the Kafka configuration properties to which they map.

Configuration Object Type	Configuration Property	Kafka Configuration Property
File-based Trust Manager Provider	`trust-store-file`	`ssl.truststore.location`

Configuration Object Type	Configuration Property	Kafka Configuration Property
File-based Trust Manager Provider	`trust-store-pin`, `trust-store-pin-property`, `trust-store-pin-environment-variable`, or `trust-store-pin-file`	`ssl.truststore.password`
File-based Key Manager Provider	`key-store-file`	`ssl.keystore.location`
File-based Key Manager Provider	`key-store-pin`, `key-store-pin-property`, `key-store-pin-environment-variable`, or `key-store-pin-file`	`ssl.keystore.password`
File-based Key Manager Provider	`private-key-pin`, `private-key-pin-property`, `private-key-pin-environment-variable`, or `private-key-pin-file`	`ssl.key.password`

Message format

The distinguished name (DN) of a changed entry represents the default key for published messages. This value can be overridden in either of the following ways:

- With the `message-key-attribute` property of the Kafka sync destination configuration object
- With a `KafkaSyncDestinationPlugin` extension point

The value of the message is a JavaScript Object Notation (JSON) object that includes the following fields:

- `type` – Type of change, such as `ADD`, `MODIFY`, `DELETE`, or `RESYNC`.
- `dn` – DN of the changed entry.
- `changeID` – Unique identifier for the change.
- `modifiedAttributes` – List of modified attributes. This field is available only when the type is `MODIFY`.
- `current` – Entry after the change in JSON format. This field is unavailable when the type is `DELETE`.

  The JSON format of a `current` entry is compatible with the PingDirectory REST API.
- `previous` – Entry before the change in JSON format. This field is unavailable if the type is `RESYNC` or `CREATE`.

  The JSON format of a `previous` entry is compatible with the PingDirectory REST API.

Example ADD

The following code provides an example of an addition:

```
{
  "type": "ADD",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=1",
  "current": {
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "telephoneNumber": [
      "+1 123 123 1234"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Example MODIFY

The following code provides an example of a modification:

```
{
  "type": "MODIFY",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=2",
  "modifiedAttributes": [
    "telephoneNumber"
  ],
  "previous": {
    "telephoneNumber": [
      "+1 123 123 1234"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  },
  "current": {
    "telephoneNumber": [
      "+1 321 321 3210"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Example DELETE

The following code provides an example of a deletion:

```
{
  "type": "DELETE",
  "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
  "changeID": "changeNumber=3",
  "previous": {
    "telephoneNumber": [
      "+1 321 321 3210"
    ],
    "objectClass": [
      "top",
      "person",
      "organizationalPerson",
      "iNetOrgPerson"
    ],
    "sn": [
      "Smith"
    ],
    "cn": [
      "John Smith"
    ],
    "uid": [
      "jsmith"
    ]
  }
}
```

Message customization

After PingDataSync maps the attributes and filters the results, any entries that are changed will use the fields of a Kafka message. To restrict the information that is published to a topic, exclude the unwanted attributes from mapping, or include only the attributes that you want to publish.

By using the `KafkaSyncDestinationPlugin` extension point within the Server SDK, you can fully change the message key or value. For more information, including examples, see the documentation that is included with the Server SDK packaging.

Synchronize through PingDirectoryProxy servers

Because most data centers deploy directory servers in a proxied environment, PingDataSync can also synchronize data through a proxy server in both load-balanced and entry-balancing deployments.

> **Important**
>
> PingDirectoryProxy servers are the only supported endpoints.

The following topics detail a Sync-through-Proxy deployment and provide background information on how it works. Before setting up PingDataSync, review the PingDirectoryProxy Server Administration Guide.

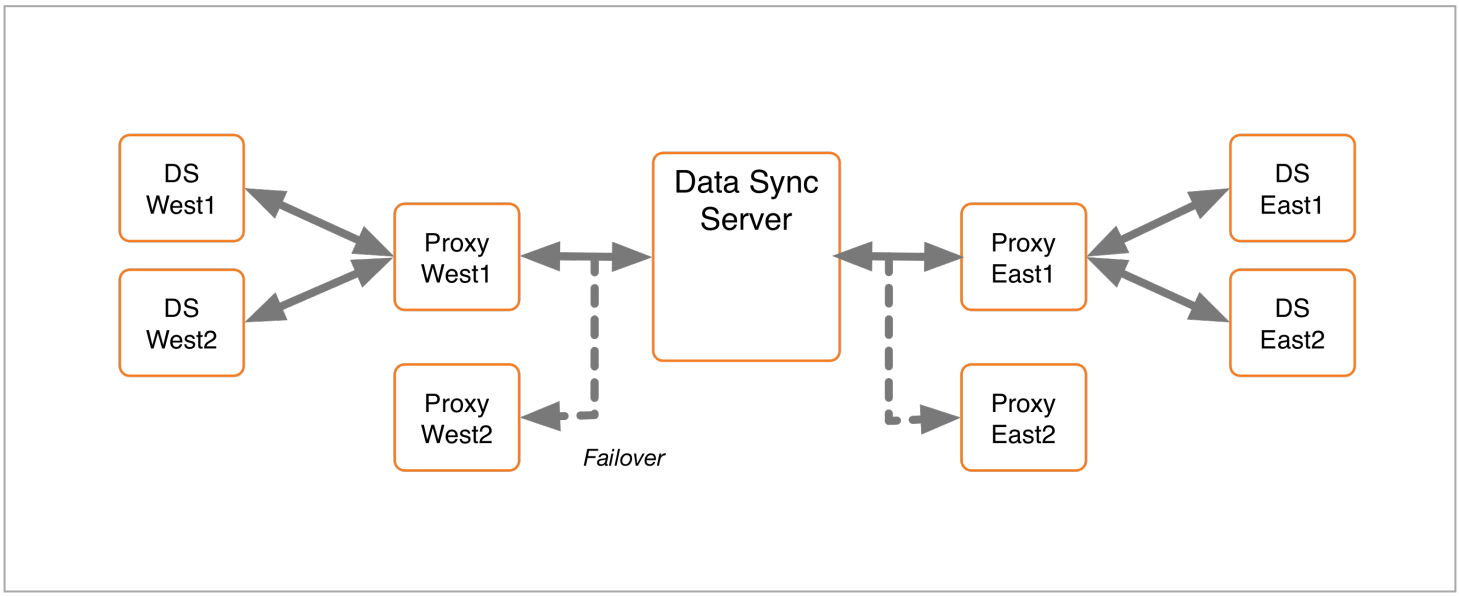
Synchronization through a PingDirectoryProxy server overview

To handle data synchronization through a PingDirectoryProxy server, PingDirectory servers have a `cn=changelog` state management system that supports a token-based API.

In a standard, non-proxied configuration, PingDataSync polls the source server for changes, determines if a change is necessary, and fetches the full entry from the source. Then, it finds the corresponding entry in the destination endpoint using correlation rules and applies the minimal set of changes. The server fetches and compares the full entries to make sure it does not synchronize any stale data from the change log.

In a proxied environment, PingDataSync passes the request through a proxy server to the backend set of directory servers. PingDataSync uses the highest priority proxy server designated in its endpoint server configuration and can use others in the event of a failover.

The following figure illustrates a deployment with two endpoints consisting of a proxy server deployment in front of the backend set of directory servers.



Change log operations

When PingDataSync runs a poll for any changes, it sends a get change log batch extended request to the `cn=changelog` backend. The batch request looks for entries in the change log and asks for the server ID, change number, and replica state for each change.

The PingDirectoryProxy server routes the request to a directory server instance, which then returns a changed entry plus a token identifying the server ID, change number and replica state for each change. The PingDirectoryProxy server then sends a get change log batch response back to PingDataSync with this information. For entry-balancing deployments, the PingDirectoryProxy server must re-package the directory server tokens into its own proxy token to identify the specific data set.

The first time that PingDataSync issues the batch request, it also issues a get server ID request to identify the specific server ID that is processing the extended request. The PingDirectoryProxy server routes the request to the directory server instance, and then returns a server ID in the response. With the next request, PingDataSync sends a route to server request that specifies the server instance to access again in this batch session. It also issues a server ID request in the event that the particular server is down. This method avoids round-robin server selection and provides more efficient overall change processing.

PingDirectory server and PingDirectoryProxy server tokens

The PingDirectory server maintains a change log database index to determine when to resume sending changes (for ADD, MODIFY, or DELETE operations) in its change log. While a simple stand-alone directory server can track its resume point by the last change number sent, replicated servers or servers deployed in entry balancing environments have a different change number ordering in its change log because updates can come from a variety of sources.

The following figure illustrates two change logs in two replicated directory servers, server A and B. "A" represents the replica identifier for a replicated subtree in Server A, and "B" represents the replica identifier for the same replicated subtree in server B. The replica identifiers with a hyphen ("-") mark any local, non-replicated but different changes. While the two replicas record all of the changes, the two change logs have two different change number orderings because updates come in at different times.

Server A			Server B		
ChangeNumber	ReplicaIdentifier	ReplicationCSN	ChangeNumber	ReplicaIdentifier	ReplicationCSN
1001	A_{ri}	10	2001	B_{ri}	11
1002	-	-	2002	A_{ri}	10
1003	A_{ri}	15	2003	-	-
1004	B_{ri}	11	2004	B_{ri}	12
1005	B_{ri}	12	2005	A_{ri}	15

To track the change log resume position, the PingDirectory server uses a change log database index to identify the latest change number position corresponding to the highest replication CSN number for a given replica. This information is encapsulated in a directory server token and returned in the get change log batch response to the PingDirectoryProxy server. The token has the following format:

```
Directory Server Token: server ID, changeNumber,replicaState
```

For example, if the PingDirectoryProxy server sends a request for any changed entries, and the directory servers return the change number 1003 from server A and change number 2005 from server B, then each directory server token would contain the following information:

```
Directory Server Token A:
  serverID A, changeNumber 1003, replicaState {15(A)}

Directory Server Token B:
  serverID B, changeNumber 2005, replicaState {12(B), 15(A)}
```

Change log tracking in entry balancing deployments

Change log tracking can become more complex because a shared area of data can exist above the entry-balancing base distinguished name (DN) in addition to each backend set having its own set of changes and tokens.

In the following figure, Server A belongs to an entry-balancing set 1, and server B belonging to an entry-balancing set 2. Shared areas that exist above the entry-balancing base DN are assumed to be replicated to all servers. "SA" represents the replica identifier for that shared area on Server A and "SB" represents the replica identifier for the same area on Server B.

Set 1 - Server A			Set 2 - Server B		
ChangeNumber	**ReplicaIdentifier**	**ReplicationCSN**	**ChangeNumber**	**ReplicaIdentifier**	**ReplicationCSN**
1001	SA_{ri}	5	2001	SB_{ri}	10
1002	A_{ri}	10	2002	B_{ri}	20
1003	SB_{ri}	15	2003	SA_{ri}	5

The PingDirectoryProxy server cannot pass a directory server token from the client to the directory server and back again. In an entry-balancing deployment, the PingDirectoryProxy server must maintain its own token mechanism that associates a directory server token (`changeNumber` , `replicaIdentifier` , `replicaState`) to a particular backend set.

```
Proxy Token:
backendSetID 1: ds-token 1 (changeNumber, replicaIdentifier, replicaState)
backendSetID 2: ds-token 2 (changeNumber, replicaIdentifier, replicaState)
```

For example, if the PingDirectoryProxy server returned change 1002 from Server A and change 2002 from Server B, then the Proxy token would contain the following:

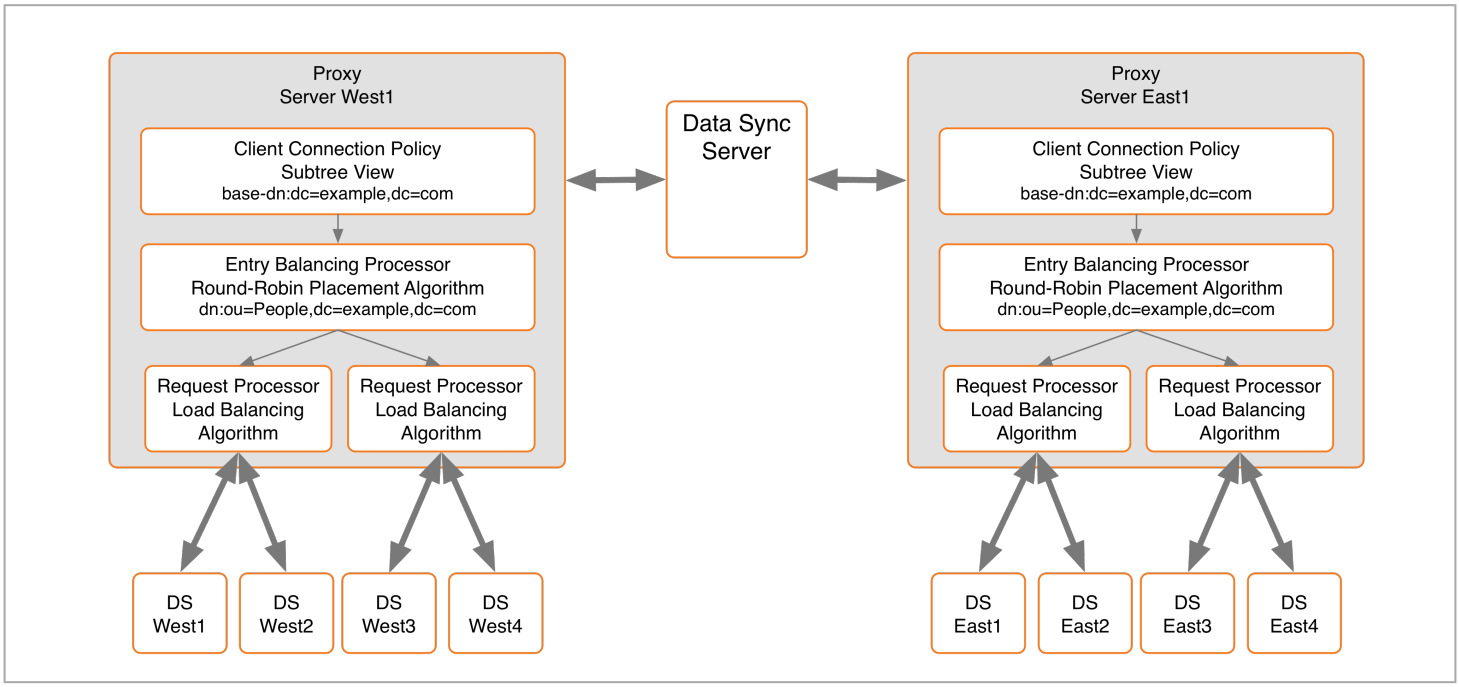
```
Proxy Token:
backendSetID 1: ds-token-1 {serverID A, changeNumber 1002, replicaState (5
(SA), 15(A)}
backendSetID 2: ds-token-2 {serverID B, changeNumber 2002, replicaState (10
(SB), 20(B)}
```

For each change entry returned by a backend, the PingDirectoryProxy server must also decide whether it is a duplicate of a change made to the backend set above the entry-balancing base. If the change is a duplicate, then it is discarded. Otherwise, any new change is returned with a new value of the proxy token.

Example configuration

This example configures synchronization through a proxy and uses two endpoints consisting of a PingDirectoryProxy server with a backend set of PingDirectory servers. Both sets are replicated.

The PingDirectoryProxy server uses an entry-balancing environment for the distinguished name (DN) `ou=People,dc=example,dc=com` and provides a subtree view for `dc=example,dc=com` in its client connection policy. For this example, communication is over standard Lightweight Directory Access Protocol (LDAP) and failover servers are not installed or designated in PingDataSync.



Configure the source PingDirectory server

About this task

The following procedure configures a backend set of directory servers. The procedure is the same for the source servers and the destination servers in a synchronization topology. For directory server installation and configuration details, see the PingDirectory Server Administration Guide.

Steps

1. On each backend PingDirectory server that will participate in synchronization, enable the change log database, either from the command line or by using a `dsconfig` batch file.

```
$ dsconfig --no-prompt set-backend-prop \
  --backend-name changelog \
  --set enabled:true
```

2. Stop the server if it is running, and import the dataset for the first backend set into the first server in the backend set before the import.

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ../dataset.ldif
$ bin/start-server
```

3. On the first server instance in the first backend set, configure replication between this server and the second server in the same backend set.

```
$ bin/dsreplication enable --host1 ldap-west-01.example.com \
  --port1 389 \
  --bindDN1 "cn=Directory Manager" \
  --bindPassword1 password \
  --replicationPort1 8989 \
  --host2 ldap-west-02.example.com \
  --port2 389 \
  --bindDN2 "cn=Directory Manager" \
  --bindPassword2 password \
  --replicationPort2 9989 \
  --adminUID admin \
  --adminPassword admin \
  --baseDN dc=example,dc=com \
  --no-prompt
```

4. Initialize the second server in the backend set with data from the first server in the backend set. This command can be run from either instance.

```
$ bin/dsreplication initialize \
  --hostSource ldap-west-01.example.com \
  --portSource 389 \
  --hostDestination ldap-west-02.example.com \
  --portDestination 389 \
  --baseDN "dc=example,dc=com" \
  --adminUID admin \
  --adminPassword admin \
  --no-prompt
```

5. Run the following command to check replica status.

```
$ bin/dsreplication status \
  --hostname ldap-west-01.example.com \
  --port 389 \
  --adminPassword admin \
  --no-prompt
```

6. Repeat steps 2 through 5 (import, enable replication, initialize replication, check status) for the second backend set.

Configure a proxy server

About this task

The following procedure configures a proxy server, including defining the external servers and configuring the client-connection policy. The procedure is the same for the source servers and the destination servers in a synchronization topology.

For additional changes, use the `dsconfig` command. For proxy installation and configuration details, see the PingDirectoryProxy Server Administration Guide.

Steps

1. From the PingDirectoryProxy server root directory, run the `prepare-external-server` command to set up the `cn=Proxy User` account for access to the backend directory servers. The server tests the connection and creates the `cn=Proxy User` account.

```
$ bin/prepare-external-server --no-prompt \
  --hostname ldap-west-01.example.com \
  --port 389 --bindDN "cn=Directory Manager" \
  --bindPassword password \
  --proxyBindDN "cn=Proxy User,cn=Root DNs,cn=config" \
  --proxyBindPassword pass \
  --baseDN "dc=example,dc=com"
```

2. Repeat step 1 for any other directory server instances.

3. Run the `dsconfig` command to define the external servers and their types. For this example, round-robin load balancing algorithms are defined, which do not require health checks or locations to be specified.

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-01 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-01.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-02 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-02.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name ldap-west-03 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-03.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server
  --server-name ldap-west-04 \
  --type "ping-identity-ds" \
  --set "server-host-name:ldap-west-04.example.com" \
  --set "server-port:389" \
  --set "bind-dn:cn=Proxy User" \
  --set "password:password" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

4. Create a load-balancing algorithm for each backend set.

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
  --algorithm-name "test-lba-1" \
  --type "round-robin" --set "enabled:true" \
  --set "backend-server:ldap-west-01" \
  --set "backend-server:ldap-west-02" \
  --set "use-location:false" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
  --algorithm-name "test-lba-2" \
  --type "round-robin" --set "enabled:true" \
  --set "backend-server:ldap-west-03"
  --set "backend-server:ldap-west-04"
  --set "use-location:false" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

5. Configure the proxying request processors, one for each load-balanced directory server set. A request processor provides the logic to either process the operation directly, forward the request to another server, or hand off the request to another request processor.

```
$ bin/dsconfig --no-prompt create-request-processor \
  --processor-name "proxying-processor-1" --type "proxying" \
  --set "load-balancing-algorithm:test-lba-1" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-request-processor \
  --processor-name "proxying-processor-2" --type "proxying" \
  --set "load-balancing-algorithm:test-lba-2" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

6. Define an entry-balancing request processor. This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. Multiple proxying request processors are used to process operations.

Next, define the placement algorithm, which selects the server set to use for new add operations to create new entries. In this example, a round-robin placement algorithm forwards LDAP add requests to backend sets.

```
$ bin/dsconfig --no-prompt create-placement-algorithm \
  --processor-name "entry-balancing-processor" \
  --algorithm-name "round-robin-placement" \
  --set "enabled:true" \
  --type "round-robin" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

7. Define the subtree view that specifies the base distinguished name (DN) for the entire deployment.

```
$ bin/dsconfig --no-prompt create-subtree-view \
  --view-name "test-view" \
  --set "base-dn:dc=example,dc=com" \
  --set "request-processor: entry-balancing-processor" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

8. Finally, define a client connection policy that specifies how the client connects to the proxy server.

```
$ bin/dsconfig --no-prompt set-client-connection-policy-prop \
  --policy-name "default" \
  --add "subtree-view:test-view" \
  --bindDN "cn=Directory Manager" \
  --bindPassword pxy-pwd
```

Configure PingDataSync

About this task

Configure PingDataSync after the PingDirectoryProxy server and its backend set of PingDirectory server instances are configured and fully functional for each endpoint, which are labeled as `ldap-west` and `ldap-east` in this example.

For information about installing and configuring PingDataSync, see Installing the PingDataSync server.

Steps

1. From the PingDataSync root directory, run the `create-sync-pipe-config` command.

```
$ bin/create-sync-pipe-config
```

2. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
3. On the Synchronization Mode menu, press Enter to select Standard mode.
4. On the Synchronization Directory menu, choose the option for one-way or bidirectional synchronization.

5. On the First Endpoint Type menu, enter the number for the type of backend data store for the first endpoint. In this example, type the number corresponding to the PingDirectoryProxy server.

```
>>>> First Endpoint Type
Enter the type of datastore for the first endpoint:
1) Ping Identity Directory Server
2) Ping Identity Directory Proxy Server
3) Alcatel-Lucent Directory Server
4) Alcatel-Lucent Proxy Server
5) Sun Directory Server
6) Microsoft Active Directory
7) Microsoft SQL Server
8) Oracle Database
9) Custom JDBC

b) back
q) quit
Enter choice [1]: 2
```

6. Enter a descriptive name for the first endpoint.
7. Enter the base DN where PingDataSync can search for the entries on the first endpoint server.
8. Specify the type of security when communicating with the endpoint server.
9. Enter the host name and port of the endpoint server. PingDataSync tests the connection. Repeat this step if configuring another server for failover.
10. Enter the Sync User account that will be used to access the endpoint server, or press Enter to accept the default `cn=Sync User,cn=Root DNs,cn=config`. Enter a password for the account.
11. The first endpoint deployment is defined using the PingDirectoryProxy server (`ldap-west`). Repeat steps 5-10 to define the second proxy deployment (`ldap-east`) on PingDataSync.
12. Prepare the endpoint servers in the topology. This step confirms that the Sync User account is present on each server and can communicate between PingDataSync and the PingDirectoryProxy servers. In addition to preparing the PingDirectoryProxy server, PingDataSync prepares the backend set of directory servers as the proxy server passes through the authorization to access these servers.
13. Repeat the previous step to prepare the second endpoint server. If other servers have not been prepared, make sure that they are before synchronization.
14. Define the Sync Pipe from proxy 1 to proxy 2. In this example, accept the default "Ping Identity Proxy 1 to Ping Identity Proxy 2."
15. To customize on a per-entry basis how attributes get synchronized, define one or more Sync Classes. Create a Sync Class for the special cases, and use the default Sync Class for all other mappings.
16. For the default Sync Class Operations, specify the operations that will be synchronized.
17. Review the configuration settings, and write the configuration to PingDataSync in the `sync-pipe-cfg.txt` file.

Test the configuration

About this task

If the `create-sync-pipe-config` tool was not used to create the synchronization configuration, two properties must be verified on each endpoint: `proxy-server` and `use-changelog-batch-request`. The `proxy-server` property should specify the name of the proxy server. The `use-changelog-batch-request` property should be set to `true` on the Sync Source only. The `use-changelog-batch-request` property is not available on the destination endpoint.

The PingDataSync connection parameters (`hostname`, `port`, `bind DN`, and `bind password`) are required.

Steps

1. The following commands check the properties on a Sync Source.

   On the Sync Source:

   ```
   $ bin/dsconfig --no-prompt \
     get-sync-source-prop \
     --source-name "Ping Identity Proxy 1" \
     --property "proxy-server" \
     --property "use-changelog-batch-request"
   ```

   On the Sync Destination:

   ```
   $ bin/dsconfig --no-prompt \
     get-sync-source-prop \
     --source-name "Ping Identity Proxy 2" \
     --property "proxy-server"
   ```

2. From the server root directory, run the `dsconfig` command to set a flag indicating that the endpoints are PingDirectoryProxy servers:

   ```
   $ bin/dsconfig --no-prompt \
     set-sync-source-prop \
     --source-name "Ping Identity Proxy 1" \
     --set proxy-server:ldap-west-01 \
     --set use-changelog-batch-request:true
   ```

   ```
   $ bin/dsconfig --no-prompt \
     set-sync-source-prop \
     --source-name "Ping Identity Proxy 2" \
     --set proxy-server:ldap-east-01
   ```

3. Run the `resync --dry-run` command to test the configuration settings for each Sync Pipe and debug any issues.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
--dry-run
```

4. Run `realtime-sync set-startpoint` to initialize the starting point for synchronization.

```
$ realtime-sync set-startpoint --end-of-changelog \
  --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2" \
  --port 389 \
  --bindDN "cn=Directory Manager" \
  --bindPassword password
```

> **Note**
>
> For synchronization through proxy deployments, the `--change-number` option cannot be used with the `realtime-sync set-startpoint` command, because PingDataSync cannot retrieve specific change numbers from the backend directory servers. Use `--change-sequence-number`, `--end-of-changelog`, or other available options.

5. Run the `resync` command to populate data on the endpoint destination server if necessary.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
\
  --numPasses 3
```

6. Run the `realtime-sync start` command to start the Sync Pipe.

```
$ bin/realtime-sync start \
  --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
```

7. Monitor PingDataSync using the status commands and logs.

Index the LDAP changelog

About this task

The PingDirectory server supports attribute indexing in the changelog backend to enable get changelog batch requests to filter results that include only changes of specific attributes. For example, in an entry balanced proxy deployment, PingDataSync sends a get changelog batch request to the PingDirectoryProxy server, which will send out individual requests to each backend server.

Each directory server that receives a request must iterate over the whole range of changelog entries, and then match entries based on search criteria for inclusion in the batch. The majority of this processing involves determining whether a changelog entry includes changes to a particular attribute or set of attributes, or not. Changelog indexing can dramatically speed up throughput when targeting specific attributes.

Attribute indexing is configured using the `index-include-attribute` and `index-exclude-attribute` properties on the changelog backend. The properties can accept the specific attribute name or special Lightweight Directory Access Protocol (LDAP) values "*" to specify all user attributes or "+" to specify all operational attributes.

Perform the following steps to configure changelog indexing:

Steps

1. On all source directory servers, enable changelog indexing for the attributes that will be synchronized. Use the `index-include-attribute` and `index-exclude-attribute` properties. The following example specifies that all user attributes (`index-include-attribute:*`) be indexed in the changelog, except the description and location attributes (`index-exclude-attribute:description` and `index-exclude-attribute:location`).

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --set "index-include-attribute:*" \
     --set "index-exclude-attribute:description \
     --set "index-exclude-attribute:location
   ```

   > **Note**
   >
   > There is little performance and disk consumption penalty when using `index-include-attribute:*` with a combination of `index-exclude-attribute` properties, instead of explicitly defining each attribute using `index-include-attribute` . The only cautionary note about using `index-include-attribute:*` is to be careful that unnecessary attributes get indexed.

2. On PingDataSync, configure the `auto-map-source-attributes` property to specify the mappings for the attributes that need to be synchronized.

Result

PingDataSync will write a NOTICE message to the error log when the Sync Pipe first starts, indicating whether the server is using changelog indexing or not.

```
[30/Mar/2016:13:21:36.781 -0500] category=SYNC severity=NOTICE
msgID=1894187256 msg="Sync Pipe 'TestPipe' is not using changelog indexing on
the source server"
```

Changelog synchronization considerations

If the Sync Source is configured with `use-changelog-batch-request=true` , PingDataSync will use the get changelog batch request to retrieve changes from the Lightweight Directory Access Protocol (LDAP) changelog. This extended request can contain an optional set of selection criteria, which specifies changelog entries for a specific set of attributes.

PingDataSync takes the union of the source attributes from PingDataSync distinguished name (DN) mappings, attribute mappings, and the `auto-mapped-source-attributes` property on the Sync Class to create the selection criteria. However, if it encounters the value "-all-" in the `auto-mapped-source-attributes` property, it cannot make use of selection criteria because the Sync Pipe is interested in all possible source attributes.

When the PingDirectory server receives a get changelog request that contains selection criteria, it returns changelog entries for one or more of the attributes that meet the criteria.

- For ADD and MODIFY changelog entries, the changes must include at least one attribute from the selection criteria.
- For MODDN changelog entries, one of the RDN attributes must match the selection criteria.
- For DELETE changelog entries, one of the `deletedEntryAttrs` much match the selection criteria.

If `auto-mapped` is not set to `all` source attributes, at least one should be configured to show up in the `deletedEntryAttrs` (with the `changelog-deleted-entry-include-attribute` property on the changelog backend).

Another way to do this is to set `use-reversible-form` to `true` on the changelog backend. This includes all attributes in the `deletedEntryAttrs`.

Synchronize in notification mode

PingDataSync supports a notification synchronization mode that transmits change notifications on a source endpoint to third-party destination applications.

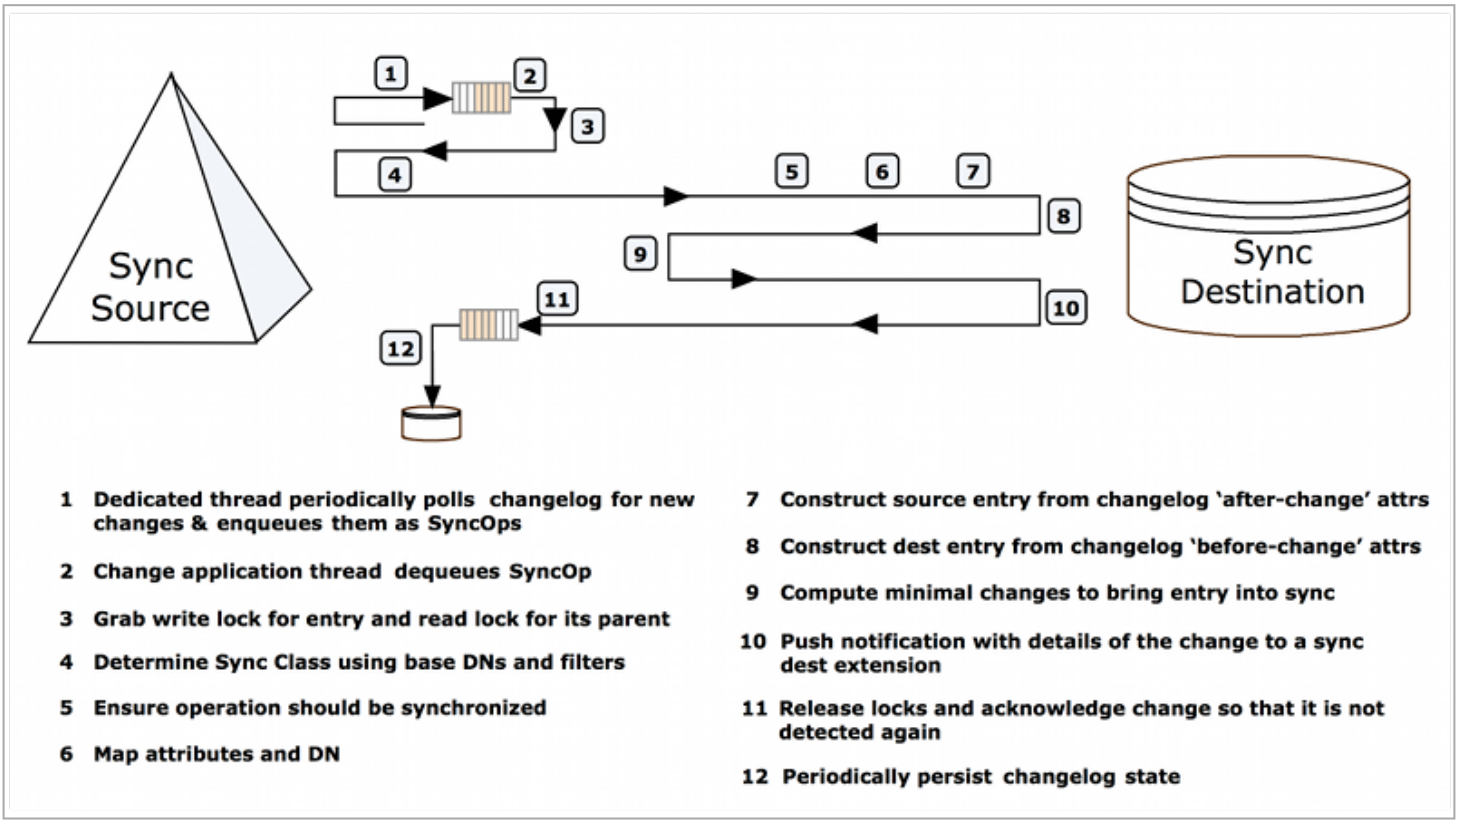
As with standard mode, notifications can be filtered based on the type of entry that was changed, the specific attributes that were changed, and the type of change (ADD, MODIFY, DELETE). PingDataSync can send a notification to arbitrary endpoints by using a custom server extension.

Notification mode overview

PingDataSync supports standard and notification synchronization modes. Notification mode polls the directory server's Lightweight Directory Access Protocol (LDAP) change log for changes on any entry but skips the fetch and compare phases of processing in standard mode. Instead, the Sync Destination is notified of the change regardless of the current state of that entry at the source or destination. PingDataSync accesses state information on the change log to reconstruct the before-and-after values of any modified attribute (for example, for MODIFY change operation types). It passes in the change information to a custom server extension based on the Server SDK.

Third-party libraries can be employed to customize the notification message to an output format required by the client application or service. For example, the server extension can use a third-party XML parsing library to convert the change notifications to a SOAP XML format.

Notification mode can only be used with an PingDirectory Server or PingDirectoryProxy server as the source endpoint.



PingDataSync can use notification mode with any type of endpoint; therefore, it is not an absolute requirement to have a custom server extension in your system. For example, it is possible to set up a notification Sync Pipe between two LDAP server endpoints.

Implementation considerations

Before implementing and configuring a Sync Pipe in notification mode, answer the following questions:

- What is the interface to client applications?
- What type of connection logic is required?
- How will the custom server extension handle timeouts and connection failures?
- What are the failover scenarios?
- What data needs to be included in the change log?
- How long do the change log entries need to be available?
- What are the scalability requirements for the system?
- What attributes should be used for correlation?
- What should happen with each type of change?
- What mappings must be implemented?

Use the Server SDK and LDAP SDK

To support notification mode, the Server SDK provides a `SyncDestination` extension to synchronize with any client application. The PingDataSync engine processes the notification and makes it available to the extension, which can be written in Java or Groovy. This generic extension type can also be used for standard synchronization mode.

Similar to database synchronization, the custom server extension is stored in the `<server-root>/lib/groovy-scripted-extensions` directory (for Groovy-based extensions) or the jar file in the `<server-root>/lib/extensions` directory (for Java-based extensions) before configuring PingDataSync for notification mode. Groovy scripts are compiled and loaded at runtime.

The Server SDK's `SyncOperation` interface represents a single synchronized change from the Sync Source to the Sync Destination. The same `SyncOperation` object exists from the time a change is detected, through when the change is applied at the destination.

The LDAP SDK's `UnboundIDChangelogEntry` class (in the `com.unboundid.ldap.sdk.unboundidds` package) has high-level methods to work with the `ds-changelog-before-value`, `ds-changelogafter-values`, and `ds-changelog-entry-key-attr-values` attributes. The class is part of the commercial edition of the LDAP SDK for Java and is installed automatically with PingDataSync. For detailed information and examples, see the LDAP SDK Javadoc.

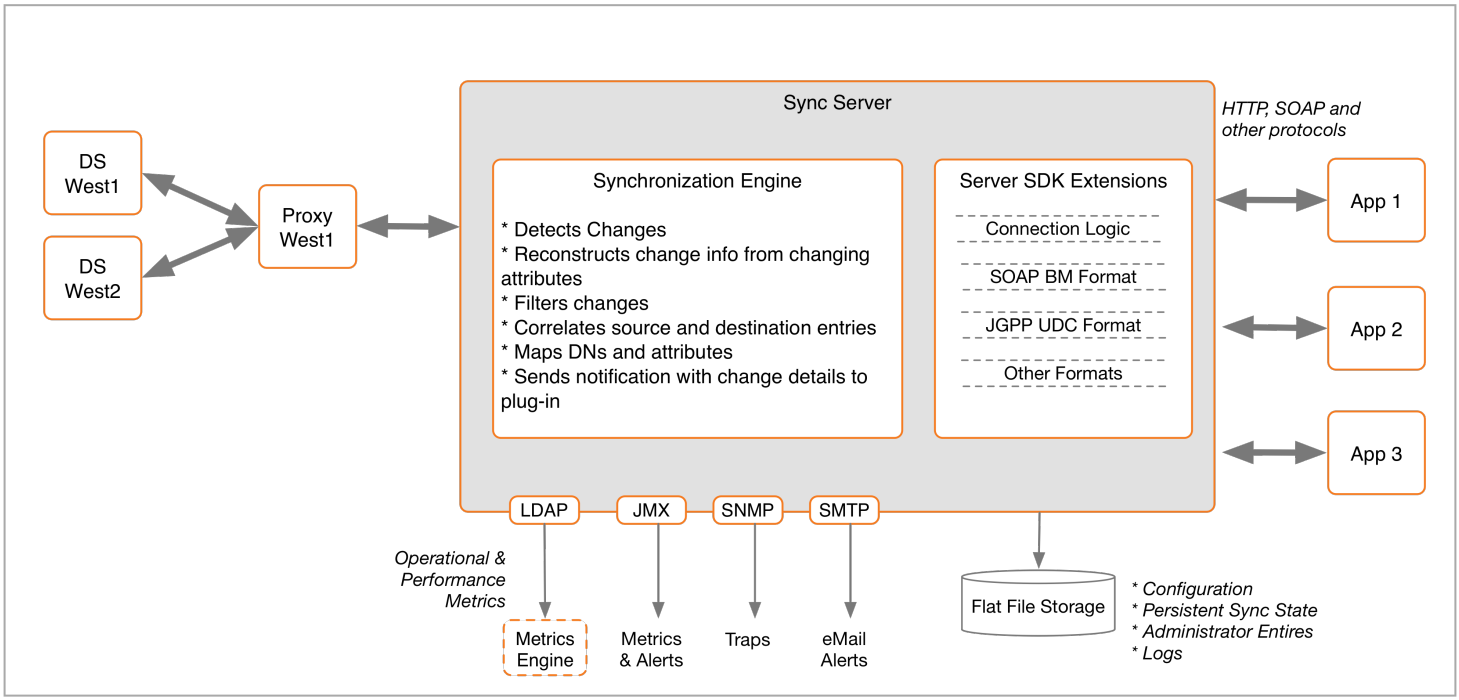
Notification mode architecture

Notification mode, a configuration setting on the Sync Pipe, requires a one-way directional Sync Pipe from a source endpoint topology to a target client application.

PingDataSync detects the changes in the PingDirectory server's Lightweight Directory Access Protocol (LDAP) change log, filters the results specified in the Sync Classes, applies any distinguished name (DN) and attribute mappings, then reconstructs the change information from the change log attributes. A server extension picks up the notification arguments from the `SyncOperation` interface (part of the Server SDK) and converts the data to the desired output format. The server extension establishes the connections and protocol logic to push the notification information to the client applications or services. All of the operations, administration, and management functions available in standard mode, such as monitoring, (LDAP, JMX, SNMP), alerts (JMX, SNMP, SMTP), and logging features are the same for notification mode.

> **Note**
>
> The Server SDK includes documentation and examples on how to create a directory server extension to support notification mode.

For a given entry, PingDataSync sends notifications in the order that the changes occurred in the change log even if a modified attribute has been overwritten by a later change. For example, if an entry's `telephoneNumber` attribute is changed three times, three notifications will be sent in the order they appeared in the change log.



Sync source requirements

A separate Sync Pipe is required for each client application that should receive a notification.

The Sync sources must consist of one or more instances of the following directory or proxy servers with PingDataSync:

- PingDirectory Server and PingDirectoryProxy Server 3.0.5 or later
- A Sync destination of any type

You should not configure PingDataSync to interact with backend source servers through a load balancer. You can use PingDirectoryProxy for this configuration instead, assuming you are using PingDirectory servers as your backends.

> **Note**
>
> Although the PingDirectoryProxy server can front other vendor's directory servers, such as Active Directory (AD) and Sun DSEE, for processing LDAP operations, PingDataSync cannot synchronize changes from these sources through a proxy server. Synchronizing changes directly from AD and Sun DSEE cannot be done with notification mode.

Failover capabilities

For sync source failovers, configure replication between the PingDirectory servers to ensure data consistency between the servers. A PingDirectoryProxy server can also front the backend PingDirectory server set to redirect traffic if connection to the primary server fails. A PingDirectoryProxy server must be used for synchronizing changes in an entry-balancing environment. Once the primary PingDirectory server is online, it assumes control with no information loss because its state information is kept across the backend PingDirectory servers.

For sync destination failovers, connection retry logic must be implemented in the server extension, which will use the Sync Pipe's advanced property settings to retry failed operations. There is a difference between a connection retry and an operation retry. An extension should not retry operations because PingDataSync does this automatically. However, the server extension is responsible for re-establishing connections to a destination that has gone down, or failing over to an alternate server. The server extension can also be designed to trigger its own error-handling code during a failed operation.

For PingDataSync failovers, the secondary PingDataSync servers will be at or slightly behind the state where the primary server initiated a failover. Both primary and secondary PingDataSyncs track the last failed acknowledgement, so once the primary server fails over to a secondary server, the secondary server will not miss a change.

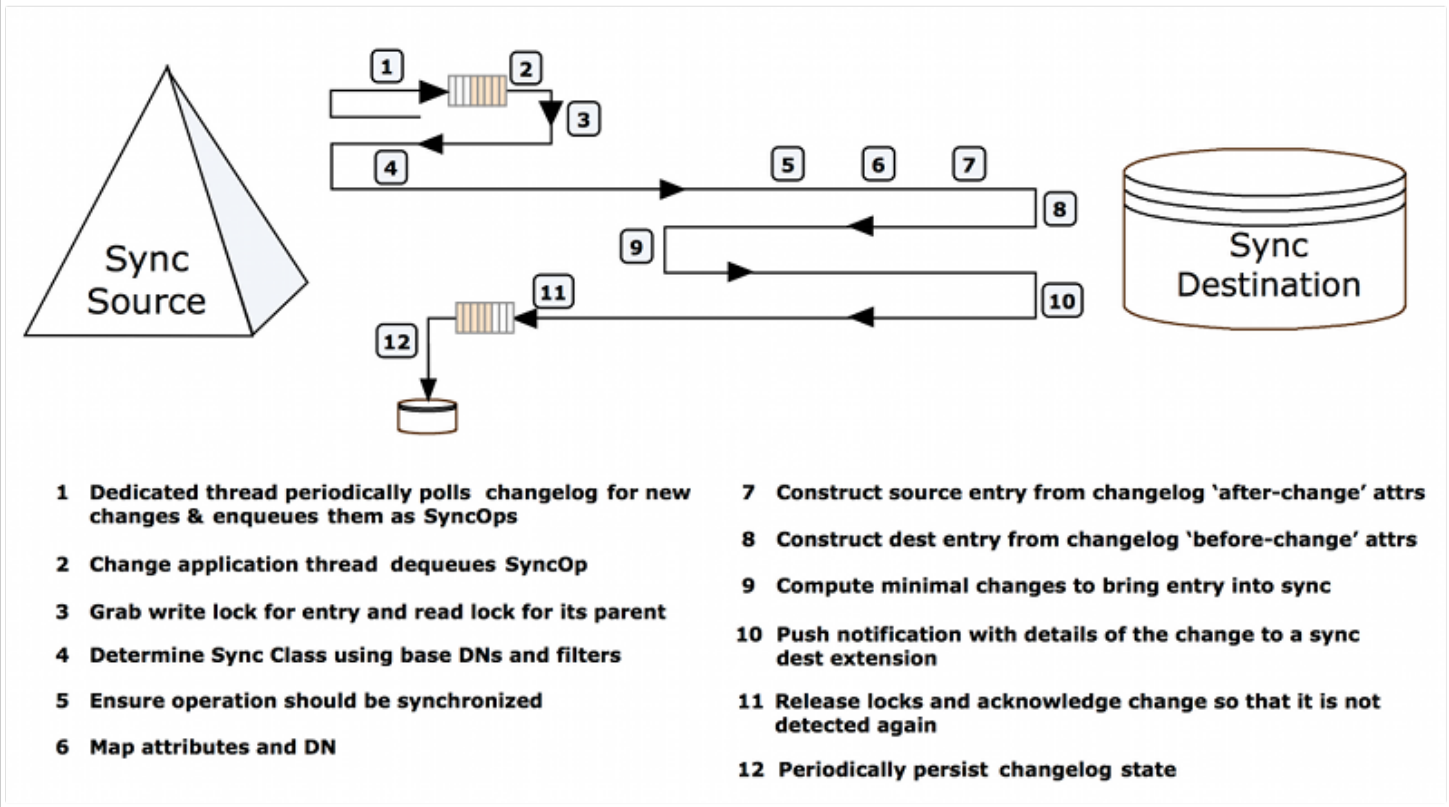
> **Note**
>
> If failover is a concern between PingDataSync servers, change the `sync-failover-polling-interval` property from 7500 ms to a smaller value. This will result in a quicker failover, but will marginally increase traffic between the two PingDataSync servers. The `sync-failover-connection-timeout` and `sync-failover-response-timeout` properties can also be updated to use different failover timeout durations. Use the **`dsconfig`** command to access the property on the Global Sync Configuration menu.

Notification sync pipe change flow

Multi-threaded Sync Pipes allow PingDataSync to process multiple notifications in parallel in the same manner as synchronizing changes in standard mode, which increases throughput and offsets network latency. A single change-detection thread pulls in batches of change log entries and queues them internally. To guarantee consistency, PingDataSync's internal locking mechanisms ensure the following properties:

- Changes to the same entry will be processed in the same order that they appear in the change log.
- Changes to parent entries will be processed before changes to its children.
- Changes to entries with the same RDN value are handled sequentially.

The number of concurrent threads is configurable on the Sync Pipe using the `num-worker-threads` property. In general, single-threading should be avoided.



Configure notification mode

PingDataSync supports notification mode with the following components.

Use the create-sync-pipe-config tool

The `create-sync-pipe-config` tool supports the configuration of notification mode. Any pre-existing Sync Sources can be read from the local configuration (in the `config.ldif` file).

LDAP change log features required for notifications

The PingDirectory server requires the following advanced global change log properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

These properties are enabled and configured during the `create-sync-pipe-config` configuration process on PingDataSync. The properties can also be enabled on the directory servers by using the `dsconfig` advanced properties setting on the Backend Changelog menu.

changelog-include-key-attribute

The `changelog-include-key-attribute` property specifies one or more attributes that should always be included in the change log entry. These are attributes needed to correlate entries between the source and destination, such as `uid`, `employeeNumber`, or `mail`. These properties are also needed for evaluating any filters in the Sync Class. For example, if notifications are only sent for user entries, and the Sync Class included the filter `(objectclass=people)`, the `objectclass` attribute must be configured as a `changelog-include-key-attribute` so that the Sync Pipe can evaluate the inclusion criteria when processing the change. In standard mode, values needed in the filter are read from the entry itself after it is fetched instead of from the changelog entry. These attributes are always included in a change log entry, also called a change record, regardless if they have changed or not.

The `changelog-include-key-attribute` property causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the change log entry. This applies for all change types. During a delete operation, the values are from the entry before it was deleted. The key values are recorded on every change and override any settings configured in the `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute` properties in the directory server changelog. For more information, see Configuring the PingDirectory server.

Normal Lightweight Directory Access Protocol (LDAP)-to-LDAP synchronization topologies typically use `dn` as a correlation attribute. If `dn` is used as a correlation attribute only, the `changelog-include-key-attribute` property does not need to be set. However, if another attribute is used for correlation, this property must be set during the Sync Pipe configuration.

The LDAP change log attribute, `ds-changelog-entry-key-attr-values`, stores the attribute that is always included in a change log entry on every change for correlation purposes. In addition to regular attributes, virtual and operational attributes can be specified as entry keys.

To view an example, see the PingDirectory Server Administration Guide.

changelog-max-before-after-values

The `changelog-max-before-after-values` property specifies the maximum number of "before and after" values (default 200) that should be stored for any changed attribute in the change log. Also, when enabled, it will add the `ds-changelog-before-values` and `ds-changelog-after-values` attributes to any change record that contains changes (for Modify and ModifyDN).

The main purpose of the `changelog-max-before-after-values` property is to ensure that an excessively large number of changes is not stored for multi-valued attributes. In most cases, the directory server's schema defines a multi-valued attribute to be unlimited in an entry. For example, if a group entry whose member attribute references 10000 entries, the desire might be to not have all of the attributes if a new member added.

If either the `ds-changelog-before-values` or the `ds-changelog-after-values` attributes exceed the count set in the `changelog-max-before-after-values` property, the attribute values are no longer stored in a change record, but its attribute name and number is stored in the `ds-changelog-attr-exceeded-max-values-count` attribute, which appears in the change record.

In addition to this property, set the `use-reversible-form` property to `TRUE`. This guarantees that sufficient information is stored in the change log for all operation types to be able to replay the operations at the destination. The `create-sync-pipe-config` tool configures these properties when it prepares the servers.

The `changelog-max-before-after-values` property configures the following change log attributes:

- `ds-changelog-before-values` – Captures all "before" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).
- `ds-changelog-after-values` – Captures all "after" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).
- `ds-changelog-attr-exceeded-max-values-count` – Stores the attribute names and number of "before" and "after" values on the change log entry after the maximum number of values (set by the `changelog-max-before-after-values` property) has been exceeded. This is a multi-valued attribute with the following format:

  ```
  attr=attributeName,beforeCount=200,afterCount=201
  ```

  In this multi-valued attribute definition, `attributeName` is the name of the attribute, and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. In either case (before or after the change), if the number of values is exceeding the maximum, those values will not be stored.

LDAP change log for notification and standard mode

Both notification and standard mode Sync Pipes can consume the same LDAP Change Log without affecting the other. Standard mode polls the change record in the change log for any modifications, fetches the full entries on the source and the destination, and then compares them for the specific changes. Notification mode gets the before and after values of a changed attribute to reconstruct an entry, and bypasses the fetch-and-compare phase. Both can consume the same LDAP Change Log with no performance loss or conflicts.

> **Note**
>
> If the configuration obtains the change log through a PingDirectoryProxy server, the contents of the change log will not change as it is being read from the change logs on the directory server backend.

Implementing the server extension

Notification mode relies heavily on the server extension code to process and transmit the change using the required protocol and data formats needed for the client applications.

Create the extension using the Server SDK, which provides the APIs to develop code for any destination endpoint type. The Server SDK's documentation (Javadoc and examples) is delivered with the Server SDK built-in zip format. The SDK provides all of the necessary classes to extend the functionality of PingDataSync without code changes to the core product. After the server extension is in place, use other third-party libraries to transform the notification to any desired output format.

Consider the following when implementing the extension:

Use the `manage-extension` tool

Use the manage-extension tool in the `bin` directory or `bat` directory (Windows) to install or update the extension. Learn more in Managing Server SDK extensions.

Review the Server SDK package

Review Server SDK documentation and examples before building and deploying a Java or Groovy extension.

Connection and protocol logic

The Server SDK extension must manage the notification connection and protocol logic to the client applications.

Implementing extensions

Test the create, delete, and modify methods for each entry type. Update the configuration as needed. Finally, package the extensions for deployment. Logging levels can be increased to include more details.

Use the SyncOperation type

The `SyncOperation` class encapsulates everything to do with a given change. Objects of this type are used in all of the synchronization SDK extensions. See the Server SDK Javadoc for the `SyncOperation` class for information on the full set of methods.

Use the EndpointException type

The Sync Destination type offers an exception type called `EndpointException` to extend a standard Java exception and provide custom exceptions. There is also logic to handle Lightweight Directory Access Protocol (LDAP) exceptions, using the LDAP SDK.

About the PostStep result codes

The `EndpointException` class uses PostStep result codes that are returned in the server extension:

- `retry_operation_limited` – Retry a failed attempt up to the limit set by `max_operation_attempts`.
- `retry_operation_unlimited` – Retry the operation an unlimited number of times until a success, abort, or `retried_operation_limited`. This should only be used when the destination endpoint is unavailable.
- `abort_operation` – Abort the current operation without any additional processing.

Use the ServerContext class for logging

The `ServerContext` class provides several logging methods that can be used to generate log messages and/or alerts from the scripted layer: `logMessage()`, `sendAlert()`, `debugCaught()`, `debugError()`, `debugInfo()`, `debugThrown()`, `debugVerbose()`, and `debugWarning()`. These methods are described in the Server SDK API Javadocs. Logging related to an individual `SyncOperation` should be done with the `SyncOperation#logInfo` and `SyncOperation#logError` methods.

Diagnosing script errors

When a Groovy extension does not behave as expected, first look in the error log for stack traces. If `classLoader` errors are present, the script could be in the wrong location or might not have the correct package. Groovy checks for errors at runtime. Business logic errors must be systematically found by testing each operation. Make sure logger levels are set high enough to debug.

Configure the Notification sync pipe

The following procedure configures a one-way Sync Pipe with a PingDirectory server as the Sync Source and a generic sync destination. The procedure uses the `create-sync-pipe-config` tool in interactive command-line mode and highlights the differences for configuring a Sync Pipe in notification mode.

Considerations for configuring sync classes

When configuring a Sync Class for a Sync Pipe in notification mode, consider the following:

- Exclude any operational attributes from synchronizing to the destination so that its before and after values are not recorded in the change log. For example, the following attributes can be excluded: `creatorsName`, `createTimeStamp`, `ds-entry-unique-id`, `modifiersName`, and `modifyTimeStamp`. Filter the changes at the change log level instead of making the changes in the Sync Class to avoid extra configuration settings with the following:
  - Use the directory server's `changelog-exclude-attribute` property with `(+)` to exclude all operational attributes (`change-log-exclude-attribute:+`).
  - Configure a Sync Class that sets the `excluded-auto-mapped-source-attributes` property to each operational attribute to exclude from the synchronization process.
  - Use the directory server's `changelog-exclude-attribute` property to specify each operational attribute to exclude in the synchronization process. Set the configuration using the `dsconfig` tool on the directory server Change Log Backend menu. For example, `setchangelog-exclude-attribute:modifiersName`.
- Use the `destination-create-only-attribute` advanced property on the Sync Class. This property sets the attributes to include on CREATE operations only.
- Use the `replace-all-attr-values` advanced property on the Sync Class. This property specifies whether to use the ADD and DELETE modification types (reversible), or the REPLACE modification type (non-reversible) for modifications to destination entries. If set to `true`, REPLACE is used.
- If targeting specific attributes that require higher performance throughput, consider implementing change log indexing. See Synchronize through PingDirectoryProxy servers for more information.

Create the sync pipe

About this task

The initial configuration steps show how to set up a single Sync Pipe from a directory server instance to a generic Sync Destination.

Before starting:

- Place any third-party libraries in the `<server-root>/lib/extensions` folder.

- Implement a server extension for any custom endpoints and place it in the appropriate directory.

Steps

1. If necessary, start PingDataSync:

```
$ bin/start-server
```

2. Run the `create-sync-pipe-config` tool.

```
$ bin/create-sync-pipe-config
```

3. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
4. On the Synchronization Mode menu, select the option for notification mode.
5. On the Synchronization Directory menu, enter the option to create a one-way Sync Pipe in notification mode from the directory to a generic client application.

Configure the sync source

Steps

1. On the Source Endpoint Type menu, enter the option for the Sync Source type.
2. Choose a pre-existing Sync Source, or create a new sync source.
3. Enter a name for the Source Endpoint and a name for the Sync Source.
4. Enter the base distinguished name (DN) for the directory server used for Lightweight Directory Access Protocol (LDAP) searches, such as `dc=example,dc=com`, and press Enter to return to the menu. If entering more than one base DN, make sure they do not overlap.
5. On the Server Security menu, select the type of communication that PingDataSync will use with endpoint servers.
6. Enter the host and port of the first Source Endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. PingDataSync contacts this first server if it is available, then contacts the next highest priority server if the first server is unavailable. The server tests the connection.
7. On the Sync User Account menu, enter the DN of the sync user account and password, or press Enter to accept the default, `cn=Sync User,cn=Root DNs,cn=config`. This account allows PingDataSync to access the source endpoint server.

Configure the destination endpoint server

Steps

1. On the Destination Endpoint Type menu, select the type of datastore on the endpoint server. In this example, select the option for Custom.
2. Enter a name for the Destination Endpoint and a name for the Sync Destination.

3. On the Notifications Setup menu, select the language (Java or Groovy) used to write the server extension.
4. Enter the fully qualified name of the Server SDK extension that implements the abstract class. A Java, extension should reside in the `/lib/extensions` directory. A Groovy script should reside in the `/lib/groovy-scripted-extensions` directory.
5. Configure any user-defined arguments needed by the server extension. Typically, these are connection arguments, which are defined by the extension itself. The values are then entered here and stored in the server configuration.
6. Configure the maximum number of before and after values for all changed attributes. Notification mode requires this. Set the cap to something well above the maximum number of values that any synchronized attribute will have. If this cap is exceeded, PingDataSync issues an alert. For this example, we accept the default value of 200.

```
Enter a value for the max changelog before/after values,
or -1 for no limit [200]:
```

7. Configure any key attributes in the change log that must be included in every notification. These attributes can be used to find the destination entry corresponding to the source entry, and are present regardless of whether the attributes changed. Later, any attributes used in a Sync Class include-filter must also be configured as key attributes in the Sync Class.
8. In both standard and notification modes, the Sync Pipe processes the changes concurrently with multiple threads. If changes must be applied strictly in order, the number of Sync Pipe worker threads will be reduced to 1. This will limit the maximum throughput of the Sync Pipe.

Next steps

The rest of the configuration steps follow the same process as a standard synchronization mode Sync Pipe. For more information see Sync user account.

Access control filtering on the sync pipe

PingDataSync provides an advanced Sync Pipe configuration property, `filter-changes-by-user`, which performs access control filtering on a changelog entry for a specific user.

Since the changelog entry contains data from the target entry, the access controls filter out attributes that the user does not have the privileges to see before it is returned. For example, values in the changes, `ds-changelog-before-values`, `ds-changelog-after-values`, `ds-changelog-entry-key-attr-values`, and `deletedEntryAttrs` are filtered out through access control instructions.

> **Note**
>
> This property is only available for notification mode and can be configured using the **`create-sync-pipe-config`** or **`dsconfig`** commands.

The source server must be a PingDirectory server or a PingDirectoryProxy server that points to a PingDirectory server.

Considerations for access control filtering

- The directory server will not return the changelog entry if the user is not allowed to see the target entry.

- The directory server strips out any attributes that the user is not allowed to see.
- If no changes are left in the entry, no changelog entry will be returned.
- If only some attributes are stripped out, the changelog entry will be returned.
- Access control filtering on a specific attribute value is not supported. Either all attribute values are returned or none.
- If a sensitive attribute policy is used to filter attributes when a client normally accesses the directory server, this policy will not be taken into consideration during notifications since the Sync User is always connecting using the same method. Configure access controls to filter out attributes, not based on the type of connection made to the server, but based on who is accessing the data. The `filter-changes-by-user` property will be able to evaluate if that person should have access to these attributes.

Configure the sync pipe to filter changes by access control instructions

Steps

1. Set the filter-changes-by-user property to filter changes based on access controls for a specific user.

```
$ bin/dsconfig set-sync-pipe-prop \
  --pipe-name "Notifications Sync Pipe" \
  --set "filter-changes-by-user:uid=admin,dc=example,dc=com"
```

2. On the source directory server, set the `report-excluded-changelog-attributes` property to include the names of users that have been removed through access control filtering. This will allow PingDataSync to warn about attributes that were supposed to be synchronized but were filtered out. This step is recommended but not required.

```
$ bin/dsconfig set-backend-prop \
  --backend-name "changelog" \
  --set "report-excluded-changelog-attributes:attribute-names"
```

> **Note**
>
> PingDataSync only uses the `attribute-names` setting for the PingDirectory server's `report-excluded-changelog-attributes` property. It does not use the `attribute-counts` setting for the property.

Configuring Synchronization with SCIM

PingDataSync provides data synchronization between directory servers or proxy servers and System for Cross-domain Identity Management (SCIM) 1.1 applications over HTTP. Synchronization can be done with custom SCIM applications, or with the PingDirectory server and the PingDirectoryProxy server configured as SCIM servers using the SCIM extension.

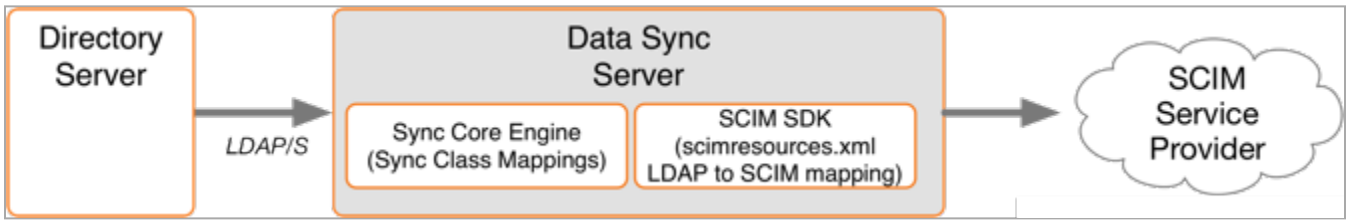
Synchronize with a SCIM sync destination overview

The System for Cross-domain Identity Management (SCIM) 1.1 protocol is designed to make managing user identity in cloud-based applications and services easier. SCIM enables provisioning identities, groups, and passwords to, from, and between clouds. PingDataSync can be configured to synchronize with SCIM service providers.

> **Note**
>
> Both the PingDirectory server and the PingDirectoryProxy server can be configured to be SCIM servers using the SCIM HTTP Servlet Extension.

PingDataSync is LDAP-centric and operates on Lightweight Directory Access Protocol (LDAP) attributes. The SCIM sync destination server component acts as a translation layer between a SCIM service provider's schema and an LDAP representation of the entries. While PingDataSync is LDAP-centric and typically at least one endpoint is an LDAP Directory server, this is not a strict requirement. For example, a Java database connectivity (JDBC) to SCIM sync pipe can be configured.

PingDataSync contains sync classes that define how source and destination entries are correlated. The SCIM sync destination contains its own mapping layer, based on `scimresources.xml` that maps an LDAP schema to and from SCIM.



> **Note**
>
> PingDataSync can use SCIM only as a sync destination. There is no mechanism in the SCIM protocol for detecting changes, so it cannot be used as a Sync Source.

SCIM destination configuration objects

The `SCIMSyncDestination` object defines a SCIM 1.1 service provider Sync Pipe destination that is accessible over HTTP through the SCIM protocol. It is configured with the following properties:

- `server` – Specifies the names of the SCIM External Servers that are used as the destination of synchronization.
- `resource-mapping-file` – Specifies the path to the `scim-resources.xml` file, a configuration file that defines the SCIM schema and maps it to the LDAP schema. This file is located in `<server_root>/config/scim-resources.xml` by default, and it can be customized to define and expose deployment-specific resources.
- `rename-policy` – Specifies how to handle the rename of a SCIM resource.

The SCIM Sync Destination object is based on the SCIM SDK. Before configuring a SCIM destination, review the following documents on the Simple Cloud web site:

- SCIM Core Schema
- SCIM REST API

Considerations for synchronizing to a SCIM destination

When configuring an LDAP to SCIM Sync Pipe, consider the following:

Use `scim-resources.xml` for attribute and DN mappings

There are two layers of mapping: once at the Sync Class level and again at the SCIM Sync Destination level in the `scim-resources.xml` file. To reduce complexity, do all possible mappings in the `scim-resources.xml` file.

Avoid groups unless the SCIM ID is DN based

Group synchronization is supported if the SCIM ID is based on the distinguished name (DN). If the SCIM ID is not the DN itself, it must be one of the components of the RDN, meaning that the DNs of group members must contain the necessary attribute.

SCIM modifies entries using PUT

The SCIM Sync Destination modifies entries using the full HTTP PUT method. For every modify, SCIM replaces the entire resource with the updated resource. For information about the implications of this on password updates, see Password considerations with SCIM.

Rename a SCIM resource

The SCIM 1.1 protocol does not support changes that require the SCIM resource to be renamed, such as a MODDN operation. Instead, when a change is detected to an attribute value that is used as part of the SCIM ID attribute, PingDataSync handles it in one of the following ways:

- Deletes the specified SCIM resource and then adds the new resource with the new SCIM ID.
- Adds the new resource with the new SCIM ID and then deletes the old resource.
- Skips the rename portion of the change. If renames are expected on the source endpoint, a careful set of destination-correlation attributes should be chosen so that the destination can still be found after it is renamed on the source.

Configure this by setting the `rename-policy` property of the SCIM sync destination.

Password considerations with SCIM

Because the SCIM sync destination modifies entries using a full PUT method, special considerations need to be made for password attributes.

A Ping Identity SCIM server allows password attributes to be omitted from a change when they have not been modified by an operation. This prevents passwords from inadvertently being overwritten during the PUT operation, which does not include the password attribute. Ideally, other SCIM service providers will not wipe a password because a PUT request does not contain it. Check with the SCIM vendor to confirm this behavior before starting a SCIM sync pipe.

Configure synchronization with SCIM

Configure synchronization with System for Cross-domain Identity Management (SCIM) using the `create-sync-pipe-config` utility and the `dsconfig` command. Configuring synchronization between an Lightweight Directory Access Protocol (LDAP) server and a SCIM service provider includes the following:

- Configure one external server for every physical endpoint.

- Configure the Sync Source server and designate the external servers that correspond to the source server.
- Configure the Sync Destination server and designate the external servers that correspond to the SCIM sync destination.
- Configure the LDAP to SCIM Sync Pipe.
- Configure the Sync Classes. Each Sync Class represents a type of entry that needs to be synchronized. When specifying a Sync Class for synchronization with a SCIM service provider, avoid including attribute and distinguished name (DN) mappings. Instead use the Sync Class to specify the operations to synchronize and which correlation attributes to use.
- Set the evaluation order for the Sync Classes to define the processing precedence for each class.
- Configure the `scim-resources.xml` file. If possible, change the `<resourceIDMapping>` element(s) to use whatever the SCIM Service Provider uses as the SCIM ID.
- Set Up Communication for each External Server. Run `prepare-endpoint-server` once for every LDAP external server that is part of the Sync Source.
- Use `realtime-sync` to start the Sync Pipe.

Configure the external servers

About this task

Perform the following to configure an external server for each host in the deployment:

Steps

1. Configure a PingDirectory server as an external server, which will later be configured as a Sync Source. On PingDataSync, run the following `dsconfig` command:

```
$ bin/dsconfig create-external-server \
  --server-name source-ds \
  --type ping-identity-ds \
  --set server-host-name:ds1.example.com \
  --set server-port:636 \
  --set "bind-dn:cn=Directory Manager" \
  --set password:secret \
  --set connection-security:ssl \
  --set key-manager-provider:Null \
  --set trust-manager-provider:JKS
```

2. Configure the System for Cross-domain Identity Management (SCIM) server as an external server, which will later be configured as a Sync Destination. The `scim-service-url` property specifies the complete URL used to access the SCIM service provider. The user-name property specifies the account used to connect to the SCIM service provider. By default, the value is `cn=Sync User,cn=Root DNs,cn=config`. Some SCIM service providers might not have the user name in distinguished name (DN) format.

```
$ bin/dsconfig create-external-server \
  --server-name scim \
  --type scim \
  --set scim-service-url:https://scim1.example.com:8443 \
  --set "user-name:cn=Sync User,cn=Root DNs,cn=config" \
  --set password:secret \
  --set connection-security:ssl \
  --set hostname-verification-method:strict \
  --set trust-manager-provider:JKS
```

Configure the PingDirectory server sync source

About this task

Configure the Sync source for the synchronization network. More than one external server can be configured to act as the Sync source for failover purposes. If the source is a PingDirectory server, also configure the following items:

- Enable the changelog password encryption plugin on any directory server that will receive password modifications. This plugin intercepts password modifications, encrypts the password, and adds an encrypted attribute to the change log entry.
- Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend, so that PingDataSync can record which attributes were removed during a DELETE operation.

Perform the following steps to configure the Sync source:

Steps

1. Run the `dsconfig` command to configure the external server as the Sync source. Based on the previous example where the PingDirectory server was configured as `source-ds`, run the following command:

```
$ bin/dsconfig create-sync-source --source-name source \
  --type ping-identity \
  --set base-dn:dc=example,dc=com \
  --set server:source-ds \
  --set use-changelog-batch-request:true
```

2. Enable the change log password encryption plugin on any server that receives password modifications. The encryption key can be copied from the output, if displayed, or accessed from the `<server-root>/bin/sync-pipe-cfg.txt` file, if the `create-sync-pipe-config` tool was used to create the sync pipe.

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Changelog Password Encryption" \
  --set enabled:true \
  --set changelog-password-encryption-key:<key>
```

3. On PingDataSync, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

```
$ bin/dsconfig set-global-sync-configuration-prop \
  --set changelog-password-decryption-key:ej5u9e39pq-68
```

4. Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set changelog-deleted-entry-include-attribute:objectClass
```

Configure the SCIM sync destination

Configure the System for Cross-domain Identity Management (SCIM) sync destination to synchronize data with a SCIM service provider. Run the `dsconfig` command:

```
$ bin/dsconfig create-sync-destination \
  --destination-name scim \
  --type scim \
  --set server:scim
```

Configure the sync pipe, sync classes, and evaluation order

About this task

Configure a Sync Pipe for Lightweight Directory Access Protocol (LDAP) to System for Cross-domain Identity Management (SCIM) synchronization, create Sync classes for the Sync Pipe, and set the evaluation order index for the Sync classes.

> **Note**
>
> The synchronization mode must be set to standard. Notification mode cannot be used with SCIM.

Steps

1. After the source and destination endpoints have been configured, configure the Sync Pipe for LDAP to SCIM synchronization. Run `dsconfig` to configure an LDAP-to-SCIM Sync Pipe:

```
$ bin/dsconfig create-sync-pipe \
  --pipe-name ldap-to-scim \
  --set sync-source:source \
  --set sync-destination:scim
```

2. The next set of steps define three Sync Classes. The first Sync Class is used to match user entries in the Sync Source. The second class is used to match group entries. The third class is a DEFAULT class that is used to match all other entries.

   Run `dsconfig` to create the first Sync Class and set the Sync Pipe Name and Sync Class name:

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name user
```

3. Run `dsconfig` to set the base distinguished name (DN) and filter for this Sync class. The `include-base-dn` property specifies the base DN in the source, which is `ou=people,dc=example,dc=com` by default. This Sync Class is invoked only for changes at the `ou=people` level. The include-filter property specifies an LDAP filter that tells PingDataSync to include `inetOrgPerson` entries as user entries. The `destination-correlation-attributes` specifies LDAP attributes that allow PingDataSync to find the destination resource on the SCIM server. The value of this property will vary. See Identify a SCIM resource at the destination for details.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name user \
  --add include-base-dn:ou=people,dc=example,dc=com \
  --add "include-filter:(objectClass=inetOrgPerson)" \
  --set destination-correlation-attributes:externalId
```

4. Create a second Sync class, which is used to match group entries:

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name group
```

5. For the second Sync class, set the base DN and the filters to match the group entries.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name group \
  --add include-base-dn:ou=groups,dc=example,dc=com \
  --add "include-filter:(|(objectClass=groupOfEntries)\
    (objectClass=groupOfNames)(objectClass=groupOfUniqueNames)\
    (objectClass=groupOfURLs))"
```

6. For the third Sync class, create a DEFAULT Sync class that is used to match all other entries. To synchronize changes from only user and group entries, set `synchronize-creates`, `synchronize-modifies`, and `synchronize-delete` to false.

```
$ bin/dsconfig create-sync-class \
  --pipe-name ldap-to-scim \
  --class-name DEFAULT \
  --set evaluation-order-index:99999 \
  --set synchronize-creates:false \
  --set synchronize-modifies:false \
  --set synchronize-deletes:false
```

7. After all of the Sync classes needed by the Sync Pipe are configured, set the evaluation order index for each Sync class. Classes with a lower number are evaluated first. Run `dsconfig` to set the evaluation order index for the Sync class. The actual number depends on the deployment.

```
$ bin/dsconfig set-sync-class-prop \
  --pipe-name ldap-to-scim \
  --class-name user \
  --set evaluation-order-index:100
```

Configure communication with the source server

Configure communication between PingDataSync and the Lightweight Directory Access Protocol (LDAP) source servers with the `prepare-endpoint-server` tool. If user accounts do not exist, this tool creates the appropriate user account and its privileges. Also, because the source is an PingDirectory server, this tool enables the changelog.

> **Note**
>
> The **`prepare-endpoint-server`** tool can only be used on LDAP directory servers. For the SCIM server, manually create a sync user entry.
> Run the **`prepare-endpoint-server`** command to set up communication between PingDataSync and the source server(s). The tool will prompt for the bind distinguished name (DN) and password to create the user account and enable the change log.

```
$ bin/prepare-endpoint-server \
  --hostname ds1.example.com \
  --port 636 \
  --useSSL \
  --trustAll \
  --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
  --syncServerBindPassword "password" \
  --baseDN "dc=example,dc=com" \
  --isSource
```

Start the sync pipe

About this task

The `realtime-sync` tool sets a specific starting point for real-time synchronization, so that changes made before the current time are ignored.

Steps

1. Run `realtime-sync` to set the startpoint for the Sync source.

```
$ bin/realtime-sync set-startpoint \
  --end-of-changelog \
  --pipe-name ldap-to-scim
```

2. When ready to start synchronization, run the following command:

```
$ bin/realtime-sync start \
  --pipe-name ldap-to-scim \
  --no-prompt
```

Mapping the LDAP schema to the SCIM resource schema

The resources configuration file is used to define the System for Cross-domain Identity Management (SCIM) resource schema and its mapping to Lightweight Directory Access Protocol (LDAP) schema. The default configuration of the `scim-resources.xml` file provides definitions for standard SCIM Users and Groups resources, and mappings to standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes. It is installed with the PingDirectory server. This file can be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

The default configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. In all cases, this must be changed to match the attribute that the destination SCIM service provider is using for its SCIM resource ID. For example, if the destination uses the value of the `uid` attribute, modify the `scim-resources.xml` file to change the `resourceIDMapping` as follows:

```
<resourceIDMapping ldapAttribute="uid"/>
```

Ideally, this would be an attribute that exists on the source LDAP entry. If not, PingDataSync can construct it using a Constructed Attribute Mapping. For example, the SCIM service provider used the first and last initials of the user, concatenated with the employee ID (given by the `eid` attribute) as the SCIM resource ID. In this case, an attribute mapping would be constructed as follows:

```
$ dsconfig create-attribute-mapping \
  --map-name MyAttrMap \
  --mapping-name scimID \
  --type constructed \
  --set 'value-pattern:{givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid}'
```

This creates an attribute called `scimID` on the mapped entry when processed by the Sync engine. For example, if the user's name was John Smith, with employee ID 12345, then the `scimID` would be `js12345`. After this has been done, configure the `scim-resources.xml` file as follows:

```
<resourceIDMapping ldapAttribute="scimID"/>
```

This will cause it to pull out the constructed `scimID` value from the entry and use that at the SCIM resource ID when making requests to the service provider.

> **Note**
>
> Constructed attribute mappings support multivalued source attributes for conditional (using the `conditional-value-pattern` property) and non-conditional (using the `value-pattern` property) value patterns. Only one of the source attributes that contribute to a given value pattern can be multivalued.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base distinguished name (DN)s of the PingDirectory server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. If using the SCIM HTTP Servlet Extension for the PingDirectory server, this can be implemented in many ways, such as:

- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

LDAP attributes are allowed to contain characters that are invalid in XML, because not all valid UTF-8 characters are valid XML characters. Make sure that any attributes that contain binary data are declared using `dataType=binary` in the `scim-resources.xml` file. When using the Identity Access API, make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes that contain binary data. This instructs the server to base64-encode the data before returning it to clients.

If attributes that are not declared as binary in the schema and contain binary data (or just data that is invalid in XML), the server will check for this before returning them to the client. If the client has set the content-type to XML, then the server can choose to base64-encode any values that include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scimresources.xml` file.

<resource> element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A `resource` element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.

- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

<attribute> element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An `attribute` element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
- `simple`: specifies a simple, singular SCIM attribute.
- `complex`: specifies a complex, singular SCIM attribute.
- `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
- `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

<simple> element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simple` element contains the following XML element in sequence:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

<complex> element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard type, primary, and display sub-attributes do not need to be specified.

<simpleMultiValued> element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is email.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (in other words, the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

<complexMultiValued> element

A `complexMultiValued` element has the following XML attributes:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard `addresses` SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

<subAttribute> element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false`.

- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

<canonicalValue> element

A `canonicalValue` element has the following XML attributes:

- `name`: specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers, and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element in sequence:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

<mapping> element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP, and LDAP to SCIM. The available transformations are described in Mapping the LDAP schema to the SCIM resource schema.

<subMapping> element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. Available transformations are described in Mapping the LDAP schema to the SCIM resource schema.

<LDAPSearch> element

An `LDAPSearch` element has the following XML attributes:

- `baseDN`: a required element specifying the LDAP search base DN to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.

- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN.

> **Note**
>
> The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them with an `ID` attribute.

<resourceIDMapping> element

A `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `<scim-consumer>`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or directory, (as would be the case if the mapped LDAP attribute is `entryUUID`).

If the LDAP attribute value is not listed as a destination correlation attribute, this setting is not used by PingDataSync.

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

<LDAPAdd> element

An `LDAPAdd` element has the following XML attributes:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template can reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

<fixedAttribute> element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The default value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made.

A `fixedAttribute` element contains the following XML element:

- `fixedValue`: one or more elements specifying the fixed LDAP values.

Identify a SCIM resource at the destination

When a System for Cross-domain Identity Management (SCIM) Sync Destination needs to synchronize a change to a SCIM resource on the destination SCIM server, it must first fetch the destination resource. If the destination resource ID is known, the resource will be retrieved by its ID. If not, a search is performed using the mapped destination correlation attributes. Configuring this requires coordination between the Sync Class and the `scim-resources.xml` mapping file.

The `scim-resources.xml` mapping file treats the value of the `<resourceIDMapping>` element's `ldapAttribute` attribute as the SCIM ID of the source entry. If this value is also listed as a value of the Sync Class's `destination-correlation-attributes` property, then the value of this Lightweight Directory Access Protocol (LDAP) attribute is used as the SCIM ID of the destination resource.

If no value of `destination-correlation-attributes` matches the `<resourceIDMapping>` element's `ldapAttribute` attribute, the SCIM ID of the destination resource is considered unknown. In this case, the SCIM Sync Destination treats the values of `destination-correlation-attributes` as search terms, using them to construct a filter for finding the destination resource. Each value of `destination-correlation-attributes` will be mapped to a corresponding SCIM attribute name, and equality matches will be used in the resulting filter.

If the `ldapAttribute` value is not listed as a destination correlation attribute, this setting is not used by PingDataSync.

The following table illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

Identifying a SCIM resource

Method for retrieving SCIM resource	Condition	Example condition	Example request
Retrieve resource directly	Used if a `destination-correlation-attribute` value matches the `<resourceIDMapping> ldapAttribute` value.	`destination-correlation-attribute=mail,uid;<resourceIDMapping ldapAttribute="mail" createdBy= "directory"/>`	`GET scim/Users/ person@example.com`
Retrieve resource using search	Used if no `destination-correlation-attribute` value matches the `<resourceIDMapping> ldapAttribute` value.	`destination-correlation-attribute=mail,uid;<resourceIDMapping ldapAttribute="entryUUID" createdBy = "directory"/ >`	`GET /scim/Users? filter=emails+eq+"person@example.com" and+userName+eq"person"`

The unique ID of a destination SCIM resource will most likely be unknown, and the search method will need to be used. However, not all SCIM service providers support the use of filters. Therefore, not all SCIM service providers might be usable as SCIM Sync Destinations.

Configuring synchronization to a SCIM 2.0 server

The PingDataSync server supports System for Cross-domain Identity Management (SCIM) 2.0 servers as a sync destination, which means that it is possible to push changes (including creates, modifies, and deletes) read from another source to a server using the SCIM 2.0 protocol described in RFC 7644.

> **Note**
>
> To view an example Active Directory to SCIM 2.0 configuration, see the file located at `<server-root>/config/sample-dsconfig-batch-files/reference-sync-activedirectory-to-scim2.dsconfig`.

> **Note**
>
> It is currently not possible to use a SCIM 2.0 server as a source, enabling changes made in that server to synchronize to other types of destinations.

The `create-sync-pipe-config` tool does not provide support for creating a sync pipe with a SCIM 2.0 sync destination, so you will need to create the necessary configuration manually using a tool like `dsconfig` or the admin console. This involves the following steps:

1. Creating a sync source to allow the PingDataSync server to pull the changes to be synchronized. See Configure the sync source.
2. Optionally configuring a changelog password decryption key in the PingDataSync server if the source is a PingDirectory server instance. See Configure the changelog password decryption key in the PingDataSync server (optional).
3. Configuring a SCIM 2.0 external server with the details necessary to connect and authenticate to the destination server. See Configure the SCIM 2.0 external server.
4. Configuring a set of SCIM 2.0 attribute mappings to describe how the PingDataSync server should map attributes from the internal LDAP representation of entries obtained from the sync source into a form that can be sent to the SCIM 2.0 server. See Configure SCIM 2.0 attribute mappings.
5. Configuring one or more SCIM 2.0 endpoint mappings to provide information about the endpoints to which changes will be synchronized in the SCIM 2.0 server, including the attribute mappings for attributes associated with each endpoint. See Configure SCIM 2.0 endpoint mappings.
6. Configuring a SCIM 2.0 sync destination, which references the SCIM 2.0 external server and endpoint mappings created in earlier steps, and provides additional configuration options. See Configure the SCIM 2.0 sync destination.
7. Configuring a sync pipe to associate the appropriate sync source with the SCIM 2.0 sync destination. See Configure a sync pipe.
8. Configuring one or more sync classes for that sync pipe to indicate how the PingDataSync server should treat various types of entries read from the source when pushing changes to the destination. See Configure sync classes.
9. Optionally using the `realtime-sync set-startpoint` command to set the startpoint at the end of the changelog if the source is a PingDirectory server instance. See Set the changelog startpoint for the sync source (optional).
10. Using the `resync` tool to perform an initial bulk synchronization of the content in the sync source into the SCIM 2.0 sync destination. See Perform an initial bulk synchronization with the `resync` command.

11. Using the `realtime-sync start` command to start synchronizing changes from the source into the SCIM 2.0 sync destination. See Start real-time synchronization.

Configure the sync source

The sync source describes the service from which entries and changes are read so that they can be synchronized to the sync destination.

The process for configuring a sync source varies based on the type of service that you use, such as an LDAP server or a relational database, so you should consult the appropriate documentation for the specific type of sync source that you want to use.

Currently, the `create-sync-pipe-config` tool does not offer support for the System for Cross-domain Identity Management (SCIM) 2.0 sync destination, so you might need to configure the sync source manually with a tool like `dsconfig` or the admin console. However, if you plan to synchronize from the desired source to another type of destination, and if that destination is one that is supported by the `create-sync-pipe-config` tool, then you can reuse the sync source created for that pipe.

If the sync source server is a PingDirectory server, then you can use the `prepare-endpoint-server` tool to make necessary changes to allow the PingDataSync server to interact with that directory server instance. This includes creating the account that the PingDataSync server uses to authenticate to the PingDirectory server and enabling the changelog to allow the PingDataSync server to retrieve information about changes processed in the PingDirectory server.

Running `prepare-endpoint-server --help` shows you the complete usage for the tool, but the following example demonstrates a sample usage:

```
bin/prepare-endpoint-server \
     --hostname ds-source.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore \
     --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
     --syncServerBindPasswordFile sync-user-password.txt \
     --baseDN dc=example,dc=com \
     --isSource
```

In addition, if the source server is a PingDirectory server instance, then you should enable the Changelog Password Encryption plugin in that server to indicate that it should store an encrypted representation of clear-text passwords in the changelog along with their encoded form. See Configuring password encryption.

Doing this allows the PingDataSync server to retrieve those clear-text passwords so that they can be synchronized to the SCIM 2.0 sync destination. You can do this with a change like the following:

```
dsconfig set-plugin-prop \
     --plugin-name "Changelog Password Encryption" \
     --set enabled:true \
     --set changelog-password-encryption-key:<this-is-the-key-you-want-to-use>
```

Configure the changelog password decryption key in the PingDataSync server (optional)

If the sync source is a PingDirectory server instance that has the Changelog Password Encryption plugin enabled, then you need to configure the PingDataSync server with the same key so that it can decrypt those passwords.

You can do this with a change like the following:

```
dsconfig set-global-sync-configuration-prop \
     --set changelog-password-decryption-key:<this-is-the-key-you-want-to-use>
```

Configure the SCIM 2.0 external server

The System for Cross-domain Identity Management (SCIM) 2.0 external server configuration object provides the information that the PingDataSync server needs to connect and authenticate to the SCIM 2.0 service.

First, you must create an HTTP authentication method that allows the PingDataSync server to authenticate to the SCIM 2.0 server to authorize requests. In most cases, this authentication is an OAuth 2.0 bearer token, and you will likely want to obtain that token using the client credentials grant type. This allows you to provide a client ID and client secret to the OAuth authorization server to obtain a bearer token.

In this case, the client secret is sensitive information, so the PingDataSync server uses a passphrase provider to access it, which allows it to be obtained from a variety of sources, like an optionally encrypted file, Amazon Secrets Manager, Azure Key Vault, a CyberArk Conjur instance, or a HashiCorp Vault instance. For example:

```
dsconfig create-passphrase-provider \
     --provider-name "SCIMv2 Client Secret" \
     --type file-based \
     --set enabled:true \
     --set password-file:config/scimv2-client-secret.txt

dsconfig create-http-authorization-method \
     --method-name "SCIMv2 Authorization Method" \
     --type client-credentials-bearer-token \
     --set enabled:true \
     --set oauth-server-token-endpoint-url:https://oauth.example.com/as/token \
     --set hostname-verification-method:strict \
     --set oauth-client-id:this-is-the-client-id \
     --set "oauth-client-secret-passphrase-provider:SCIMv2 Client Secret" \
     --set request-method:get \
     --set credentials-submission-method:basic-authorization \
     --set "maximum-token-lifetime:1 h"
```

The SCIM 2.0 external server configuration offers the following properties:

`scim-service-url`

> The base URL to the SCIM 2.0 service to be used. This should not include any endpoint name because that will be appended through the endpoint mapping. This is required.

`key-manager-provider`

A key manager provider to use during SSL negotiation with the SCIM 2.0 server. This is optional, and it will likely only be used if the PingDataSync server needs to supply a client certificate to the SCIM 2.0 server.

`ssl-cert-nickname`

The nickname (alias) of the client certificate to present to the SCIM 2.0 server. This is only needed if a `key-manager-provider` is specified and only if the associated key store has multiple certificates that could be used.

`trust-manager-provider`

A trust manager provider to use to determine whether to trust the certificate chain presented by the SCIM 2.0 server during Secure Sockets Layer (SSL) negotiation. This is optional, and if you don't specify it, then the PingDataSync server will rely primarily on the Java Virtual Machine (JVM)'s default set of trusted issuers. If the SCIM 2.0 server is using a certificate signed by one of those trusted issuers, then you can leave this property unset.

`hostname-verification-method`

Indicates whether the PingDataSync server should verify that the certificate presented by the SCIM 2.0 server is appropriate for the intended address. A value of `strict`, which is the default, indicates that the connection should only be established if the certificate has a subject alternative name extension with a value that matches the address provided in the `scim-service-url` property (or if the certificate does not have a subject alternative name extension, then it falls back to using the `CN` attribute of the certificate subject). A value of `allow-all` indicates that the PingDataSync server should not attempt to confirm that the certificate was issued for the intended server.

`http-authorization-method`

The HTTP authorization method that the PingDataSync server should use to authenticate to and authorize requests in the SCIM 2.0 server. This is required.

`response-timeout`

The maximum length of time that the PingDataSync server should wait for a response from the SCIM 2.0 server when issuing requests. If this is not specified, a default of 10 seconds is used.

`client-reconnect-interval`

The maximum length of time that a SCIM 2.0 client instance will be used before a new one is created, which might potentially include obtaining new credentials. If the client credentials grant HTTP authorization method is used and the OAuth authorization server specified an expiration time for the bearer token that it issued, then the actual reconnect interval is based on the lesser of the two values. If this is not specified, and if the HTTP authorization method does not indicate a maximum lifetime for its credentials, then the same SCIM 2.0 client instance is used indefinitely.

> **Note**
>
> The server will automatically try to refresh the credentials if the SCIM 2.0 service returns a 401 (unauthorized) error in response to any request.

For example, you can use the following change to configure a SCIM 2.0 external server:

```
dsconfig create-external-server \
     --server-name "SCIMv2 Server" \
     --type scim2 \
     --set scim-service-url:https://scim2.example.com/scim/v2 \
     --set "http-authorization-method:SCIMv2 Authorization Method"
```

Configure SCIM 2.0 attribute mappings

System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings are used to construct the SCIM representations of attributes from the information contained in the internal mapped Lightweight Directory Access Protocol (LDAP) representation of an entry that SCIM uses.

Even though the PingDataSync server can perform its own attribute mapping on data read from the source server (as configured in the sync class), this isn't sufficient on its own to interact with a SCIM 2.0 server.

In some cases, it might be necessary to transform values in a way that's not easily accomplished with the existing attribute mapping mechanism that the PingDataSync server provides, for example, from a generalized time representation that is typically used for timestamps in LDAP entries to the ISO 8601 format described in RFC 3339 that SCIM 2.0 servers typically use.

The existing attribute mapping can also be inconvenient for generating SCIM 2.0 complex attributes.

Each SCIM 2.0 attribute mapping is associated with a syntax. The server supports the following types of SCIM 2.0 attribute mappings.

SCIM 2.0 attribute mappings	Description
String	Used for SCIM 2.0 attributes represented as JSON strings. See String SCIM 2.0 attribute mappings.
Number	Used for SCIM 2.0 attributes represented as JSON numbers. See Number SCIM 2.0 attribute mappings.
Boolean	Used for SCIM 2.0 attributes represented as JSON Boolean values. See Boolean SCIM 2.0 attribute mappings.
DateTime	Used for SCIM 2.0 attributes in which the LDAP representation is a timestamp in the generalized time format, and the SCIM 2.0 representation uses the format described in RFC 3339. See DateTime SCIM 2.0 attribute mappings.
Postal Address	Used for SCIM 2.0 attributes in which the LDAP representation is a string that represents multiple lines using the dollar sign character ($) as the line delimiter, and the SCIM 2.0 representation uses newline characters (\n) to separate the lines. See Postal address SCIM 2.0 attribute mappings.
Composed Complex	Used for SCIM 2.0 complex attributes in which the sub-attributes are defined with other SCIM 2.0 attribute mappings. See Composed complex SCIM 2.0 attribute mappings

SCIM 2.0 attribute mappings	Description
JSON-Formatted Complex	Used for SCIM 2.0 complex attributes in which the JSON objects that represent the complex attributes are read from a specified attribute in the mapped LDAP representation of the entry. See JSON-formatted complex SCIM 2.0 attribute mappings.

Each of these will be described in more detail in its own section, but all types of attribute mappings share the following configuration properties:

`scim-attribute-name`

The name of the attribute as it appears in SCIM 2.0 entries. This is required.

`attribute-usage`

The ways in which the associated attribute is used. It must have at least one of the following values:

- `fetch` – The attribute is to be retrieved from the SCIM 2.0 server when fetching entries.
- `create-during-realtime-sync` – The attribute is to be included when creating a new entry in the SCIM 2.0 server during real-time synchronization.
- `create-during-resync` – The attribute is to be included when creating a new entry in the SCIM 2.0 server during resync processing.
- `update-during-realtime-sync` – The attribute is to be updated if necessary when applying changes to existing entries in the SCIM 2.0 server during real-time synchronization.
- `update-during-resync` – The attribute is to be updated if necessary when applying changes to existing entries in the SCIM 2.0 server during resync processing.

`failed-mapping-behavior`

Indicates how the PingDataSync server should handle cases in which an error occurs when trying to map a value between the LDAP and SCIM 2.0 representations of an entry, such as if the value doesn't conform to the expected syntax. The value for this property can be one of the following:

- `reject` – Indicates that the associated synchronization operation should be rejected. This is the default behavior that will be used if no value is specified.
- `ignore-entire-attribute` – Indicates that the associated synchronization operation should proceed as if the entire attribute had been omitted, even if it's a multivalued attribute in which other values can be successfully mapped.
- `ignore-individual-values` – Indicates that the associated synchronization operation should proceed as if any unmappable values had been omitted. For single-valued attributes, or for multivalued attributes in which none of the values can be successfully mapped, this behavior will be the same as ignore-entire-attribute. For multivalued attributes in which at least one value can be successfully mapped, only the unmappable values will be omitted.

always-patch-with-replace

Indicates whether to always use the `replace` operation type when updating values of this attribute with a SCIM 2.0 PATCH operation (this property does not apply when replacing the entire entry with a PUT operation). By default, this property has a value of `false`, to indicate that it should attempt to update values for the attribute with the `add` and `remove` operation types when possible. However, for some types of attributes (for example, if the SCIM 2.0 server allows you to update passwords but not retrieve them, or if it only allows retrieving them in an encoded form that does not match the form in which it was obtained from the source server), it might be necessary to always use the `replace` operation type.

Just as it might be necessary to change the value of the `always-patch-with-replace` property when synchronizing passwords, you might also need to treat the `attribute-usage` property specially for passwords as well. This is especially true in cases where the clear-text password is available during real-time synchronization, but not during a resync.

This can occur, for example, when synchronizing from a PingDirectory server with the Changelog Password Encryption Plugin enabled because the plugin includes an encrypted representation of the clear-text password in the changelog record for operations in which a clear-text password was provided, but the clear-text password is not available during resync processing.

In such cases, you might need to omit the `create-during-resync` and `update-during-resync` behaviors if the SCIM 2.0 server cannot handle passwords in their encoded form.

String SCIM 2.0 attribute mappings

String System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used for cases in which the SCIM attribute has a value that is a single JavaScript Object Notation (JSON) string or an array of JSON strings. The value will not be transformed in any way when converting between the Lightweight Directory Access Protocol (LDAP) and SCIM representations of an entry.

Additional configuration properties that are available for string SCIM 2.0 attribute mappings include:

ldap-attribute-name

The name of the LDAP attribute (in the mapped representation of the source entry generated by the sync class) whose values will be used as the values of the SCIM 2.0 attribute. This is required.

single-valued

Indicates whether the SCIM 2.0 attribute is single-valued or multivalued. If this is `true`, then the SCIM 2.0 representation of the attribute value will be as a JSON string. If this is `false`, then the SCIM 2.0 representation of the attribute value will be as a JSON array of strings.

You can use the following example configuration change to create a string SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name userName \
     --type string \
     --set scim-attribute-name:userName \
     --set ldap-attribute-name:uid \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set single-valued:true
```

Number SCIM 2.0 attribute mappings

You can use number System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings for cases in which the SCIM attribute has a value that is a single JavaScript Object Notation (JSON) number (whether integer or floating-point) or an array of JSON numbers. The value will not be transformed in any way when converting between the Lightweight Directory Access Protocol (LDAP) and SCIM representations of an entry.

Additional configuration properties that are available for number SCIM 2.0 attribute mappings include:

`ldap-attribute-name`

The name of the LDAP attribute (in the mapped representation of the source entry generated by the sync class) whose values will be used as the values of the SCIM 2.0 attribute. This is required, and the LDAP attribute must have values that can be parsed as JSON numbers.

`single-valued`

Indicates whether the SCIM 2.0 attribute is single-valued or multivalued. If this is `true`, then the SCIM 2.0 representation of the attribute value will be as a JSON string. If this is `false`, then the SCIM 2.0 representation of the attribute value will be as a JSON array of strings.

You can use the following example configuration change to create a number SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "Example Numeric Value" \
     --type number \
     --set scim-attribute-name:exampleSCIMAttributeName \
     --set ldap-attribute-name:exampleLDAPAttributeName \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set single-valued:true
```

Boolean SCIM 2.0 attribute mappings

Boolean System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used for cases in which the SCIM attribute has a value that is a single JavaScript Object Notation (JSON) Boolean value.

Additional configuration properties that are available for Boolean SCIM 2.0 attribute mappings include:

`ldap-attribute-name`

The name of the Lightweight Directory Access Protocol (LDAP) attribute (in the mapped representation of the source entry generated by the sync class) whose value will be used as the value of the SCIM 2.0 attribute. This is required, and the LDAP attribute must have a value of either `true` or `false`.

> **Note**
>
> This SCIM 2.0 attribute mapping type does not support multivalued attributes because it doesn't make sense for a Boolean attribute to have multiple values.

You can use the following example configuration change to create a Boolean SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "Account Enabled" \
     --type boolean \
     --set scim-attribute-name:active \
     --set ldap-attribute-name:accountEnabled \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set single-valued:true
```

DateTime SCIM 2.0 attribute mappings

DateTime System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used for cases in which the SCIM attribute has a value that is a JavaScript Object Notation (JSON) string or an array of JSON strings representing timestamps in the ISO 8601 format described in RFC 3339.

The corresponding LDAP attribute has values in the generalized time format. The values will be transformed as appropriate when converting between the LDAP and SCIM 2.0 representations.

Additional configuration properties that are available for DateTime SCIM 2.0 attribute mappings include:

`ldap-attribute-name`

The name of the LDAP attribute (in the mapped representation of the source entry generated by the sync class) whose values will be used as the values of the SCIM 2.0 attribute. This is required, and the LDAP attribute must have values that can be parsed using the generalized time syntax.

single-valued

Indicates whether the SCIM 2.0 attribute is single-valued or multivalued. If this is `true`, then the SCIM 2.0 representation of the attribute value will be as a JSON string. If this is `false`, then the SCIM 2.0 representation of the attribute value will be as a JSON array of strings.

You can use the following example configuration change to create a DateTime SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "Create Time" \
     --type date-time \
     --set scim-attribute-name:created \
     --set ldap-attribute-name:createTimestamp \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set single-valued:true
```

Postal address SCIM 2.0 attribute mappings

Postal address System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used for cases in which an attribute represents a postal address in a multi-line format.

In this case, the SCIM 2.0 representation of the address will use the newline character (\n) to separate lines, but the Lightweight Directory Access Protocol (LDAP) representation uses the dollar sign character ($) to separate lines. The values will be transformed as appropriate when converting between the LDAP and SCIM 2.0 representations.

Additional configuration properties that are available for postal address SCIM 2.0 attribute mappings include:

ldap-attribute-name

The name of the LDAP attribute (in the mapped representation of the source entry generated by the sync class) whose values will be used as the values of the SCIM 2.0 attribute. This is required.

single-valued

Indicates whether the SCIM 2.0 attribute is single-valued or multivalued. If this is `true`, then the SCIM 2.0 representation of the attribute value will be as a JavaScript Object Notation (JSON) string. If this is `false`, then the SCIM 2.0 representation of the attribute value will be as a JSON array of strings.

You can use the following example configuration change to create a postal address SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "Postal Address" \
     --type postal-address \
     --set scim-attribute-name:formatted \
     --set ldap-attribute-name:postalAddress \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set single-valued:true
```

Dot notation support for SCIM 2.0 sub-attributes

There is a known issue with using dot notation for SCIM 2.0 operations on sub-attributes within an entry.

The PingDirectory server can't properly interpret the dot notation that defines sub-attributes in the SCIM 2.0 standard. To perform the desired operation, modify your SCIM statements by defining any sub-attributes as child objects of the parent attribute.

For example, when updating complex or extended SCIM attributes, don't use these formulations, which rely on dot notation to define the sub-attribute:

```
\\ Incorrect complex attribute example
        {
          "schemas":[
            "urn:ietf:params:scim:api:messages:2.0:PatchOp"
          ],
          "Operations":[
            {
              "op":"replace",
              "value":{
                "name.formatted":"test1 test2",
                "name.familyName":"test1"
              }
            }
          ]
        }
```

```
\\ Incorrect extended attribute example
{
  "schemas":[
        "urn:ietf:params:scim:api:messages:2.0:PatchOp"
  ],
  "Operations":[
        {
          "op":"replace",
          "value":{
                "urn:ietf:params:scim:schemas:extension:myown:2.0:User.lastname":"test3",
                "urn:ietf:params:scim:schemas:extension:myown:2.0:User.section":"test4"
          }
        }
  ]
}
```

Use the following formulations instead:

```
\\ Correct complex attribute example
        {
          "schemas":[
            "urn:ietf:params:scim:api:messages:2.0:PatchOp"
          ],
          "Operations":[
            {
              "op":"replace",
              "value":{
                "name":{
                  "formatted":"test1 test2",
                  "familyName":"test1"
                }
              }
            }
          ]
        }
```

```
\\ Correct extended attribute example
        {
          "schemas":[
                "urn:ietf:params:scim:api:messages:2.0:PatchOp"
          ],
          "Operations":[
            {
              "op":"replace",
              "value":{
                "urn:ietf:params:scim:schemas:extension:myown:2.0:User":{
                  "lastname":"test3",
                  "section":"test4"
                }
              }
            }
          ]
        }
```

Composed complex SCIM 2.0 attribute mappings

Composed complex System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used to create a single-valued complex attribute in which the sub-attributes are created from other SCIM 2.0 attribute mappings.

For example, the `name` complex attribute described in RFC 7643 section 8.7.1 can have sub-attributes, such as `formatted`, `familyName`, and `givenName`, that might correspond to the `cn`, `sn`, and `givenName` Lightweight Directory Access Protocol (LDAP) attributes. If you had SCIM 2.0 attribute mappings defined for each of those attributes, then you could use a composed complex SCIM 2.0 attribute mapping that uses those mappings to construct an appropriate value for the name complex attribute.

> **Note**
>
> Because the order in which values are presented in multivalued LDAP attributes is not considered significant, you can only use composed complex SCIM 2.0 attribute mappings to generate single-valued complex attributes. If you need a multivalued complex attribute, use the JavaScript Object Notation (JSON)-formatted complex SCIM 2.0 attribute mapping type.

Additional configuration properties that are available for composed complex SCIM 2.0 attribute mappings include:

`sub-attribute-mapping`

A reference to one or more attribute mappings for the sub-attributes to include in the complex attribute. This is required.

You can use the following example configuration change to create a composed complex SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "name Complex Attribute" \
     --type composed-complex \
     --set scim-attribute-name:name\
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set "sub-attribute-mapping:Formatted Name" \
     --set "sub-attribute-mapping:First Name" \
     --set "sub-attribute-mapping:Last Name"
```

JSON-formatted complex SCIM 2.0 attribute mappings

JavaScript Object Notation (JSON)-formatted complex System for Cross-domain Identity Management (SCIM) 2.0 attribute mappings can be used to create complex SCIM attributes from Lightweight Directory Access Protocol (LDAP) attributes whose values are the string representations of JSON objects.

Unless the data is already stored in that format in the sync source, then it could be more complicated to produce this format (possibly requiring sync attribute mappings or even a sync destination plugin), but it does provide the ability to generate multivalued complex attributes.

Additional configuration properties that are available for JSON-formatted complex SCIM 2.0 attribute mappings include:

`ldap-attribute-name`

The name of the LDAP attribute (in the mapped representation of the source entry generated by the sync class) whose values will be used as the values of the SCIM 2.0 attribute. This is required, and the LDAP attribute must have values that can be parsed as JSON objects.

`single-valued`

Indicates whether the SCIM 2.0 attribute is single-valued or multivalued. If this is `true`, then the SCIM 2.0 representation of the attribute value will be as a JSON string. If this is `false`, then the SCIM 2.0 representation of the attribute value will be as a JSON array of strings.

You can use the following example configuration change to create a JSON-formatted complex SCIM 2.0 attribute mapping:

```
dsconfig create-scim2-attribute-mapping \
     --mapping-name "Email Addresses" \
     --type json-formatted-complex \
     --set scim-attribute-name:emails \
     --set ldap-attribute-name:ubidEmailJSON \
     --set attribute-usage:fetch \
     --set attribute-usage:create-during-realtime-sync \
     --set attribute-usage:create-during-resync \
     --set attribute-usage:update-during-realtime-sync \
     --set attribute-usage:update-during-resync \
     --set single-valued:false
```

Custom SCIM 2.0 attribute mappings for extended schemas

You can map custom attributes defined in extended schemas to System for Cross-domain Identity Management (SCIM) 2.0 sync destinations.

Consider the following example JSON that creates `testUser` using SCIM 2.0 and includes the custom attributes `workAnniversary` and `employeeAge` from an extended schema:

```
{
"schemas": [
"urn:ietf:params:scim:schemas:extension:gluu:2.0:User",
"urn:ietf:params:scim:schemas:core:2.0:User"
],
"id": "7e929a2d-18d3-462f-8c32-653a9ed170e2",
"meta": {
"resourceType": "User",
"created": "2022-12-07T03:33:45.469Z",
"lastModified": "2022-12-07T03:34:45.830Z",
"location": "https://rhel8/identity/restv1/scim/v2/Users/7e929a2d-18d3-462f-8c32-653a9ed170e2"
},
"userName": "testUser",
"name": {
"familyName": "User",
"givenName": "Test",
"formatted": "Test User"
},
"active": true,
"displayName": "Test User",
"urn:ietf:params:scim:schemas:extension:gluu:2.0:User": {
"workAnniversary": "1994-12-16T10:32:00Z",
"employeeAge": 55
}
}
```

To map custom attributes for synchronization with the SCIM 2.0 destination, you must:

- Create a composed complex attribute mapping with the custom schema URN
- Define any custom attributes associated with the custom schema as sub-attributes of the complex attribute

For example, to map the custom attributes `workAnniversary` and `employeeAge`, use the following commands.

To map the sub-attribute `employeeAge`:

```
dsconfig create-scim2-attribute-mapping \
--mapping-name urn:ietf:params:scim:schemas:extension:gluu:2.0:User.employeeAge \
--type number \
--set scim-attribute-name:employeeAge \
--set attribute-usage:create-during-realtime-sync \
--set attribute-usage:create-during-resync \
--set attribute-usage:update-during-realtime-sync \
--set attribute-usage:update-during-resync \
--set ldap-attribute-name:loginGraceLimit \
--set single-valued:true \
--set default-value:55
```

To map the sub-attribute `workAnniversary`:

```
dsconfig create-scim2-attribute-mapping \
--mapping-name urn:ietf:params:scim:schemas:extension:gluu:2.0:User.workAnniversary \
--type date-time \
--set scim-attribute-name:workAnniversary \
--set attribute-usage:create-during-realtime-sync \
--set attribute-usage:create-during-resync \
--set attribute-usage:update-during-realtime-sync \
--set attribute-usage:update-during-resync \
--set ldap-attribute-name:loginTime \
--set single-valued:true \
--set default-value:1994-12-16T10:32:00Z
```

To map the composed complex attribute:

```
dsconfig create-scim2-attribute-mapping \
--mapping-name urn:ietf:params:scim:schemas:extension:gluu:2.0:User \
--type composed-complex \
--set scim-attribute-name:urn:ietf:params:scim:schemas:extension:gluu:2.0:User \
--set attribute-usage:create-during-realtime-sync \
--set attribute-usage:create-during-resync \
--set attribute-usage:fetch \
--set attribute-usage:update-during-realtime-sync \
--set attribute-usage:update-during-resync \
--set sub-attribute-mapping:urn:ietf:params:scim:schemas:extension:gluu:2.0:User.employeeAge \
--set sub-attribute-mapping:urn:ietf:params:scim:schemas:extension:gluu:2.0:User.workAnniversary
```

After running the previous example commands, you must add the composed complex attribute to the list of attribute mappings for the appropriate SCIM 2.0 endpoint mapping.

Configure SCIM 2.0 endpoint mappings

A System for Cross-domain Identity Management (SCIM) 2.0 endpoint mapping provides information about a specific endpoint in the SCIM 2.0 server and the kinds of entries available at that endpoint.

SCIM 2.0 servers can have multiple endpoints for different kinds of entries (for example, one for users and another for groups), and if you want to be able to synchronize different kinds of entries, then you'll need a separate SCIM 2.0 endpoint mapping for each.

The following configuration properties are associated with a SCIM 2.0 endpoint mapping:

`endpoint-path`

The relative path used to access the target endpoint in the SCIM 2.0 server. This is the portion of the path that needs to be appended to the `scim-service-url` property from the SCIM 2.0 external server to get the full path to the endpoint. For example, if the full path to an endpoint to use for accessing user entries is `https://scim2.example.com/scim/v2/Users`, and if the `scim-service-url` value is `https://scim2.example.com/scim/v2`, then the appropriate endpoint-path value would be `Users`. This is required.

`schema-urn`

The URN of the SCIM 2.0 schema for the entries that are associated with this endpoint. This is required, and multiple values can be specified if there are multiple schemas associated with the endpoint.

`attribute-mapping`

The set of attribute mappings that will be used to construct the SCIM 2.0 representation of an entry from the LDAP representation of the source entry constructed by a sync class. These attribute mappings will be used when:

- Fetching an entry from the SCIM 2.0 server to determine whether the entry needs to be created or updated
- Creating a new entry
- Updating an existing entry

At least one attribute mapping must be defined, but there will probably be several.

`search-attribute-mapping`

The set of attribute mappings that will be used to construct a SCIM 2.0 filter that will be used to search for the SCIM entry that corresponds to the mapped Lightweight Directory Access Protocol (LDAP) representation of the source entry. For example, when mapping an LDAP user to a SCIM 2.0 user, you might map the `uid` LDAP attribute to the `userName` SCIM attribute, and an LDAP entry with a `uid` value of `jdoe` could result in a SCIM 2.0 search filter of `userName eq "jdoe"`. This is required, and multiple values can be provided if there should be multiple search attributes (which will be combined in an `AND` filter).

`sync-class-name`

The name of the sync class that will be used to map source entries for synchronization to the target endpoint. This is optional, and it can be omitted if the SCIM 2.0 sync destination is only associated with a single endpoint. If the SCIM 2.0 sync destination will be associated with multiple endpoints, then this property must be specified. It can be given multiple values if multiple sync classes can be used to map source entries for the same endpoint.

You can use the following example configuration change to create a SCIM 2.0 endpoint mapping:

```
dsconfig create-scim2-endpoint-mapping \
     --mapping-name "Users Endpoint" \
     --set endpoint-path:Users \
     --set schema-urn:urn:ietf:params:scim:schemas:core:2.0:User \
     --set "attribute-mapping:User Name Mapping" \
     --set "attribute-mapping:Name Mapping" \
     --set "attribute-mapping:Display Name Mapping" \
     --set "attribute-mapping:Email Address Mapping" \
     --set "attribute-mapping:Postal Address Mapping" \
     --set "attribute-mapping:Phone Number Mapping" \
     --set "search-attribute-mapping:User Name Mapping" \
```

Configure the SCIM 2.0 sync destination

The System for Cross-domain Identity Management (SCIM) 2.0 sync destination associates a SCIM 2.0 external server with a set of one or more endpoint mappings and can also specify additional configuration properties.

Available properties include:

`server`

The SCIM 2.0 external server to which changes will be synchronized. This is required.

`endpoint-mapping`

A set of one or more SCIM 2.0 endpoint mappings to use when synchronizing changes to the SCIM 2.0 server. This is required.

`query-method`

The HTTP request method that should be used when querying the SCIM 2.0 server to fetch existing entries. The value can be one of the following:

- `get` – Use the HTTP GET method to submit the query. This is the default value that will be used if the property is not specified.
- `post` – Use the HTTP POST method to submit the query.

`update-method`

The HTTP request method that should be used when applying changes to existing SCIM 2.0 entries. The value can be one of the following:

- `put` – Use the HTTP PUT method to replace the entire entry. SCIM 2.0 servers must support this method, but it is less efficient and more risky than using the PATCH method because it has greater potential of losing changes to the entry made by other SCIM 2.0 clients.
- `patch` – Use the HTTP PATCH method to specify which specific changes should be applied to the entry. This method is an optional part of the SCIM 2.0 specification, so it might not be available in all servers, but it is more efficient and safer than the PUT method, so this is the default that will be used if the property is not specified.

You can use the following example configuration change to create a SCIM 2.0 sync destination:

```
dsconfig create-sync-destination \
     --destination-name "SCIMv2 Destination" \
     --type scim2 \
     --set "server:SCIMv2 Server" \
     --set "endpoint-mapping:Users Endpoint"
```

Configure a sync pipe

A sync pipe associates a sync source, from which changes will be read, with a sync destination, to which corresponding changes will be applied.

Although there are many useful configuration properties associated with a sync pipe, including those used to control retry attempts, rate limiting, and the number of worker threads, most of those properties already have good default values. The only properties you need to specify are:

`sync-source`

The sync source from which the changes will be read. This is required.

`sync-destination`

The sync destination to which the corresponding changes will be applied. This is required.

You can use the following example configuration change to create a sync pipe:

```
dsconfig create-sync-pipe \
     --pipe-name "LDAP Source to SCIMv2 Destination" \
     --set "sync-source:LDAP Source" \
     --set "sync-destination:SCIMv2 Destination"
```

Configure sync classes

Sync classes specify how to handle different kinds of entries read from the sync source when preparing to synchronize them to the sync destination.

When synchronizing to a System for Cross-domain Identity Management (SCIM) 2.0 server, you should have at least one sync class for each endpoint. The most important configuration properties you might need to specify include:

`evaluation-order-index`

A numeric value that indicates the order in which the sync class should be evaluated relative to other classes that are associated with the same sync pipe. Each class should have a different index, and classes will be examined in ascending order from lowest index to highest. The first class that is appropriate for a given type of change (based on criteria like the base distinguished name (DN), filter, and change type) will be used. This is required, but if you only have a single sync class for a sync pipe, then you can just use the default value of 9999.

include-base-dn

An optional base DN for source entries on which this sync class can operate. For example, if you are synchronizing users from an Lightweight Directory Access Protocol (LDAP) server, and if all of the users you want to synchronize are below `ou=People,dc=example,dc=com`, then you could use that as the base DN.

include-filter

An optional filter to use to determine which kinds of entries on which this sync class can operate. If a source entry does not match this filter, the sync class will not be used. For example, if the user entries you want to synchronize all have the `inetOrgPerson` object class, then you could use a filter of `(objectClass=inetOrgPerson)`.

attribute-map

An optional attribute map to identify and convert source attributes for use in the destination entry.

> **Note**
>
> This is different from the SCIM 2.0 attribute mapping that will be used by the SCIM 2.0 sync destination in that it is more general and is not tied to any specific type of destination. In some advanced use cases, you might need to provide values for this property (especially if you need to apply transformations that SCIM 2.0 attribute mappings can't do on their own), but in many cases, the `auto-mapped-source-attribute` property will be sufficient.

auto-mapped-source-attribute

A list of the attributes that should be automatically mapped from the source entry to the destination (before any SCIM 2.0 attribute mapping is applied, which might narrow down the set of attributes that will actually be used, and which might apply additional transformations). This might be a list of specific attribute names, but you can also use the special value `-all-` to indicate that all attributes from the source entry should be mapped to destination, or the value of `-none-` to indicate that no attributes should be automatically mapped and that only those attributes referenced in the `attribute-map` property should be included. This is required.

synchronize-creates

Indicates whether to attempt to synchronize new entries created in the sync source to the destination. This property has a default value of `true`.

synchronize-modifies

Indicates whether to attempt to synchronize changes to existing entries created in the sync source to the destination. This property has a default value of `true`.

synchronize-deletes

Indicates whether to attempt to synchronize entries removed from the sync source to the destination. This property has a default value of `true`.

`attribute-comparison-method`

The method to use when comparing attributes between the source and destination versions of an entry to see if the value has changed. If specified, the value should be one of:

- `syntax-based` – Uses the syntax and matching rules for the associated attribute type to determine whether a value has changed. This is the default behavior, and it might ignore changes that aren't considered significant by the equality matching rule (for example, if the value differs only in its use of capitalization in an attribute that uses case-insensitive matching).
- `byte-for-byte` – Uses a byte-for-byte comparison of the source and destination versions of each value to determine whether it was changed. Any difference in the value will be considered significant, even if it would not have been considered significant in accordance with the syntax and matching rules.

`modifies-as-creates`

Indicates how the server should behave if an existing entry is modified in the sync source, but no corresponding version of that entry is found in the sync destination. By default, the value is `false`, and the synchronization operation will fail, leaving the entry absent from the destination. However, if this property is set to true, then the entry will be created in the destination.

`creates-as-modifies`

Indicates how the server should behave if a new entry is created in the sync source, but a corresponding version of that entry already exists in the sync destination. By default, the value is `false`, and the synchronization operation will fail, leaving the existing destination entry unchanged. However, if this property is set to `true`, then the source and destination versions of the entry will be compared, and the add might be converted into a modify if any differences are identified.

`plugin`

An optional set of plugins that can be invoked when mapping entries from the source to the destination.

You can use the following example configuration change to create a sync class:

```
dsconfig create-sync-class \
     --pipe-name "LDAP Source to SCIMv2 Destination" \
     --class-name "User Class" \
     --set include-base-dn:ou=People,dc=example,dc=com \
     --set include-filter:(objectClass=inetOrgPerson) \
     --set auto-mapped-source-attribute:-all-
```

Set the changelog startpoint for the sync source (optional)

If the sync source is an instance of the PingDirectory server, then you should tell the PingDataSync server to record the record that is currently at the end of its changelog so that real-time synchronization can begin from there after it's started.

You can do this using the `realtime-sync set-startpoint` command. For example:

```
bin/realtime-sync set-startpoint \
     --hostname sync.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore \
     --bindDN "cn=Directory Manager" \
     --bindPasswordFile directory-manager-password.txt \
     --pipe-name "LDAP Source to SCIMv2 Destination" \
     --end-of-changelog \
     --no-prompt
```

resync command">

Perform an initial bulk synchronization with the `resync` command

You can use the `resync` command to perform an initial synchronization from the source to the destination. It iterates through all entries in the source server and compares them with their counterparts in the destination server.

Any source entries that are not found in the destination are created. For entries that exist in both the source and the destination, any differences identified between them will cause the destination entry to be updated to match the source.

You can run the `resync --help` command to see the complete usage information for the tool, but in many cases, you only need to specify the name of the sync pipe. For example:

```
resync --pipe-name "LDAP Source to SCIM 2.0 Destination"
```

> **Note**
>
> Because the System for Cross-domain Identity Management (SCIM) 2.0 sync destination uses its own attribute mapping in addition to the mapping performed by the sync class, there might be cases in which the **`resync`** command believes the source and destination versions of an entry to be out of sync when they are actually in sync. This is especially true if the sync class is configured with an **`auto-mapped-source-attribute`** value of `-all-`.
> This can cause the **`resync`** command to report that a lot more entries are being modified than actually are being updated because the SCIM 2.0 sync destination performs its own comparison of the source and destination entries and might not attempt any update if it already sees that they are equivalent.
> This doesn't have any adverse effects, but you can update the `auto-mapped-source-attribute` property to explicitly list only the names of the source attributes that might be used to create the SCIM 2.0 representation of the entry.

Start real-time synchronization

After the initial synchronization is complete, you can tell the PingDataSync server to begin real-time synchronization for the sync pipe, at which point it will start watching the source for changes and making a corresponding set of updates to the destination server.

You can do this using the `realtime-sync start` command:

```
realtime-sync start \
     --hostname sync.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore \
     --bindDN "cn=Directory Manager" \
     --bindPasswordFile directory-manager-password.txt \
     --pipe-name "LDAP Source to SCIMv2 Destination" \
     --no-prompt
```

Managing Logging, Alerts, and Alarms

Each PingDirectory server supports extensive logging features to track all aspects of the PingDirectory topology.

This section contains the following topics:

Logs and log publishers

PingDirectory servers support different types of log publishers that can be used to provide the monitoring information for operations, access, debug, and error messages that occur during normal server processing. The server provides a standard set of default log files as well as mechanisms to configure custom log publishers with their own log rotation and retention policies.

Types of log publishers

Several types of log publishers can be used to log processing information about the server, including:

Audit loggers

Provide information about actions that occur within the server. Specifically, this type of log records:

- All changes applied, detected or failed
- Dropped operations that were not completed
- Changes dropped because of being out of scope
- No changes needed for an operation

The log also shows the entries that were involved in a process.

Error loggers

Provide information about warnings, errors, or significant events that occur within the server.

Debug loggers

Provide detailed information about processing performed by the server, including:

- Any exceptions caught during processing
- Detailed information about data read from or written to clients
- Accesses to the underlying database

Access loggers

Provide information about Lightweight Directory Access Protocol (LDAP) operations processed within the server. This log only applies to operations performed in the server. This includes:

- Configuration changes
- Searches of monitor data
- Bind operations for authenticating administrators using the command-line tools and the admin console

View the list of log publishers

View the list of log publishers on each server using the `dsconfig` tool:

```
$ bin/dsconfig list-log-publishers
Log Publisher                       : Type              : enabled
------------------------------------:-------------------:--------
Debug ACI Logger                    : debug-access      : false
Expensive Operations Access Logger : file-based-access : false
Failed Operations Access Logger
File-Based Access Logger
File-Based Audit Logger
: file-based-access : true
: file-based-access : true
: file-based-audit  : false
File-Based Debug Logger
File-Based Error Logger
Replication Repair Logger
: file-based-debug  : false
: file-based-error  : true
: file-based-error  : true
```

Log compression

PingDirectory servers support the ability to compress log files as they are written. Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled when the logger is created. Compression cannot be turned on or off once the logger is configured. If the server encounters an existing log file at startup, it will rotate that file and begin a new one rather than attempting to append it to the previous file.

Compression is performed using the standard `gzip` algorithm. Because it can be useful to have an amount of uncompressed log data for troubleshooting, having a second logger defined that does not use compression might be preferred.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger. See Creating a new log publisher for details.

Configuring log file encryption

About this task

The server supports the ability to encrypt log files as they are written. The encrypt-log configuration property controls whether encryption will be enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension (and if both encryption and compression are enabled, the extension will be `.gz.encrypted`). Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger has been configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This will also reduce the overall size of the log file. The `encrypt-file` command (or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`) is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption will be performed with the server's preferred encryption settings definition. To explicitly specify which definition should be used for the encryption, the `encryption-settings-definition-id` property can be set with the ID of that definition. You should create the encryption settings definition from a passphrase so that the file can be decrypted by providing that passphrase, even if the original encryption settings definition is no longer available. A randomly generated encryption settings definition can also be created, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data can remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written. To examine the contents of a log file that is being actively written, use the `rotate-log` command to force the file to be rotated before attempting to examine it.

The following commands can be used to set log file encryption:

Steps

1. Use `dsconfig` to enable encryption for a Log Publisher. In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted
Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
   --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
   --set "retention-policy:Size Limit Retention Policy"
```

2. To decrypt and decompress the file:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...DoneWriting decrypted
data to file '/ds/PingDirectory/decrypted-access' using a key generated
from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'Success
fully wrote 123,456,789 bytes of decrypted data
```

Synchronization logs and messages

PingDataSync provides a standard set of default log files to monitor the server activity. View this set of logs in the `<server-root>/logs` directory. The following default log files are available.

PingDataSync logs

Log file	Description
access	File-based Access Log that records Lightweight Directory Access Protocol (LDAP) operations processed by PingDataSync. Access log records can be used to provide information about problems during operation processing and about the time required to process each operation.
config-audit.log	Records information about changes made to the server configuration in a format that can be replayed using the `dsconfig` command.
errors	File-based Error Log that provides information about warnings, errors, and significant events that are not errors but occur during server processing.
server.out	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information will be written to `server.out`.
server.pid	Stores the server's processID.
server.status	Stores the timestamp, a status code, and an optional message that provides additional information about the server status.
setup.log	Records messages that occur during the initial server configuration with the `setup` command.
sync	File-based Sync Log that records synchronization operations processed by the server. Specifically, the log records all changes applied, detected or failed; dropped operations that were not synchronized; changes dropped because of being out of scope, or no changes needed for synchronization.
sync-pipe-cfg.txt	Records the configuration changes used with the `bin/create-sync-pipe-config` command. The file is placed wherever the command is run. Typically, this is in `<server-root>` or in the `bin` directory.
tools	Holds logs for long running utilities. Current and previous copies of the log are present in the directory.
update.log	Records messages that occur during a server upgrade.

Sync log message types

PingDataSync logs certain types of log messages with the sync log. Message types can be included or excluded from the logger, or added to a custom log publisher.

Sync log message types

Message type	Description
change-applied	Default summary message. Logged each time a change is applied successfully.
change-detected	Default summary message. Logged each time a change is detected.
change-failed-detailed	Default detail message. Logged when a change cannot be applied. It includes the reason for the failure and details about the change that can be used to manually repair the failure.
dropped-op-type-not-synchronized	Default summary message. Logged when a change is dropped because the operation type (for example, ADD) is not synchronized for the matching Sync Class.
dropped-out-of-scope	Default summary message. Logged when a change is dropped because it does not match any Sync Class.
no-change-needed	Default summary message. Logged each time a change is dropped because the modified source entry is already synchronized with the destination entry.
change-detected-detailed	Optional detail message. Logged each time a change is detected. It includes attribute values for added and modified entries. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
entry-mapping-details	Optional detail message. Logged each time a source entry (attributes and distinguished name (DN)) are mapped to a destination entry. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
change-applied-detailed	Optional detail message. Logged each time a change is applied. It includes attribute values for added and modified entries. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
change-failed	Optional summary message. Logged when a change cannot be applied. It includes the reason for the failure but not enough information to manually repair the failure.
intermediate-failure	Optional summary message. Logged each time an attempt to apply a change fails. Note that a subsequent retry of applying the change might succeed.

Creating a new log publisher

About this task

PingDirectory servers provide customization options to create log publishers with the `dsconfig` command. After creating a new log publisher, configure the log retention and rotation policies. For more information, see Configure log retention and log rotation policies.

Steps

1. Use the `dsconfig` command to create and configure the new log publisher. (If using `dsconfig` in interactive mode, log publishers are created and managed under the Log Publisher menu.) The following example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access --publisher-name "Disconnect Logger" \
  --set enabled:true \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set log-connects:false \
  --set log-requests:false --set log-results:false \
  --set log-file:logs/disconnect.log
```

   To configure compression on the logger, add the following option to the previous command:

```
--set compression-mechanism: gzip
```

   Compression cannot be disabled or turned off after it has been configured for the logger. Determine logging requirements before configuring this option.

2. View log publishers with the following command:

```
$ bin/dsconfig list-log-publishers
```

Configuring log signing

About this task

PingDirectory servers support the ability to cryptographically sign a log to ensure that it has not been modified. For example, financial institutions require tamper-proof audit logs files to ensure that transactions can be properly validated and ensure that they have not been modified by a third-party entity or internally by an unauthorized person.

When enabling signing for a logger that already exists, the first log file will not be completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled will be considered completely valid. For the same reason, if a log file is still open for writing, then signature validation will not indicate that the log is completely valid because the log will not include the necessary "end signed content" indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server (or the `bat` directory on Windows systems). After this property has been enabled, disable and then re-enable the log publisher for the changes to take effect.

Perform the following steps to configure log signing:

Steps

1. Use `dsconfig` to enable log signing for a Log Publisher. In this example, set the `sign-log` property on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the Log Publisher for the changes to take effect.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:false
```

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true
```

3. To validate a signed file, use the `validate-file-signature` tool to check if a signed file has been altered.

```
$ bin/validate-file-signature --file logs/audit
```

```
All signature information in file 'logs/audit' is valid
```

If any validation errors occur, a message displays that is similar to this:

```
One or more signature validation errors were encountered while validating
the contents of file 'logs/audit':
* The end of the input stream was encountered without encountering the end
of an active signature block. The contents of this signed block cannot be
trusted because the signature cannot be verified
```

Configure log retention and log rotation policies

PingDirectory servers enable configuring log rotation and log retention policies.

Log retention

When any retention limit is reached, the server removes the oldest archived log before creating a new log. Log retention is only effective if a log rotation policy is in place.

A new log publisher must have at least one log retention policy configured. The following policies are available:

File Count Retention policy

Sets the number of log files for the server to retain. The default file count is 10 logs. If the file count is set to 1, the log will continue to grow indefinitely without being rotated.

Free Disk Space Retention policy

Sets the minimum amount of free disk space. The default free disk space is 500 MB.

Size Limit Retention policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MB.

Custom Retention policy

Create a new retention policy that meets the server's requirements. This will require developing custom code to implement the desired log retention policy.

Never Delete Retention policy

Used in a rare event that does not require log deletion.

Configure the log retention policy

Use `dsconfig` to modify the log retention policy for the access logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Log rotation

When a rotation limit is reached, the server rotates the current log and starts a new log. A new log publisher must have at least one log rotation policy configured. The following policies are available:

Time Limit Rotation policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every seven days.

Fixed Time Rotation policy

Rotates the logs every day at a specified time (based on 24-hour). The default time is 2359.

Size Limit Rotation policy

Rotates the logs when the file reaches the maximum size. The default size limit is 100 MB.

Never Rotate policy

Used in a rare event that does not require log rotation.

Configure the log rotation policy

Use `dsconfig` to modify the log rotation policy for the access logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configure log listeners

The server provides two log file rotation listeners: the copy log file rotation listener and the summarize log file rotation listener, which can be enabled with a log publisher. Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file will be subject to deletion by a log file retention policy, but the copy will not be automatically removed.

Use the following command to create a new copy log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true</screen>
```

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that will be written there. The server will automatically monitor free disk space on the target file system and will generate administrative alerts if the amount of free space gets too low.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently rotated log file and writes its output to a file in a specified location.

This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types. Use the following command to create a new summarize log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically be deleted. Though files are generally small in comparison to the log files themselves, make sure that there is enough space available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

System alarms, alerts, and gauges

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability. A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state. Gauges are used for monitoring continuous values like CPU load or free disk space (Numeric Gauge), or an enumerated set of values such as `server available` or `server unavailable` (Indicator Gauge).

Gauges generate alarms, when the gauge's severity changes because of changes in the monitored value. Like alerts, alarms have severity (NORMAL, WARNING, MINOR, MAJOR, CRITICAL), name, and message. Alarms will always have a `Condition` property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a `ProbableCause` property and `AlarmType` property are also listed. Alarms can be configured to generate alerts when the alarm's severity changes.

There are two alert types supported by the server - standard and alarm-specific. The server constantly monitors for conditions that might need attention by administrators, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`. The server can be configured to generate alarm-specific alerts instead of, or in addition to, standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

The server installs a set of gauges that are specific to the product and that can be cloned or configured through the **`dsconfig`** tool. Existing gauges can be tailored to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered. The Stats Logger can be used to view historical information about the value and severity of all system gauges.

PingDirectory servers are compliant with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state can result in one or more alerts. An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when Condition and Resource property are the same. The Alarm Manager, which governs the actions performed when an alarm state is entered, is configurable through the **`dsconfig`** tool and admin console.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. Alarms can be viewed with the **`status`** tool. As with other alert types, alert handlers can be configured to manage the alerts generated by alarms. A complete listing of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

Alert handlers

Alert notifications can be sent to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The server provides several alert handler implementations configured with the **`confined`** tool, including:

Error Log Alert Handler

Sends administrative alerts to the configured server error logger(s).

JMX Alert Handler

Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. The server uses JMX for monitoring entries and requires that the JMX connection handler be enabled.

SNMP Alert Handler

Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.

> **Important**
>
> SNMP is deprecated.

If needed, the Server SDK can be used to implement additional, third-party alert handlers.

Configure alert handlers

Alert handlers can be configured with the `dsconfig` tool. PingDirectory servers support JMX, SMTP, and SNMP. Use the `--help` option for a list of configuration options. The following is a sample command to create and enable an SMTP Alert handler from the command line:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%\%alert-type\%\%" \
  --set "message-body:Administrative alert:\\n\%\%alert-message\%\%"
```

Testing alerts and alarms

About this task

After alarms and alert handlers are configured, verify that the server takes the appropriate action when an alarm state changes by manually increasing the severity of a gauge. Alarms and alerts can be verified with the `status` tool.

Steps

1. Configure a gauge with `dsconfig` and set the `override-severity` property to critical. The following example uses the CPU Usage (Percent) gauge.

```
$ dsconfig set-gauge-prop \
  --gauge-name "CPU Usage (Percent)" \
  --set override-severity:critical
```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms. The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status
```

```
                       --- Administrative Alerts ---

```

Use the status tool

PingDirectory servers provides the `status` tool, which outputs the health of the server. The `status` tool polls the current health of the server and displays summary information about the number of operations processed in the network. The tool provides the following information:

Status tool sections

Status section	Description
Server Status	Displays the server start time, operation status, number of connections (open, max, and total).
Server Details	Displays the server details including host name, administrative users, install path, server version, and Java version.
Connection Handlers	Displays the state of the connection handlers including address, port, protocol and current state.

Status section	Description
Admin Alerts	Displays the 15 administrative alerts that were generated over the last 48-hour period. Limit the number of displayed alerts using the `--maxAlerts` option. For example, `status --maxAlerts 0` suppresses all alerts.

Synchronization-specific status

The `status` tool displays the following information for PingDataSync.

PingDataSync status information

Status section	Description
Sync Topology	Displays information about the connected Sync topology and any standby PingDataSync instances.
Summary for Sync Pipe	Displays the health status for each Sync Pipe configured on the topology. Status for each Sync Pipe includes the following: • Started – Indicates whether the Sync Pipe has started. • Current Ops Per Second – Lists the current throughput rate in operations per second. • Percent Busy – Lists the number of current operations currently divided by the number of worker threads. • Changes Detected – Lists the total number of changes detected. • Ops Completed Total – Lists the total number of changes detected and completed. • Num Ops In Flight – Lists the number of operations that are in flight. • Num Ops In Queue – Lists the number of operations that are on the input queue waiting to be synchronized. • Source Unretrieved Changes – Lists how many outstanding changes are still in the source change log that have not yet been retrieved by PingDataSync. If this is greater than zero, it indicates a backlog, because the internal queue is too full to include these changes. • Failed Op Attempts – Lists the number of failed operation attempts. • Poll For Source Changes Count – Lists the number of times that the source has been polled for changes.

Status section	Description
Operations completed for the Sync Pipe	Displays the completed operation statistics for the sync pipe, including the following: • Success – Lists the number of changes that completed successfully. • Out Of Scope – Lists the number of changes that were included in the Sync Pipe, but were dropped because they did not match criteria in a Sync Class. • Op Type Not Synced – Lists the number of changes that completed because the operation type is not synchronized. • No Change Needed – Lists the number of changes that completed because no change was needed. • Entry Already Exists – Lists the number of changes that completed unsuccessfully because the entry already existed for a Create operation. • No Match Found – Lists the number of changes that completed unsuccessfully because no match for an operation (such as Modify) was found. • Multiple Matches Found – Lists the number of changes that completed unsuccessfully because multiple matches for a source entry were found at the destination. • Failed During Mapping – Lists the number of changes that completed unsuccessfully because there was a failure during attribute or distinguished name (DN) mapping. • Failed At Resource – Lists the number of changes that completed unsuccessfully because they failed at the source. • Unexpected Exception – Lists the number of changes that completed unsuccessfully because there was an unexpected exception during processing. • Total – Lists the number of operations completed.
Sync Pipe source stats	Displays the source statistics for the external server, including the following: • Is Connected – Indicates whether the Sync Source is connected or not. • Connected Server – Indicates the host name and port number of the connected server. • Successful Connect Attempts – Indicates the number of successful connection attempts. • Failed Connect Attempts – Indicates the number of failed connection attempts. • Forced Disconnects – Indicates the number of forced disconnects. • Root DSE Polls – Indicates the number of polling attempts of the root DSE. • Unretrieved Changes – Indicates the number of unretrieved changes. • Entries Fetched – Indicates the number of entries fetched from the source. • Failed To Decode Changelog Entry – Indicates the operations that failed to decode changelog entries. • Ops Excluded By Modifiers Name – Indicates the number of operations excluded by modifier's name. • Num Backtrack Batches Retrieved – Indicates the number of backtrack batches retrieved.

Status section	Description
Sync Pipe destination stats	Displays the destination statistics for the external server, including the following: • Is Connected – Indicates whether the Sync Source is connected or not. • Connected Server – Indicates the connection URL of the connected server. • Successful Connect Attempts – Indicates the number of successful connection attempts. • Failed Connect Attempts – Indicates the number of failed connection attempts. • Forced Disconnects – Indicates the number of forced disconnects. • Entries Fetched – Indicates the number of entries fetched. • Entries Created – Indicates the number of entries created. • Entries Modified – Indicates the number of entries modified. • Entries Deleted – Indicates the number of entries deleted.

Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

About this task

You can configure the Monitoring Endpoint using the `dsconfig` command or the admin console.

Steps

- To create the StatsD monitoring Endpoint, use either of the following:

  Choose from:

  - To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option.

    This example configures a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`.

    ```
    dsconfig create-monitoring-endpoint \
        --type statsd \
        --endpoint-name StatsDEndpoint \
        --set enabled:true \
        --set hostname:localhost \
        --set server-port:8125 \
        --set connection-type:unencrypted-udp
    ```

  - To use the admin console:

    1. From the admin console, click Show Advanced Configuration.
    2. In the Logging, Monitoring, and Notifications section, click Monitoring Endpoints.
    3. Click New Monitoring Endpoint.

When you configure Monitoring Endpoint include:

- The endpoint's host name
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

  You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

  ```
  example.metric:123|g|#tag1:value1,tag2:value2
  ```

  > **Note**
  >
  > You can send data to any number of monitoring endpoints.

Sending Metrics to Splunk with StatsD

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

Using the StatsD Endpoint type, you can send metric data to a Splunk installation. In Splunk, you can use Secure Sockets Layer (SSL) to secure ports that are open for StatsD. You can configure open UDP or TCP ports in Splunk to accept only connections from a certain hostname or IP address.

> **Note**
>
> StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

To securely send UDP or TCP data to Splunk:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Request that the forwarder use SSL to communicate with the Splunk Indexer.

Monitor PingDataSync

PingDataSync exposes its monitoring information under the `cn=monitor` entry. Various tools can be used to surface the server's information including the admin console, JConsole, Lightweight Directory Access Protocol (LDAP) command-line tools, or SNMP. The following information is collected for PingDataSync.

PingDataSync monitoring component

Component	Description
Active Operations	Provides information about the operations currently being processed by the server including the number of operations, information about the operation, and the number of active persistent searches.
Backend	Provides general information about the state of the server backend, including the backend ID, base DN(s), entry counts, entry count for the `cn=admin` data, writability mode, and whether it is a private backend. The following backend monitors are provided: • adminRoot • ads-truststore • alerts • backup • config • monitor • schema • tasks • userRoot
Berkeley DB JE Environment	Provides information about the state of the Oracle Berkeley DB Java Edition database used by the PingDataSync backend.
Client Connections	Provides information about all client connections to the server.
Disk Space Usage	Provides information about the disk space available to various components of the server. The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations can still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `config` directory, the location of every log file, all JE backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.
Connection Handler	Provides information about the available connection handlers on the server, which include the LDAP and LDIF connection handlers. These handlers are used to accept client connections.
General	Provides general information about the server, including product name and server version.
JVM Stack Trace	Provides a stack trace of all threads processing within the Java Virtual Machine (JVM).
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages, and operations handled.

Component	Description
Processing Time Histogram	Categorizes operation processing times into several user-defined buckets of information, including the total number of operations processed, overall average response time, and number of processing times between `0ms` and `1ms`.
System Information	Provides general information about the system and the JVM on which the server is running, including host name, operating system, JVM architecture, Java home, and Java version.
Version	Provides information about the product version, including build ID and revision number.
Work Queue	Provides information about the state of the PingDataSync work queue, which holds requests until they can be processed by a worker thread. The work queue configuration has a `monitor-queue-time` property set to `true` by default. This logs messages for new operations with a `qtime` attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue. A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations be processed using the administrative thread pool, the requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

DevOps and infrastructure as code

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- Pets — With the pets service model, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- Cattle — With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-primary datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Before server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see Server profiles.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

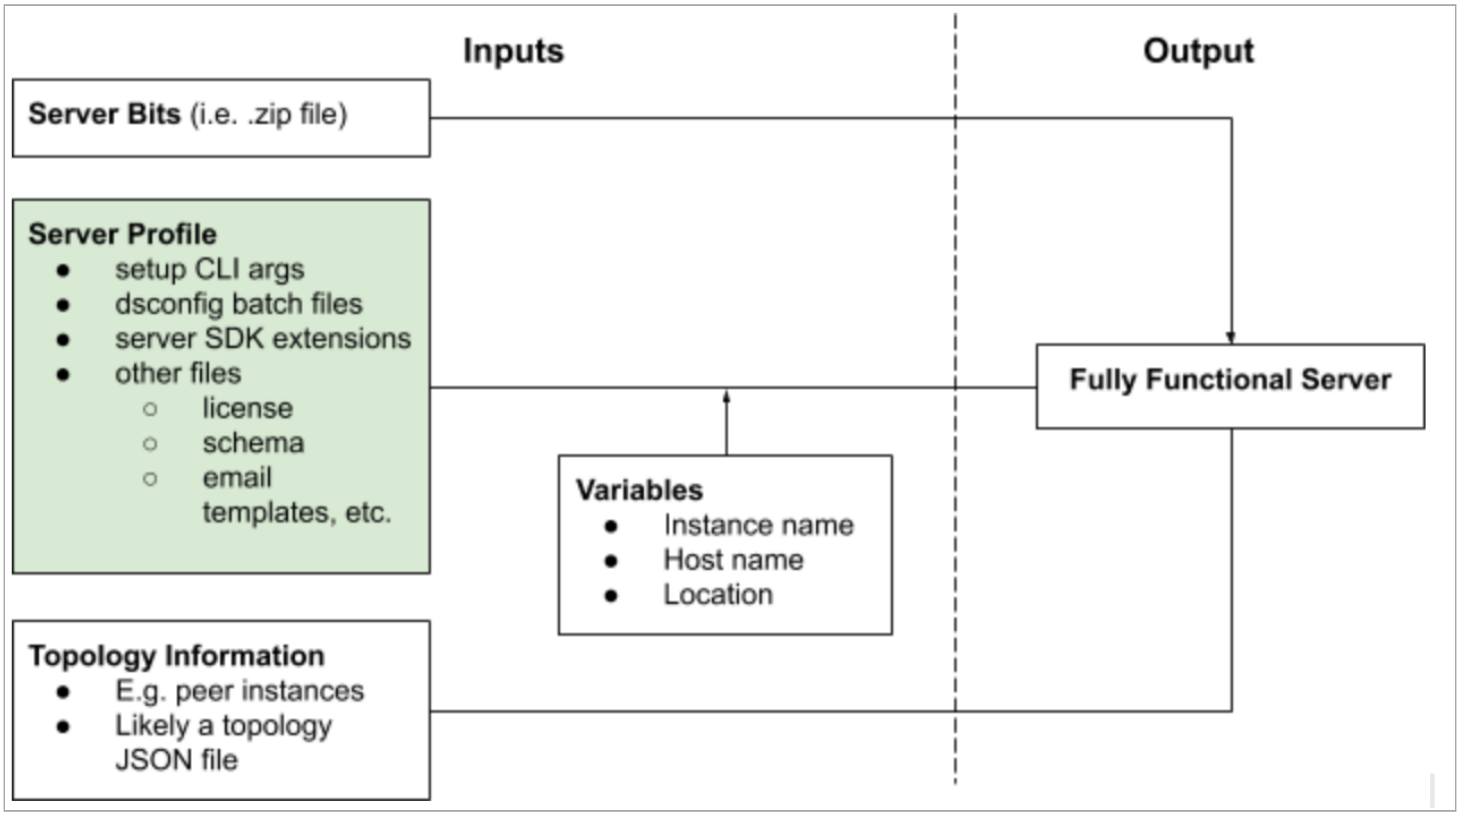
Server profiles

Regardless of the service model that your company follows, server profiles help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDataSync and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.



As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see Variable substitution.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the `manage-profile replace-profile` subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, `manage-profile setup` can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files before its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
`PING_SERVER_ROOT`	Evaluates to the absolute path of the server's root directory
`PING_PROFILE_ROOT`	Evaluates to the individual profile's root directory **Note** Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

For more information about the tool's usage, run the command `bin/manage-profile --help`.

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- ldif/
      |-- userRoot/
  |-- misc-files/
  |-- pre-setup-dsconfig/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
  |-- variables-ignore.txt
```

setup-arguments.txt

When creating a profile, the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/ and pre-setup-dsconfig/

You can include `dsconfig` batch files in the server profile with information about changes to apply to the out-of-box system configuration. Any batch files in the server profile must include a `.dsconfig` extension. `dsconfig` batch files in the server profile can't make changes to any topology configuration, including topology admins and server instances, so you should make topology configuration changes outside of the server profile.

The batch files can be placed in the following server profile directories:

`dsconfig/`

Contains information about changes to apply after the `manage-profile` tool runs `setup`, copies any post-setup files into place, and installs any Server SDK extensions contained in the server profile. The `dsconfig/` directory should be used for most configuration changes applied to the server.

`pre-setup-dsconfig/`

Holds information about changes to apply immediately before the `manage-profile` tool runs `setup`. You should only use the `pre-setup-dsconfig/` directory when setting up the server with a pre-existing encryption settings database and applying the changes required for configuring and activating the cipher stream provider needed to access the encryption settings database.

Note

If multiple batch files are present in the directory that the `manage-profile` tool is using, the files are processed in ascending lexicographic order. For example, `00-base.dsconfig` is processed before `01-second.dsconfig`.

Tip

You can use the `config-diff` tool to create a `dsconfig` batch file that reproduces the current topology configuration.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the server-root/pre-setup directory.

server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

> **Note**
>
> Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

manage-profile generate-profile

To create a server profile from a configured server, use the `generate-profile` subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server

- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by `generate-profile`, and must be provided values when other `manage-profile` subcommands use the generated profile.

The `--excludeSetupArguments` option generates a server profile without a setup-arguments.txt file. This is useful when generating server profiles for use with Docker images.

manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the pre-setup files to the server root
- Runs the setup tool
- Copies the post-setup files to the server root
- Installs any server SDK extensions
- Runs any dsconfig batch files
- Imports any LDIF files
- Starts the server

While manage-profile setup is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

manage-profile replace-profile

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

The `--skipValidation` option which skips the validation step when running on an offline server

> **Important**
>
> When you run the **`manage-profile replace-profile`** tool with an SDK extension included in the new profile, the tool invokes the **`setup`** command.
> The **`manage-profile replace-profile`** tool can update the server version when needed, but will fail if you attempt to downgrade the server to an earlier version. It can also directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to **`dsconfig`**.

Server profiles in a pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Command-line tools

The server provides a full suite of command-line tools necessary for administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Available command-line tools

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	`--help`	**`dsconfig --help`**
A list of subcommands	`--help-subcommands`	**`dsconfig --help-subcommands`**
More information about a subcommand	`--help` with the subcommand	**`dsconfig list-log-publishers --help`**

Command-Line Tools

`audit-data-security`	Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data. This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using **`dsconfig list-data-security-auditors --advanced --property name`**. Either the `--includeAuditor` or the `--excludeAuditor` arguments can be used to limit the scope of the audit. Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`authrate`	Perform repeated authentications against the PingDirectory server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.

`backup`	Back up one or more directory server backends. Each backend backup is stored in a separate backend backup directory. A backend backup directory can contain multiple backups of the backend. Each backend backup directory contains a `backup.info` file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID can be provided to the backup command, or an ID is generated from a current timestamp. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`base64`	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
`check-replication-domains`	Scan the `replicationChanges` database for all known replication domains and identify any obsolete replicas still listed as part of a topology. Run this tool before upgrading replicated topologies to help avoid lockdown mode. Learn more about Discovering obsolete replicas.
`collect-support-data`	Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative. Information collected can include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that might be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive can be encrypted if you desire, you might want to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.
`compare-ldap-schemas`	Compares the schemas of two LDAP servers to identify schema elements that might be present in one but not the other, or elements that might be present in both servers but have differences between them.

`config-diff`	Compares directory server configurations and produces a `dsconfig` batch file needed to bring the source inline with the target. Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration. Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration. Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the `--includeExpectedDifferences` command. Further differences can be excluded with the `--exclude` option. This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a `dsconfig` batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using `dsconfig --offline`.
`create-rc-script`	Create a Run Control (RC) script that you can use to start, stop, and restart the PingDirectory server on UNIX-based systems.
`create-systemd-script`	Create a systemd script to start and stop the PingDirectory server on Linux-based systems.
`dbtest`	Inspect the contents of the PingDirectory server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool. Each local DB backend has a root container, identified by the backend ID. Each root container has an entry container for each base distinguished name (DN) in the backend. Each entry container has several database containers that store entries, attribute indexes and system indexes. The `dbtest` command allows the contents of root containers, entry containers and database containers to be inspected.
`deliver-one-time-password`	Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate using the UNBOUNDID-DELIVERED-OTP SASL mechanism.

`deliver-password-reset-token`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
`dsconfig`	View and edit the PingDirectory server configuration. This utility offers three primary modes of operation, the interactive mode, the non-interactive mode, and the batch mode: • The interactive mode supports viewing and editing the configuration using an intuitive, menu driven environment. Running `dsconfig` in interactive provides a user-friendly, menu-driven interface for accessing and configuring the server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` shell script or batch file without any arguments. • The non-interactive mode provides a simple way to make arbitrary changes to the PingDirectory server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the `dsconfig` command in non-interactive mode. • The batch mode reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each `dsconfig` call. You can view the `logs/config-audit.log` file to review the configuration changes made to the PingDirectory server and to use them in the batch file.
`dsjavaproperties`	Configure the JVM options used to run the PingDirectory server and its associated tools. The options managed by this tool are stored in `config/java.properties`. Typically, you should not edit that file directly. Instead, run the tool specifying `--jvmTuningParameter` arguments to customize JVM options appropriate for this system. Note that the changes will only apply to this PingDirectory server installation. No modifications will be made to your environment variables. Memory and other settings for the JVM tools, including the `start-server` tool, can be tuned during initialization by specifying one or more instances of the `--jvmTuningParameter` option when invoking this tool. Supported values are as follows: • `NONE`: Explicitly specify no parameters. • `AGGRESSIVE`: This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly. • `SEMI_AGGRESSIVE`: This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly. If no parameters are specified, the parameters specified by the previous invocation of this tool or setup will be used. Use the `NONE` option to explicitly specify no parameters.

`dsreplication`	Manage data replication between two or more PingDirectory server instances. For replication to work, you must first to enable replication using the **`enable`** subcommand. Then, you initialize the contents of one of the servers with the contents of the other using the **`initialize`** subcommand.
`dump-dns`	Obtain a listing of all of the DNs for all entries below a specified base DN in the PingDirectory server.
`encode-password`	Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.
`encrypt-file`	Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDAP Data Interchange Format (LDIF) exports, and log files generated by the server.
`encryption-settings`	Manage the server encryption settings database. More information about the cipher algorithms and transformations available for use can be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.
`enter-lockdown-mode`	Request that the PingDirectory server enter lockdown mode, during which it only processes operations requested by users holding the `lockdown-mode` privilege. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the `lockdown-mode` privilege.
`export-ldif`	Export data from the PingDirectory server backend in LDIF form. To export data from a remote PingDirectory server, the server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data can be appended to an existing file instead of overwriting it, and the output can be optionally compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.

`export-reversible-passwords`	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. Include the following arguments to configure the output of the tool: **`--filter`** The export only includes entries matching the specified filter. **`--exportNonReversiblePasswords`** The export includes entries with non-reversible passwords. **`--exportEntriesWithoutPasswords`** The export includes entries that don't have passwords. **`--includeAdditionalAttribute`** The exported entries include the specified attribute(s) in addition to the user's DN and password. You can use `"*"` to include all user attributes and `"+"` to include all operational attributes. **`--includeVirtualAttributes`** The exported entries include the values of virtual attributes in addition to real attributes. This tool can only be used over a secure connection and when authenticated as a user with the `permit-export-reversible-passwords` privilege. The server encrypts the output using a key generated from either a user-supplied passphrase or an encryption settings definition.

`extract-data-recovery-log-changes`	Extracts changes matching a given set of criteria from a PingDirectory server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error). This tool is designed to be used in conjunction with the server's data recovery log files (in the `logs/data-recovery` directory). It can be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that might have been provided in the request. This tool must not be used with a log file that the server can update while the tool is running, or that can have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, use the `rotate-log` tool to force the current active file to be rotated. To use this tool to revert an inappropriate set of changes, run it with `--direction revert` and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.). To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with `--direction replay` and an appropriate set of arguments to select the desired set of changes. Also, make sure to use `dsreplication pre-external-initialization` before performing the restore or import and applying the changes, and then use `dsreplication post-external-initialization` after the changes have been applied. See the PingDirectory Server Administration Guide for additional information. This tool will extract changes from the selected log file (and any previously rotated files, unless the `--doNotFollowRotationChain` argument is provided) and output them in LDIF change format. If the `--outputFile` argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the `--doNotCompressOutput` argument was provided), and the output will be encrypted if the input files were encrypted (unless the `--doNotEncryptOutput` argument was provided). You might want to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, you can use a tool like `ldapmodify` or `parallel-update` to apply those changes to the server.
`generate-totp-shared-secret`	Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.
`identify-references-to-missing-entries`	Identify entries containing one or more attributes which reference entries that do not exist. This might require the ability to perform unindexed searches and/or the ability to use the simple paged results control.

`identify-unique-attribute-conflicts`	Identify unique attribute conflicts. That is, it can identify values of one or more attributes that are supposed to exist only in a single entry but are found in multiple entries.
`import-ldif`	Import LDIF data into a PingDirectory server backend. Connection parameters are not required when importing to a local PingDirectory server that is not running. However, connection parameters are required if the server is remote, or if it is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file can be compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`indent-ldap-filter`	Parse a provided LDAP filter string and display it a multi-line form that makes it easier to understand its hierarchy and embedded components. If possible, the tool might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
`ldap-debugger`	Intercept and decode LDAP communication.

`ldap-diff`	**Compare the contents of two LDAP servers.** **The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted. For example: `"^attrToExclude"`. When retrieving entries from a PingDirectory server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectClass.** **This command can be used on servers actively being modified, without reporting false positives caused by replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as the requirement that child entries be deleted before parents and parents be added before children.** **The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry** • `ds-cfg-default-root-privilege-name: unindexed-search` • `ds-cfg-default-root-privilege-name: bypass-acl` • `ds-rlim-size-limit: 0` • `ds-rlim-time-limit: 0` • `ds-rlim-idle-time-limit: 0` • `ds-rlim-lookthrough-limit: 0` **For servers from other vendors, consult their documentation for configuring the proper privileges.** **The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` parameter in the `config/java.properties` file and running the `dsjavaproperties` command.**

`ldap-result-code`	Display and query LDAP result codes. This tool can be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring. At most, one of the `--list`, `--int-value`, and `--search` arguments can be provided. If none of them is provided, then the `--list` option will be chosen by default.
`ldapcompare`	Perform compare operations in an LDAP directory server. Compare operations can be used to efficiently determine whether a specified entry has a given value. The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the `--useCompareResultCodeAsExitCode` argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered. The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID can be followed by two colons and the base64-encoded representation of the assertion value, or it can be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value). The DNs of the entries to compare can either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they can be read from a file whose path is provided using the `--dnFile` argument. If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you can use the `--assertionFile` argument to specify the path to a file containing both attribute-value assertions and entry DNs.
`ldapdelete`	Delete one or more entries from an LDAP directory server. You can provide the DNs of the entries to delete using named arguments, trailing arguments, a file, or standard input. Alternatively, you can identify entries to delete using a search base DN and filter.
`ldapmodify`	Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.

`ldappasswordmodify`	Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the `--passwordChangeMethod` argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password-change method will be selected, using a regular LDAP modify operation to update the `unicodePwd` attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. The new password to be set for the user can be specified in one of several ways. It can be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank so that the server generates a new password for the user and includes it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error. The current password for the user can also be specified. This is optional, although some servers might require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a deletion of the current value and an addition of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.
`ldapsearch`	Process one or more searches in an LDAP directory server. The criteria for the search request can be specified in several different ways, including providing all of the details directly using command-line arguments, providing all of the arguments except the filter using command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.

`ldif-diff`	Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file. This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out-of-memory error while running the tool, you might need to increase the amount of memory available to the JVM used to invoke it. The amount of memory available to the JVM can be customized by invoking the JVM with the `-Xms` and `-Xmx` arguments, which specify the initial and maximum amounts of memory that it can use, respectively. These arguments should be immediately followed, without any intervening space, by an integer and a unit to specify the amount of memory to be used. The unit can be either `m` to indicate that the size is in megabytes, or `g` to indicate that it is in gigabytes. For example, `-Xms512m` indicates that the JVM should be given an initial heap size of 512 megabytes, while `-Xmx2g` indicates that it should be given a maximum heap size of two gigabytes. When invoking the **`ldif-diff`** tool included in the installation of a Ping Identity server product, you can edit the `config/java.properties` file to specify the arguments to use when invoking the JVM. After modifying the file, run the **`dsjavaproperties`** tool to ensure that those changes will be used for subsequent tool invocations.
`ldifmodify`	Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike **`ldapmodify`**, the **`ldifmodify`** command cannot read the changes to apply from standard input. All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires. Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete. Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record). Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.
`ldifsearch`	Search one or more LDIF files to identify entries matching a given set of criteria.

`leave-lockdown-mode`	Request that the PingDirectory server leave lockdown mode and resume normal operation. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the lockdown-mode privilege. Note that the PingDirectory server can place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that might have otherwise resulted in exposure of sensitive data).
`list-backends`	List the backends and base DNs configured in the PingDirectory server.
`load-ldap-schema-file`	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool can only be used in conjunction with a server instance running on the local system.
`make-ldif`	Generate LDIF data based on a definition in a template file. See the server's `config/MakeLDIF` directory for example template files. In particular, the `examples-of-all-tags.template` file shows how to use all of the tags for generating values.
`manage-account`	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the `password-reset` privilege to use this extended operation.
`manage-certificates`	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
`manage-extension`	Install or update PingDirectory server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectory server. Extension bundles are installed from a zip archive or file system directory. The server will be restarted if running to activate the extension(s).
`manage-profile`	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including `dsconfig`, initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
`manage-tasks`	Access information about pending, running, and completed tasks scheduled in the PingDirectory server.

`manage-topology`	Manage the topology registry. The topology registry is a branch of the configuration DIT (`cn=Topology,cn=config`). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The **`dsconfig`** tool, configuration API, or the management console can be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
`migrate-ldap-schema`	Migrate schema information from an existing LDAP server into a PingDirectory server instance. This tool can be used to migrate schema information from an existing LDAP server into this PingDirectory server instance. The source server can be any standards-compliant LDAPv3 server. All attribute type and object class definitions, which are contained in the source LDAP server but not in the target PingDirectory server instance, will be either added to the target instance or written to a schema file.
`migrate-sun-ds-config`	Update an instance of the PingDirectory server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x. This tool can be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory server instances in order to identify any differences and update the PingDirectory server configuration to more closely match that of the Sun server instance.
`modrate`	Perform repeated modifications against an LDAP directory server.
`move-subtree`	Move all entries in a specified subtree from one server to another.
`oid-lookup`	Search the OID registry to retrieve information about items that match a given OID or name. The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.

`parallel-update`	Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file. As with other tools like **`ldapmodify`**, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes. This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent can be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.
`populate-composed-attribute-values`	Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins. This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It can be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`profile-viewer`	View information in data files captured by the PingDirectory server profiler. Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the `profile-action` attribute to `stop` to end collection and have the plugin write the file to `logs/profile`.{timestamp}.

`re-encode-entries`	Re-encode all or a specified portion of the entries in a local DB backend. This tool can be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled). This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`rebuild-index`	Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches might behave differently while a rebuild is active than when it is not. An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include attribute indexes, VLV indexes, and JSON field indexes. **Note** PingDirectory does not support the rebuilding of system indexes, regardless of whether the rebuild is attempted online or offline. If you need to rebuild a system index, you must export the backend to LDIF and re-import it. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`register-yubikey-otp-device`	Registers a YubiKey OTP device with the PingDirectory server for a specified user so that the device can be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it can be used to deregister one or more YubiKey OTP devices for a user so that they can no longer be used to authenticate that user.

`reload-http-connection-handler-certificates`	Reload HTTPS Connection Handler certificates. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-attribute-type-from-schema`	Safely remove an attribute type definition from the server schema. The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type can be removed. • The requester must have the update-schema privilege. • The attribute type must not be referenced by any other schema element. • The attribute type must not be defined in any schema file that is included with the PingDirectory server. Only custom attribute types can be removed from the schema. • The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). • The attribute type must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-backup`	Safely remove a backup from the specified PingDirectory server backend. This tool deletes the specified backup archive and updates the backup descriptor accordingly. As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The `--retainFullBackupCount` argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed. The `--retainFullBackupAge` argument can be used to indicate that any full backups older than the specified age are eligible to be removed.
`remove-defunct-server`	Remove a server from this server's topology. This tool will remove the specified server from the topology. In general, the `uninstall` tool should be used to remove a server from the topology. The `remove-defunct-server` tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running remove-defunct-server from it will cleanly remove it from the topology. If it cannot reach the other servers, then remove-defunct-server must also be run from one of the online servers.

`remove-object-class-from-schema`	Safely remove an object class definition from the server schema. The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class can be removed. • The requester must have the update-schema privilege. • The object class must not be referenced by any other schema element. • The object class must not be defined in any schema file that is included with the PingDirectory server. Only custom object classes can be removed from the schema. • The object class must not be referenced in the server configuration. • The object class must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`replace-certificate`	Replace the listener certificate for this PingDirectory server instance.
`restore`	Restore a backup of a PingDirectory server backend. Only one backend can be restored at a time by the restore command. The PingDirectory server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`revert-update`	Revert this server package's most recent update.
`review-license`	Review and/or indicate your acceptance of the license agreement defined in `legal/LICENSE.txt`.

`rotate-log`	Trigger the rotation of one or more log files. If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files. You must have the `config-read` and `config-write` privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`sanitize-log`	Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the **`scramble-ldif`** tool.
`schedule-exec-task`	Schedule an exec task to run a specified command in the server. To run an exec task, several conditions must be satisfied: • The server's global configuration must have been updated to include `com.unboundid.directory.server.tasks.ExecTask` in the set of allowed-task values • The requester must have the `exec-task` privilege • The command to execute must be listed in the `exec-command-whitelist.txt` file in the server's `config` directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.
`search-and-mod-rate`	Perform repeated searches against an LDAP directory server and modify each entry returned.
`search-logs`	Search across log files to extract lines matching the provided patterns, like the **`grep`** command-line tool. The benefits of using the **`search-logs`** tool over **`grep`** are its ability to handle multi-line log messages, extract log messages within a given time range, and the inclusion of rotated log files.
`searchrate`	Perform repeated searches against an LDAP directory server.

`server-state`	View information about the current state of the PingDirectory server process.
`set-delegated-admin-aci`	Request that the PingDirectory server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.
`setup`	Perform the initial setup for a server instance. This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.
`start-server`	Start the PingDirectory server.
`status`	Display basic server information. This tool prints information about the server, such as version, connection handlers, and data sources. Some information might not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.
`stop-server`	Stop or restart the server. This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.
`subtree-accessibility`	List or update the set of subtree accessibility restrictions defined in the PingDirectory server.
`sum-file-sizes`	Calculate the sum of the sizes for a set of files. This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.
`summarize-access-log`	Examine one or more access log files to display several metrics about operations processed within the server.
`sync-pipe-view`	PingDataSync only: Display the detailed configuration of a sync pipe or pipes in PingDataSync and all commands necessary to replicate a specified sync pipe. You can use the `sync-pipe-view` tool online with the PingDataSync server connection credentials or you can use the tool offline. The sync pipe information can be output in a text, CSV, JSON, or tab-delimited format and can be output to a file. The `sync-pipe-view` tool features both an interactive mode and a non-interactive mode.
`transform-ldif`	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.

`uninstall`	Uninstall the PingDirectory server. This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the `dsreplication disable` command.
`update`	Update a deployed server so its version matches the version of this package.
`validate-acis`	Validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
`validate-file-signature`	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
`validate-ldap-schema`	Validate an LDAP schema read from one or more LDIF files.
`validate-ldif`	Validate the contents of an LDIF file against the server schema.
`verify-index`	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be verified include system indexes, attribute indexes and VLV indexes. Any errors found during verification are written to the output. The verification process is exhaustive and can take a long time.
`watch-entry`	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

Saving options in a file

The PingDirectory server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing the PingDirectory server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

The PingDirectory server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Server uses ...
No command-line options	The options in the default `<server-root>/config/tools.properties` file.
Command-line options other than the `--propertiesFilePath <my-properties-file>` option	The command-line options, which take priority if the options are also in the `<server-root>/config/tools.properties` file. The file options for options that are only in the default `<server-root>/config/tools.properties` file.
Only the `--propertiesFilePath <my-properties-file>` option	The options in `<my-properties-file>`.
The `--propertiesFilePath <my-properties-file>` option and other command-line options	The command-line options, which take priority if the options are also in `<my-properties-file>`. The file options for options that are only in `<my-properties-file>`.
The `--noPropertiesFile` option and other command-line options	Only the options you specify on the command line, ignoring the default properties file.

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

  In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

  ```
  $ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
    --propertiesFilePath bin/tools.properties "(objectclass=*)"
  ```

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If you do not specify any command-line options, the server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command:

```
$ bin/ldapsearch "(objectclass=*)"
```

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

> **Note**
>
> If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

   Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of Lightweight Directory Access Protocol (LDAP) connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

> **Note**
>
> Properties files do not allow quotation marks of any kind around values.
> Escape spaces and special characters.
> Whenever you specify a path, do not use `~` to refer to the home directory. The server does not expand the `~` value when read from a properties file.

3. Set or change properties that apply to specific tools.

   Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

   ```
   hostname=server1.example.com
   port=1389
   ldapsearch.port=2389
   bindDN=cn=Directory\ Manager
   ```

4. Save your changes and close the file.

dsconfig batch files">

Sample `dsconfig` batch files

The `config/sample-dsconfig-batch-files` directory contains `dsconfig` batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the `dsconfig` tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-request.dsconfig \
  --no-prompt
```

Running task-based tools

The PingDirectory server has a Tasks subsystem that allows you to schedule basic operations, such as `backup`, `restore`, `rotate-log`, `schedule-exec-task`, `stop-server`, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Options for task-based operations

Option	Description
`--task`	Indicates that the tool is invoked as a task. The `--task` option is required. If you invoke a tool as a task without this `--task` option, then a warning message is displayed stating that it must be used. If the `--task` option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
`--start <startTime>`	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
`--dependency <taskID>`	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
`--failedDependencyAction <action>`	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: • `CANCEL` (the default) Cancels the task. • `DISABLE` Disables the task so that it is not eligible to run until you manually enable it again. • `PROCESS` Runs the task.
`--startAlert`	Generates an administrative alert when the task starts running.
`--errorAlert`	Generates an administrative alert when the task fails to complete successfully.
`--successAlert`	Generates an administrative alert when the task completes successfully.
`--startNotify <emailAddress>`	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.

Option	Description
`--completionNotify <emailAddress>`	**Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed.** **You can use this option multiple times in a single command.**
`--errorNotify <emailAddress>`	**Specifies an email address to notify if an error occurs when this task executes.** **You can use this option multiple times in a single command.**
`--successNotify <emailAddress>`	**Specifies an email address to notify when this task completes successfully.** **You can use this option multiple times in a single command.**

Managing access control

The PingDirectory and PingDirectoryProxy servers provide a fine-grained access control model to ensure that users are able to access the information they need but are prevented from accessing information that they shouldn't see.

The access control model includes a privilege subsystem that provides even greater flexibility and protection.

This section presents the access control model and provides examples that illustrate the use of key access control functionality.

Overview of access control

The access control model uses access control instructions (ACIs) to determine what a user or a group of users can do with a set of entries, down to the attribute level.

The ACIs are stored in the `aci` operational attribute. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specify four items:

Resources

Resources are the targeted items or objects that specifies the set of entries and operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.

Name

Name is the descriptive label for each ACI. Typically, you have multiple ACIs for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an ACI labeled "ACI to grant full access to administrators."

Clients

Clients are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:/// cn=admins,ou=groups,dc=example,dc=com."`

Rights

Rights are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

Key access control features

The directory server provides important access control features that provide added security for its entries.

Improved validation and security

The server provides an access control model with strong validation to help ensure that invalid access control instructions (ACIs) are not allowed into the server.

The server ensures that all access control rules (ACRs) added over LDAP are valid and can be fully parsed. The server rejects any operation that attempts to store one or more invalid ACIs. It also validates ACIs contained in data imported from an LDIF file. The server rejects any entry containing a malformed `aci` value.

As an additional level of security, the server examines and validates all ACIs stored in the data whenever a backend is brought online. If the server finds any malformed ACIs in the backend, it generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed because of an ACI not being enforced. When the problem has been corrected, the administrator can use the **`leave-lockdown-mode`** tool or restart the server to allow it to resume normal operation.

Global ACIs

Global ACIs are a set of ACIs that apply to entries anywhere in the server or scoped to only apply to a specific set of entries.

Global ACIs work in conjunction with ACRs stored in user data and provide a convenient way to define ACIs that span disparate portions of the directory information tree (DIT).

In the Server, global ACIs are defined within the server configuration, in the `global-aci` property of the configuration object for the access control handler. To view and manage global ACIs, use configuration tools like **`dsconfig`** and the admin console.

The global ACIs available by default in the Server include:

- Allow anyone, including unauthenticated users, to access key attributes of the root DSA-specific entry (DSE), including:
  - `namingContexts`
  - `subschemaSubentry`
  - `supportedAuthPasswordSchemes`
  - `supportedControl`
  - `supportedExtension`
  - `supportedFeatures`
  - `supportedLDAPVersion`
  - `supportedSASLMechanisms`
  - `vendorName`
  - `vendorVersion`
- Allow anyone, including unauthenticated users, to access key attributes of the subschema subentry, including:
  - `attributeTypes`
  - `dITContentRules`
  - `dITStructureRules`
  - `ldapSyntaxes`

- `matchingRules`
- `matchingRuleUse`
- `nameForms`
- `objectClasses`

- Allow anyone, including unauthenticated users, to include the following controls in requests made to the server:
  - Authorization identity request
  - Manage DSA IT
  - Password policy
  - Real attributes only
  - Virtual attributes only
- Allow anyone, including unauthenticated users, to request the following extended operations:
  - Get symmetric key
  - Password modify request
  - Password policy state
  - StartTLS
  - Who Am I?

Access controls for public or private backends

Depending on their intended purpose, the PingDirectory server classifies backends as either public or private.

A backend is private if one of the following applies:

- Its content is generated by the server itself, such as the root DSE, monitor, and backup backends.
- It is used in the operation of the server, such as the configuration, schema, task, and trust store backends.
- Its content is maintained by the server, such as the LDAP changelog backend.

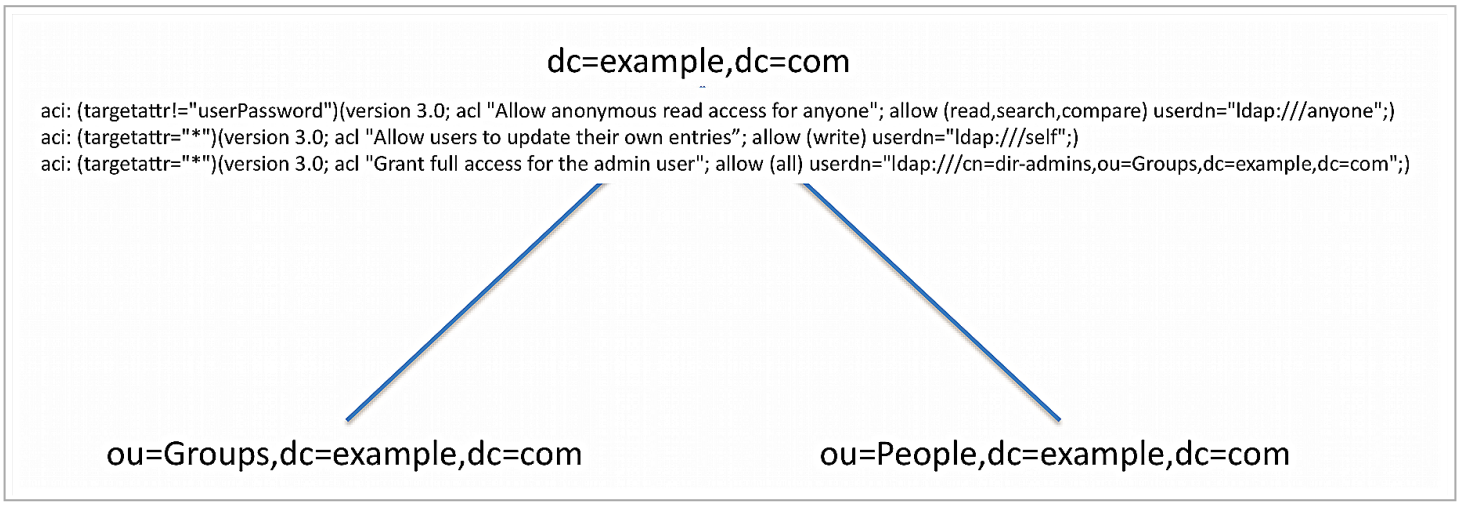
A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, you should define any ACI intended to permit or restrict access to information in private backends as global ACIs, rather than attempting to add those instructions to the data for that private backend.

General format of the access control rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the directory information tree (DIT).

Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The directory server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied so that a user who has an ACI at an entry can also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.



ACI

An access control rule has the following basic syntax:

```
aci : (targets) (version 3.0; acl "name";
        permissions
        bind rules
        ;)
```

Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and attributes to which an access control rule applies. Use the following syntax: `(target keyword = || != expression)`
name	Specifies the name of the ACI
permissions	Specifies the type of operations to which an access control rule might apply. Use the following syntax: `allow||deny (permission)`

Access Control Component	Description
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requester. Use the following syntax: `bind rule keyword = ||!= expression;` **Note** The bind rule syntax requires that it be terminated with a `;`.

Summary of access control keywords

This section provides an overview of the supported keywords in the server access control implementation.

Targets

A target expression specifies the set of entries and attributes to which an access control rule applies.

A target expression has three components:

```
(keyword[=||!=]expression)
```

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, `=`, or not-equal, `!=`.

> **Note**
> You cannot use the `!=` operator with the `targattrfilters` and `targetscope` keywords.

You can use the following keywords in the target portion of ACIs:

Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
`extop`	Specifies the OIDs for any extended operations to which the access control rule should apply.	No

Target Keyword	Description	Wildcards

`requestcriteria`	Determines whether an access control rule applies to an operation based on whether that operation matches a given request criteria definition.
	If present in an access control rule, the operator must be either "=" or "!=". The value must be enclosed in quotation marks and it must be the name or full DN of the configuration object that defines the desired request criteria.
	For example, let's say that you want to allow members of the `cn=Sales Administrators,ou=Groups,dc=example,dc=com` group to be able to read from and write to the entries for the users that are members of the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. To do this, you must first create a request criteria object that will match entries for users in the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. You can do this with the following configuration change:
	`dsconfig create-request-criteria \ --criteria-name "Requests Targeting Sales Employees" \ --type simple \ --set "any-included-target-entry-group-dn:cn=Sales Employees,ou=Groups,dc=example,dc=com"`
	With that request criteria defined, you can use a modification like the following to create the corresponding access control rule:
	`dn: dc=example,dc=com changetype: modify add: aci aci: (targetattr="*")(requestcriteria="Requests Targeting Sales Employees")(version 3.0; acl "Allow sales administrators to manage sales employees"; allow (read,search,compare,write) groupdn="ldap:///cn=Sales Administrators,ou=Groups,dc=example,dc=com";)`	

`target`	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	Yes
`targattrfilters`	Identifies specific attribute values based on filters that can be added to or removed from entries to which the access control rule applies.	Yes
`targetattr`	Specifies the set of attributes to which the access control rule should apply.	Yes
`targetcontrol`	Specifies the OIDs for any request controls to which the access control rule should apply.	No
`targetfilter`	Specifies one or more search filters that can be used to indicate the set of entries to which the access control should apply.	Yes

Target Keyword	Description	Wildcards
`targetscope`	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply.	No

> **Tip**
>
> Learn more about target keywords in Working with targets.

Permissions

Permissions indicate the types of operations to which an access control rule could apply.

You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you can grant read access to targeted entries using the `allow (read)` permission. You can also deny access to the target entries and attributes using the `deny (read)` permission. You can list multiple permissions as required in the ACI.

```
allow(permission1...,permission2,...permissionN)
```

```
deny(permission1...,permission2,...permissionN)
```

You can use the following keywords in the permissions portion of ACIs:

Keyword	Description
`add`	Indicates that the access control applies to `add` operations. Learn more about Changing the allow add ACI behavior for entries.
`compare`	Indicates that the access control applies to `compare` operations and to search operations with a base-level scope that targets a single entry.
`delete`	Indicates that the access control applies to `delete` operations.
`export`	Indicates that the access control applies only to `modify DN` operations in which an entry is moved below a different parent by specifying a new superior distinguished name (DN) in the `modify DN` request. The requestor must have the `export` permission for operations against the entry's original DN. The requestor must have the `import` permission for operations against the entry's new superior DN. For `modify DN` operations that alter the relative distinguished name (RDN) of an entry but keeps it below the same parent, such as renaming the entry, only the `write` permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
`import`	See the description for the `export` permission.

Keyword	Description
`proxy`	Indicates that the access control rule applies to operations that attempt to use an alternate authorization identity, such as operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a Simple Authentication and Security Layer (SASL) mechanism that allows an alternate authorization identify to be specified.
`read`	Indicates that the access control rule applies to search result entries returned by the server.
`search`	Indicates that the access control rule applies to `search` operations with a non-base scope.
`selfwrite`	Indicates that the access control rule applies to operations in which a user attempts to add or remove their own DN to the values for an attribute, such as users adding or removing themselves from groups.
`write`	Indicates that the access control rule applies to `modify` and `modify DN` operations.
`all`	An aggregate permission that includes all other permissions except `import`, `export`, and `proxy`. This is equivalent to providing a permission of `add`, `compare`, `delete`, `read`, `search`, `selfwrite`, and `write`.

Bind rules

The bind rules indicate whether an access control rule should apply to a given requester.

The syntax for the target keyword has three components:

Keyword

The keyword specifies the type of target element.

Expression

The expression specifies the items that are targeted by the access control rule.

Operator

The operator is either equal, `=`, or not-equal, `!=`.

You must use the semicolon delimiter symbol, `;`, after the end of the final bind rule.

```
keyword[=||!=]expression;
```

For added access control precision, you can combine multiple bind rules using the Boolean operations `AND`, `OR`, and `NOT`. The standard Boolean rules for evaluation apply:

- Innermost to outer parentheses first
- Left to right expressions

- `NOT` before `AND` or `OR`

For example, an access control instruction (ACI) with the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets users that are `uid=admin,dc=example,dc=com` and authenticate using Simple Authentication and Security Layer (SASL) EXTERNAL or access the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

You can use the following keywords in the bind rule portion of ACIs:

Bind Rule Keyword	Description

`authmethod`	Indicates that the requester's authentication method is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	Use the syntax `authmethod = method` where *method* is one of the following representations:
	• `none`
	• `simple` indicates that the client is authenticated to the server using a bind DN and password.
	• `ssl` indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.
	• `sasl \{sasl_mechanism}` indicates that the client is authenticated to the server using a specified SASL mechanism.
	The following example allows users who authenticate with an SSL/TLS certificate (for example, using SASL EXTERNAL) to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (userdn="ldap:///self" and authmethod="ssl");)`

Bind Rule Keyword	Description

`connectioncriteria`	Allows or denies an operation based on whether the client connection matches a given connection criteria definition.
	If present in an access control rule, the operator must be either "`=`" or "`!=`". The value must be enclosed in quotation marks, and it must be the name or full DN of the configuration object that defines the desired connection criteria.
	For example, you can use a modification like the following to allow any client matching the "Root Users and Topology Administrators" connection criteria to have full read and write access to entries below `dc=example,dc=com`:
	`dn: dc=example,dc=com`
	`changetype: modify`
	`add: aci`
	`aci: (targetattr="*")(version 3.0; acl "Full read and write access for administrators"; allow (read,search,compare,write) connectioncriteria="Root Users and Topology Administrators";)`

`dayofweek`	Indicates that the day of the week is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	You can separate multiple day of week values by commas. Use the following syntax.
	`dayofweek = day1, day2, ...`
	day is one of the following:
	• `sun`
	• `mon`
	• `tues`
	• `wed`
	• `thu`
	• `fri`
	• `sat`
	The following example allows users who authenticate on weekdays with an SSL/TLS certificate, such as SASL EXTERNAL, to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (dayofweek!="sun,sat" and userdn="ldap:///self"`
	`and authmethod="ssl");)`

Bind Rule Keyword	Description

`dns`	Indicates that the requester's DNS-resolvable host name is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.
	You can separate multiple DNS patterns by commas. Use the following syntax.
	`dns = dns-host-name`
	The following example allows users on host name `server.example.com` to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (dns="server.example.com" and userdn="ldap:///self");)`

`groupdn`	Indicates that the requester's group membership is taken into account when determining whether the access control rule should apply to any operation. You cannot use wildcards in this expression.
	`groupdn [ = || != ] "ldap:///groupdn [ || ldap:///groupdn ] ..."`
	The following example allows users in the managers group to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write)`
	`(groupdn="ldap:///cn=managers,ou=groups,dc=example,dc=com");)`

`ip`	Indicates that the requester's IP address is taken into account when determining whether the access control rule should apply to an operation. You can use wildcards in this expression.
	You can separate multiple IP address patterns by commas. Use the following syntax.
	`ip [ = || != ] <ipAddressList>`
	ipAddressList is one of the following:
	• A specific IPv4 address: 127.0.0.1
	• An IPv4 address with wildcards to specify a subnetwork: 127.0.0.*
	• An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0
	• An IPv4 address range using CIDR notation: 123.4.5.0/24
	• An IPv6 address as defined by RFC 2373.
	The following example allows users on 10.130.10.2 and localhost to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) (ip="10.130.10.2,127.0.0.1" and userdn="ldap:///self");)`

Bind Rule Keyword	Description

`oauthscope`	Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client is taken into account when determining whether the access control rule applies to an operation.
	Use the following syntax.
	`oauthscope [ = || != ] "<scopeIdentifier>"`
	scopeIdentifier is one of the following:
	• The name of a single scope to match. The name will be treated as case-sensitive.
	• A substring assertion that contains one or more asterisks as wildcards.
	• A single asterisk by itself, which will match any scope.
	The following example grants all rights to any client that presented an OAuth 2.0 token that is associated with the `scim_admin` scope.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope";`
	`allow (all) oauthscope="scim_admin";)`

`secure`	Allows or denies an operation based on whether the client is communicating with the server over a secure connection; for example, using LDAPS or StartTLS over LDAP.
	If present in an access control rule, the operator must be either "`=`" or "`!=`", and the value must be either `"true"` or `"false"` including the quotation marks. With this in mind, the `secure` bind rule takes the following forms:
	• `secure="true"` indicates that the ACI will apply only if the connection was received over a secure connection.
	• `secure="false"` indicates that the ACI will only apply if the connection was received over a non-secure connection.
	• `secure!="true"` indicates that the ACI will apply only if the connection was received over a non-secure connection.
	• `secure!="false"` indicates that the ACI will apply only if the connection was received over a secure connection.
	For example, you can use a modification like the following to allow users below `dc=example,dc=com` to update their own passwords over a secure connection:
	`dn: dc=example,dc=com`
	`changetype: modify`
	`add: aci`
	`aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update`
	`their own passwords over a secure connection"; allow (write)`
	`userdn="ldap:///self" and secure="true";)`

Bind Rule Keyword	Description

`timeofday`	Indicates that the time of day is taken into account when determining whether the access control rule should apply to an operation. You cannot use wildcards in this expression.
	Use the following syntax.
	`timeofday [ = || != || >= || > || <= || < ]  <time>`
	time is one of the following:
	• 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour)
	• You cannot use wildcards in this expression
	The following example allows users to update their own entries if the request is received before 12 noon.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users who authenticate before noon`
	`to update their own entries";`
	`allow (write) (timeofday<1200 and userdn="ldap:///self"`
	`and authmethod="simple");)`

`userattr`

Indicates that the requester's relation to the value of the specified attribute is taken into account when determining whether the access control rule should apply to an operation.
Use the following syntax.

```
userattr =  "<attrName># [ <bindType> || <attrValue> ]"
```

Where:

- *attrName* = name of the attribute for matching
- *bindType*= `USERDN`, `GROUPDN`, `LDAPURL`
- *attrValue* = an attribute value. The *attrVALUE* of the attribute must match on both the bind entry and the target of the ACI.

A *bindType* value of `USERDN` indicates that the target attribute should have a value which matches the DN of the authenticated user. A *bindType* value of `GROUPDN` indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A *bindType* value of `LDAPURL` indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user.
Any value other than `USERDN`, `GROUPDN`, or `LDAPURL` is expected to be present in the target attribute of the authenticated user's entry.
The following example allows a manager to change employee's entries. If the bind DN is specified in the manager attribute of the targeted entry, the bind rule is evaluated to `TRUE`.

```
aci: (targetattr="*")
(version 3.0; acl "Allow a manager to change employee entries";
allow (write) userattr="manager#USERDN";)
```

The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the `allowEditors` attribute of the targeted entry, the bind rule is evaluated to `TRUE`.

```
aci: (targetattr="*")
(version 3.0; acl "Allow allowEditors to change employee entries";
allow (write) userattr="allowEditors#GROUPDN";)
```

The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (`0`, `1`, `2`, `3`, `4`) below the targeted entry, with zero `0` indicating the targeted entry.

```
aci: (targetattr="*")
(version 3.0; acl "Allow managers to change employees entries two levels below";
allow (write) userattr="parent[0,1,2].manager#USERDN";)
```

The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.

```
aci: (targetattr="*")
(version 3.0; acl "Allow any member of Eng Dept to update any other member of the
enginering department at or below the ACI";
allow (write) userattr="department#ENGINEERING";)
```

The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the `allowedEditorCriteria` attribute of the target entry.

Bind Rule Keyword	Description

	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow a user that matches the filter to change entries";`
	`allow (write) userattr="allowedEditorCriteria#LDAPURL";)`

`userdn`	Indicates that the user's DN is taken into account when determining whether the access control rule should apply to an operation.
	Use the following syntax.
	`userdn [ = || != ] "ldap:///<value>"  [ || "ldap:///<value>  ..."]`
	Where *value* is one of the following representations:
	• The DN of the target user
	• A value of `anyone` to match any client, including unauthenticated clients.
	• A value of `all` to match any authenticated client.
	• A value of `parent` to match the client authenticated as the user defined in the immediate parent of the target entry.
	• A value of `self` to match the client authenticated as the user defined in the target entry.
	If the value provided is a DN, then that DN can include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks can be used to match zero or more DN components.
	The following example allows users to update their own entries.
	`aci: (targetattr="*")`
	`(version 3.0; acl "Allow users to update their own entries";`
	`allow (write) userdn="ldap:///self";)`

Access token validators

Access token validators verify the tokens that HTTP client applications submit when they request access to protected resources and associate each token with an identity stored in the directory server.

To authenticate to PingDirectory server's HTTP services, clients use OAuth 2 bearer token authentication to present an access token in the HTTP Authorization request header.

To process the incoming access tokens, PingDirectory server uses access token validators, which determine whether to accept an access token and translate it into a set of properties, called claims, which PingDirectory server's HTTP services use to make access control decisions.

Most access tokens identify a user as its subject using the `sub` claim. Access token validators can retrieve the token subject's attributes from the directory using an identity mapper, which correlates the access token subject to an Lightweight Directory Access Protocol (LDAP) entry.

Access token validators are used by the following services:

- Directory REST API
- SCIM 2
- Delegated Admin
- Consent API

You can configure the PingDirectory server to accept access tokens provided by LDAP clients using the OAUTHBEARER Simple Authentication and Security Layer (SASL) authentication method.

Access token validator processing

You can configure any number of access token validators for the server.

Each access token validator has an evaluation order index, which is an integer that determines the processing priority when multiple access token validators are configured. Lower values are processed before higher values.

> **Note**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by PingDirectory server.

Processing steps

1. If an incoming HTTP request contains an access token, the token is sent to the access token validator with the lowest evaluation order index.
2. The access token validator validates the access token. Validation logic varies by access token validator type, but the validator generally verifies the following information:
    - A trusted source issued the token.
    - The token is not expired.
3. If the access token contains a subject, the access token validator uses its identity mapper to find a matching Lightweight Directory Access Protocol (LDAP) entry.
4. If the access token validator is unable to validate the access token, it passes the token to the access token validator with the next lowest evaluation order index, and the previous two steps are repeated.
5. HTTP request processing continues, and the policy request is sent to the HTTP service, such as the Directory REST API, for further evaluation.
6. Using either the access token claims parsed by the access token validator or the LDAP entry found by the identity mapper, the HTTP service determines whether the request should be accepted and which access control rules should be applied. This access control behavior varies by each HTTP service.

Access token validator types

The server works with a variety of access token validators.

This section contains the following topics:

Configuring a sample PingFederate access token validator

To verify the access tokens that a PingFederate authorization server issues, the PingFederate access token validator uses HTTP to submit the tokens to PingFederate server's token introspection endpoint.

Before you begin

Before using a PingFederate access token validator, create a client that represents the access token validator in the PingFederate configuration. This client must use the Access Token Validation grant type.

About this task

This step allows the authorization server to determine whether a token is valid.

> **Note**
>
> Access tokens issued using the OAuth 2 client credentials grant type are issued directly to a client and do not contain a subject. Such tokens cannot be accepted by the directory server.

Because this step requires an outgoing HTTP request to the authorization server, the PingFederate access token validator might perform slower than other access token validator types. The validation result is guaranteed to be current, which is an important consideration if the authorization server permits the revocation of access tokens.

Steps

1. In PingFederate, create a client with the following properties:
    - Client ID: Ping Identity
    - Client authentication: Client Secret
    - Allowed grant types: Access Token Validation
2. Take note of the client secret and use the directory server's `dsconfig` command to create an access token validator, as shown.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com
# Change the host name and port below, as needed
dsconfig create-external-server \
  --server-name "PingFederate External Server" \
  --type http \
  --set base-url:https://example.com:9031
# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "PingFederate Access Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "authorization-server:PingFederate External Server" \
  --set client-id:PingDirectory \
  --set "client-secret:<client secret>"
  --set evaluation-order-index:2000
  --set "identity-mapper:User ID Identity Mapper"
```

Learn more about the configuration options for a PingFederate access token validator in the PingDirectory Configuration Reference Guide.

3. Replace <*client secret*> with the client secret value generated by the PingFederate client.

JWT access token validator

The JWT access token validator verifies access tokens that are encoded in JSON Web Token (JWT) format, which can be signed in JSON web signature (JWS) format or signed and encrypted in JSON web encryption (JWE) format.

The JWT access token validator inspects the JWT token without presenting it to an authorization server for validation. Because the JWT access token validator does not make a token introspection request for every access token that it processes, it performs faster than the PingFederate access token validator. The access token is self-validated, so the JWT access token validator cannot determine whether the token has been revoked.

Supported JWS/JWE features

For signed tokens, the JWT access token validator supports the following JWT web algorithm (JWA) types:

- RS256
- RS384
- RS512
- ES256
- ES384

- ES512

For encrypted tokens, the JWT access token validator supports the following key-encryption algorithms:

- RSA-OAEP
- ECDH-ES
- ECDH-ES+A128KW
- ECDH-ES+A192KW
- ECDH-ES+A256KW

For encrypted tokens, the JWT access token validator supports the following content-encryption algorithms:

- A128CBC-HS256
- A192CBC-HS384
- A256CBC-HS512

The JWT access token validator configuration defines three allow lists for the JWS/JWE signing and encryption algorithms that it accepts. Customize these allow lists to reflect only the signing and encryption algorithms used by your access token issuer and no others. This minimizes the access token validator's security threat surface.

Configure these allow lists using the following configuration properties:

`allowed-signing-algorithm`

Specifies the signing algorithms that the access token validator accepts.

`allowed-key-encryption-algorithm`

Specifies the key-encryption algorithms that the access token validator accepts.

`allowed-content-encryption-algorithm`

Specifies the content-encryption algorithms that the access token validator accepts.

Learn more about the configuration options for a JWT access token validator.

Handling signed tokens

The token issuer must cryptographically sign all access tokens that the JSON web token (JWT) access token validator handles. The JWT access token validator validates a token's signature using a public signing key provided by the issuer.

Steps

- Configure the JWT access token validator with the issuer's public signing key:

  Choose from:

  - Store the public key as a trusted certificate in the server's local configuration using the `trusted-certificate` property.

- Provide the issuer's JSON Web Key Set (JWKS) endpoint using the `jwks-endpoint-path` property.

> **Note**
>
> To ensure that the JWT access token validator uses updated copies of the issuer's public keys, the validator checks the configured JWKS endpoint in the following cases:
>
> - When the validator initializes
> - If the validator can't find a suitable key for verification in its current set of keys

Example: Use a locally configured trusted certificate

The following example configures a JWT access token validator to use a locally stored public signing certificate to validate access token signatures. The signing certificate is assumed to have been obtained out-of-band and must be a PEM-encoded X.509v3 certificate.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Add the public signing certificate to the server configuration
dsconfig create-trusted-certificate \
        --certificate-name "JWT Signing Certificate" \
        --set "certificate</path/to/signing-certificate.pem"

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:RS256 \
        --set "trusted-certificate:JWT Signing Certificate"
        --set "identity-mapper:User ID Identity Mapper"
```

Example: Use the issuer's JWKS endpoint

The following example configures a JWT access token validator to retrieve public keys from a PingFederate authorization server's JWKS endpoint.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
        --server-name "PingFederate External Server" \
        --type http \
        --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:RS256 \
        --set "authorization-server:PingFederate External Server" \
        --set jwks-endpoint-path:/ext/oauth/jwks
        --set "identity-mapper:User ID Identity Mapper"
```

Handling encrypted tokens

Configure the JSON web token (JWT) access token validator to accept encrypted access tokens. You must configure the access token validator with a private and public key pair and provide the public key to the token issuer.

Steps

1. Create an encryption key pair.
2. Create the JWT access token validator.
3. Export the public encryption key from the PingDirectory server and provide it to your token issuer.

   Choose from:

   - To copy the public key to a file, run `dsconfig`.
   - Copy the value of the key pair's `certificate-chain` property in the admin console.

   > **Note**
   >
   > Without this public encryption key, the issuer cannot encrypt tokens that can be decrypted by the JWT access token validator.

Example

The following example configures a JWT access token validator to handle access tokens signed and encrypted using elliptic curve algorithms.

For RSA signing and encryption algorithms, the configuration is similar, but you choose different values for the `allowed-signing-algorithm` and `allowed-encryption-algorithm` properties.

1. Create an encryption key pair.

```
# Create an encryption key pair
        dsconfig create-key-pair \
        --pair-name "JWT Elliptic Curve Encryption Key Pair" \
        --set key-algorithm:EC_256
```

2. Create the JWT access token validator.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
        --mapper-name "User ID Identity Mapper" \
        --type exact-match \
        --set enabled:true \
        --set match-attribute:uid \
        --set match-base-dn:ou=people,dc=example,dc=com

# Change the host name and port below, as needed
dsconfig create-external-server \
        --server-name "PingFederate External Server" \
        --type http \
        --set base-url:https://example.com:9031

# Create the Access Token Validator
dsconfig create-access-token-validator \
        --validator-name "JWT Access Token Validator" \
        --type jwt \
        --set enabled:true \
        --set evaluation-order-index:1000 \
        --set allowed-signing-algorithm:ES256 \
        --set "authorization-server:PingFederate External Server" \
        --set jwks-endpoint-path:/ext/oauth/jwks \
        --set "encryption-key-pair:JWT Elliptic Curve Encryption Key Pair" \
        --set allowed-key-encryption-algorithm:ECDH_ES
        --set "identity-mapper:User ID Identity Mapper"
```

3. Export the public encryption key from the PingDirectory server and provide it to your token issuer.

   The following command copies the key to a file.

```
dsconfig get-key-pair-prop \
        --pair-name "JWT Elliptic Curve Encryption Key Pair" \
        --property certificate-chain \
        --no-prompt \
        --script-friendly > jwt-public-encryption-key.pem
```

Mock access token validator

A mock access token validator is a special access token validator type for development or testing purposes.

A mock access token validator accepts arbitrary tokens without validating whether a trusted source issued them. This allows you to make bearer token-authenticated requests without first setting up an authorization server.

Mock access tokens are formatted as plain-text JSON objects using standard JSON web token (JWT) claims.

Always provide the boolean `active` claim when creating a mock token. If this value is `true`, the token is accepted. If this value is `false`, the token is rejected.

If the `sub` claim is provided, a token owner lookup populates the `TokenOwner` policy request attribute as with the other access token validator types.

The following example cURL command shows a mock access token in an HTTP request.

```
curl -k -X GET https://localhost:1443/directory/v1/Me -H 'Authorization: Bearer {"active": true, "sub":"user.1",
"scope":"email profile", "client_id":"client1"}'
```

> **Important**
>
> Never use mock access token validators in a production environment because they do not verify whether a trusted source issued an access token.

Sample configuration

The configuration for a mock access token validator resembles the configuration for a JWT access token validator. However, the JSON web signature (JWS) signatures require no configuration because mock tokens are not authenticated.

```
# Create an identity mapper that expects the token subject to be a uid
dsconfig create-identity-mapper \
  --validator-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-base-dn:ou=people,dc=example,dc=com

# Create the Access Token Validator
dsconfig create-access-token-validator \
  --validator-name "Mock Access Token Validator" \
  --type mock --set enabled:true \
  --set evaluation-order-index:9999 \
  --set "identity-mapper:User ID Identity Mapper"
```

Learn more about the configuration options for a mock access token validator.

Third-party access token validator

To create custom access token validators, use the Server SDK. Learn more about the configuration options for a third-party access token validator.

Working with targets

The following section presents a detailed look and examples of the target access control instruction (ACI) keywords:

- `target`
- `targetattr`
- `targetfilter`
- `targattrfilters`
- `targetscope`
- `targetcontrol`
- `extop`

target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN).

The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com`, within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where *DN* is the distinguished name of the entry or branch:

```
(target = ldap:///<DN>)
```

For example, to target a specific entry, use a clause like the following.

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

> **Note**
>
> In most cases, you should avoid specifying a target DN. Instead, define the ACI in that entry and omit the `target` element altogether.
> For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, you should define it in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the not equal operator (`!=`) to indicate that all entries within the scope of the given branch that do not match the expression be targeted for the ACI. The following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (`*`) characters as wildcards to match elements within the distinguished name.

- The following target expression matches all entries that contain and begin with `john.d`.

  ```
  (target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
  ```

  Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=People,dc=example,dc=com` would match the target expression.

- The following target expression matches all entries whose DN begins with `john.d` and matches the `ou` attribute.

  ```
  (target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
  ```

  Entries such as `john.doe,ou=People,dc=example,dc=com` and `john.davies,ou=asia-branch,dc=example,dc=com` would match the target expression.

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci:(target="ldap:///ou=People,dc=example,dc=com")
(targetattr="*")
(version 3.0; acl "Allow all the ou=People branch to modify their own entries";
allow (write) userdn="ldap:///self";)
```

targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply.

There are four general forms that it can take in the Server:

`(targetattr="*")`

Indicates that the access control rule applies to all user attributes. Operational attributes are not automatically included in this set.

`(targetattr="+")`

Indicates that the access control rule applies to all operational attributes. User attributes are not automatically included in this set.

`(targetattr="<attr1>||<attr2>||<attr3>||…||<attrN>")`

Indicates that the access control rule applies only to the named set of attributes.

`(targetattr!="attr1||attr2||attr3||…||attrN")`

Indicates that the access control rule applies to all user attributes except the named set of attributes. It does not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overrided default constraints like size limit, time limit, or look-through limit for that user.

The Server distinguishes between these two types of attributes in its access control implementation. The PingDirectory server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes.

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (`cn`), surname (`sn`) and state (`st`) attribute.

```
(targetattr="cn||sn||st")
```

You can use the `+` symbol to indicate that the rule should apply to all operational attributes.

```
(targetattr="+")
```

To include all user and all operational attributes, use both symbols.

```
(targetattr="*||+")
```

If you need to target a specific operational attribute rather than all operational attributes, include it in the values of the `targetattr` clause.

```
(targetattr="ds-rlim-size-limit")
```

If you want to target all user attributes and a specific operational attribute, use them in the `targetattr` clause.

```
(targetattr="*||ds-rlim-size-limit")
```

The following sample ACIs are placed on the `dc=example,dc=com` tree. The first ACI allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword")(version 3.0; acl "Allow anonymous
   read access for anyone"; allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
   allow (write) userdn="ldap:///self";)
aci: (targetattr="*")(version 3.0; acl "Grant full access for the admin user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

When assigning access to user and operational attributes, it is easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. The following example shows the implications of the PingDirectory server not distinguishing between these attributes.

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a common rule and seems harmless, but has serious consequences for a PingDirectory server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for several malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users, including administrators granted full rights by access control rules, but excluding users with the `bypass-acl` privilege allows them to edit any other attributes in their own entry, including those excluded by rules like `uid` and `employeeNumber` in the previous example, or add, modify, or delete any entries below his or her own entry.

Because the Server does not automatically include operational attributes in the target attribute list, these types of ACIs do not present a security risk for it. Users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn||sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword` and the second allows `cn` and `sn`.

targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter.

The `targetfilter` clause has the following syntax.

```
(targetfilter =  <ldap_filter>)
```

For example, the following clause targets all entries that contain the `ou=engineering` attribute.

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the `OR` operator. The following clause targets all entries that contain `ou=engineering`, `ou=accounting`, and `ou=marketing`.

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
  (targetattr="departmentNumber||cn||sn")
  (version 3.0; acl "example"; allow (write)
   userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

targattrfilters

The `targattrfilters` keyword targets specific attribute values that match a filtered search criteria.

This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following format.

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrN:FilterN" )
```

Where:

`add`

Represents the operation of adding an attribute value to the entry.

`del`

Represents the operation of removing an attribute value from the entry.

`<attr1>, <attr2>... <attrN>`

Represents the targeted attributes.

`<filter1>, <filter2>... <filterN>`

Represents filters that identify matching attribute values.

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci:(targattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read)")
  (version 3.0; acl "Allow members of the the directory server admins group to grant the
   soft-delete-read privilege"; allow (write)
   groupdn="ldap:///cn=PingDirectory Server admins,ou=group,dc=example,dc=com";)
```

targetscope

Use the `targetscope` keyword to restrict the scope of an access control rule (ACR).

ACIs use a subtree scope by default, meaning they are applied to the target entry and all entries below it, either as defined by the target clause of the ACI or the entry in which the ACI is defined if it does not include a target. However, you can add the `targetscope` element into an ACR to restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

base

Indicates that the ACR applies only to the target entry and not to any of its subordinates.

onelevel

Indicates that the ACR applies only to entries that are immediate children of the target entry and not to the target entry itself nor to any subordinates of the immediate children of the target entry.

subtree

Indicates that the ACR applies to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.

subordinate

Indicates that the ACR applies to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes present in the root DSA-specific entry (DSE):

- `supportedControl`
- `supportedExtension`

- `supportedFeatures`
- `supportedSASLMechanisms`
- `vendorName`
- `vendorVersion`

In the following example, `targetscope` is set to `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///")(targetscope="base")
    (targetattr="supportedControl||supportedExtension||
     supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
    (version 3.0; acl "Allow users to view Root DSE Operational Attributes";
     allow (read,search,compare) userdn="ldap:///anyone")
```

targetcontrol

Use the `targetcontrol` keyword to indicate whether a given request control can be used by users targeted in the ACI.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying control OIDs, wildcards are not allowed.

The following ACI example shows the controls required to allow an administrator to use and manage the soft delete feature. The soft delete request control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The hard delete request control allows the user to permanently remove an entry or soft-deleted entry. The undelete request control allows the user to undelete a currently soft-deleted entry. The soft-deleted entry access request control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||
   1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
  (version 3.0; acl "Allow admins to use the Soft Delete Request Control,
   Hard Delete Request Control,Undelete Request Control, and
   Soft-deleted entry access request control";
   allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

extOp

Use the `extop` keyword to indicate whether a given extended request operation can be used.

You can provide multiple OIDs by separating them with two pipe characters, optionally surrounded by spaces. When specifying extended request OIDs, wildcards are not allowed.

The following ACI example allows the `uid=user-mgr` to use the password modify request, `OID=1.3.6.1.4.1.4203.1.11.1`, and the StartTLS, `OID=1.3.6.1.4.1.1466.20037`, which are extended request OIDs.

```
aci:(extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
  (version 3.0; acl "Allows the mgr to use the Password Modify Request and StartTLS;
   allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

Examples of common access control rules

This section demonstrates access controls that are commonly used in your environment.

To modify access control definitions in the server, a user must have the `modify-acl` privilege.

Administrator access

The following access control instructions (ACIs) grant members of the `cn=admins,ou=groups,dc=example,dc=com` group the following permissions:

- Add, modify, and delete entries
- Reset passwords
- Read operational attributes, such as `isMemberOf` and password policy state

```
aci: (targetattr="+")(version 3.0; acl "Administrators can read, search or compare operational attributes";
allow (read,search,compare) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
aci: (targetattr="*")(version 3.0; acl "Administrators can add, modify and delete entries";
allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
```

Anonymous and authenticated access

The following ACIs allow anonymous read, search, and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. An authenticated user inherits the privileges of the anonymous ACI and can also change `userPassword`.

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Anyone can access names and email addresses of entries representing people";
allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="departmentNumber || manager || isMemberOf")(targetfilter="(objectClass=inetorgperson)")
(version 3.0; acl "Authenticated users can access these fields for entries representing people";
allow (read,search,compare) userdn="ldap:///all";)
aci: (targetattr="userPassword")(version 3.0; acl "Authenticated users can change password";
allow (write) userdn="ldap:///all";)
```

To prevent anonymous access to the directory server, set the global configuration property `reject-unauthenticated-requests` to `true`.

Delegated access to a manager

The following ACI allows an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which indicates that the target entry's manager attribute must have a value equal to the distinguished name (DN) of the authenticated user.

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct reports";
allow (read,search,compare,write) userattr="manager#USERDN";)
```

Proxy authorization

The following ACI allows the application `cn=OnBehalf,ou=applications,dc=example,dc=com` to use the proxied authorization V2 control to request that operations be performed using an alternate authorization identity.

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///cn=OnBehalf,ou=applications,dc=example,dc=com";)
```

Note

The application user must have the `proxied-auth` privilege.

Validating ACIs before migrating data

Identify any access control instruction (ACI) syntax problems before migrating data.

Many directory servers allow for a less restrictive application of their access control instructions so that they accept invalid ACIs. For example, if an Oracle directory server encounters an access control rule that it can't parse, it ignores the rule without providing a warning, and the server might not offer the intended access protection.

The PingDirectory server rejects any ACIs that it can't interpret, which ensures that data access is limited as intended. However, this can cause problems when migrating data with existing access control rules to PingDirectory.

To validate an ACI, PingDirectory provides a `validate-acis` tool in the `bin` directory on UNIX or Linux systems or in the `bat` directory on Windows systems. The `validate-acis` tool identifies any ACI syntax problems before you migrate data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified.

Each entry in the output contains a single ACI. If an entry in the input contains multiple ACIs, then it can be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values. All other attributes are ignored.

Validating ACIs from a file

Use the `validate-acis` tool to process data contained in an LDIF file.

About this task

Note

The **`validate-acis`** tool ignores all attributes except `aci` and ignores all entries that do not contain the `aci` attribute. You can use any existing LDIF file that contains access control rules.

Steps

1. Run the `validate-acis` tool and specify the input file and output file.

   Choose from:

   - UNIX or Linux: `bin/validate-acis`
   - Windows: `bat\validate-acis`

   If the output file already exists, the existing file contents are re-written. If no output file is specified, the results are written to standard output.

   Example:

   ```
   $ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-acis.ldif
   ```

   Result:

   ```
   # Processing complete # Total entries examined: 1
   # Entries found with ACIs: 1
   # Total ACI values found: 3
   # Malformed ACI values found: 0
   # Other processing errors encountered: 0
   ```

2. Open the output file and review the results.

   Example:

   For example, the `validated-acis.ldif` file generated in the previous step reads as follows.

   ```
   # The following access control rule is valid
   dn: dc=example,dc=com
   aci: (targetattr!="userPassword")
     (version 3.0; acl "Allow anonymous read access for anyone";
       allow (read,search,compare) userdn="ldap:///anyone";)

   # The following access control rule is valid
   dn: dc=example,dc=com
   aci: (targetattr="*")
     (version 3.0; acl "Allow users to update their own entries";
       allow (write) userdn="ldap:///self";)

   # The following access control rule is valid
   dn: dc=example,dc=com
   aci: (targetattr="*")
     (version 3.0; acl "Grant full access for the admin user";
       allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
   ```

   Example:

If the input file has any malformed access control instructions (ACIs), then the generated output file will show what was incorrectly entered. For example, if `userPassword` in the `test-acis.ldif` file does not have quotation marks around it, the output file reports an error. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFIle test-acis.ldif --outputFile validated-acis.ldif \
  --onlyReportErrors
```

Result:

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 1
# Other processing errors encountered: 0
```

The output file shows the following message:

```
# The following access control rule is malformed or contains an unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0; acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone";)' could not be parsed as a valid Access Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Validating ACIs in another directory server

Use the `validate-acis` tool to examine access control instructions (ACIs) in data that exists in another directory server that you are planning to migrate to the current server.

About this task

The tool helps to determine whether the PingDirectory server accepts those ACIs.

Steps

- Run the `validate-acis` tool.

  Choose from:

  - UNIX or Linux: `bin/validate-acis`
  - Windows: `bat\validate-acis`

    Provide arguments that specify:

  - The address and port of the target PingDirectory server
  - Credentials to use to bind
  - The base DN of the subtree containing the ACIs to validate

  Example:

  ```
  $ bin/validate-acis
  ```

  Result:

  ```
  # Processing complete # Total entries examined: 1
  # Entries found with ACIs: 1
  # Total ACI values found: 3
  # Malformed ACI values found: 0
  # Other processing errors encountered: 0
  ```

Migrating ACIs from Oracle to the PingDirectory server

This section describes the most important differences in access control evaluation between Oracle and the server.

Support for macro ACIs

Oracle supports macro access control instructions (ACIs), making it possible to define a single ACI that you can use to apply the same access restrictions to multiple branches in the same basic structure.

Macro ACIs are infrequently used and can cause severe performance degradation, so the server does not support them. However, you can achieve the same result by creating the same ACIs in each branch.

Support for the roleDN bind rule

Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms.

The server does not support Oracle Directory Server Enterprise Edition (DSEE) roles and does not support the use of the `roleDN` ACI bind rule. However, you can achieve the same behavior by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

Targeting operational attributes

The Oracle access control model doesn't differentiate between user attributes and operational attributes.

In the Oracle access control model, using `targetattr="*"` automatically targets both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` automatically targets all operational attributes in addition to all user attributes except `userPassword`. This presents several significant security holes here users are unintentionally given access to operational attributes. In some cases, it could allow users to exempt themselves from password policy restrictions.

The server treats operational attributes differently from user attributes and never automatically includes operational attributes. For example, `targetattr="*"` targets all user attributes but no operational attributes, and `targetattr!="userPassword"` targets all user attributes except `userPassword` but no operational attributes.

You can target specific operational attributes by including the names in the list, such as `targetattr="creatorsName||modifiersName"`. You can target all operational attributes by using the `"+"` character. For example, `targetattr="+"` targets all operational attributes but no user attributes, and `targetattr="*||+"` targets all user and operational attributes.

Example

The following example searches for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn`, `givenName`, and all operational attributes.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope one '(objectclass=*)' \
     sn givenName "+"
```

Example

You can use compound filters to search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree. The following example limits the returned entry amount to 200, and the server will spend no more than 5 seconds processing the request.

```
ldapsearch --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --baseDN ou=People,dc=example,dc=com --searchScope sub --sizeLimit 200 \
     --timeLimit 5 "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id \
     entryUUID
```

Returning all user and operational attributes in a schema search

Specify `"*"` in a search attribute list to represent all user attributes. Specifying `"+"` retrieves all operational attributes.

About this task

The following standards are used in PingDirectory as part of the LDAP specification.

Standard	Overview
RFC 3673	Describes the use of `"+"` to represent all operational attributes
RFC 4511	Describes the use of `"*"` to represent all user attributes

Steps

- To search the `cn=schema` entry and return all user and operational attributes, run `ldapsearch`.

  Example:

  ```
  bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)" "*" "+"
  ```

Exclude attributes

The server accepts syntax, in addition to the RFC 3673, RFC 4511, and RFC 4529 standards, that allows you to exclude attributes from search results.

About this task

To exclude an attribute from the search results in PingDirectory:

Steps

- Prefix the attribute name with either `"^"` or `"!"`

  Example:

  The following example returns organizational units (OUs) that are part of the object class `group` in Colorado with the exception of OUs in Denver.

  ```
  (&(objectClass=group)(&(ou:dn:=Colorado)(!(ou:dn:=Denver))))
  ```

  Example:

  The following example returns all users that aren't `device`.

  ```
  (&(objectClass=user)(!(objectClass=device)))
  ```

  > **Note**
  >
  > To exclude all attributes associated with an object class, prefix the object class name with either `"^@"` or `"!@"`.

Specification of global ACIs

Both Oracle Directory Server Enterprise Edition (DSEE) and the server support global ACIs, which you can use to define ACIs that apply throughout the server.

In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI rather than maintaining an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSA-specific entry (DSE) to add values of the `aci` attribute. In the server, you manage global ACIs with `dsconfig` referenced in the `global-aci` property of the access control handler.

Defining ACIs for non-user content

In Oracle Directory Server Enterprise Edition (DSEE), you can write to the following backends to define ACIs:

- Configuration
- Monitor
- Changelog
- Tasks

In the server, you should define access control for private backends as global ACIs, such as the following backends:

- Configuration
- Monitor
- Schema
- Changelog
- Tasks
- Encryption settings
- Backups
- Alerts

Limiting access to controls and extended operations

Oracle Directory Server Enterprise Edition (DSEE) provides limited support for restricting access to controls and extended operations.

To the extent that you can control access to controls and extended operations with access control instructions (ACIs), DSEE defines entries with a distinguished name (DN), such as `oid={oid},cn=features,cn=config`, where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control.

```
oid=2.16.840.1.113730.3.4.3,cn=features,cn=config
```

In the server, you can use the `targetcontrol` keyword to define ACIs that grant or deny access to controls. You can use the `extop` keyword to define ACIs that grant or deny access to extended operation requests.

Tolerance for malformed ACI values

If the server is running with less than the intended set of access control instructions (ACIs), it might prevent access to data that should be allowed or grant access to data that should be restricted. In Oracle Directory Server Enterprise Edition (DSEE), if the server encounters a malformed access control rule (ACR), it ignores the rule. This can cause the server to run with less than the intended set of ACIs. To guard against this, the server is more strict about the ACRs that it accepts.

When performing an LDIF import, the server rejects any entry containing a malformed or unsupported ACR. The server also rejects any `add` or `modify` request that attempts to create an invalid ACI.

In the unlikely event that a malformed ACI is accepted into the data, the server immediately places itself in lockdown mode. In lockdown mode, the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

> **Note**
>
> To review any rejected ACIs, run the **`import-ldif`** tool with the `--rejectFile` option.

About the privilege subsystem

In Oracle Directory Server Enterprise Edition (DSEE), only the root user is exempt from access control evaluation.

While administrators can create access control instructions (ACIs) that give normal users full access to any content, they can also create ACIs that would make a portion of the data inaccessible to those users. Additionally, some tasks can only be accomplished by the root user and the capabilities assigned to the root user can't be restricted.

The server uses a privilege subsystem to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. Additionally, certain risky actions require that the requester have certain privileges in addition to the sufficient access control rights to process the operation.

These risky actions include:

- Interacting with the server configuration
- Changing another user's password
- Impersonating another user
- Shutting down and restarting the server

Identifying unsupported ACIs

To determine whether access control instructions (ACIs) are suitable for use, the server provides a **`validate-acis`** tool that you can use to examine content in an LDIF file or data in another directory server, such as an Oracle Directory Server Enterprise Edition (DSEE) instance.

When migrating data from a DSEE deployment into a server instance, use the **`validate-acis`** tool to determine whether ACIs contained in the data are acceptable. If any problems exist, update the data to redefine the ACIs so they are suitable for use in the server.

For more information, see Validating ACIs before migrating data.

Working with privileges

In addition to the access control implementation, the server includes a privilege subsystem that you can use to control what users are allowed to do.

The privilege subsystem works in conjunction with the access control subsystem to only allow privileged operations that are permitted by the access control configuration. The user must also have all of the necessary privileges.

You can use privileges to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. The capabilities given to root users in the server are all granted through privileges, so you can create a normal user account with the ability to perform the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. To restrict root users to only the tasks that they must perform, define multiple root users in the server with different sets of privileges.

Available privileges

The following privileges are defined in the server.

Summary of Privileges

Privilege	Description
`audit-data-security`	This privilege is required to initiate a data security audit on the server, which is invoked by the `audit-data-security` tool.
`backend-backup`	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`backend-restore`	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`bypass-acl`	This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed. **Note** This does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation. For example, a user with the `bypass-acl` privilege but without the `config-read` privilege is not allowed to access the server configuration.
`bypass-pw-policy`	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is also evaluated for bind operations, meaning password restrictions are also bypassed when binding as a user who has this privilege.
`bypass-read-acl`	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation can still be enforced for other types of operations.

Privilege	Description
`config-read`	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
`config-write`	This privilege is required for a user to alter the server configuration. The user must also have the `config-read` privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
`disconnect-client`	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
`jmx-notify`	This privilege is required for a user to subscribe to Java Management Extensions (JMX) notifications generated by the server. The user is also required to have the `jmx-read` privilege.
`jmx-read`	This privilege is required for a user to access any information provided by the server through the JMX.
`jmx-write`	This privilege is required for a user to update any information exposed by the server through the JMX. The user is also required to have the `jmx-read` privilege. **Note** Currently, all of the information exposed by the server over JMX is read-only.
`ldif-export`	This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global access control instruction (ACI) that allows access to members of an Administrators group.
`ldif-import`	This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as described in the previous description of the `ldif-export` privilege.
`lockdown-mode`	This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.
`modify-acl`	This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the `aci` operational attribute.
`password-reset`	This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the `userPassword` attribute to the target entry.

Privilege	Description
`privilege-change`	This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the `ds-privilege-name` operational attribute.
`proxied-auth`	This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege bears some security risk, because it allows users to inherit the level of access of any user, including root users and administrators. Consider restricting proxy users as described in the section Restricting proxy users.
`server-restart`	This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`server-shutdown`	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
`soft-delete-read`	This privilege is required for a user to access a soft-deleted-entry.
`stream-values`	This privilege is required for a user to perform a stream values extended operation, which obtains all entry distinguished names (DNs) and all values for one or more attributes for a specified portion of the directory information tree (DIT).
`unindexed-search`	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
`update-schema`	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

Privileges automatically granted to root users

The special abilities that root users have are granted through privileges.

You can assign privileges to root users in two ways:

- By default, root users can be granted a specified set of privileges.

> **Note**
>
> You can create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.

- You can grant additional privileges to individual root users and remove some automatically-granted privileges from individual root users.

The `default-root-privilege-name` property of the root distinguished name (DN) configuration object controls the set of privileges that are automatically granted to root users. By default, these privileges include:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`
- `lockdown-mode`
- `manage-topology`
- `metrics-read`
- `modify-acl`
- `password-reset`
- `permit-get-password-policy-state-issues`
- `privilege-change`
- `server-restart`
- `server-shutdown`
- `soft-delete-read`
- `stream-values`
- `unindexed-search`
- `update-schema`

The privileges not granted to root users by default include:

- `bypass-pw-policy`
- `bypass-read-acl`
- `jmx-read`
- `jmx-write`
- `jmx-notify`

- `permit-externally-processed-authentication`
- `permit-proxied-mschapv2-details`
- `proxied-auth`

You can change the set of default root privileges to add or remove values as necessary. This requires the `config-read`, `config-write`, and `privilege-change` privileges, and either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to change the server's configuration.

Assigning additional privileges for administrators

Steps

- To allow access to the Tasks backend, set up a global access control instruction (ACI) using `dsconfig` that allows access to members of an Administrators group.

  Example:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks")(targetattr="*||+")
        (version 3.0; acl "Access to the tasks backend for administrators";
         allow (all) groupdn="ldap:///
         cn=admins,ou=groups,dc=example,dc=com";)'
```

Assigning privileges to normal users and individual root users

You can grant privileges to normal users on an individual basis.

Add the `ds-privilege-name` operational attribute to the user's entry with the names of the desired privileges. For example, the following change grants the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account.

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change must have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

You can use the same method to grant root users privileges that aren't included in the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges and removes the `server-restart` and `server-shutdown` privileges.

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

Note

Because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

Disabling privileges

Although the privilege subsystem in the server is a powerful feature, it might break some applications if they expect to perform an operation requiring a privilege that they do not have.

In the majority of these cases, you can assign the necessary privilege manually to the account used by that application. However, if this workaround isn't sufficient, or if you need to remove a particular privilege, such as allowing anyone to access information through Java Management Extensions (JMX) without requiring the `jmx-read` privilege, then you can disable privileges on an individual basis.

The `disabled-privilege` property in the global configuration object controls the set of disabled privileges. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

Working with proxied authorization

The PingDirectory server supports the Proxied Authorization Control (RFC 4370) to allow an authorized Lightweight Directory Access Protocol (LDAP) client to authenticate to the server as another user.

Typically, LDAP servers are deployed as backend authentication systems that store user credentials and authorization privileges necessary to carry out an operation. Single sign-on (SSO) systems can retrieve user credentials from the PingDirectory server and then issue permissions that allow the LDAP client to request operations under the identity as another user. The proxied authorization control allows client applications to securely process requests without binding or re-authenticating to the server for every operation.

The PingDirectory server supports the proxied authorization v1 and v2 request controls. The proxied authorization v1 request control is based on early versions of the `draft-weltman-ldapv3-proxy` Internet draft and is available primarily for legacy systems. You should use the proxied authorization v2 request control based on RFC 4370.

The proxied authorization v2 control requests that the associated operation is performed as if it had been requested by another user. You can use this control in conjunction with add, delete, compare, extended, modify, modify DN, and search requests. In such case, the associated operation processes under the authority of the specified authorization identity rather than the identity associated with the client connection, such as the user as whom that connection is bound. Specify the target authorization identity for this control as an `authzid` value, either with `dn:`, followed by the distinguished name of the target user or `u:`, followed by the user name.

> **Note**
>
> Because of the security risks when using the proxied authorization control, most directory servers enforce strict restrictions on users that can request this control. If a user attempts to use the proxied authorization v2 request control without the sufficient permission, the server returns a failure response with the `AUTHORIZATION_DENIED` result code.

Configuring proxied authorization

About this task

Configuring proxied authorization requires a combination of access control instructions (ACIs) and the `proxied-auth` privilege to the entry that will perform operations as another user.

> **Note**
>
> You cannot use the `cn=Directory Manager` root DN as a proxying DN. Unless your use case requires proxying root users and administrators, consider restricting proxy users as described in Restricting proxy users.

Steps

1. **Open a text editor and create a user entry that will request operations as another user. Include the `proxied-auth` privilege. Save the file as `add-user.ldif`.**

   Example:

   In this example, the user entry `uid=clientApp` will request operations as `uid=admin,dc=example,dc=com`.

   ```
   dn: ou=Applications,dc=example,dc=com
   objectClass: top
   objectClass: organizationalUnit
   objectClass: extensibleObject
   ou: Admins
   ou: Applications

   dn: uid=clientApp,ou=Applications,dc=example,dc=com
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   givenName: Client
   uid: clientApp
   cn: Client App
   sn: App
   userPassword: password
   ds-privilege-name: proxied-auth
   ```

2. **Add the file using `ldapmodify`.**

   Example:

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

3. To allow the target, open a text editor and create an LDIF file to assign an ACI to that branch so that the client app user can access it as a proxy auth user. Add the file using the `ldapmodify`.

   The client application targets a specific subtree in the Directory Information Tree (DIT) for its operations. For example, a client might need access to an accounts subtree to retrieve customer information while another client might need access to another subtree, such as a subscriber subtree.

   Example:

   In this example, the client application targets the `ou=People,dc=example,dc=com` subtree.

   > **Note**
   >
   > The ACI should be on a single line of text. The example shows the ACI over multiple lines for readability.

   ```
   dn: ou=People,dc=example,dc=com
   changetype: modify
   add: aci
   aci:  (version 3.0; acl "People Proxy Access"; allow(proxy)
     userdn="ldap:///uid=clientApp,ou=Applications,dc=example,dc=com";)
   ```

4. Run a search to test the configuration using the bind DN `uid=clientApp` and the `proxyAs` option.

   Prefix `dn:` to the proxying entry or `u:` to the user name.

   Example:

   The `uid=clientApp` binds to the server and proxies as `uid=admin` to access the `ou=People,dc=example,dc=com` subtree.

   ```
   $ bin/ldapsearch --port 1389 \
     --bindDN "uid=clientApp,ou=Applications,dc=example,dc=com" \
     --bindPassword password \
     --proxyAs "dn:uid=admin,dc=example,dc=com" \
     --baseDN ou=People,dc=example,dc=com \
     "(objectclass=*)"
   ```

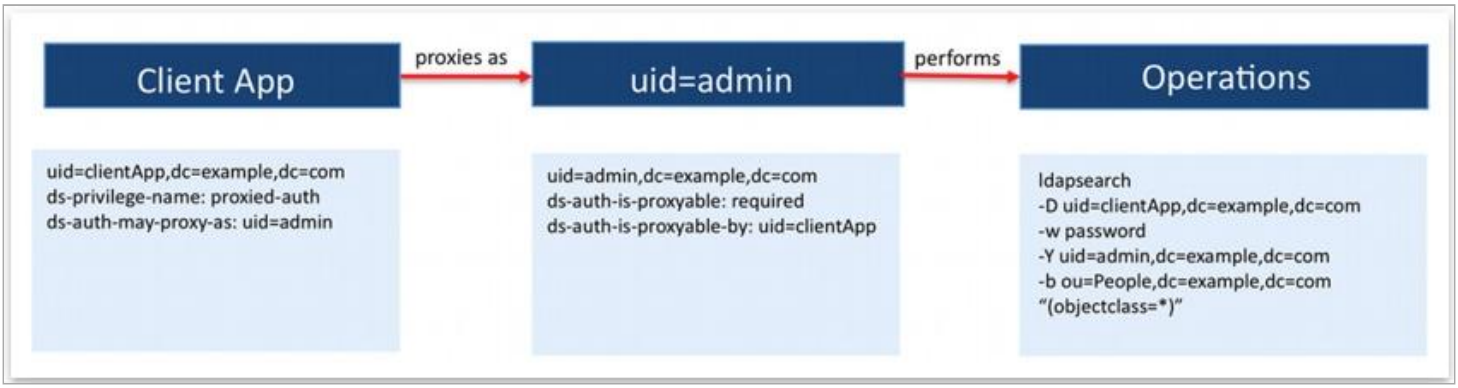
Restricting proxy users

The PingDirectory server provides a set of operational attributes that restrict the proxied authorization capabilities of a client application and its proxyable target entry.

When present in an entry, the PingDirectory server evaluates each operational attribute together to form a whitelist of potential users that can be proxied. If none of those attributes are present, the user can potentially proxy as anyone.

The PingDirectory server supports a two-tier provision system that can restrict specific users for proxied authorization:

- The first tier is a set of `ds-auth-may-proxy-as-*` operational attributes on the client entry that binds to the server and carries out operations under the identity of another user.
- The second tier is a set of `ds-auth-is-proxyable-*` operational attributes on the user entry that defines whether access is allowed, prohibited, or required through proxied authorization. If proxied authorization is allowed or required, the attributes define which client entries can proxy as the user.



Proxying operational attributes

For example, the following command demonstrates the client application `uid=clientApp` requesting to search the `ou=People,dc=example,dc=com` branch as the user `uid=admin`.

```
ldapsearch --bindDN uid=clientApp,dc=example,dc=com \
--bindPassword password \
--proxyAs uid=admin,dc=example,dc=com \
--baseDN ou=People,dc=example,dc=com \
"(object-class=*)
```

At bind, the PingDirectory server evaluates the list of users in the `uid=clientApp` entry based on the presence of any `ds-auth-may-proxy-as-*` attributes.

In the previous figure, the `uid=clientApp` entry has a `ds-auth-may-proxy-as` attribute with a value of `uid=admin`, meaning the client app user can proxy only as the `uid=admin` account.

Next, the server confirms that `uid=admin` is in the list of proxyable users and then evaluates the `ds-auth-is-proxyable-*` attributes present in the `uid=admin` entry. These attributes determine the list of restricted users that either are allowed, prohibited, or required to proxy as the `uid=admin` entry. In this case, the `uid=admin` entry has the `ds-auth-is-proxyable` attribute with a value of `required`, meaning the entry can only be accessed by means of proxied authorization.

The `uid=admin` entry also has the `ds-auth-is-proxyable-by` attribute with a value of `uid=clientApp`, meaning it can only be requested by the `uid=clientApp` entry. When both sets of attributes have been satisfied, the `uid=clientApp` can bind to the server as the authenticated user.

Next, the PingDirectory server performs access control instruction (ACI) evaluation on the branch and determines if the requested user has access rights to the branch. If the `uid=clientApp` entry can access the branch, the search request is processed.

About the ds-auth-may-proxy-as-* operational attributes

The PingDirectory server first evaluates the list of potential users that can be proxied for the authenticated user depending on the presence of the `ds-auth-may-*` operational attributes in the entry.

These operational attributes are multi-valued and are evaluated together if all are present in an entry:

`ds-auth-may-proxy-as`

Specifies the user distinguished names (DNs) that the associated user can proxy as. For example, you can specify in the `uid=clientApp` entry that it can proxy operations as `uid=admin` and `uid=agent1`.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as: uid=admin,dc=example,dc=com
ds-auth-may-proxy-as: uid=agent1,ou=admins,dc=example,dc=com
```

`ds-auth-may-proxy-as-group`

Specifies the group DNs and its group members that the associated user can proxy as. For example, you can specify that the potential users that the `uid=clientApp` entry can proxy as are those members who are present in the group `cn=Agents,ou=Groups,dc=example,dc=com`. This attribute is multi-valued, so you can specify more than one group. Nested static and dynamic groups are also supported.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-group: cn=Agents,ou=Groups,dc=example,dc=com
```

`ds-auth-may-proxy-as-url`

Specifies the DNs that are returned based on the criteria defined in an LDAP URL that the associated user can proxy as. For example, the attribute specifies that the client can proxy as those entries that match the criteria in the LDAP URL. This attribute is multi-valued, so you can specify more than one LDAP URL.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-url: ldap:///ou=People,dc=example,dc=com??sub?(l=austin)
```

About the ds-auth-is-proxyable-* operational attributes

After the PingDirectory server evaluates the list of users that the authenticated user can proxy as, the server checks to see if the requested authorized user is in the list.

If the requested authorized user is present in the list, then the server continues processing the proxable attributes in the entry. If the requested authorized user is not present in the list, the bind fails.

The operational attributes on the proxying entry are as follows:

`ds-auth-is-proxyable`

Specifies whether the entry is proxyable or not. Possible values are:

`allowed`

Operations can be proxied as this user.

`prohibited`

Operations can't be proxied as this user.

`required`

The account cannot authenticate directly but can only be accessed by some form of proxied authorization.

`ds-auth-is-proxyable-as`

Specifies any users allowed to use this entry as a target of proxied authorization.

`ds-auth-is-proxyable-as-group`

Specifies any groups allowed to use this entry as a target of proxied authorization. Nested static and dynamic groups are also supported.

`ds-auth-is-proxyable-as-url`

Specifies the LDAP URLs that are used to determine any users that are allowed to use this entry as a target of proxied authorization.

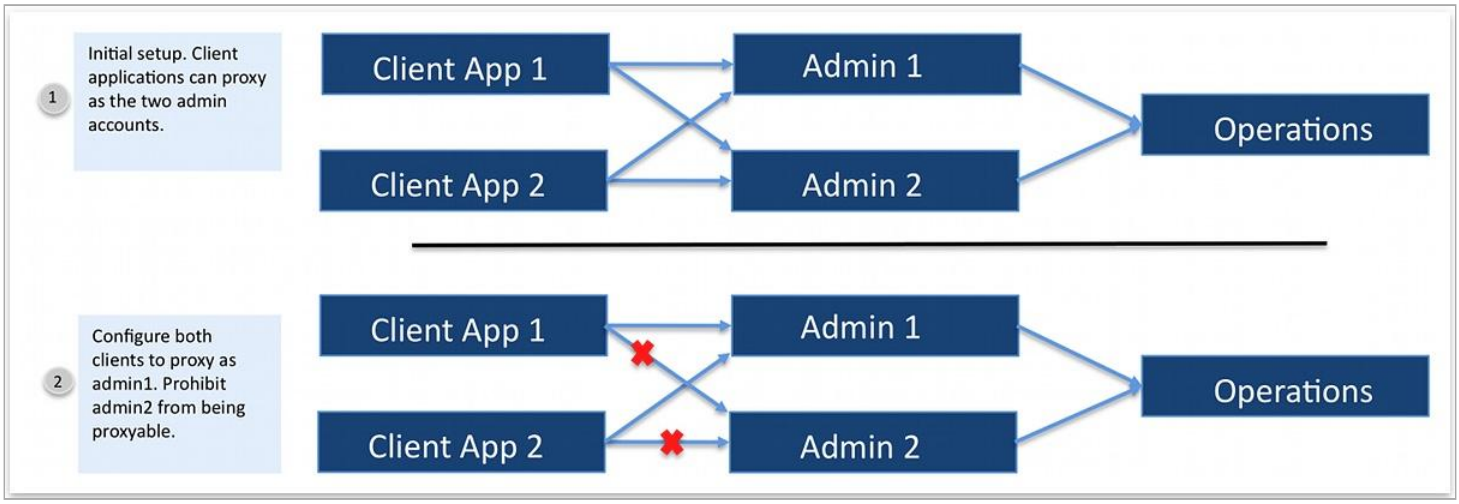
Restricting proxied authorization for specific users

Use the following example scenario with proxied users to restrict proxied authorization.

About this task

To illustrate how the proxied authorization operational attributes work, set up a simple example where two LDAP clients, `uid=clientApp1` and `uid=clientApp2`, can freely proxy two administrator accounts, `uid=admin1` and `uid=admin2`. Add the `ds-auth-may-proxy-as-*` and `ds-auth-is-proxyable-*` attributes to these entries to restrict how each account can use proxied authorization.

For example, the two client applications can continue to proxy the `uid=admin1` account but the `uid=admin2` account are no longer able to be used as a proxied entry.



Proxy Users Example Scenario

Steps

1. **Set up two user entries, `uid=clientApp1` and `uid=clientApp2`, with the `proxied-auth` privilege assigned to them.**

   The user entries will proxy as the `uid=admin1` and `uid=admin2` accounts to access the `ou=People,dc=example,dc=com` subtree.

   1. **Open a text editor and create an LDIF file.**
   2. **Add the file using the `ldapmodify` tool.**

      Example:

      > **Note**
      >
      > In this example, **…** indicates that other attributes present in the entry are not included for readability purposes.

      ```
      dn: uid=clientApp1,ou=Applications,dc=example,dc=com
      objectClass: top
      ...
      ds-privilege-name: proxied-auth

      dn: uid=clientApp2,ou=Applications,dc=example,dc=com
      objectClass: top
      ...
      ds-privilege-name: proxied-auth
      ```

2. **Assign the access control instruction (ACI) for each client application to the subtree, `ou=People,dc=example,dc=com`.**

   > **Note**
   >
   > ACIs should be on one line of text. The following example displays ACIs over multiple lines for readability.

   Example:

```
dn: ou=People,dc=example,dc=com
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
       userdn="ldap:///uid=clientApp1,ou=Applications,dc=example,dc=com";)
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
       userdn="ldap:///uid=clientApp2,ou=Applications,dc=example,dc=com";)
```

3. Run a search for each entry.

   Example:

   In this example, assume that there are two admin accounts, `admin1` and `admin2`, that have full access rights to user attributes. You should be able to proxy as the `uid=admin1` and `uid=admin2` entries to access the subtree for both clients.

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin1,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"

$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

4. Limit the proxied authorization capabilities for each client application.

   In the following example, the `ds-auth-may-proxy-as` attribute specifies that `uid=clientApp1` can proxy as the `uid=admin1` entry.

   1. Open a text editor and create the following LDIF file.
   2. Update the `uid=clientApp1` entry to add the `ds-auth-may-proxy-as` attribute.

      > **Note**
      >
      > `ds-auth-may-proxy-as` is multi-valued.

   3. Save the file and add it using `ldapmodify`.

      Example:

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as
ds-auth-may-proxy-as: uid=admin1,dc=example,dc=com
```

5. Repeat the previous step for the `uid=clientApp2` entry, but specify the `ds-auth-may-proxy-as-url` attribute.

   The client entry can proxy as any distinguished name (DN) that matches the LDAP URL.

Example:

```
dn: uid=clientApp2,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as-url
ds-auth-may-proxy-as-url: ldap:///dc=example,dc=com??sub?(uid=admin*)
```

6. To illustrate the `ds-auth-proxyable-by-group` attribute, create a group of client applications that has `uid=clientApp1` and `uid=clientApp2` as its `uniquemembers`.

   Example:

   This example sets up a static group using the `groupOfUniqueNames` object class.

   ```
   dn: ou=Groups,dc=example,dc=com
   objectClass: top
   objectClass: organizationalunit
   ou: groups

   dn: cn=Client Applications,ou=Groups,dc=example,dc=com
   objectClass: top
   objectClass: groupOfUniqueNames
   cn: Client Applications
   ou: groups
   uniquemember: uid=clientApp1,ou=Applications,dc=example,dc=com
   uniquemember: uid=clientApp2,ou=Applications,dc=example,dc=com
   ```

7. Update the `uid=admin1` entry to provide the DN that it can be proxied as.

   1. Open a text editor and create the following LDIF file.
   2. Use the `ds-auth-is-proxyable` to make the `uid=admin1` a required proxyable entry, meaning that it can only be accessed by some form of proxied authorization.
   3. Use the `ds-auth-is-proxyable-by` attribute to specify each DN that can proxy as `uid=admin1`.
   4. Save the LDIF file and add it using `ldapmodify`.

      Example:

```
dn: uid=admin1,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: required
-
add: ds-auth-is-proxyable-by
ds-auth-is-proxyable-by: ou=clientApp1,ou=Applications,dc=example,dc=com
ds-auth-is-proxyable-by: ou=clientApp2,ou=Applications,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-group
ds-auth-is-proxyable-by-group: cn=Client Applications,ou=Groups,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-url
ds-auth-is-proxyable-by-url: ldap:///ou=Applications,dc=example,dc=com??sub?(uid=clientApp*)
```

Note

The example includes all three types of `ds-auth-is-proxable-by-*` attributes as an illustration, but only one type of attribute is necessary if they all target the same entries.

8. Prohibit proxying for the `uid=admin2` entry.

    1. Open a text editor and create the following LDIF file.
    2. Set the `ds-auth-is-proxyable` attribute to `prohibited`.
    3. Save the LDIF file and add it using `ldapmodify`.

    Example:

    ```
    dn: uid=admin2,dc=example,dc=com
    changetype: modify
    add: ds-auth-is-proxyable
    ds-auth-is-proxyable: prohibited
    ```

9. Run a search using the proxied account.

    1. To return a successful operation, run a search with `uid=clientApp1` or `uid=clientApp2` that proxies as `uid=admin1`.
    2. To return an unsuccessful operation, run a search for `uid=clientApp1` that proxies as `uid=admin2`.

    Example:

    ```
    $ bin/ldapsearch --port 1389 \
      --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
      --bindPassword password \
      --proxyAs "dn:uid=admin2,dc=example,dc=com" \
      --baseDN ou=People,dc=example,dc=com \
      "(objectclass=*)"
    ```

    Result:

The operation is unsuccessful because `uid=admin2` does not match the list of potential entries that can be proxied. The `ds-auth-may-proxy-as-*` attributes specify that the client can only proxy as `uid=admin1`.

```
One of the operational attributes (ds-auth-may-proxy-as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow
that user to be proxied as user 'uid=admin2,dc=example,dc=com'

Result Code: 123 (Authorization Denied)

Diagnostic Message: One of the operational attributes (ds-auth-may-proxy-as,
ds-auth-may-proxy-as-group, ds-auth-may-proxy-as-url) in user entry
'uid=clientApp1,ou=Applications,dc=example,dc=com' does not allow that
user to be proxied as user 'uid=admin2,dc=example,dc=com'
```

10. Run another search using `uid=clientApp2`, which attempts to proxy as `uid=admin2`.

Example:

```
$ bin/ldapsearch --port 1389 \
  --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
  --bindPassword password \
  --proxyAs "dn:uid=admin2,dc=example,dc=com" \
  --baseDN ou=People,dc=example,dc=com \
  "(objectclass=*)"
```

Result:

The operation is unsuccessful because the `ds-auth-is-proxyable:prohibited` operational attribute states that `uid=admin2` is not available for proxied authorization.

```
The 'ds-auth-is-proxyable' operational attribute
in user entry 'uid=admin2,dc=example,dc=com' indicates that
user may not be accessed via proxied authorization

Result Code: 123 (Authorization Denied)

Diagnostic Message: The 'ds-auth-is-proxyable' operational
attribute in user entry 'uid=admin2,dc=example,dc=com' indicates
that user may not be accessed via proxied authorization
```

Working with parameterized ACIs

The PingDirectory server supports the use of parameterized access control instructions (ACIs) to control access to subtrees with homogenous administrative group or user patterns, which can be used in multi-tenant deployments.

A single parameterized ACI can take the place of specifying identical ACIs on each tenant's subtree. For example, consider the following parameterized ACI.

```
(target="ldap:///o=($1),dc=example,dc=com")(version 3.0; acl \
"Subtree Admin Group members may search for and read entries in their subtree."; allow \
(search, read) groupdn="ldap:///cn=Subtree Admin Group,ou=groups,o=($1),dc=example,dc=com";)
```

This parameterized ACI enables:

- Members of a group with the distinguished name (DN) `"cn=Subtree Admin Group,ou=groups,o=Customers, dc=example,dc=com"` to search for and read entries in the `"o=Customers, dc=example,dc=com"` subtree.
- Members of a group with the DN `"cn=Subtree Admin Group,ou=groups,o=Partners, dc=example,dc=com"` to search for and read entries in the `"o=Partners, dc=example,dc=com"` subtree

The same access is granted for any substitution value for the `($1)` parameter variable. If an operation tries to read the `uid=user.1,o=acme,dc=example,dc=com` entry, this ACI is considered. This ACI would allow a read action if the operation's user is a member of the `cn=Subtree Admin Group,ou=groups,o=acme,dc=example,dc=com` group.

You can replace attribute values from the target DN with different variables, `($#)`, and then reference those variables in the group DN or user DN. Construct the string representation of a parameter variable as follows:

1. An open parenthesis
2. A dollar sign
3. A positive integer
4. A closing parenthesis

Consider the following example.

```
"population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme"
```

The `($2)` variable is the population ID in the DN of the target entry, and `($1)` is the environment ID in the DN of the target entry. Those values from the target entry's DN are substituted into the group DN or user DN value.

Parameter variables present in a parameterized ACI's target will be associated with the actual values from the resource DN. Each actual value will be substituted for its respective parameter variable in the ACI's target and group bind rule DNs when performing access control on the resource entry.

Parameter variables can be used in multiple relative distinguished names (RDNs) in a parameterized target. A given RDN can have at most one parameter variable as its attribute value. A given parameter variable can appear only once in the parameterized target.

The following values are examples of valid parameterized target DNs:

- `ou=($1),dc=example,dc=com`
- `population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme`
- `o=($1)` (for a global ACI)

An ACI on an entry only applies to that entry's subtree. If an ACI with a parameterized target is stored on an entry, that entry's DN must appear in a non-parameterized form as the rightmost RDN of the parameterized target's DN. For example, if an ACI with a parameterized target is stored on the `dc=example,dc=com` entry, that parameterized target must end in `dc=example,dc=com` in a non-parameterized form. Global ACIs do not have this restriction. Each global ACI can have parameter variables in any or all of its parameterized target's RDNs.

Additional restrictions for parameterized targets include:

- They cannot be pattern ACIs, meaning they cannot contain wildcards (`*`).
- RDNs that are parameterized must be single-valued. For example, a given parameterized RDN cannot consist of two or more type-value pairs joined by `+` .

$attr.attrName macro

The `($attr.attrName)` macro extracts a value from a specified attribute in the target entry rather than extracting a value from a field with the same number in the target distinguished name (DN).

For example, `($attr.description)` is replaced with the value of the `description` attribute in the target entry. If there are multiple values for the specified attribute, then multiple actualized DNs are produced for the bind DN, and the first matching actualized DN is used.

The `($attr.attrName)` macro expands only the attribute's value so that you can extract values from the target DN and build relative distinguished names (RDNs) with different attribute names and types. Because the `($attr.attrName)` macro extracts only the attribute's value, you can combine it with a type other than what is in the target DN.

Managing servers and certificates

The following provides a detailed description of PingDirectory server certificate types.

The PingDirectory server uses two main types of certificates:

Listener certificates

Used to secure communication through TLS.

Inter-server certificates

Used to authenticate between server instances in a topology.

Listener certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client and the certificate at the head of the chain functions as a listener certificate.

Because the client decides whether to trust the certificate chain, it is recommended that the chain be signed by an issuer whom the client is likely to trust or that the client can be easily configured to trust.

You can create self-signed certificates with long lifespans, but a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, but some authorities use shorter validity windows.

Short certificate lifespans offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a shorter validity window minimizes the timeframe that a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, administrative inconvenience can be kept to a minimum.

Listener certificates are stored in key stores that are referenced by key manager providers, which in turn provide the logic and configuration for accessing the key stores. If a server component, like a connection handler, requires access to a certificate that it presents to a peer during the TLS negotiation process, that component must reference the key manager provider that points to the key store containing the appropriate certificate. If the key store contains multiple certificates, and if the component referencing the key store includes a property specifying the certificate's nickname, the certificate with that alias is selected. Otherwise, the server lets the Java virtual machine (JVM) select a certificate that might not be well-defined.

The server also provides trust manager providers, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified trust store file, but other options include the JVM default trust store, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

> **Note**
>
> Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing listener certificates

Certificate authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you are likely replacing the certificates on a regular basis.

About this task

The `replace-certificate` tool performs the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations.
3. Update the server instance listener configuration with the new certificate.

The `replace-certificate` tool offers the following modes of operation:

Interactive mode

Walks you through the process of obtaining a new certificate and installing it in the server. Interactive mode also displays the non-interactive commands that are required to achieve the same result.

Non-interactive mode

Useful when scripting the process of replacing a certificate.

Steps

- To replace a listener certificate, run the `replace-listener-certificate` subcommand of the `replace-certificate` tool.

> **Note**
>
> You can replace certificates manually, but the **`replace-certificate`** tool automates the process. The **`replace-certificate`** tool provides information about multiple listener certificates during the transitional phase that occurs when you install them.
> The **`replace-listener-certificate`** subcommand takes arguments that provide the following information:
> - Arguments required to authenticate to PingDataSync, such as `--bindDN` and `--bindPasswordFile`
> - Details about the key store, PEM, or DER file that contains the new certificate
> - Updates that must be made to the key and trust manager providers
> - Whether to signal the HTTP connection handler to reload its certificates after the update is complete

The following arguments are available:

Argument	Description
`--source-certificate-file <path>`	The path to the PEM or DER file that contains the new certificate chain. Either this argument or `--source-key-store-file <path>` must be provided. If you are providing a certificate chain with multiple certificates, order the chain with the server certificate first. Each subsequent certificate should be the issuer for the previous certificate. You can provide `--source-certificate-file` multiple times if the certificates in the chain are in separate files rather than one file.

Argument	Description
`--source-private-key-file <path>`	The path to the PEM or DER file that contains the private key that correlates to the new PEM or DER server certificate. This argument must be provided when including `--source-certificate-file <path>`.
`--source-key-store-file <path>`	The path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. Either this argument or `--source-certificate-file <path>` must be provided.
`--source-key-store-password <password>`	The clear-text password needed to access the contents of the source key store.
`--source-key-store-password-file <path>`	The path to a file containing the password needed to access the contents of the source key store. The file can contain the password in the clear, or it can be encrypted with a definition from the server's encryption settings database.
`--source-certificate-alias <alias>`	The alias of the private key entry in the source key store that contains the certificate chain for the new listener certificate. If the source key store has more than one private key entry, then this argument must be provided to indicate which one to use.
`--source-private-key-password <password>`	The password needed to access the appropriate private key in the source key store, PEM, or DER file. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, then the key store password is also used as the private key password.
`--source-private-key-password-file <path>`	The path to a file containing the password needed to access the appropriate private key in the source key store, PEM, or DER file. The file can contain the password in the clear, or it can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, then the key store password is also used as the private key password.
`--key-manager-provider <name>`	The name of the key manager provider that will be updated to use the new certificate chain. It must be a file-based key manager provider, and it must be enabled. If this argument is not provided, a default value of "JKS" is assumed.

Argument	Description
`--trust-manager-provider <name>`	The name of the trust manager provider that will be updated with the information needed to trust the new certificate chain. It must be a file-based trust manager provider, and it must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, then the tool assumes that the trust manager provider has the same name as the key manager provider, though these providers remain separate and distinct.
`--use-jvm-default-trust-manager-provider`	Indicates that the server should be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the cacerts trust store provided with the JVM, rather than updating an existing trust manager provider.
`--target-certificate-alias <alias>`	The alias to use for the new certificate in the key manager provider's key store and also for any appropriate updates in the trust manager provider's trust store. If this is not provided, a default alias of "server-cert" is used. **Note** If the key manager provider's key store or the trust manager provider's trust store already contains an entry with the given alias, the existing entry will be renamed.
`--reload-http-connection-handler-certificates`	Indicates that the tool should request that the server cause any HTTPS-based connection handlers to reload their certificates so that they will start using the updated certificate. LDAP connection handlers reacts to the change right away and start presenting the new certificate chain during any subsequent TLS negotiations, but HTTPS connection handlers will continue using the former certificate until the connection handler is restarted or until it is specifically asked to reload its certificates. **Note** Using this option can prevent clients with existing TLS sessions negotiated with the former certificate from being resumed.

The following example illustrates what you see when you run the `replace-certificate replace-listener-certificate` command with the `--help` argument:

```
replace-certificate replace-listener-certificate \
     --bindDN uid=admin,dc=example,dc=com \
     --bindPasswordFile admin-password.txt \
     --source-key-store-file new-listener-certificate-keystore.jks \
     --source-key-store-type JKS \
     --source-key-store-password-file new-listener-certificate-keystore.pin \
     --source-certificate-alias new-listener-cert \
     --key-manager-provider JKS \
     --trust-manager-provider JKS \
     --target-certificate-alias server-cert
```

The following example illustrates replacing a PEM-encoded listener certificate:

```
replace-certificate replace-listener-certificate \
     --bindDN cn=Directory Manager \
     --bindPasswordFile admin-password.txt \
     --source-certificate-file new-listener-certificate-chain.pem \
     --source-private-key-file new-private-key.pem \
     --source-private-key-password-file encrypted-private-key-password.txt \
     --key-manager-provider JKS \
     --trust-manager-provider JKS \
     --target-certificate-alias server-cert
```

- The following example demonstrates using the `replace-certificate` tool in interactive mode to replace the listener certificate chain. The output also includes the non-interactive commands needed to perform the corresponding operations.

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses forTLS
        communication
2 - Replace the inter-server certificate that the server uses to
        authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
        topology registry
4 - Purge any retired inter-server certificates for this server from the
        topology registry
q - Quit without doing anything

Enter your choice: 1

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

NOTE:  'JKS' is the only key manager provider that is suitable to be
updated with a new listener certificate.  Automatically selecting that
provider

Which trust manager provider do you wish to update with information needed
to trust the new listener certificate?

1 - JKS
d - Use the JVM-default trust manager provider to trust any certificate
        signed by an authority in the JVM's default set of trusted issuers

Enter your choice [1]: 1

How would you like to obtain the new listener certificate?

1 - Generate a new self-signed certificate
2 - Generate a request for a certificate to be signed by a certification
    authority
3 - Use a certificate in an existing key store
q - Quit without doing anything

Enter your choice: 2

Enter the subject DN that you would like to use for the new certificate.
The subject DN typically includes some or all of the following components:

* CN -- The common name for the certificate.  This is typically the
  fully-qualified name (not an IP address) that most clients will use to
  connect to the server (alternate names and IP addresses may be provided
  later).  We strongly recommend including a CN attribute in the
  certificate subject
* OU -- Typically the name of the department or organizational unit that
  manages the server
```

```
* O -- Typically the name of the company or organization that manages the
  server
* L -- Typically the name of the city or locality in which the server is
  located
* ST -- Typically the full name (NOT an abbreviation) of the state or
  province in which the server is located
* ST -- Typically the two-character ISO 3166 country code for the country
  in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory
Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: CN=ds1.example.com,O=Example Corp,C=US

Enter the complete set of resolvable names (not IP addresses) that clients
are expected to use to access the server.  These names will be included in
the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk
as a wildcard in the leftmost component that will match any host name in
that component.  For example, '*.example.com' indicates that the
certificate may be used in any server whose fully-qualified name consists of
exactly three components, and in which the last two components are
'example.com'

The current set of DNS names to include in the set of subject alternative
names is:

* ds1.example.com
* ip6-localhost
* localhost

What would you like to do?

1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: 2

Enter the new DNS name to include: ds.example.com

The current set of DNS names to include in the set of subject alternative
names is:

* ds.example.com
* ds1.example.com
* ip6-localhost
* localhost

What would you like to do?

1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: 1
```

```
Enter the complete set of IPv4 and IPv6 addresses that clients are
expected to use to access the server.  These addresses will be included in
the certificate's subject alternative name extension.  Wildcards are not
allowed

The current set of IP addresses to include in the set of subject
alternative names is:

* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:fe1d:811d

What would you like to do?

1 - Use the current set of IP addresses
2 - Add another IP address
3 - Remove a specific IP address
4 - Clear the current set of IP addresses
5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: 1

Generating a certificate signing request with the following command:

     manage-certificates \
          generate-certificate-signing-request \
          --output-file /ds/tmp/replace-certificate-certificate-signing-request-6730986100632343057.pem \

How would you like to import the signed certificate into the key store?

1 - I expect to get the signed certificate back right away.  Walk me
        through the process of importing it into the key store
2 - I will manually import the signed certificate

Enter your choice [1]: 1
Enter the path to the file containing the signed certificate (and
optionally any necessary issuer certificates): /ca/server-cert.pem

NOTICE:  Certificate file '/ca/server-cert.pem' ends with certificate
'CN=ds1.example.com,O=Example Corp,C=US' that was signed by issuer
'CN=Example Intermediate CA,O=Example Corp,C=US', but that issuer
certificate could not be found in the JVM-default trust store

Enter the path to a file containing the
'CN=Example Intermediate CA,O=Example Corp,C=US' certificate (and
optionally its issuer chain): /ca/intermediate-ca-cert.pem

NOTICE:  Certificate file '/ca/intermediate-ca-cert.pem' ends with
certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' that was
signed by issuer 'CN=Example Root CA,O=Example Corp,C=US', but that issuer
certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Root CA,O=Example
Corp,C=US' certificate (and optionally its issuer chain): /ca/root-ca-cert.pem

Would you like to request that the server reload any certificates
associated with HTTP connection handlers configured with support for HTTPS
so that they will start using the new certificate right away?  Note that
```

```
this may prevent clients from resuming TLS sessions created before the
reload

1 - Yes.  Reload the certificates associated with any HTTPS-enabled HTTP
        connection handlers
2 - No.  Do not reload the certificates.  HTTPS connection handlers will
        continue to use their current certificates until the server (or at
        least the connection handler) is restarted, or until the
        reload-http-connection-handler-certificates tool is run
q - Quit without doing anything else

Enter your choice [1]: 1

About to invoke the following command:

     replace-certificate \
          replace-listener-certificate \
          --bindDN "cn=Directory Manager" \
          --bindPassword '*****REDACTED*****' \
          --key-manager-provider JKS \
          --trust-manager-provider JKS \
          --source-key-store-file /ds/tmp/replace-certificate-temporary-key-store-281484917294163222.jks \
          --source-key-store-password-file /ds/config/ads-truststore.pin \
          --source-certificate-alias generated-certificate \
          --reload-http-connection-handler-certificates

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No.  Quit without doing anything else

Enter your choice [1]: 1
Successfully replaced the listener certificate
```

- To remove earlier certificates from the server instance listener configuration, run the `purge-retired-listener-certificates` subcommand.

> **Note**
>
> The **`purge-retired-listener-certificates`** subcommand does not take arguments other than the ones that are required to authenticate to the server.
> By default, the **`replace-certificate`** tool updates the server instance listener configuration object to include the new listener certificate, and it merges the old and new certificates residing in the configuration object.

Repairing broken listener certificate trust in replication

PingDirectory replication configuration depends on listener certificates. When certificate trust is broken between servers, replication and client traffic continues, but topology changes are disrupted.

PingDirectory uses a mirrored subtree service to keep configuration subtrees synchronized across a replicated topology. This synchronization depends on listener certificates being trusted between servers. If you discover (for example, during a topology change or from a peer connection alert) that these certificates are out of sync, the certificate trust is broken and the topology can't be properly mirrored. For example, when one server tries to send changes to trusted servers, the operation fails if the receiving servers have a different master than the sending server, or don't have a master at all.

Note

Common causes of a broken mirrored subtree:

- Replacing one or more LDAPS connection handler certificates before adding the listener certificate trust to the topology
- Updating the key store on disk without running the `replace-certificate` tool
- Replacing the listener certificate trust with the new certificate without including the old certificate
- Using an older or untested custom script to replace the certificate
- Making a typo when replacing the certificate
- Allowing the server certificate to expire

When you have a large number of servers in your environment, and your listener certificates fall out of sync, repairing trust and restoring topology mirroring can become complex. Rollback after a certificate rotation might not be possible because the new certificate is already serving client traffic. To troubleshoot, you check the logs and statuses for multiple servers. After you find the root cause, you update all server members lacking the appropriate trust, but you have to force each of these servers as master because the topology is read-only, due to the lack of trust.

Instead of following this long and complicated troubleshooting procedure, you can use the `repair-topology-listener-certificates` CLI tool. This tool helps restore trust and bring replicated environments back to a working state, greatly reducing the effort required to fix this issue.

Using the `repair-topology-listener-certificates` tool

Before you begin

Forced masters

The `repair-topology-listener-certificates` tool can fail if there are multiple masters in the topology. You must ensure no servers have `force-as-master-for-mirrored-data` set to `true` in the global configuration of any server in the topology.

Topology credentials

To update all server instances, you must supply an ID that exists on all servers in the topology and has the same password. If your root user accounts have differing passwords on all server nodes, you can use the topology administrator credentials, which consist of the same ID and password across the cluster.

About this task

You can use the `repair-topology-listener-certificates` tool to repair a broken PingDirectory topology by replacing the listener certificates for one or more server instances. The tool connects to each server in the topology and collects the certificates that they present during TLS negotiation for LDAPS, LDAP StartTLS, and HTTPS. It then examines the topology registry for each server to identify any updates that need to be made and attempts to apply those updates.

Note

Because you might need to run the tool multiple times to repair trust across the entire topology, each execution generates log files and LDIF change files to a separate directory, so that you can correlate changes to a specific run. By default, these subdirectories are stored within the current working directory and are named as follows: `repair-topology-listener-certificates-<timestamp>` .

Important arguments for `repair-topology-listener-certificates` are listed in the following tables. See the CLI for a complete list.

LDAP connection and authentication arguments

Argument	Description
`--hostname <host>`	The IP address or resolvable name to use to connect to a specific instance of the PingDirectory server. If you don't provide this value, the tool uses `localhost`.
`--port <port>`	The port to use to connect to the server. If you don't provide this value, the tool uses a default value of `389`.
`--bindDN <DN>`	The DN to use to bind to the server when performing simple authentication.
`--bindPassword <password>`	The password to use to bind to the server when performing simple authentication or a password-based SASL mechanism.
`--bindPasswordFile <path>`	The path to the file containing the password to use to bind to the server when performing simple authentication or a password-based SASL mechanism.
`--promptForBindPassword`	Indicates that the tool should interactively prompt the user for the bind password.
`--useSSL`	The tool uses SSL when communicating with the server.
`--useStartTLS`	The tool uses StartTLS when communicating with the server.
`--defaultTrust`	The tool uses the JVM's default trust store, and optionally an additional trust store specified using the `--trustStorePath` argument, to non-interactively determine whether to trust any certificate chain presented during TLS negotiation. If the chain can't be trusted based on any of those sources, then negotiation fails without prompting the user.
`--trustAll`	The tool trusts any certificate presented by the server.
`--keyStorePath <path>`	The path to the file to use as the key store for obtaining client certificates when communicating securely with the server.
`--keyStorePassword <password>`	The password to use to access the key store contents.
`--keyStorePasswordFile <path>`	The path to the file containing the password to use to access the key store contents.
`--promptForKeyStorePassword`	Indicates that the tool should interactively prompt the user for the password to use to access the key store contents.

Argument	Description
`--keyStoreFormat <format>`	The format for the key store file. For example, JKS, PKCS12, PKCS11, or BCFKS.
`--trustStorePath <path>`	The path to the file to use as trust store when determining whether to trust a certificate presented by the server.
`--trustStorePassword <password>`	The password to use to access the trust store contents.
`--trustStorePasswordFile <path>`	The path to the file containing the password to use to access the trust store contents.
`--promptForTrustStorePassword`	Indicates that the tool should interactively prompt the user for the password to use to access the trust store contents.
`--trustStoreFormat <format>`	The format for the trust store file. For example: JKS, PKCS12, PKCS11, or BCFKS.
`--verifyCertificateHostnames`	Indicates that the tool should verify that the host name or IP address used to establish connections to the server matches an address for which the server's TLS certificate was issued.
`--certNickname <nickname>`	The alias of the client certificate in the key store to present to the server for SSL client authentication.
`--enableSSLDebugging`	Enables Java's low-level support for debugging SSL/TLS communication. This is equivalent to setting the `javax.net.debug` property to `all`.
`--saslOption <name=value>`	A name-value pair that provides information for the server to use when performing SASL authentication.
`--useSASLExternal`	The tool uses the SASL EXTERNAL mechanism to authenticate.
`--helpSASL`	Provides information about the supported SASL mechanisms, including the properties available for use with each.

Usage arguments

Argument	Description
`--dryRun`	The tool identifies any updates that need to be applied to the topology registry but doesn't attempt to apply them. The identified changes are written as LDIF files in the output directory.

Argument	Description
`--forceAsMasterDelay <delay>`	The length of time that the tool should wait to update topology data for a server instance after forcing that instance to temporarily act as the topology master. If you include this argument, you must supply a value that includes an integer followed by a time unit. For no delay, supply a value of `0 seconds`. If you don't include this argument, the tool uses a default delay of 10 seconds.
`--interactive`	Launches the tool in interactive mode.
`--outputDirectory <path>`	The path to a directory where the tool should write output files, including a log file with detailed information about the processing performed by this tool and LDIF files with any changes to be applied. If you don't supply this argument, the tool creates a subdirectory named `repair-topology-listener-certificates-<timestamp>` in the current working directory.

Steps

1. (Optional) To review the changes needed before applying them, run the tool using the `--dryRun` argument.

   Example:

   ```
   $ bin/repair-topology-listener-certificates \
     --hostname ds1.example.com \
     --port 636 --useSSL \
     --trustStorePath /path/to/ds1/trust/store \
     --bindDN "cn=Directory Manager" \
     --bindPasswordFile /path/to/password.txt \
     --dryRun
   ```

2. Run the tool to apply the necessary topology registry changes.

   Choose from:

   - Remove the `--dryRun` argument and re-run the command to apply the changes identified during the dry run.
   - Build a command using the arguments needed from the previous tables and run the command to identify and apply changes.
   - Run `repair-topology-listener-certificates --interactive` to enter interactive mode and enable the CLI to prompt you for any information the tool needs to run.

3. Review the tool output and verify whether the topology trust has been restored:

   If trust is fully restored, no further steps are needed.

   Troubleshooting:

If trust hasn't been fully restored:

1. Review the command and make any adjustments needed.
2. Re-run the command.
3. Return to the beginning of this step.

Inter-server certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process.

The inter-server certificate is not exposed to clients, so a trusted issuer does not need to sign it. Instead, the topology registry, representing a mirrored portion of the configuration with information about every PingDirectory server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the inter-server certificate

During the installation process, the inter-server certificate is generated with a long lifespan and does not require replacement under normal circumstances. You should replace the inter-server certificate only if you suspect that its private key is compromised.

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

The `replace-certificate replace-inter-server-certificate` command performs the following steps:

- Acquires the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store
- Makes the necessary updates to the `config/ads-truststore` file in the server key store
- Updates the server instance configuration object to include the new inter-server certificate

Note

To avoid the need to replace the inter-server certificate on a regular basis,use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair
- Has a minimum key size of 2048 bits
- Has a maximum key size of 3072 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits
- Certificates with an RSA key that is larger than 3072 bits

Steps

- To replace the inter-server certificate, run the `replace-inter-server-certificate` subcommand of the `replace-certificate`.

  The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

  - `--source-key-store-file <path>`
  - `--source-key-store-password <password>`
  - `--source-key-store-password-file <path>`
  - `--source-certificate-alias <alias>`
  - `--source-private-key-password <password>`
  - `--source-private-key-password-file <path>`

  The following example illustrates what you see when you run `replace-certificate replace-inter-server-certificate` with the `--help` argument:

```
replace-certificate replace-inter-server-certificate \
     --bindDN uid=admin,dc=example,dc=com \
     --bindPasswordFile admin-password.txt \
     --source-key-store-file new-inter-server-certificate-keystore.jks \
     --source-key-store-type JKS \
     --source-key-store-password-file new-inter-server-certificate-keystore.pin \
     --source-certificate-alias new-inter-server-cert
```

- To delete earlier values that are no longer needed, run the `purge-retired-inter-server-certificates` subcommand.

> **Note**
>
> By default, the new inter-server certificate is merged with the existing values in the server instance configuration entry.

X.509 certificates

The server supports X.509 certificates, the most common type of certificates. RFC 5280 describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

X.509 encoding version

Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or later version of the specification.

Serial number of the certificate

Integer value that uniquely identifies a certificate as issued by a certification authority.

Subject DN

Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see Certificate subject DNs.

Issuer DN

Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.

Validity window

Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:

- `notBefore`

  Specifies the earliest time at which the certificate is considered valid.

- `notAfter`

Specifies the latest time at which the certificate is considered valid.

Public key

Public portion of a pair of cryptographically linked keys. For more information, see Certificate key pairs.

Signature

A type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. A self-signed certificate is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

Subject unique ID

Uniquely identifies the certificate. This component has been deprecated in favor of the subject key identifier extension, so it is generally omitted from X.509v3 certificates.

Issuer unique ID

Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.

Set of extensions

Provides additional context for the certificate and the manner in which it is used. For more information, see Certificate extensions.

Certificate subject DNs

A certificate's subject distinguished name (DN) provides information about how the certificate should be used.

Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. However, unlike an LDAP DN, the attribute names in a certificate subject DN are typically written in all uppercase characters.

A certificate's subject DN is also referred to as its subject. The following attributes commonly appear in a certificate subject.

Attribute name	Attribute description
`CN`	Common name **Note** For a listener certificate, the `CN` attribute typically identifies the host name that clients use to access the certificate. However, the subject alternative name extension is recommended more highly for accomplishing the same task. Most certificate subject DNs include at least the `CN` attribute.
`E`	Email address
`OU`	Name of the organizational unit, such as the relevant department
`O`	Name of the organization or company
`L`	Name of the locality, such as the appropriate city
`ST`	Full name of the state or province
`C`	ISO 3166 country code

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key.

Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult, a process categorized in cryptographic terms as computationally infeasible.

When generating a key pair, one key is designated as the public key, and the other key is designated the private key. The public key can be made widely available, but the private key must be kept secret and not shared with anyone.

As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption, sometimes referred to as confidentiality

  If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Only you possess the private key, so only you can decrypt the message.

- Digital signatures

  If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

  > **Note**
  >
  > When generating a digital signature, the entire message is generally not encrypted. Only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.
  > This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that the message came from you and that it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA, which is based on the multiplication of large prime numbers
- EC, which is based on computations that involve special types of elliptical curves

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, you should use an RSA certificate and choose a key size of at least 2,048 bits.

If all of your clients support EC certificates, you should use an EC certificate with a key size of at least 256 bits.

Certificate extensions

Extensions provide additional context for a certificate.

Some of the more common extension types include the following:

Subject key identifier

Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

Authority key identifier

Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.

Subject alternative name

Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

> **Note**
>
> Clients must take this information into account when deciding whether to trust a server's certificate.
> The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

Key usage

Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:

`digitalSignature`

Indicates that the certificate can be used for digitally signing data, excluding certificates and certificate revocation lists (CRL).

`nonRepudiation`

Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.

`keyEncipherment`

Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.

`dataEncipherment`

Indicates that the certificate can be used for encrypting data directly.

`keyAgreement`

Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.

`keyCertSign`

Indicates that the certificate can act as a certification authority and be used for signing other certificates.

`cRLSign`

Indicates that the certificate can be used to sign CRLs.

`encipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.

`decipherOnly`

When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.

Extended key usage

Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:

`serverAuth`

Indicates that the server can present the certificate to the client during TLS negotiation.

`clientAuth`

Indicates that the client can present the certificate to the server during TLS negotiation.

`codeSigning`

Indicates that the certificate can be used to sign source and compiled code.

`emailProtection`

Indicates that the certificate can be used to sign or encrypt email messages.

`timeStamping`

Indicates that the certificate can be used to assert the time that an event occurred.

`ocspSigning`

Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.

Basic constraints

Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can follow it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certificate authority (CA) certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and then the root CA.

Intermediate certificate authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

> **Note**
>
> If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising any of the certificates. A compromised certificate must be revoked along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

> **Note**
>
> The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not always need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates. The server can leave that root CA off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. When a client receives an incomplete chain, the client looks in its default trust store to determine whether the trust store contains the issuer certificate, which it can identify by using properties like the issuer distinguished name (DN) or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the end-entity certificate. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is referred to as the server certificate. If the certificate appears at the head of a chain that a client presents, it is referred to as a client certificate. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

About representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plain-text format called PEM can be used.

PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in RFC 5958 describes the encoding for private keys. This approach uses a DER encoding with a PEM variant that instead uses the following header and footer, respectively.

```
 -----BEGIN PRIVATE KEY-----
-----END PRIVATE KEY-----
```

RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in RFC 2986 describes the CSR format. This format uses a DER encoding with a PEM variant that uses the following header and footer, respectively.

```
-----BEGIN CERTIFICATE REQUEST-----
-----END CERTIFICATE REQUEST-----
```

Some implementations use the following alternate, nonstandard forms.

```
-----BEGIN NEW CERTIFICATE REQUEST-----
-----END NEW CERTIFICATE REQUEST-----
```

Certificate trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the change, and the malicious application might be capable of stealing data or altering the communication. Consequently, you should avoid `trust all` or `blind trust` options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps.

Processing steps

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

> **Note**
>
> If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

> **Note**
>
> This step is generally performed by ensuring that the root certificate authority (CA) certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

> **Note**
>
> The chain is not trusted under the following conditions:
> - When the `notBefore` value of any certificate in the chain is later than the current time.
> - When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate at the head of the chain is suitable for the server with which the client thinks it is communicating.

> **Note**
>
> The client must verify that the address used to connect to the server matches one of the following values:
> - The `CN` attribute of the certificate's subject.
> - One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and truststores

A keystore is a type of database that holds certificates.

The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format

- File that uses the standard PKCS #12 format
- Collection of files that holds certificates and private keys, typically in PEM or DER format
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11

The server supports file-based keystores by using the JKS and PKCS #12 formats and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

Private key entries

Contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.

Secret key entries

Contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, sometimes called a PIN, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

> **Note**
>
> A truststore is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is pre-populated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore, such as a private corporate certification authority, a separate truststore is required.

Transport Layer Security (TLS)

TLS describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other.

TLS is the successor to SSL, and the two terms are often used interchangeably, even though such usage might not technically be correct.

> **Note**
>
> SSL remains the more widely recognized term. The abbreviation TLS occasionally generates confusion with the StartTLS extended operation, particularly in LDAP.

TLS provides security in the form of the following main components:

Certificate trust

Is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see Certificate Trust.

Cipher selection

Involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:

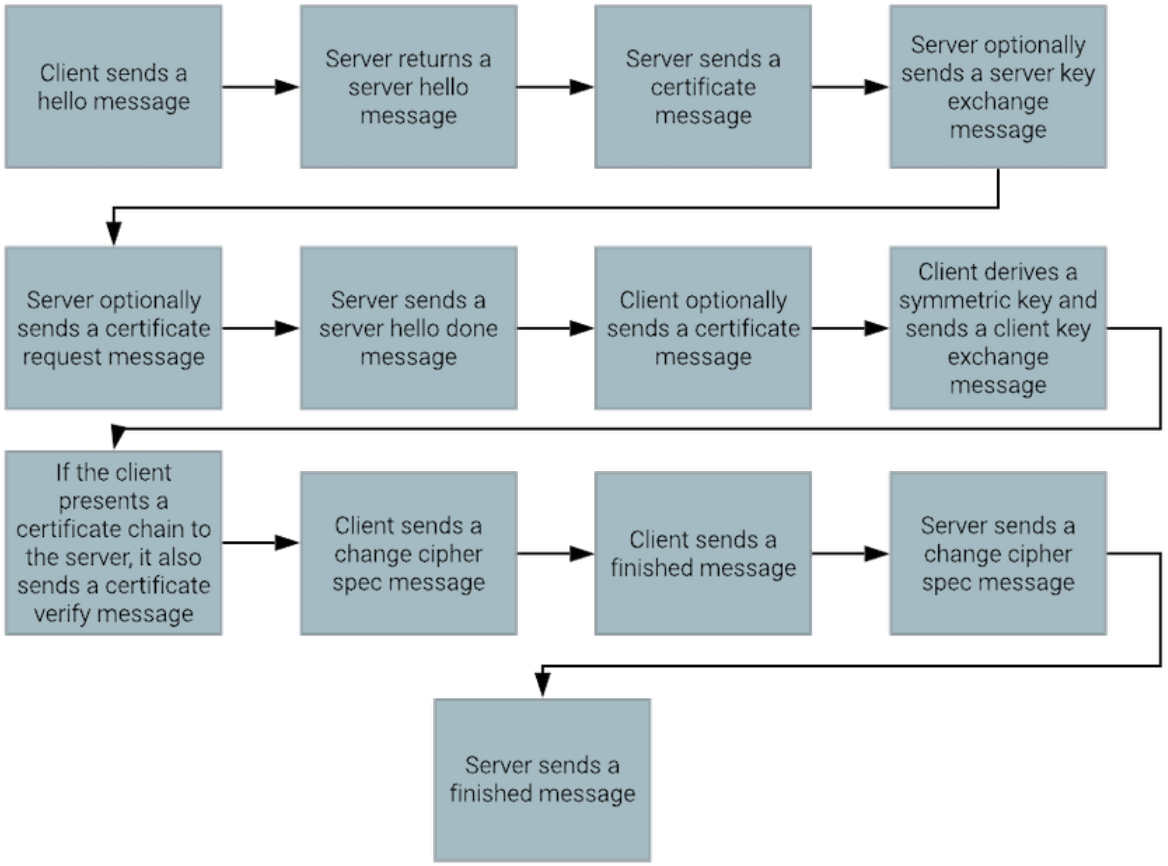
- Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
- Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called asymmetric encryption because different keys are used to encrypt and decrypt data.
- If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than relying solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key to use after completing the negotiation process.

TLS handshakes

The process of negotiating the TLS is referred to as the handshake.

Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLS 1.2 handshake:



TLS processing steps

1. The client sends a `hello` message that provides the server with the following information:
    - Highest supported version of the TLS protocol
    - The cipher suites that the client uses
    - Set of extensions with additional information:
        - The address that the client uses to communicate with the server
        - The signature algorithms and elliptic curves that the client supports
        - Whether the client supports secure renegotiation
2. The server returns a `server hello` message that provides the client with the following information:
    - The TLS protocol version that the server uses
    - The cipher suite that the server selects

    The server can also provide its own extensions to the client.

3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

> **Note**
>
> The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain. The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server. The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.
9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. TLS 1.2 requires two round-trips. To accomplish this task, TLS 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. The server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Key agreement

Key agreement processing provides a critical component of TLS negotiation.

It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

RSA key exchange

The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.

Diffie-Hellman (DH) key exchange

The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, use ECHDE over DHE, and either of those options over RSA. The DH algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. The use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS extended operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS).

The client begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use opportunistic encryption, in which the client performs the following steps:

    1. Queries the root DSE to determine whether the server supports StartTLS.
    2. Secures the connection, if possible.

    Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To ensure that a communication is always secure, use LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

> **Note**
>
> Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, the server does not support this strategy.

The manage-certificates tool

The server offers a `manage-certificates` tool that enables interaction with Java KeyStore (JKS) and PKCS #12 key stores.

Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

Available subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

Subcommand	Function
`list-certificates`	Lists the certificates in a keystore.
`import-certificate`	Imports a certificate into a trusted certificate entry or imports a certificate chain and private key into a private key entry.
`export-certificate`	Exports a certificate from a keystore.
`export-private-key`	Exports a private key from a keystore.
`generate-self-signed-certificate`	Generates a self-signed certificate.
`generate-certificate-signing-request`	Generates a certificate-signing request that can be provided to a certification authority.
`sign-certificate-signing-request`	Signs a certificate-signing request with a specified issuer certificate.
`check-certificate-usability`	Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
`trust-server-certificate`	Initiates the TLS-negotiation process with a specified server to obtain its certificate chain so that a truststore can be updated with the necessary information to trust the chain.
`display-certificate-file`	Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.

Subcommand	Function
`display-certificate-signing-request-file`	Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
`change-certificate-alias`	Changes the alias for an entry in a keystore.
`change-keystore-password`	Changes the password for a keystore.
`change-private-key-password`	Changes the password that protects the private key for a specified entry in a keystore.

Common arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of `JKS` or `PKCS12`. If you do not specify the keystore type, a default value of `JKS` is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.
- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plain-text password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

Listing the certificates in a keystore

List the certificates available in a keystore.

Steps

- To list the certificates in a keystore, use the `list-certificates` subcommand.

  This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

Option	Description
`--alias {alias}`	Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
`--display-pem-certificate`	Includes a PEM-encoded representation of each certificate as part of the output.
`--verbose`	Includes details about each certificate.

  Example:

  The following command demonstrates the basic listing of a keystore that contains a single certificate chain.

```
$ bin/manage-certificates list-certificates \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin

Alias:  server-cert (Certificate 1 of 2 in a chain)
Subject DN:  CN=ds1.example.com,O=Example Corp,C=US

Generating self-signed certificates

The process of creating a self-signed certificate is straightforward because a self-signed certificate claims itself as its own issuer.

Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, you should not use them as listener certificates in production environments.

The `manage-certificates` tool offers a `generate-self-signed-certificate` subcommand that can create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available.

Argument	Description
`--subject-dn {subject}`	Subject DN for the certificate to create. This value is required.
`--days-valid {number}`	Number of days that the certificate remains valid. Defaults to `365` if no value is specified.
`--validity-start-time {timestamp}`	Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form `YYYYMMDDhhmmss`, where a value of `20190102030405` indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
`--key-algorithm {name}`	Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically `RSA` or `EC`. Defaults to `RSA` if no value is specified. **Note** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.
`--key-size-bits {number}`	Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified. Typical key sizes are: • RSA key – 2048 or 4096 bits If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used. • Elliptic curve key – 256 or 384 bits
`--signature-algorithm {name}`	Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than `RSA`, then `--signature-algorithm {name}` must also be specified. If the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified. Typical signature algorithms include `SHA256withRSA` for certificates with RSA keys, and `SHA256withECDSA` for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of `SHA256withRSA` is used.

Argument	Description
`--replace-existing-certificate`	Uses the new certificate to replace an existing certificate in the key store (within the same alias), and reuses the key for that certificate.
`--inherit-extensions`	Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided, but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
`--subject-alternative-name-dns {name}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (`*`) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.
`--subject-alternative-name-ip-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.
`--subject-alternative-name-email-address {address}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
`--subject-alternative-name-uri {uri}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
`--subject-alternative-name-oid {oid}`	Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.

Argument	Description
`--basic-constraints-is-ca {value}`	Indicates that the certificate is expected to have a basic constraints extension, with a specified value of `true` or `false`, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates. • For root and intermediate certificate authority (CA) certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of `true`. • For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of `false`. • For a self-signed certificate, specify the `--basic-constraints-is-ca {value}` argument with a value of `false` to indicate that the certificate is not considered a CA certificate.
`--basic-constraints-maximum-path-length {number}`	Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of `true`. A path length constraint value of `0` indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of `1` indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than `1` indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.
`--key-usage {value}`	Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed: • `digital-signature` • `non-repudiation` • `key-encipherment` • `data-encipherment` • `key-agreement` • `key-cert-sign` • `crl-sign` • `encipher-only` • `decipher-only` To include multiple key usages, specify the `--key-usage {value}` argument multiple times.

Argument	Description
`--extended-key-usage {value}`	**Indicates that the certificate is expected to have an extended key usage extension with the specified value. The following values are allowed:** • `server-auth` • `client-auth` • `code-signing` • `email-protection` • `time-stamping` • `ocsp-signing`

Example

For example, the following command can be used to generate a self-signed server certificate.

```
bin/manage-certificates generate-self-signed-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=ds.example.com,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST
                     (0 seconds ago)
Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST
                   (364 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: 4f:41:82:7f:08:e9:d8:05:8c:19:8b:3e:5b:bc:59:98:d3:15:71:3a
SHA-256 Fingerprint:

```

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information that a certification authority requires to issue a certificate.

RFC 2986 defines the request format, also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject distinguished name (DN) for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a key store with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. The following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

`--output-file {path}`

Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.

`--output-format {value}`

Format to use when writing the certificate signing request. This value can be `PEM` or `DER`, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to `PEM` if the `--output-format {value}` argument is not provided.

`--use-existing-key-pair`

Indicates that the CSR uses a key pair that already exists in the key store with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the key store.

The following example command creates a CSR.

```
bin/manage-certificates generate-certificate-signing-request \
     --output-file ds1-cert.csr \
     --output-format PEM \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-dns localhost \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --subject-alternative-name-ip-address 127.0.0.1 \
     --subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ds/build/package/PingDirectory/ds1-cert.csr'.
```

If the contents of the resulting CSR file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the key store.

To print the contents of a certificate signing request file, use the `display-certificate-signing-request-file` subcommand, which supports the following arguments:

`--certificate-signing-request-file {path}`

Path to the file that contains the certificate signing request to display.

`--verbose`

Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command.

```
$ bin/manage-certificates display-certificate-signing-request-file \
                                --certificate-signing-request-file ds1-cert.csr

                                PKCS #10 Certificate Signing Request Version:  v1
                                Subject DN:  CN=ds.example.com,O=Example Corp,C=US
                                Signature Algorithm:  SHA-256 with ECDSA
                                Public Key Algorithm:  EC (secP256r1)
```

The following example demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr \
     --verbose

PKCS #10 Certificate Signing Request Version:  v1

```

Importing signed and trusted certificates

Use the `manage-certificates import-certificate` command to import certificates into a keystore.

This command is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a trust store. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the key store and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to import. The certificate can be in PEM or DER format and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.

`--private-key-file {path}`

Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.

`--no-prompt`

Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the key store that generates the certificate signing request.

```
$ bin/manage-certificates import-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --certificate-file ds1-cert.pem \
     --certificate-file ca-cert.pem

The following certificate chain will be imported into the keystore into alias
'server-cert', preserving the existing private key associated with that alias:

Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US

                     (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                   (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint: 1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:
                     50:dc:a4:34:95:37:be:89:45:86:1f:5d:79:c3:93

Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                     (13 minutes, 32 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                   (7299 days, 23 hours, 46 minutes, 27 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP384r1)
SHA-1 Fingerprint: 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint: 77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:
                     12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.
```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

`--certificate-file {path}`

Path to the file that contains the certificate to view.

`--verbose`

Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

Exporting certificates

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a key store to a file in PEM or DER format.

The `export-certificate` subcommand supports the normal arguments about the key store and certificate alias, in addition to the following arguments:

`--output-file {path}`

Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.

`--output-format {format}`

Format in which exported certificates are written. The value can be `PEM` or `DER`, but the DER format can be used only if the output is written to a file. Defaults to `PEM` if no value is specified.

`--export-certificate-chain`

Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported.

`--separate-file-per-certificate`

Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain.

```
$ bin/manage-certificates export-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert.pem \
     --output-format PEM \
     --export-certificate-chain \
     --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
                     (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
                           (364 days, 20 hours, 33 minutes, 36 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint: 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:
1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
86:1f:5d:79:c3:93

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
                     (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
                   (7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP384r1)
SHA-1 Fingerprint: 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
   77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
   05:b7:b9:0d:02:e0:38:3e
```

The `export-certificate` subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the `export-private-key` subcommand, which supports the following arguments, in addition to the usual key store and alias arguments:

`--output-file {path}`

Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.

`--output-format {format}`

Format in which the exported private key is written. The value can be `PEM` or `DER`, but the DER format is used only if the output is written to a file. Defaults to `PEM` if no value is specified.

The following code provides an example of the `export-private-key` subcommand .

```
$ bin/manage-certificates export-private-key \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert-key.pem \
     --output-format PEM

Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service.

About this task

If you control every client that accesses the servers, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can use the `manage-certificates` tool to create a certificate authority (CA) certificate that you can use to sign certificate-signing requests.

Steps

1. Create a CA certificate.

   A CA certificate is a self-signed certificate that possesses the following extensions:

   - A key usage extension that includes at least the keyCertSign usage
   - A basic constraints extension that identifies the certificate as a CA certificate

   If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of `0`. If you plan to use an intermediate CA certificate, the path length constraint must be `1`. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

   Example:

   The following example creates a new root CA certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --keystore-type JKS \
     --alias root-ca-cert \
     --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
     --days-valid 7300 \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 1 \
     --key-usage key-cert-sign \
     --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
                  (7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint: bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:
   d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
   61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

   When you import a signed certificate, you can import the public portion of the root CA certificate as a standalone certificate into trust stores as well as into part of a certificate chain.

3. Create a new certificate signing request to create an intermediate CA certificate,

   The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, its basic constraints extension must have a path length constraint of `0`, rather than `1`, to indicate that it is used only to sign end-entity certificates and that it cannot create subordinate CA certificates by itself.

   Example:

   The following example command creates a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \
     --keystore /ca/intermediate-ca-keystore \
     --keystore-password-file /ca/intermediate-ca-keystore.pin \
     --keystore-type JKS \
     --alias intermediate-ca-cert \
     --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 0 \
     --key-usage key-cert-sign \
     --key-usage crl-sign \
     --output-file /ca/intermediate-ca-cert.csr \
     --output-format PEM

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.
```

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate with the `sign-certificate-signing-request` subcommand.

   The `sign-certificate-signing-request` subcommand takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

   - The key store that contains the certificate uses the provided key store arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
   - To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
   - To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
   - To specify the format, `PEM` or `DER`, in which the certificate is written to the output file, provide an `--output-format` argument.
   - To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
   - To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

     > **Note**
     >
     > Because the requester generated the key, you cannot specify the key algorithm or the key length.

   - To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

Example:

The following example command signs the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --signing-certificate-alias root-ca-cert \
     --days-valid 7300 \
     --include-requested-extensions \
     --request-input-file /ca/intermediate-ca-cert.csr \
     --certificate-output-file /ca/intermediate-ca-cert.pem \
     --output-format PEM

Read the following certificate signing request:

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with RSA
Public Key Algorithm:  RSA (4096-bit)

Do you really want to sign this request? yes

Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

> **Note**
>
> Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS support during setup

Enable TLS support in the server.

To enable TLS support in the server, you should complete one of the following tasks during the setup procedure:

- Provide a key store that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When using the `setup` tool in interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS?  After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

    1)  Generate self-signed certificate (recommended for testing purposes
        only)
    2)  Use an existing certificate located on a Java Keystore (JKS)
    3)  Use an existing certificate located on a PKCS12 keystore
    4)  Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

    1)  Generate a default JKS truststore
    2)  Use an existing JKS truststore
    3)  Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}
```

When using `setup` in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
`--ldapsPort {port}`	Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
`--httpsPort {port}`	Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based admin console on the specified TCP port.

Argument	Description
`--enableStartTLS`	LDAP connection handler enables support for the StartTLS extended operation.
`--generateSelfSignedCertificate`	`setup` generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--useJavaKeyStore {path}`	Server uses the specified Java KeyStore (JKS) key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS12KeyStore {path}`	Server uses the specified PKCS #12 key store to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS11KeyStore`	Server uses a PKCS #11 key store, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The Java Virtual Machine (JVM) must already be configured to access the appropriate key store through PKCS #11.
`--keyStorePassword {password}`	Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. The `setup` tool assumes that the private key password matches the key store password.
`--keyStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.
`--certNickname {alias}`	Alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the key store contains multiple certificates.
`--useJavaTrustStore {path}`	Server uses the specified JKS trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation.
`--usePKCS12TrustStore {path}`	Server uses the specified PKCS #12 trust store to determine whether to trust certificate chains that are presented to it during TLS negotiation
`--trustStorePassword {password}`	Password that is needed to interact with the specified JKS or PKCS #11 trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 trust store.

The following example command sets up the PingDirectory server in non-interactive mode with an existing certificate.

```
$ ./setup \
     --no-prompt \
     --acceptLicense \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile root-pw.txt \
     --maxHeapSize 10g \
     --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
     --instanceName ds1 \
     --location Austin \
     --noPropertiesFile

Enabling TLS support after setup

If the server has been set up without support for TLS, enable TLS support later by completing the following tasks.

Steps

1. Obtain a certificate chain.

   To prepare a Java KeyStore JKS or PKCS #12 key store with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a trust store that the server can use. Learn more in Certificate chains.

2. Configure the key and trust manager providers.

3. Configure connection handlers.

Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. In most cases, you can update the appropriate key manager provider to reference the key store that you plan to use, as shown in the following example:

```
dsconfig set-key-manager-provider-prop \
    --provider-name JKS \
    --set enabled:true \
    --set key-store-file:config/keystore \
    --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store, as shown in the following example:

```
dsconfig set-trust-manager-provider-prop \
    --provider-name JKS \
    --set enabled:true \
    --set include-jvm-default-issuers:true \
    --set trust-store-file:config/truststore \
    --set trust-store-pin-file:config/truststore.pin
```

Note

If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Caching key and trust managers

When you create key and trust manager providers, caching is enabled by default, allowing the manager providers to avoid loading key store and trust store files from disk when establishing connections to process requests.

Invalidating the cache

The manager provider reloads files from the configured key store or trust store and refreshes the cache under any of the following conditions:

- The cached manager for the configured store has a `null` value.
- The path to the cached store doesn't match the path of the configured store.
- The length of the cached store doesn't match the length of the configured store.
- The last-updated time for the cached store doesn't match the last-updated time for the configured store.

Enabling or disabling caching (optional)

You can define whether caching is enabled by using the `enable-key-manager-caching` or `enable-trust-manager-caching` properties. Supply a value of `false` to disable caching, causing manager providers to load managers for each connection. Supply a value of `true` to re-enable caching.

To create a key manager provider with caching disabled, supply the `enable-key-manager-caching` property with a value of `false`, as shown in the following example:

```
dsconfig create-key-manager-provider \
    --provider-name JKS \
    --type file-based \
    --set enabled:true \
    --set key-store-file:config/keystore \
    --set key-store-type:JKS \
    --set key-store-pin-file:config/keystore.pin \
    --set enable-key-manager-caching:false
```

To create a trust manager provider with caching disabled, supply the `enable-trust-manager-caching` property with a value of `false`, as shown in the following example:

```
dsconfig create-trust-manager-provider \
    --provider-name JKS \
    --type file-based \
    --set enabled:true \
    --set trust-store-file:config/truststore \
    --set trust-store-type:JKS \
    --set enable-trust-manager-caching:false
```

To re-enable caching, set a value of `true` for the same caching property used to create the manager provider, as shown in the following example:

```
dsconfig set-trust-manager-provider-prop \
    --provider-name JKS \
    --set enable-trust-manager-caching:true
```

Configuring connection handlers

After you configure the key and trust manager providers, update the connection handlers to use the key and trust manager providers.

Steps

- For the LDAP connection handler, use the following command to enable StartTLS with a configuration change. By default, the LDAP connection handler accepts non-secure connections.

  Example:

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAP Connection Handler" \
    --set allow-start-tls:true \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert \
    --set ssl-client-auth-policy:optional
  ```

- If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. You must set `allow-start-tls` to `false` and `use-ssl` to `true`. See the following code for an example configuration.

  Example:

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "LDAPS Connection Handler" \
    --set enabled:true \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert \
    --set ssl-client-auth-policy:optional
  ```

  Example:

  The following example uses a similar configuration change to enable the HTTPS connection handler.

  ```
  dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:true \
    --set listen-port:443 \
    --set key-manager-provider:JKS \
    --set trust-manager-provider:JKS \
    --set ssl-cert-nickname:server-cert
  ```

Updating the topology registry

After the server connection handlers are updated to enable TLS, update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication, such as replication, mirroring portions of the configuration, and the PingDirectory server's automatic backend server-discovery functionality.

The following table details the two types of entries that require updating:

Configuration types and their update descriptions

Configuration Type	Update description

Server instance listener configuration	• Provides information that is needed to trust the TLS certificates that instances in the topology present.
	• The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use `dsconfig` to import the certificate from a file, as shown in the following example.
	`bin/dsconfig set-server-instance-listener-prop \`
	`--instance-name ds1 \`
	`--listener-name ldap-listener-mirrored-config \`
	`--set server-ldap-port:636 \`
	`--set connection-security:ssl \`
	`--set 'listener-certificate>/ca/ds1-cert.pem'`
	Note
	The less-than operator `>` in the final line indicates that the value is read from a file rather than provided directly. In addition, you might not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Server instance configuration	• Provides information about options for communicating with those instances.
	• Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance.
	The following example code sets the LDAPS and HTTPS ports, indicates that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance.
	`dsconfig set-server-instance-prop \`
	`--instance-name ds1 \`
	`--set ldaps-port:636 \`
	`--set https-port:443 \`
	`--set preferred-security:ssl \`
	`--set start-tls-enabled:true`

Troubleshooting TLS-related issues

Use this section for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as the PingDirectory server.

- Log messages
- manage-certificates check-certificate-usability
- ldapsearch
- Using low-level TLS debugging

Log messages

The following describes how to use the server's log messages to troubleshoot TLS-related issues.

To troubleshoot TLS-related issues, start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

The `CONNECT` message does not appear

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit can be a network problem, a firewall that is blocking attempts to communicate, or the client is trying to use an incorrect address or port.

The `CONNECT` message does appear

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages.

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are using LDAPS

If you are attempting to use LDAPS, one of the following log messages appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – The issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

> **Note**
>
> The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand to examine a specified entry in a key store and to identify potential issues that might interfere with secure communication.

The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the key store includes a private key and a complete certificate chain
- Checks whether the certificate at the root of the chain is found in the Java virtual machine's (JVM's) default set of trusted certificates
- Ensures that the current time lies is within the validity window for all certificates in the chain
- Validates the signatures for all certificates in the chain
- Warns if the end-entity certificate is self-signed
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage
- Warns if the issuer certificates do not have a key usage extension with the `keyCertSign` usage
- Warns if the issuer certificates do not have a basic constraints extension indicating that it can operate as a certification authority

  If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256

  The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.
- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23
hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' at the head of
the chain includes an extended key usage extension, and that extension
includes the serverAuth usage.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a basic constraints extension, and the certificate chain
satisfies those constraints.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a key usage extension with the keyCertSign usage flag set to
true.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a basic constraints extension, and the certificate chain satisfies those
constraints.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a key usage extension with the keyCertSign usage flag set to true.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a
signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a 2048-bit
RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
4096-bit RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit
RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the
certificate chain.
```

If any usability issues are identified, they might be responsible for communication problems.

ldapsearch

The `ldapsearch` command-line utility is a powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following table details arguments that are the most useful for TLS-related communication.

TLS-related communication arguments and their descriptions

Argument	Description
`--hostname {address}`	Address of the server to which the connection is established
`--port {port}`	TCP port of the server to which the connection is established. The standard port for non-secure LDAP, or LDAP to be secured with StartTLS, is `389`, and the standard port for secure LDAPS is `636`. Many deployments use alternate ports, especially non-privileged ports above `1024`.
`--useSSL`	The tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
`--trustStorePath {path}`	Path to the trust store that is used when determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the `--trustAll` argument is provided, the tool prompts you interactively whether to trust server certificates that are not signed by an issuer in the Java virtual machine's (JVM's) default trust store.
`--trustStoreFormat {format}`	Format for the trust store, which is typically `JKS` or `PKCS12`.
`--trustStorePassword {password}`	Password that is required to access the contents of the trust store.
`--trustStorePasswordFile {path}`	Path to the file that contains the password that is required to access the contents of the trust store.
`--trustAll`	The tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, it is not recommended for general use.

Argument	Description
`--keyStorePath {path}`	**Path to the key store to use if a client certificate chain is presented to the server.** **Note** Use this argument only when one of the following conditions is satisfied: • The server is configured to require clients to present a certificate. • You intend to use the certificate to authenticate through SASL EXTERNAL.
`--keyStoreFormat {format}`	**Format for the key store, which is typically `JKS` or `PKCS12`.**
`--keyStorePassword {password}`	**Password to access the key store.**
`--keyStorePasswordFile {path}`	**Path to the file that contains the password necessary to access the key store.**
`--certNickname {alias}`	**Alias of the private key entry in the key store. Use when obtaining the certificate chain to present to the server.**
`--useSASLExternal`	**The client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.**
`--enableSSLDebugging`	**The tool activates the low-level TLS-debugging feature that the JVM provides.**

The following command provides an example of the simplest method for testing TLS communication with the PingDirectory server.

Example

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
The server presented the following certificate chain:

     Subject: CN=ds1.example.com,O=Example Corp,C=US
     Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
     Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
     SHA-1 Fingerprint:
        6a:22:2a:bd:0b:1b:09:35:63:bc:12:3e:2c:9e:e7:70:bc:a4:73:de
     256-bit SHA-2 Fingerprint:
        7a:8c:e4:76:d4:47:15:fd:65:f5:26:0e:d2:55:77:d7:03:7a:e6:79:9f:bc:

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Trust stores and trust-related arguments

If no trust-related arguments are provided, the tool uses the JVM's default trust store to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default trust store, `ldapsearch` prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a trust store instead of being prompted interactively, use the `--trustStorePath` argument that points to the appropriate trust store. If you are using a Java Keystore (JKS) trust store, you might not need to provide the trust store password. If you are using a PKCS #12 trust store, you need to provide the trust store password. The following code provides an example.

Example

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Client certificate chains and key stores

To present a client certificate chain to the server, either because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required` or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism, provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client key store contains multiple certificates. The following code provides an example.

Example

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --keyStorePath client-keystore \
     --keyStorePasswordFile client-keystore.pin \
     --certNickname client-cert \
     --useSASLExternal \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

If you need to further troubleshoot a TLS-related issue

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see Using low-level TLS debugging.

Using low-level TLS debugging

Use tools other than the command-line tools that are provided with the PingDirectory server for performing low-level TLS debugging.

Before you begin

> **Note**
>
> If you need to use low-level debugging options, enable the Java Virtual Machine (JVM)'s support for TLS debugging. Many of the command-line tools that are provided with the PingDirectory server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process.

Steps

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool.

   ```
   -Djavax.net.debug=all
   ```

2. For the changes to take effect, run the `bin/dsjavaproperties` command.

Next steps

The next time the tool is run, an output is generated detailing the TLS-related processing that the JVM is performing. You and the Ping Identity support team can use the output to identify the issue.

Enabling low-level debugging

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

> **Note**
>
> Because this approach requires multiple server restarts, it is not a popular option. You might be able to obtain more information without a restart by using the debugging support that is built into the server. For more information and to enable this level of support, see Using the debug log publisher.

To enable low-level debugging:

Steps

1. In the `config/java.properties` file, add `-Djavax.net.debug=all` to the `start-server.java-args` property.

2. Run `bin/dsjavaproperties`.
3. Restart the server.

Using the debug log publisher

To obtain more information for troubleshooting without a restart, use the server's built-in debugging support.

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

To use the debug log publisher:

Steps

1. To enable the debug log publisher and set the debug target, run the following configuration changes:
    1. Run `dsconfig` with the `create-debug-target` option.

        Example:

        ```
        dsconfig create-debug-target \
             --publisher-name "File-Based Debug Logger" \
             --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
             --set debug-level:verbose
        ```

    2. Run `dsconfig` with the `set-log-publisher-prop` option.

        Example:

        ```
        dsconfig set-log-publisher-prop \
             --publisher-name "File-Based Debug Logger" \
             --set enabled:true
        ```

        Result:

        The `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. Although this file doesn't provide as much detail as the Java virtual machine's (JVM) built-in debugging information, it might help to pinpoint the cause of the problem and to identify potential solutions.

2. To disable the debug log publisher and remove the debug target, run the following configuration changes:
    1. Run `dsconfig` with the `set-log-publisher-prop` option.

        Example:

        ```
        dsconfig set-log-publisher-prop \
             --publisher-name "File-Based Debug Logger" \
             --set enabled:false
        ```

2. Run `dsconfig` with the `delete-debug-target` option.

Example:

```
dsconfig delete-debug-target \
     --publisher-name "File-Based Debug Logger" \
     --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
```

Tip

To troubleshoot TLS communication with a non-Java client that does not offer its own TLS debugging mechanism, and if the server-side debugging support is insufficient, use a network protocol analyzer to capture the communication between the client and the server and to examine its content. The free, open-source Wireshark utility is a graphical tool that runs on a variety of platforms and provides support for understanding TLS communication. Even if you can't decipher the encrypted content, you can view at least some of the handshake messages.

Note

More of the handshake is encrypted in TLS 1.3 than in earlier versions of the protocol. Although this change improves security and privacy, it might interfere with troubleshooting attempts.

Managing SCIM 1.1 and 2.0 servlet extensions

The PingDirectory and PingDirectoryProxy servers provide two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications securely and quickly. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

SCIM 1.1 servlet extension configuration

This SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

Understanding the basic concepts of SCIM can help you use the SCIM 1.1 extension to meet your deployment needs. SCIM allows you to:

- Provision identities. Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- Provision groups. SCIM also allows you to manage groups.
- Interoperate using a common schema. SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

> **Important**
>
> Support for SCIM 1.1 has been deprecated and will be removed in a future release.

The server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes
User resources	Yes

SCIM Feature	Supported
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes
Query result sorting*	Yes
Query result pagination*	Yes (Directory server, not Directory Proxy server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

* denotes an optional feature of the SCIM protocol.

** denotes a server extension to the basic SCIM functionality.

The Identity Access API

The PingDirectory server, PingDirectoryProxy server, and PingDataSync server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access PingDirectory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (for example, 'Users' and 'Groups'), only LDAP object classes (for example, `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there can be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (for example, `top --> person --> organizationalPerson --> inetOrgPerson`, and so forth), a client application can access an entry in multiple ways because of the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the server.

Before you begin

To set up your system for Cross-domain Identity Management (SCIM) servlet extension, the server provides a `dsconfig` batch file at `<server-root>/config/scim-config-ds.dsconfig` for PingDirectory and at `<server-root>/config/scim-config-proxy.dsconfig` for PingDirectoryProxy.

The script runs a series of commands that:

- Enable the HTTP Connection Handler and SCIM HTTP Servlet Extension.
- Increase the level of detail logged by the HTTP Detailed Access Log Publisher.
- Add access controls to allow access to LDAP controls used by the SCIM servlet.
- Add support to the request processor for LDAP controls used by the SCIM servlet.
- Set the subordinate base distinguished name (DN) property of the root DSE so that SCIM requests can be authenticated using LDAP `uid` values.

> **Note**
>
> Edit the **`dsconfig`** batch file before running the details of your deployment.

Creating your own SCIM 1.1 application

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes, and is available for download. It provides developers with a simple, concrete API to interact with a SCIM service provider.

> **Note**
>
> The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the **`scim-resource.xml`** configuration file, but not if the SCIM attribute is a core SCIM attribute.

Configuring SCIM 1.1

This section discusses details about the PingDirectory server and PingDirectoryProxy server implementations of the SCIM protocol.

Before reading these topics, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

Configuring SCIM 1.1 for PingDirectory

The PingDirectory server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (for example, changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

Configuring SCIM manually

About this task

The following example procedure assumes that you have configured the PingDirectory server using the default settings, which means that SSL and the HTTPS Connection Handler have not been configured. The example also shows the `dsconfig` non-interactive commands. You can easily use the `dsconfig` interactive commands, which uses a menu-driven interface. If you use the `dsconfig` interactive, you must change to the Standard or Advanced object menu to access many of these configuration settings.

Steps

1. Set up your certificates. Follow the examples shown in Managing certificates. You should have a keystore and truststore set up in the `config` directory. Make sure that the keystore.pin and truststore.pin are set.
2. Enable the key manager provider. The key manager provider accesses the certificate during the SSL handshaking process. If running `dsconfig` interactive, open the main menu, select "Key Manager Provider" → "View and edit an existing Key Manager Provider" → "JKS" (or the type of certificate you are working with) → "enabled" and then set the value to "true". Click "finish" to save the setting.

   Example:

   ```
   $ bin/dsconfig create-key-manager-provider \
     --provider-name JKS \
     --type file-based --set enabled:true
     --set key-store-file:config/keystore \
     --set key-store-type:JKS
     --set key-store-pin-file:config/keystore.pin
   ```

3. Enable the trust manager provider. The trust manager provider determines if a presented certificate can be trusted. If running `dsconfig` interactive, open the main menu, select "Trust Manager Provider" → "View and edit an existing Trust Manager Provider" → "JKS" (or the type of certificate you are working with) → "enabled" and then set the value to "true". Click "finish" to save the setting.

   Example:

```
$ bin/dsconfig create-trust-manager-provider
  --provider-name JKS \
  --type file-based --set enabled:true \
  --set trust-store-file:config/truststore \
  --set trust-store-type:JKS \
  --set trust-store-pin-file:config/truststore.pin
```

4. Configure the HTTPS Connection Handler. If not already created, this command creates and enables the connection handler, specifies the SCIM HTTP servlet extension and sets the listen port to a port of your choice, in this example, use 8443. The command also specifies the type of key manager and trust manager providers and sets the log publisher to "HTTP Detailed Access." If running `dsconfig` interactive, open the main menu, select "Connection Handler" → "View and edit an existing Connection Handler" → "HTTPS Connection Handler". Change the parameters to match your setup, and then, click "finish" to save the setting.

   Example:

   ```
   $ bin/dsconfig create-connection-handler \
     --handler-name "HTTPS Connection Handler" \
     --type http --set enabled:true \
     --set listen-port:8443 \
     --set use-ssl:true \
     --set http-servlet-extension:SCIM \
     --set "http-operation-log-publisher:HTTP Detailed Access" \
     --set key-manager-provider:JKS --set trust-manager-provider:JKS
   ```

   If the HTTPS Connection Handler already exists, use the following:

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --add http-servlet-extension:SCIM
   ```

5. Turn on the connection handler.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --add http-servlet-extension:SCIM
   ```

6. Add access controls to allow access to LDAP controls used by the SCIM Servlet Extension. These controls are the Post-Read Request Control (1.3.6.1.1.13.2), Server-Side Sort Request Control (1.2.840.113556.1.4.473), Simple Paged Results Control (1.2.840.113556.1.4.319), and Virtual List View Request Control (2.16.840.1.113730.3.4.9). We recommend using the following command to add access control instructions, rather than its `dsconfig` interactive equivalent.

   Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 || 1.2.840.113556.1.4.473 || 1.2.840.113556.1.4.319 ||
2.16.840.1.113730.3.4.9")
    (version 3.0;acl "Authenticated access to controls used by the SCIM servlet
     extension"; allow (all) userdn="ldap:///all";)'
```

7. Add access controls to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its `dsconfig` interactive equivalent.

   Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id ||
    createTimestamp || modifyTimestamp")
    (version 3.0;acl "Authenticated read access to operational attributes \
    used by the SCIM servlet extension"; allow (read,search,compare)
    userdn="ldap:///all";)'
```

8. (Optional) The SCIM HTTP Connection Handler automatically uses a detailed HTTP log publisher, which is implemented in a proprietary format. If you need a standard W3C common log format publisher, enter the following command. If running `dsconfig` interactive, open the main menu, select "Log Publisher" → "Create a new Log Publisher" → "new Log Publisher created from scratch" → "File Based Access Log Publisher", enter the parameters to match your setup, and then, click "finish" to save the setting. Go back to the main menu, select "Connection Handler" → "HTTPS Connection Handler", and then add "HTTP Common Access" to the `http-operation-log-publisher` property. Click "finish" to save the setting.

   Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access" \
  --type common-log-file-http-operation --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add "http-operation-log-publisher:HTTP Common Access"
```

9. (Optional) To support searching or filtering by DN using the Identity Access API, you can enable the entryDN virtual attribute. If running `dsconfig` interactive, open the main menu, select "Virtual Attribute" → "View and edit an existing Virtual Attribute" → "Entry DN", and then change the enabled property to "true". Click "finish" to save the setting.

   Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name entryDN --set enabled:true
```

10. (Optional) To support pagination, create some Virtual List View indexes. If running `dsconfig` interactive, open the main menu, select "Local DB VLV Index" → "Create a new Local DB VLV Index" and then enter the properties needed for your setup. Click "finish" to save the setting. Repeat again for the "ascending-sn" index. Then, run the `rebuild-index` command to let the VLV Indexes take effect.

    Example:

    ```
    $ bin/dsconfig create-local-db-vlv-index --backend-name userRoot \
      --index-name ascending-uid --set base-dn:dc=example,dc=com \
      --set scope:whole-subtree \
      --set "filter:(objectclass=inetorgperson)" \
      --set "sort-order:+uid"

    $ bin/dsconfig create-local-db-vlv-index --backend-name userRoot \
      --index-name ascending-sn \
      --set base-dn:dc=example,dc=com \
      --set scope:whole-subtree \
      --set "filter:(objectclass=inetorgperson)" \
      --set "sort-order:+sn"

    $ bin/rebuild-index --baseDN dc=example,dc=com \
      --index vlv.ascending-uid \
      --index vlv.ascending-sn
    ```

Enabling resource versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

Steps

1. Enable the `ds-entry-checksum` virtual attribute.

    Example:

    ```
    $ bin/dsconfig set-virtual-attribute-prop \
        --name ds-entry-checksum \
        --set enabled:true
    ```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

    Example:

    ```
    $ bin/dsconfig set-access-control-handler-prop \
        --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-
    create-time || modifyTimestamp || ds-update-time")(version 3.0;acl "Authenticated read access to operational
    attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
    ```

3. Add new access controls required by SCIM for read access to operational attributes with the addition of the `ds-entry-checksum`:

    Example:

```
$ bin/dsconfig set-access-control-handler-prop \
    --add  'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-
create-time || modifyTimestamp || ds-update-time || ds-entry-checksum")(version 3.0;acl "Authenticated read
access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare)
userdn="ldap:///all"'
```

4. Enable SCIM resource versioning using the entry checksum virtual attribute:

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
       --extension-name SCIM \
       --set entity-tag-ldap-attribute:ds-entry-checksum
   ```

   Result:

   If enabled, the value of the `ds-entry-checksum` attribute is returned as the `ETag` header value when accessing the resource through SCIM, and is checked against the `If-Match` header when updating the resource. When accessing the resource through LDAP, use the `ds-entry-checksum` attribute instead.

Configuring the SCIM servlet extension using the batch script

About this task

The following example procedure assumes that you have set up your certificates, keystore, and truststore.

Steps

1. Open the `<server-root>/config/scim-config-ds.dsconfig` script in a text editor.
2. For the optional elements (W3C common log, filtering by DN, and VLV Indexes, remove the comment (#) symbol on the `dsconfig` commands. Save the file when finished editing.
3. To enable the SCIM servlet extension, run the `dsconfig` batch file. Remember to include the bind parameters.

   Example:

   ```
   $ bin/dsconfig --batch-file config/scim-config-ds.dsconfig
   ```

Configuring SCIM 1.1 for PingDirectoryProxy

Steps

1. To allow read access to operational attributes used by the SCIM Servlet Extension, add access controls on each of the backend servers before you enable the System for Cross-domain Identity Management (SCIM) servlet extension.

   Example:

   Instead of the `dsconfig` interactive equivalent, the following example uses the non-interactive command to add access control instructions (ACIs) .

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id ||
    createTimestamp || modifyTimestamp")
    (version 3.0;acl "Authenticated read access to operational attributes \
    used by the SCIM servlet extension"; allow (read,search,compare)
    userdn="ldap:///all";)'
```

2. To enable the SCIM servlet extension, run the `dsconfig` batch file on the server.

   Example:

   ```
   $ bin/dsconfig --batch-file config/scim-config-proxy.dsconfig
   ```

3. Edit the `dsconfig` batch file to use the correct request processor name and base distingushed names (DNs) for the `set-request-processor-prop` and `set-root-dse-backend-prop` commands.

   Learn more in Configuring LDAP control support on all request processors and SCIM 1.1 servlet extension authentication.

Enabling resource versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

Steps

1. Enable the `ds-entry-checksum` virtual attribute.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop \
   --name ds-entry-checksum \
   --set enabled:true
   ```

2. Remove any existing access controls required by SCIM for read access to operational attributes.

   Example:

   ```
   $ bin/dsconfig set-access-control-handler-prop \
   --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-
   time || modifyTimestamp || ds-update-time")
   (version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension";
   allow (read,search,compare) userdn="ldap:///all"'
   ```

3. On the backend directory server, enable new access controls required by SCIM for read access to operational attributes with the following command.

> **Note**
>
> If this access control instruction (ACI) is not present, problems will occur when a SCIM client tries to authenticate with a non-root distinguished name (DN).

```
$ bin/dsconfig set-access-control-handler-prop \
--add  'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-
time || modifyTimestamp || ds-update-time || ds-entry-checksum")
(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension";
allow (read,search,compare) userdn="ldap:///all"'
```

Configuring LDAP control support on all request processors

You must configure support for the required LDAP controls on all request processors handling LDAP requests that result from SCIM requests.

About this task

Change the request processor name that was provided as an example and repeat the command for all additional request processors.

Steps

- Use `dsconfig` to change the request processor name (provided as an example) and repeat the command for all additional request processors.

  Use your deployment's request processor name.

  Example:

  ```
  $ bin/dsconfig set-request-processor-prop \
    --processor-name dc_example_dc_com-req-processor \
    --add supported-control-oid:1.2.840.113556.1.4.319 \
    --add supported-control-oid:1.2.840.113556.1.4.473 \
    --add supported-control-oid:2.16.840.1.113730.3.4.9
  ```

SCIM 1.1 servlet extension authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the PingDirectory server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, the Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

Enabling HTTPS communications

To make the System for Cross-domain Identity Management (SCIM) HTTP connection handler use SSL (which is mandated by the SCIM specification), enable a Key Manager provider and Trust Manager provider.

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

Steps

- To enable SSL during the server's initial setup, include the `--ldapsPort` and the `--generateSelfSignedCertificate` subcommands with the `setup` command.
- If your server already has a certificate that you would like to use:

  Choose from:

  - Set the `key-manager-provider` to the value you set when you enabled SSL in the server..
  - Define a new key manager provider.

> **Tip**
>
> Learn more in Configuring HTTP connection handlers.

Configuring basic authentication using an identity mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of cn.

   Example:

   ```
   $ bin/dsconfig create-identity-mapper \
     --mapper-name "CN Identity Mapper" \
     --type exact-match \
     --set enabled:true \
     --set match-attribute:cn
   ```

2. Configure the SCIM servlet to use the new Identity Mapper.

   Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set "identity-mapper:CN Identity Mapper"
```

Enabling OAuth authentication

About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

Steps

1. Install your OAuth token handler on the server using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig create-oauth-token-handler \
     --handler-name ExampleOAuthTokenHandler \
     --type third-party \
     --set extension-class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
   ```

2. Configure the SCIM servlet extension to use it as follows:

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM \
     --set oauth-token-handler:ExampleOAuthTokenHandler
   ```

Using HTTP basic authentication with bare UID on the PingDirectoryProxy server

Clients can authenticate to the System for Cross-domain Identity Management (SCIM) extension using HTTP basic authentication and a bare UID value.

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

When a SCIM extension is hosted by a PingDirectoryProxy server, you must explicitly configure the server with the names of subordinate base distinguished names (DNs) to search.

> **Note**
>
> Make sure to specify your deployment's subordinate base DN.

Steps

- To configure the server with the names of subordinate base DNs, run the following command on the PingDirectoryProxy server for every base DN that you can access using SCIM.

```
$ bin/dsconfig set-root-dse-backend-prop \
  --set subordinate-base-dn:dc=example,dc=com
```

Verifying the SCIM 1.1 servlet extension configuration

About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To verify the SCIM servlet extension configuration:

Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off curl's verification of the server certificate, since the example PingDirectory server is using a self-signed certificate.

  Example:

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
not considered to be a secure method of user authentication (unless used in
conjunction with some external secure system such as SSL), as the user
name and password are passed over the network as cleartext.","specUrl":
"http://www.ietf.org/rfc/rfc2617","documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the PingDirectory server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

  Example:

```
$ curl -u "user.0:password" \
  -k "https://localhost:8443/scim/ServiceProviderConfigs"
```

Configuring the Identity Access API

After you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API.

To allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- include-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value "*" to allow all object classes. If "*" is used, then the SCIM servlet uses the same case used in the server LDAP Schema.
- exclude-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- include-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will be exposed. If specified, only entries under these base DNs will be accessible. No parent-child relationships in the DNs are allowed here.
- exclude-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will not be exposed. If specified, entries under these base DNs will not be accessible. No parent-child relationships in the DNs are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

Configuring the Identity Access API

Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM --set 'include-ldap-objectclass:*' \
     --set include-ldap-base-dn:ou=People,dc=example,dc=com
   ```

   Result:

   The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

Disabling core SCIM resources

Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.

2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

> **Note**
>
> When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using **`dsconfig`**, the changes take effect immediately without any restart required.

Verifying the Identity Access API configuration

Steps

- Perform a curl request to verify the Identity Access API configuration.

Result:

```
$ curl -k -u "cn=directory manager:password" \
  -H "Accept: application/json" \
  "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
     attributes=entryDN,uid,givenName,sn,entryUUID"
     {"schemas":["urn:scim:schemas:core:1.0","urn:unboundid:schemas:scim:ldap:1.0"],
      "id":"56c9fd6b-f870-35ef-9959-691c783b7318",
      "meta":{"lastModified":"2013-01-11T23:38:26.489Z",
      "location":"https://example.com:443/v1/top/56c9fd6b-f870-35ef-9959-691c783b7318"},
      "urn:unboundid:schemas:scim:ldap:1.0":{"givenName":["Rufus"],"uid":["user.1"],
      "sn":["Firefly"],"entryUUID":["56c9fd6b-f870-35ef-9959-691c783b7318"],
      "entrydn":"uid=user.1,ou=people,dc=example,dc=com"}}
```

Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension.

The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll\
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

About the HTTP log publishers

HTTP operations can be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.
- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "'['dd/MM/yyyy:HH:mm:ss Z']'"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, see the `dsconfig` command-line tool help.

Monitoring resources using the SCIM extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
  --bindPassword password --baseDN cn=monitor \
  --searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called host.

```
$ bin/ldapsearch --baseDN cn=monitor \
  '(objectClass=scim-servlet-monitor-entry)'

Configuring advanced SCIM 1.1 extension features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

Learn more about schema mapping in Mapping the LDAP schema to the SCIM resource schema.

About the SCIM schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances can be present for each resource. Attributes can be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

Validating the updated SCIM schema

The Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute can result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource can also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID can be stored in the server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin can be used by the server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see Working with the Unique Attribute plugin.

> **Note**
>
> Resource IDs cannot be mapped to virtual attributes. Learn more about configuring SCIM resource IDs in About the `resourceIDMapping` element.

Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations can be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.

- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM dateTime data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the $ character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, the Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
    <groupId>com.unboundid.product.scim</groupId>
    <artifactId>scim-ldap</artifactId>
    <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory. NOTE: The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the PingDirectory server and the PingDirectoryProxy server using the OAuthTokenHandler API (meaning through a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

SCIM logging

The PingDirectory server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use "`origin=scim`" in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- HTTPConnectionHandlerStatisticsMonitorProvider — Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- SCIMServletMonitorProvider — Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, "`user-patch-404:26`".

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

SCIM 2.0 servlet extension configuration

The PingDirectoryProxy server provides a servlet extension that implements version 2 of the System for Cross-domain Identity Management (SCIM) specification.

The SCIM 2.0 extension doesn't replace the existing SCIM 1.1 extension, and there are significant differences in how they're configured.

> **Note**
>
> Configure your SCIM configurations, such as attribute mappings, on the PingDirectoryProxy server instead of on the backend PingDirectory servers.
> There is a known issue with dot notation support for SCIM 2.0 sub-attributes.

The PingDirectoryProxy server supports the following System for Cross-domain Identity Management (SCIM) 2.0 endpoints.

Endpoint	Description	Supported HTTP methods
`/ServiceProviderConfig`	Provides metadata that indicates the server's authentication scheme (OAuth 2.0) and its support for features that are optional in the SCIM standard. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET

Endpoint	Description	Supported HTTP methods
`/Schemas`	Lists the SCIM schemas that are configured for use on the server, and defines the various attributes available to resource types. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/Schemas/<schema>`	Retrieves a specific SCIM schema, as specified by the schema ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/ResourceTypes`	Lists all of the SCIM resource types that are configured for use on the server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/ResourceTypes/<resourceType>`	Retrieves a specific SCIM resource type, as specified by its ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/<resourceType>`	Creates a new resource (POST), or lists and filters resources (GET).	• GET • POST
`/<resourceType>/.search`	Lists and filters resources. This is used as an alternative to passing query parameters in the URL.	POST
`/<resourceType>/<resourceId>`	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	• GET • PUT • PATCH • DELETE

Creating your own SCIM 2.0 application

To create your own System for Cross-domain Identity Management (SCIM) 2.0 application, you must download the SCIM 2 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at GitHub.

Authentication requirements for SCIM 2.0 requests

All System for Cross-domain Identity Management (SCIM) requests on the server must use OAuth 2.0 bearer token authentication.

Bearer tokens are evaluated using the SCIM 2 servlet extension's configured access token validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server does not process any SCIM requests unless it has at least one `encryption-settings` definition in its `encryption-settings` database. You can create the necessary definitions with the `encryption-settings` command-line tool.

For more information, see Encrypting sensitive data.

> **Note**
>
> You must define encryption settings and ensure they match on the proxy and all backend PingDirectory servers.

Defining permissions for SCIM 2.0 requests

Successfully executing a System for Cross-domain Identity Management (SCIM) request on a server depends on both the configured access control instruction (ACI) in the server and the scopes present in the OAuth bearer token used to authenticate the request.

> **Note**
>
> You must define ACIs on the backend PingDirectory servers. Don't define ACIs on the PingDirectoryProxy server.

The server can authorize SCIM 2.0 requests in one of the following ways:

- Internally, the server processes all SCIM 2.0 requests using the `cn=SCIM2 Servlet,cn=Root DNs,cn=config` service account. Allowing a requested operation depends on the relevant ACIs, which can include both the rights granted to that service account and any rights granted to scopes contained in the OAuth bearer token. The `oauthscope` bind rule is useful because it allows the administrator to use the supplied `0Auth` scopes in ACI logic.
- If user mapping is enabled, the subject of the OAuth bearer token is mapped to an account in the server. In this case, whether a requested operation is allowed depends on the ACIs that apply to the mapped user for the requested operation. You can also use the `oauthscope` bind rule to grant rights based on scopes in the presented token.

Because of implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. Don't give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree to expose to clients.

Learn more in Configuring Permissions for SCIM 2.0 Operations.

> **Note**
>
> ACIs that don't use the `oauthscope` bind rule can still apply to requested operations.
> For example, an ACI that grants unconditional read access to any authenticated LDAP user also grants unconditional read access to SCIM requests regardless of the provided OAuth scopes. This is because the requests are processed through the service account.

Enabling user mapping for SCIM 2.0 operations

Access token validator identity mapping ties a local user account to an operation performed in the SCIM 2.0 servlet in the PingDirectory server.

About this task

> **Note**
>
> This topic applies only to the PingDirectory server.

The default configuration for the PingDirectory server for the SCIM 2.0 servlet doesn't require an access token to map to a local user, and operations are recorded in the logs as the `SCIM2 Servlet` user. For more detailed logging and auditing, enable the `map-access-tokens-to-local-users` property to require access tokens to map to a local user.

> **Note**
>
> The users that are being mapped to the access tokens must have the necessary access control rights required to perform the operations that the SCIM 2.0 servlet will invoke on their behalf.
> You should update the authorization server to issue tokens that include the `scim2` scope alongside any other scopes you need for access control purposes.

The `map-access-tokens-to-local-users` property is an optional configuration with the three settings shown in the following table.

Setting	Definition
`Disabled` (default)	The server doesn't attempt to map SCIM 2.0 access tokens to local users and operations are processed under the authority of the `SCIM2 Servlet` user.
`Optional`	The server attempts to map SCIM 2.0 access tokens to local users and, if successful, the operations are processed under the authority of that user. The distinguished name (DN) of the mapped user appears in the access logs. If unsuccessful, the server falls back to the default behavior.
`Required`	The server must map the SCIM 2.0 access token to one local user or the operation is rejected.

To set the `map-access-tokens-to-local-users` property:

Steps

- Run `dsconfig` with the `set-http-servlet-extension-prop` option.

  Choose from:

  - To set the property to `required`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:required
```

- To set property to `optional`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:optional
```

- To reset the property to the default setting, `disabled`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:disabled
```

SCIM 2.0 Components

Unlike the System for Cross-domain Identity Management (SCIM) 1.1 servlet extension, the SCIM 2.0 system is configured through the admin console or with the `dsconfig` command-line tool.

The SCIM 2.0 system consists of the following components:

SCIM resource type

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes available to each resource. If you enable a SCIM resource type, it must have a designated LDAP structural objectclass and an associated base distinguished name (DN).The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use:

LDAP mapping SCIM

Requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.

LDAP pass-through SCIM

Does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly

SCIM schemas

Defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

SCIM attributes

Defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it's required, single-valued, or multivalued.

SCIM sub-attributes

When a SCIM attribute consists of SCIM sub-attributes, it's defined as a complex attribute.

SCIM attribute mappings (mapping resource types only)

Defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectoryProxy server.

Correlated LDAP Data Views

Allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries. Learn more in Correlated LDAP data views.

Correlated LDAP data views

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- `primary-correlation-attribute`: The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- `secondary-correlation-attribute`: The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- `ldap-correlation-attribute-pair`: Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

> **Note**
>
> A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

```
{
      ...
        "uid": [
        "user.8"
        ],
        "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
        "urn:pingidentity:schemas:correlated:Document": {
            "documentIdentifier": [
            "user.8"
            ],
            "description": [
            "This is the description for the document user.8 under ou=Documents,dc=example,dc=com."
            ],
            ...
        },
        ...
        "schemas": [
        "urn:pingidentity:schemas:correlated:Document",
        "urn:pingidentity:schemas:passthrough:PassthroughUsers"
        ]
}
```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the correlated-ldap-data-view property in a SCIM attribute mapping.

Configuring a correlated LDAP data view

About this task

The following example shows how to add a correlated LDAP data view to a LDAP mapping SCIM resource type on a PingDirectory server. The SCIM resource type will be a user, and the correlated LDAP data view will allow access to a document that matches their user ID.

In this example, a new PingDirectory server is set up using custom sample data. When configuring the correlation, administrators should use attributes that are inherently either immutable or non-volatile, such as `uid` or `entryUUID`. This prevents errors produced by a conflict between the values of primary and secondary correlation attributes.

> **Note**
>
> Administrators can make the correlation SCIM attributes immutable by setting the `--set mutability:read-only` property when defining an attribute in the SCIM schema configuration. That way, SCIM requests cannot modify the values of those attributes.

Steps

1. Copy the following text into the server root directory and save it as `entries.ldif.template`:

```
define suffix=dc=example,dc=com
define maildomain=example.com
define numusers=101

branch: [suffix]
subordinateTemplate: admin:1
aci: (targetattr="*")(version 3.0; acl "Grant full access for the scim2allaccess OAuth 2 scope";
allow (all) oauthscope="scim2allaccess";)

branch: ou=People,[suffix]
subordinateTemplate: person:[numusers]

branch: ou=Documents,[suffix]
subordinateTemplate: document:[numusers]

template: admin
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
uid: admin
givenName: Admin
sn: User
cn: Admin User
userPassword: password

template: person
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
employeeNumber: <sequential:0>
uid: user.{employeeNumber}
sn: {uid}
cn: {uid}
userPassword: password

template: document
rdnAttr: documentIdentifier
objectClass: top
objectClass: document
documentIdentifier: user.<sequential:0>
description: This is the description for the document {documentIdentifier} under
ou=Documents,dc=example,dc=com.
```

2. Run the following command:

```
$ bin/make-ldif --templateFile entries.ldif.template --ldifFile entries.ldif
```

3. Run setup for the PingDirectory server.

Make sure to import the created `entries.ldif` file and set up encryption settings. After this is done, set up the SCIM resource type and the Correlated LDAP Data View.

4. Run the following command to define the SCIM schema:

```
"dsconfig create-scim-schema --schema-name urn:example:Users \
  --set "description:Users schema" --set display-name:Users
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name email --set required:true --set multi-valued:true
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name uid --set required:true --set mutability:read-only
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentId
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentDescription"
```

5. Run the following command to create the SCIM resource type:

```
dsconfig create-scim-resource-type \
  --type-name Users \
  --type ldap-mapping \
  --set core-schema:urn:example:Users \
  --set enabled:true \
  --set endpoint:Users \
  --set structural-ldap-objectclass:inetOrgPerson \
  --set include-base-dn:ou=people,dc=example,dc=com \
  --set create-dn-pattern:entryUUID=generated,ou=people,dc=example,dc=com
```

6. Run the following command to create the Correlated LDAP Data View:

```
dsconfig create-correlated-ldap-data-view \
  --type-name Users \
  --view-name Document \
  --set structural-ldap-objectclass:document \
  --set include-base-dn:ou=documents,dc=example,dc=com \
  --set create-dn-pattern:entryUUID=generated,ou=documents,dc=example,dc=com \
  --set primary-correlation-attribute:uid \
  --set secondary-correlation-attribute:documentIdentifier
```

7. Run the following command to create the attribute mappings for the SCIM resource type attributes.

   Note that the `correlated-ldap-data-view` property is not set.

```
# The uid attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name uid \
  --set scim-resource-type-attribute:uid --set ldap-attribute:uid \
  --set writable:false --set searchable:true

# The email attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name email \
  --set scim-resource-type-attribute:email --set ldap-attribute:mail \
  --set searchable:true
```

8. Run the following command to create the `DocumentId` attribute mapping for the correlated LDAP data view attributes.

> **Note**
>
> The only meaningful difference between mappings for SCIM resource type attributes and correlated LDAP data view attributes is the value of the `correlated-ldap-data-view` property.

```
# The documentId attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name document.id \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentId --set ldap-attribute:documentIdentifier

# The documentDescription attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name description \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentDescription \
  --set ldap-attribute:description
```

9. Run the following command to send a SCIM request:

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Users \
  -H 'Authorization: Bearer {"active":true, "scope":"scim2allaccess"}'
```

The response should look similar to the following. Notice that `'uid'` and `'documentId'` have the same value, as they are in a correlation attribute pair.

```
{
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:ListResponse"
    ],
    "totalResults": 101,
    "Resources": [
        {
            "uid": "user.8",
            "id": "3715c022-1f34-36d9-bebc-7e74912106ec",
            "documentDescription": "This is the description \
            for the document user.8 under ou=Documents,dc=example,dc=com.,
            "documentId": "user.8",
            "meta": {
                "resourceType": "Users",
                "location": "https://localhost:8443/scim/v2/Users/3715c022-1f34-36d9-bebc-7e74912106ec"
            },
            "schemas": [
                "urn:example:Users"
            ]
        },
    ...
}
```

Configuring an LDAP-mapped SCIM resource type

Add a simple mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type backed by the `inetOrgPerson` LDAP objectclass to a PingDirectoryProxy deployment.

About this task

To configure an LDAP mapped SCIM resource type:

Steps

1. Set up the PingDirectory backend server.
2. Export the `encryption-settings` definition with the tool's `export` subcommand.

   Example:

   For this example, use the default settings to use sample data and configured data encryption.

   ```
   encryption-settings export --output-file exported-key
   ```

3. Set up the PingDirectoryProxy server and import the `encryption-settings` definition file that was created in the previous step.
4. To configure the LDAP external server, use the `create-initial-proxy-config` tool.
5. Create the SCIM schema for the resource type to use.

   Example:

```
dsconfig create-scim-schema \
--schema-name urn:pingidentity:schemas:User:1.0 \
--set display-name:User
```

6. Under this schema, add the following SCIM attributes.

```
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name displayName
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--set type:complex
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name familyName
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name formatted
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name userName
```

7. Create the LDAP mapping SCIM resource type on the PingDirectoryProxy server.

Example:

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

8. To create the SCIM attribute mappings, run the following commands.

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

9. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator.

> **Note**
>
> Never use Mock Access Token Validators in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

10. To confirm that the new resource type is successfully added, send the following request to the PingDirectoryProxy server's SCIM `/ResourceTypes` endpoint.

> **Note**
>
> The HTTP port can vary depending on the deployment configuration.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

Result:

The following JSON object is displayed in the response in the `"Resources"` array.

```
{
...
"Resources": [{
"schemas":["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
"id":"Users",
"name":"Users",
"endpoint":"Users",
"schema":"urn:pingidentity:schemas:Users:1.0",
"meta":{
"resourceType":"ResourceType",
"location":"https://localhost:8443/scim/v2/ResourceTypes/Users"
}
}]
...
}
```

Configuring Permissions for SCIM 2.0 Operations

Configure permissions so that POST requests with the `userAdd` scope succeed on a PingDirectoryProxy deployment.

Before you begin

Set up an LDAP mapping System for Cross-domain Identity Management (SCIM) 2.0 resource type for the `inetOrgPerson` objectclass.

Learn more in Configuring an LDAP-mapped SCIM resource type.

About this task

To configure permissions:

Steps

1. Set the SCIM resource type property:

   Choose from:

   - If the SCIM resource type being targeted already has a value for the `create-dn-pattern` property, skip to step 2.
   - To set the SCIM resource type property, run the following `dsconfig` command on the PingDirectoryProxy server.

     ```
     dsconfig set-scim-resource-type-prop \
     --type-name Users \
     --set create-dn-pattern:entryUUID=generated,ou=People,dc=example,dc=com
     ```

2. Send the following request to the PingDirectoryProxy server's SCIM `/Users` endpoint.

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users/ \
-H 'Authorization: Bearer {"active":true}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

> **Note**
>
> The HTTP port can vary depending on the deployment configuration.

Example:

The response from the server should have a status of `403` and should contain a correlation ID similar to the following.

```
{
"schemas":["urn:ietf:params:scim:api:messages:2.0:Error"],
"status":"403",
"detail":"Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac'"
}
```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. For more information on viewing the full server error message, see Troubleshooting the SCIM 2.0 servlet Extension.

3. **Add an access control instruction (ACI) to the backend server's `ou=People,dc=example,dc=com` subtree.**

    1. **Run the following `ldapmodify` command for creating the ACI on the backend PingDirectory server (and not the PingDirectoryProxy) endpoint.**

    ```
    $ ldapmodify
    dn:ou=People,dc=example,dc=com
    changetype:modify
    add:aci
    aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
    oauthscope="userAdd";)
    ```

    > **Note**
    >
    > This ACI doesn't grant write access to attributes, which means modify operations will not succeed. For more information on ACI configurations, see Overview of access control.
    > This ACI grants permission to add entries to the specified subtree as long as the SCIM request contains the `userAdd` scope.

4. **Send the POST request to the SCIM `/Users` endpoint again, and include the `userAdd` scope in the bearer token.**

Example:

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users \
-H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

Result:

The response from the server contains the created SCIM resource, which also contains values for the name and username attributes similar to the following.

```
{
"name":{
"familyName":"User",
"formatted":"Test"
},
"username":"user.test",
"id":"6f9a89b8-e766-478c-9667-def049daf6bc",
"meta":{
"resourceType":"Users",
"location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-
def049daf6bc"
},
"schemas":["urn:pingidentity:schemas:User:1.0"]
}
```

SCIM 2.0 searches

You can cap the total number of resources that are matched by a search to prevent exhausting server resources.

The configuration for each System for Cross-domain Identity Management (SCIM) 2.0 resource type contains a `lookthrough-limit` property that defines this limit. The default `lookthrough-limit` value is 500.

If a search request exceeds the lookthrough limit, the client receives a `400` response with an error message similar to the following:

```
{
    "detail": "The search request matched too many results",
    "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
    "scimType": "tooMany",
    "status": "400"
}
```

To prevent this error:

- The client must refine its search filter to return fewer matches.
- You should configure paged searches as shown in Using paged SCIM searches.

Using paged SCIM searches

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and reduce memory usage.

Before you begin

> **Note**
>
> The paged System for Cross-domain Identity Management (SCIM) searches feature is not available for entry-balanced data sets. To use paged SCIM searches, your SCIM service's backend servers must be LDAP directory servers.

Complete the following one-time operation. You only need to run the command once per PingDirectoryProxy.

> **Tip**
>
> If you're not sure if you have run the command, you can run it again safely.

```
$ dsconfig set-request-processor-prop \
--processor-name  <proxying-request-processor>  \
--set supported-control-oid:2.16.840.1.113730.3.4.9 \
--set supported-control-oid:1.2.840.113556.1.4.473
```

`<proxying-request-processor>` is the request processor handling the entries targeted by the search.

About this task

The PingDirectoryProxy server does SCIM searches using LDAP requests. After you complete the following steps, the PingDirectoryProxy server creates LDAP requests that include request controls that ask the backend servers to sort and page the search results before returning the results.

These request controls are marked noncritical, meaning that if the backend server can't page the results, the backend server still returns the results. In this case, the PingDirectoryProxy server handles the sorting and paging itself.

If your SCIM searches result in an error because the request matched too many results, you can avoid the error by using paged searches. For more information, see SCIM 2.0 searches.

For each search:

Steps

1. Decide your SCIM search.

   > **Note**
   >
   > To get paged results, your search must include at least one of these parameters: `startIndex`, `count`, or `sortBy`.

   Example:

   Your search might look like the following.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq "TX"&sortBy=sn&sortOrder=ascending
```

This is the corresponding encoded version.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?
filter=st%20eq%20%22TX%22&sortBy=sn&sortOrder=ascending
```

On your PingDirectoryProxy server, collect some information to use later. To find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values, run the following command.

```
$ dsconfig get-scim-resource-type-prop --type-name  <SCIM-resource-type-name>  \
--property structural-ldap-objectclass \
--property include-base-dn \
--property include-filter
```

2. For each backend server:

    1. Create a Virtual List View (VLV) index for your search using `dsconfig create-local-db-vlv-index` with the following options.

Option	Description
`--index-name`	Names the index
`--backend-name`	Specifies the name of the local database backend in which to place the index. The default database backend for PingDirectory is userRoot.
`--set base-dn`	Specifies the desired base distinguished name (DN). This value must match the value of the `include-base-dn` property that you found in the previous step.
`--set scope`	Is always `whole-subtree`.
`--set filter`	Specifies the filter. Specify `(objectclass=<name-of-SCIM-resource-type-objectclass>)` where `<name-of-SCIM-resource-type-objectclass>` is the name of the objectclass used by the SCIM resource type property, which you found in the previous step. If the SCIM resource type has the `include-filter` property set, also specify that property value in the filter. For example, if the filter for the objectclass is `(objectclass=inetorgperson)` and the `include-filter` value is `(st=CA)`, specify the `--set filter` argument as `(&(objectclass=inetorgperson)(st=CA))`. Specify the LDAP attributes for all the components of your SCIM search filter. For example, if a mapping SCIM resource type maps the LDAP attribute `st` to the SCIM attribute `address.region` and the SCIM search filter requires that `address.region eq TX`, then this filter must include `(st = TX)` instead of `(address.region = TX)`.

Option	Description
`--set sort-order`	Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by. If the SCIM search doesn't specify the `sortBy` parameter, specify the sort order as `+entryUUID`.

Example:

Each SCIM search that you want to produce paged results must have its own VLV index.

Recall the original, decoded SCIM search, shown here.

```
https://<proxy-hostname>:<proxy-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

To create a VLV index for that search, run the following command:

```
$ dsconfig create-local-db-vlv-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:+sn
```

2. Using the command line, stop the server, rebuild the index, start the server, and run the `rebuild-index` command specifying the base DN and the name of the index.

```
$ rebuild-index --baseDN  <baseDN-value>  --index  <name-of-index>
```

Example:

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

> **Note**
>
> The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, PingDirectoryProxy server adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, PingDirectoryProxy server uses the following parameters.

Parameter	Default
`startIndex`	1
`count`	The value of the `lookthrough-limit` property of the SCIM resource type being searched. That default is 500.
`sortBy`	entryUUID With this default, the results appear unsorted.
`sortOrder`	ascending

If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the table.

SCIM 2.0 PATCH operations

You can use a PATCH request to modify a System for Cross-domain Identity Management (SCIM) 2.0 resource that has one or more required SCIM 2.0 attributes.

The requester needs permissions to read the values of these required attributes and to write permissions for the attributes being modified, even if the PATCH request does not alter the requirements.

Example

You can modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents.

```
{
        "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
        "id": "urn:test:schema:person",
        "attributes": [
        {
        "name": "uid",
        "type": "string",
        "multiValued": false,
        "required": true,
        "caseExact": false,
        "mutability": "readWrite",
        "returned": "default",
        "uniqueness": "none"
        },
        {
        "name": "cn",
        "type": "string",
        "multiValued": false,
        "required": false,
        "caseExact": false,
        "mutability": "readWrite",
        "returned": "default",
        "uniqueness": "none"
        }
                ],
                ...
                        }
```

The following PATCH operation fails if the SCIM 2 service account does not have access to both `uid` and `cn`.

```
{
        "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
        "Operations":[{
        "op":"add",
        "path":"cn",
        "value": "new cn value"
        }]
                }
```

Troubleshooting the SCIM 2.0 servlet Extension

To troubleshoot the SCIM 2.0 servlet extension, you must enable the Debug Trace Logger.

About this task

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something like the following.

```
{
        "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:Error"
        ],
        "status": "400",
        "detail": "Request failed: correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

Steps

- To view these messages, enable the Debug Trace Logger through the admin console or with the following `dsconfig` command.

  Example:

  ```
  dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
                          --set enabled:true --add scim-message-type:error
  ```

  Result:

  After you enable the Debug Trace Logger, the server begins logging information related to SCIM operations to the `/logs/debug-trace` file, as in the following example.

  ```
  [09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
  correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping Identity
  Directory Server" instanceName="example" startupID="Xt9fJg==" threadID=173
  from=[0:0:0:0:0:0:0:1]:53978 method=POST
  url="https://0:0:0:0:0:0:0:1:9443/scim/v2/Users"
  ```

  > **Note**
  >
  > The presence of `correlationID` in these messages allows for matching the ID in the HTTP responses to the messages in the `debug-trace` log so that the appropriate LDAP error message can be determined.

Disabling the SCIM 2.0 servlet extension

If you do not need to expose data through the System for Cross-domain Identity Management (SCIM) 2 servlet, you can disable the SCIM 2.0 servlet extension.

Steps

1. Remove the SCIM 2 HTTP servlet extension from the HTTPS connection handler as well as from any other HTTP connection handlers.
2. Restart the handler.

Example

```
dsconfig set-connection-handler-prop \
        --handler-name "HTTPS Connection Handler" \
        --remove http-servlet-extension:SCIM2 \
        --set enabled:false

        dsconfig set-connection-handler-prop \
        --handler-name "HTTPS Connection Handler" \
        --set enabled:true
```

Troubleshooting a multiple correlation entry error

When using secondary store adapters in PingAuthorize or correlated Lightweight Directory Access Protocol (LDAP) data views with the System for Cross-domain Identity Management (SCIM) 2 implementation in PingDirectory or PingDirectoryProxy, an error is displayed in the SCIM 2 response to the user request if multiple entries have a secondary correlation attribute value that matches the primary correlation attribute value. The error is applicable to each product.

There are three options for resolving this error:

- Configure one or more correlation attribute pairs on the secondary store adapter or correlated LDAP data view so that for each primary entry, there is only one other entry with matching secondary correlation attribute values. This is the recommended option.
- Modify the server data so that for each primary entry, there is only one other entry with a matching secondary correlation attribute value.

  > **Note**
  >
  > Because this option requires making changes to individual entries, it is not efficient for larger servers.

- Remove the secondary store adapter or correlated LDAP data view.

  > **Important**
  >
  > Because this option involves complete removal of the feature, only do it if the other options do not resolve the error.

Monitoring the PingDirectory Suite of Products

The PingDirectory and PingDirectoryProxy servers provide a flexible monitoring framework that enables you to track server performance.

This framework exposes its monitoring information under the `cn=monitor` entry and provides interfaces through the admin console, SNMP, Java Management Extensions (JMX), and over LDAP. The PingDirectory server also provides a tool, the Periodic Stats Logger, to profile server performance.

The monitor backend

The server exposes its monitoring information under the `cn=monitor` entry.

Administrators can use various means to monitor the servers, including SNMP, the admin console, JConsole, LDAP command-line tools, and the Periodic Stats Logger.

> **Note**
>
> To display server component activity and state, use the **`bin/status`** tool.

To see the list of all monitor entries, use **`ldapsearch`** as in the following example.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries.

Component	Description
Active Operations	Provides information about the operations currently being processed by the server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of a server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the server. The client connection information contains a name followed by an equal sign and a quoted value, such as `connID="15", connectTime="20100308223038Z"` and so forth.
Connection Handlers	Provides information about the available connection handlers on the server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the server.

Component	Description
General	Provides general information about the state of the server, including product name, vendor name, server version, etc.
Index	The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the Java virtual machine (JVM).
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.
Processing Time Histogram	Categorizes operation processing times into several user-defined buckets of information, including the total number of operations processed, overall average response time in milliseconds (ms), number of processing times between 0ms and 1ms, and so forth.
System Information	Provides general information about the system and the JVM on which the server is running, including system host name, operation system, JVM architecture, Java home, Java version, and so forth.
Version	Provides information about the server version, including build ID, version, revision number, etc.
Work Queue	Provides information about the state of the PingDirectory server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a `monitor-queue-time` property set to `true` by default. This logs messages for new operations with a `qtime` attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue. A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege, which is included for root users. By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

Monitoring disk space usage

The disk space usage monitor provides information about the amount of usable disk space available for the server components.

The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations might still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all Java Runtime Environment (JRE) backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts and take additional action if the amount of usable space drops below the defined thresholds.

You can configure three thresholds for this monitor:

Low space warning threshold

This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the server generates an administrative alert but remains fully functional. It generates alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The server generates additional alerts as the amount of usable space is further reduced, such as each time the amount of usable space drops below a value 10% closer to the low space error threshold. If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.

Low space error threshold

This threshold is also defined as either a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates an alert notification and begins rejecting all operations requested by non-root users with `UNAVAILABLE` results. The server should continue to generate alerts during this time. When the server enters this mode, an administrator has to take some kind of action, such as, running a command to invoke a task or removing a signal file, before the server resumes normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server begins rejecting requests from non-root users immediately upon detecting low usable disk space.

Out of space error threshold

This threshold can also be defined as a percentage or absolute size. If the amount of usable space drops below this threshold, the server generates a final administrative alert and shuts itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server shuts itself down rather than rejecting requests from non-root users.

The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files can be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which causes problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values might not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database might become, how much space log files might consume, and how many backups are stored.

The threshold values can be specified either as absolute sizes or as percentages of the total available disk space. You must specify all values as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server does not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database preserves its integrity but might enter a state in which it rejects all operations with an error and requires the server, or at least the affected backends, to be restarted. If the low space error threshold is also set to zero, then the server generates periodic warnings about low available disk space but remains fully functional for as long as possible. If all three threshold values are set to zero, then the server does not attempt to warn about or otherwise react to a lack of usable disk space.

About the collection of system monitoring data

All PingDirectory servers have the capability to monitor the health of the server and host system they run on for diagnostic review and troubleshooting.

> **Note**
>
> This topic applies only to the PingDirectory server.

Initially, the servers do not collect any performance data until they are prepared for monitoring by a Metrics server using the `monitored-servers add-servers` tool or an administrator enables system health data collection for real-time inspection and querying. At a high level, all of the important server and machine metrics that can be monitored are available in the `cn=monitor` backend.

The Stats Collector plugin relies exclusively on entries in the `cn=monitor` backend to sample data using LDAP queries. The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local Java Runtime Environment (JRE) databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (CPU, disk, network) and the type of data aggregation that occurs for LDAP application statistics. The Stats Collector plugin is configured with the `dsconfig` tool and collects data using LDAP queries.

For example, the `--server-info:extended` option includes collection for the following:

- CPU
- Java virtual machine (JVM) memory
- Memory
- Disk information

- Network information

Utilization metrics are gathered through externally invoked OS commands, such as `iostat` and `netstat`, using platform-specific arguments and version-specific output parsing.

Enabling the Host System monitor provider automatically gathers CPU and memory utilization but only optionally gathers disk and network information. Disk and network interfaces are enumerated in the configuration by device names, such as `eth0` or `lo`, and by disk device names, such as `sd1, sdab, sda2, scsi0`.

Monitoring key performance indicators by application

PingDirectory server can be configured to track many key performance metrics, such as throughput and response-time, by the client applications requesting them.

This feature is invaluable for measuring whether the identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data:

- Can be accessed in the `cn=monitor` backend
- Can be accessed in the Periodic Stats Logger
- Can be made available for collection by the Metrics server

For more information on using the Stats Logger, see Profiling server performance using the Stats Logger.

Proxy considerations for tracked applications

In a proxy environment, the criteria should be defined in the PingDirectoryProxy server, because the PingDirectoryProxy server passes the application name through to the PingDirectory server in the intermediate client control.

If a client of the PingDirectoryProxy server or the PingDirectory server happens to use the intermediate client control, then the client name specified in the control is used as the application name regardless of the criteria listed in the `tracked-application` property.

Monitoring using SNMP

The PingDirectory server supports real-time monitoring using SNMP. The server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a primary agent based on the AgentX protocol.

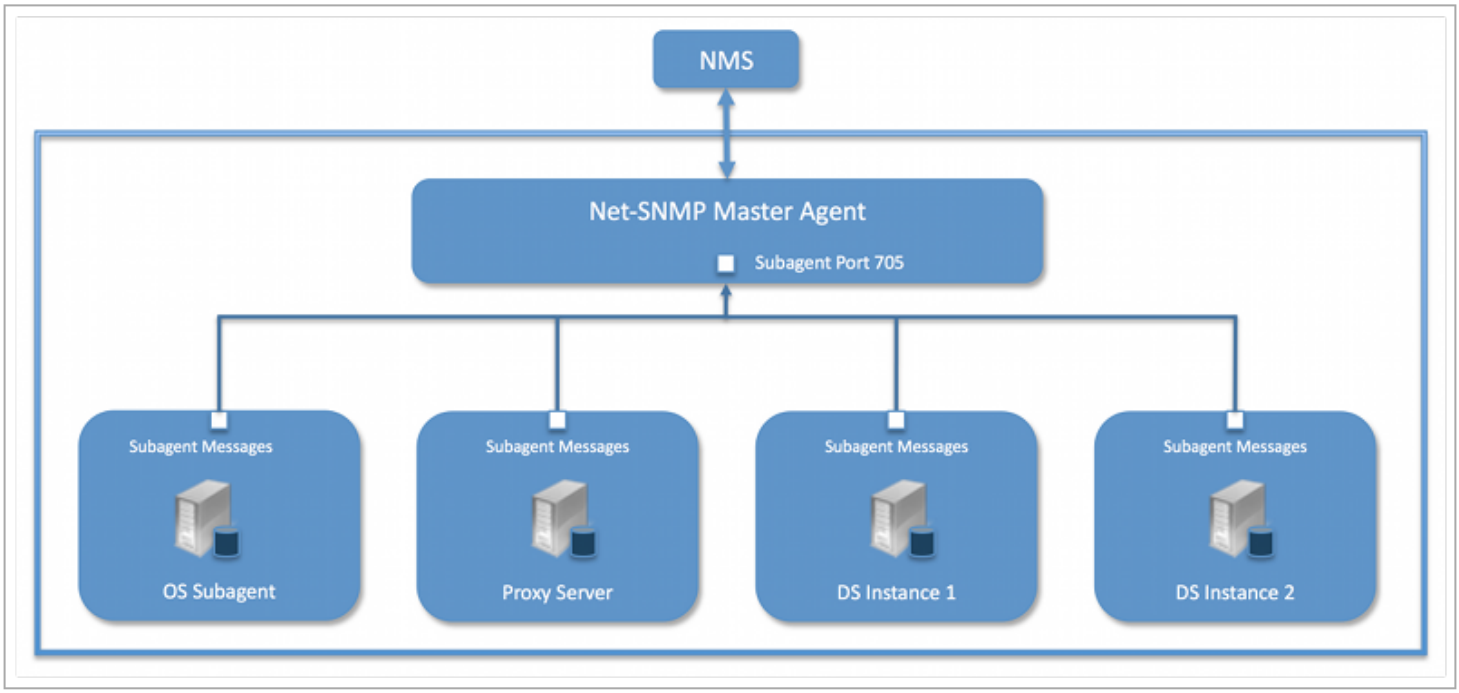
> **Important**
>
> SNMP is deprecated.

SNMP implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices.

The NMS communicates with a primary agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device, such as a PingDirectory server instance, a PingDirectoryProxy server, a PingDataSync server, or an OS Subagent. The primary agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

The server contains an SNMP subagent plugin that connects to a Net-SNMP primary agent over TCP. The main configuration properties of the plugin are the address and port of the primary agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server and then registers as a management information base (MIB) server with the server instance. After the plugin's startup method is called, it starts a session thread with the primary agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the primary agent. The server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. Set and inform operations are not supported. SNMP management applications cannot perform actions on the server on their own or through an NMS system.



Example SNMP Deployment

Note

The PingDirectory server was designed to interface with a Net-SNMP (5.3.2.2 or later) primary agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, Service Management Automation (SMA) disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP primary agent that only enables UNIX Domain Sockets, you should download and install a separate Net-SNMP binary from its website.

Configuring SNMP

Because all server instances provide information for a common set of management information bases (MIBs), each server instance provides its information under a unique SNMPv3 context name equal to the server instance name.

About this task

The server instance name is defined in the Global Configuration and is constructed from the host name and the server LDAP port by default. Information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance.

> **Note**
>
> The server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

Steps

1. **To enable the server's SNMP plugin, use the `dsconfig` tool.**

   > **Note**
   >
   > The SNMPv3 context name is limited to 30 bytes maximum. Any context name longer than 30 characters returns an error message when you attempt to enable the plugin.
   > The default context server name is the server instance name and the LDAP port number, so take note of the length of the fully-qualified DNS host name.

   1. **Specify the address and port of the SNMP primary agent.**
   2. **On each server instance, enable the SNMP subagent.**
   3. **Enable the SNMP Subagent Alert Handler so that the sub-agent sends traps for administrative alerts generated by the server.**

      Example:

      ```
      $ bin/dsconfig set-alert-handler-prop \
        --handler-name "SNMP Subagent Alert Handler" --set enabled:true
      ```

2. **View the error log.**

   Result:

   A message displays that the primary agent is not connected because it is not yet online.

   ```
   The SNMP sub-agent was unable to connect to the master
   agent at localhost/705: Timeout
   ```

3. **Edit the SNMP agent `snmpd.conf` configuration file and add the directive to run the agent as an AgentX primary agent.**

   The file is often located in `/etc/snmp/snmpd.conf`.

Example:

```
master agentx agentXSocket tcp:localhost:705
```

> **Note**
>
> Using `localhost` means that only sub-agents running on the same host can connect to the primary agent. This is necessary because there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, public (or whatever SNMP community has been configured for your environment) and the port.

   Example:

   ```
   trap2sink localhost public 162
   ```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

   Example:

   ```
   rwuser initial
   createUser initial MD5 setup_passphrase DES
   ```

6. To create the SNMPv3 user, run `snmpusm`.

   Example:

   ```
   snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
   localhost create snmpuser initial
   ```

7. Start the `snmpd` daemon.

   Result:

   A message displays in the server's error log.

   ```
   The SNMP subagent connected successfully to the master agent
   at localhost:705. The SNMP context name is host.example.com:389
   ```

8. To see the alerts that are generated by the server, set up a trap client.

   1. Create a config file in `/tmp/snmptrapd.conf`.
   2. Add the `authcommunity log, execute public` directive to the file.

      > **Note**
      >
      > The directive specifies that the trap client can process traps using the public community string and can log and trigger executable actions.

9. Install the MIB definitions for the Net-SNMP client tools in the `/usr/share/snmp/mibs` directory.

Example:

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. To run the trap client, run the `snmptrapd` command.

    Example:

    This example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), should not read any configuration files (`-C`) except the one specified with the `-c` option, should print to standard output (`-Lo`), and then specifies that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (`server-root/resource/mib`).

    ```
    $ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
      -m all -M +/usr/share/snmp/mibs
    ```

11. To test the feature, run the Net-SNMP client tools.

    You must use the following options:

    - `-v` *<SNMP version>*
    - `-u` *<user name>*
    - `-l` *<security level>*
    - `-n` *<context name (instance name)>*
    - `-A` *<user password>*

      Example:

      In this example, the `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

      ```
      $ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
      -m all localhost localDBBackendCount.0

      $ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
      -m all localhost systemStatus
      ```

MIBS

The server provides SMIv2-compliant management information base (MIB) definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definition text files are in the server's `/resource/mib` directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

LDAP Remote Server MIB

Provides information related to the health and status of the LDAP servers that the server connects to and statistics about the operations invoked by the server on those LDAP servers.

LDAP Statistics MIB

Provides a collection of connection-oriented performance data that is based on a connection handler in the server.

A server typically contain only one connection handler and therefore supplies only one table entry.

Local DB Backend MIB

Provides key metrics related to the state of the local database backends contained in the server.

Processing Time MIB

Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.

Replication MIB

Provides key metrics related to the current state of replication that can help diagnose how much outstanding work replication might have to do.

System Status MIB

Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on the PingDirectory server and the PingDirectoryProxy server, see the text files located in the server's `/resource/mib` directory.

The server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDID-ALERT-MIB.txt` file.

Monitoring with the admin console

The admin console can be used to monitor items, such as disk space usage, active operations in the server, and alarms raised.

About this task

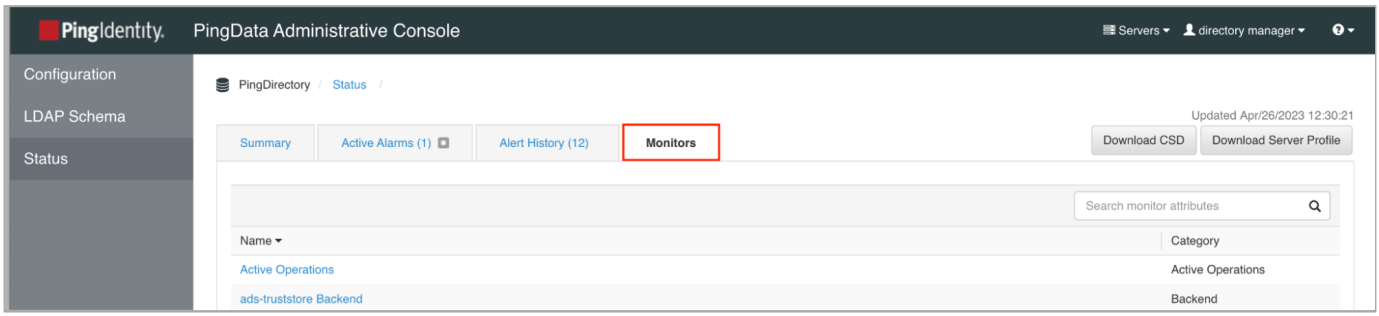
The console provides a status option that accesses the server's monitor content.

To view the monitor dashboard:

Steps

1. In your browser, go to http://<*server-name*>:<*port*>/console.
2. Enter the root user distinguished name and password. Click Login.
3. In the top-level navigation menu, select Status.

4. Click the Monitors tab.



Result

The Monitors page opens, and you can monitor your server by selecting a monitor attribute.

Accessing the Processing Time Histogram

The PingDirectory server provides a processing time histogram that classifies operation response time into user-defined buckets.

About this task

The histogram tracks the processing on a per-operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type:

- `add`
- `bind`
- `compare`
- `delete`
- `modify`
- `modifyDN`
- `search`

Steps

1. From the admin console, go to Configuration > Status > Monitors.
2. Select Processing Time Histogram.

> **Note**
>
> You can access other monitor entries in similar ways.

Monitoring with JMX

The PingDirectory server supports monitoring the Java virtual machine (JVM) through a Java Management Extensions (JMX) management agent, which can be accessed using JConsole or any other kind of JMX client.

The JMX interface provides JVM performance and resource utilization information for applications running Java. In addition to the monitor information that the server provides, you can monitor generic metrics exposed by the JVM, including:

- Memory pools
- Threads
- Loaded classes
- MBeans

You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

Running JConsole

Run `jconsole` to monitor the memory usage and thread activity of a Java virtual machine.

Before you begin

Before you can run `jconsole`, you must:

- Configure and enable the Java Management Extensions (JMX) Connection Handler for the server using the `dsconfig` tool.

  > **Note**
  >
  > For more information, see Configuring the JMX connection handler and alert handler.

- Invoke the `jconsole` executable by entering `jconsole` in your command-line interface or terminal.

  > **Note**
  >
  > If *<JDK_HOME>* is not set in your path, you can access `jconsole` in the `bin` directory of the `<JDK_HOME>` path.

Steps

1. To open the Java Monitoring & Management Console, run `jconsole`:

   Choose from:

   - To monitor a specific process ID for your application, run `jconsole <process ID>`.
   - To run `jconsole` remotely, run `jconsole <hostname:port>`.

     If SSL is configured on the JMX Connection Handler, you must specify the PingDirectory server `.jar` file in the class path when running `jconsole` over SSL, as in the following example:

```
$ jconsole -J-Dcom.unboundid.directory.server.protocol.jmx.trustStorePath=$INSTANCE_ROOT/config/
truststore -J-Dcom.unboundid.directory.server.protocol.jmx.trustStorePin=secret -J-
Dcom.unboundid.directory.server.protocol.jmx.trustStoreType=JKS -J-classpath -J"$INSTANCE_ROOT/lib/*:/
Library/Java/JavaVirtualMachines /jdk1.8.0_201.jdk/Contents/Home/lib/jconsole.jar"
```

Set the following properties in the above command:

- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePath` property with the full trust store path.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStoreType` property if the default type, Java KeyStore (JKS), is not used.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property with the trust store file password, if there is one.
- Set the `com.unboundid.directory.server.protocol.jmx.trustStorePinFile` property with the file path containing the trust store password in plain text.

  Do not use this property if the `com.unboundid.directory.server.protocol.jmx.trustStorePin` property is used.

> **Note**
>
> When establishing a connection to **`jconsole`**, a window opens asking if you want to retry connecting insecurely. Click **Insecure connection**.
> Although **`jconsole`** considers anything other than `SslRmiClientSocketFactory` to be insecure, choosing to retry insecurely will enable PingDirectory's secure client socket factory.

2. In the Java Monitoring & Administrative Console window, click Local Process, and then click the PID corresponding to the server.
3. Review the resource monitoring information.

Monitoring the server using JConsole

Set up JConsole to monitor the server using a remote process.

Steps

1. Start the server.

   Example:

   ```
   $ bin/start-server
   ```

2. Enable the Java Management Extensions (JMX) Connection handler using **`dsconfig`** with the `set-connection-handler-prop` option.

> **Note**
>
> The handler is disabled by default.
> Include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign privileges to a regular user account with the `ldapmodify` tool.

> **Warning**
>
> Do not use a root user account, as using a root user account would be a security risk.

Example:

This example grants `jmx-read`, `jmx-write`, and `jmx-notify` privileges to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. In Java Monitoring & Administrative Console, click Remote Process, and enter the following JMX URL using the host and port of your server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the Username and Password fields, enter the bind distinguished name (DN) and password for a user that has at least the `jmx-read` privilege.
6. Click Connect.
7. Click com.unboundid.directory.server, and expand the `rootDSE` node and the `cn-monitor` sub-node.
8. Select a monitoring entry.

Monitoring using the LDAP SDK

You can use the monitoring API to retrieve monitor entries from the PingDirectoryProxy server and retrieve specific types of monitor entries.

For example, you can retrieve all monitor entries published by the server, and print the information contained in each using the generic API for accessing monitor entry data as follows.

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
  {
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
      for (Object value : a.getValues())
      {
        System.out.println(" " + a.getDisplayName() + ": " + String.valueOf(value));
      }
     }
     System.out.println();
  }
```

For more information about the LDAP SDK and the methods in this example, see the LDAP SDK repository on GitHub.

Monitoring over LDAP

The PingDirectory server exposes a majority of its information under the `cn=monitor` entry.

Steps

- To access these entries over LDAP, use the `ldapsearch` tool.

  Example:

  ```
  $ bin/ldapsearch --hostname server1.example.com --port 1389 \
    --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
    --baseDN "cn=monitor" "(objectclass=*)"
  ```

Profiling server performance using the Stats Logger

The PingDirectory server includes a built-in Stats Logger that is useful for profiling server performance for a given configuration.

At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a `.csv` file, which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a value of less than 1 second. You can customize the statistics logged and their verbosity.

The Stats Logger can also be used to view historical information about server statistics, including:

- Replication
- LDAP operations

- Host information
- Gauges

To update the configuration of the existing Stats Logger Plugin, you can either:

- Set the advanced `gauge-info` property to `basic/extended` to include this information.
- Create a dedicated Periodic Stats Logger for information about statistics of interest.

Learn more in Enabling the Stats Logger.

Enabling the Stats Logger

About this task

By default, the PingDirectory server's built-in Stats Logger is disabled. To enable the Stats Logger:

Steps

1. Run `dsconfig` in interactive mode.

   When you are prompted, enter the LDAP or LDAPS connection parameters.

   Example:

   ```
   $ bin/dsconfig
   ```

2. To change to the `Advanced Objects` menu, enter `o`.
3. On the main menu, enter the selection for `Plugins`.
4. On the `Plugin` menu, enter the selection for `View and edit an existing plugin`.
5. In the `Plugin` selection list, enter the selection for `Stats Logger`.
6. On the `Stats Logger Plugin` menu, enter the selection to set the `enabled` property to `TRUE`. To save and apply the configuration, enter `f`.

   Result:

   The default logger logs information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing is logged.

   > **Note**
   >
   > To change the idle logging behavior, set the `suppress-if-idle` property to `FALSE`.

7. Run the PingDirectory server.

   Example:

   For example, if you are running in a test environment, you can run the `search-and-mod-rate` tool to apply some searches and modifications to the server.

> **Tip**
>
> To see an example command, run `search-and-mod-rate --help`.

8. View the Stats Logger output at `<server-root>/logs/dsstats.csv`.

   You can open the file in a spreadsheet.

Configuring multiple Periodic Stats Loggers

About this task

You can create multiple Periodic Stats Loggers to:

- Log different statistics
- View historical information about gauges
- To create a log at different intervals, such as logging cumulative operations statistics every hour

To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

Steps

1. Run `dsconfig` in interactive mode.

   When prompted, enter the LDAP or LDAPS connection parameters.

   Example:

   ```
   $ bin/dsconfig
   ```

2. To change to the `Advanced Objects` menu, enter `o`.
3. In the main menu, enter the selection for `Plugins`.
4. In the `Plugin management` menu, enter the selection for `Create a new plugin`.
5. To use an existing plugin as a template, in the `Create a New Periodic Stats Logger Plugin` menu, enter `t`.
6. Enter the number corresponding to the existing stats logger as a template.
7. Enter a descriptive name for the new stats logger.

   For this example, enter `Stats Logger-10s`.

8. Enter the log file path to the file.

   For this example, enter `logs/dsstats2.csv`.

9. In the menu, make any other changes to the logger. To save and apply the configuration, enter `f`.

   Example:

   For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `FALSE`.

Result

You should see two loggers, `dsstats.csv` and `dsstats2.csv`, in the `logs` directory.

Adding custom logged statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` with the Custom Logged Stats object.

This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. New Custom Logged Stats are automatically included in the Periodic Stats Logger output.

In addition to allowing a straight pass-through of the values using the raw statistic-type, you can configure attributes to be treated as any of the following:

- A counter, where the interval includes the difference in the value since the last interval
- An average value held by the attribute during the specified interval
- A minimum value held by the attribute during the specified interval
- A maximum value held by the attribute during the specified interval

The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

> **Note**
>
> Custom third-party server extensions written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To show you how to configure a Custom Logged Statistics Logger, the following sections reproduce the built-in `Consumer Total GB` column that displays in the output when the `included-resource-stat` property is set to memory-utilization on the Periodic Stats Logger.

The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows.

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

Configuring a custom logged statistic using `dsconfig` interactive

Steps

1. Run `dsconfig` and, when prompted, enter the LDAP or LDAPS connection parameters.

Example:

```
$ bin/dsconfig
```

2. In the server's `Advanced Objects menu`, enter the selection for `Custom Logged Stats`.
3. In the `Custom Logged Stats menu`, enter the selection for `Create a new Custom Logged Stats`.
4. Select the `Stats Logger Plugin` from the list if more than one is present on the system. If you only have one stats logger, press Enter to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the `Custom Logged Stats`.

   For this example, enter `Memory Usage`.
6. In the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor.

   For this example, enter `ds-memory-usage-monitor-entry`.

   > **Note**
   >
   > To view the entry, run **`ldapsearch`** using the base distinguished name (DN) `cn=JVM Memory Usage,cn=monitor` entry.
7. Enter the attributes of the monitor entry that you want to log in the stats logger, and then press Enter again to continue.

   For this example, enter `total-bytes-used-by-memory-consumers`.
8. Specify the type of statistics for the monitored attribute to appear in the log file.

   For this example, enter the option for `raw statistics` as recorded by the logger.
9. In the `Custom Logged Stats menu,` review the configuration.
10. To set up a column name that lists the memory usage, enter the option to change the `column-name` property.
11. To add a specific label for the column name, enter the option to `add a value`, and then enter `Memory Consumer Total (GB)`. To continue, press Enter.
12. Confirm that you want to use the `column-name` value that you entered in the previous step. To use the value, press Enter.
13. To scale the `Memory Consumer Totals (GB)` by 1 gigabyte (GB), in the `Custom Logged Stats menu`, enter the option to change the `divide-value-by` property.
14. In the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824`.

    1073741824 bytes is equivalent to 1 gigabyte.
15. In the `Custom Logged Stats menu`, review your configuration. To save and apply the settings, enter `f`.

    Example:

```
>>>> Configure the properties of the Custom Logged Stats
 >>>> via creating 'Memory Usage' Custom Logged Stats

         Property                  Value(s)
         ----------------------------------------------------------------
    1)   description               -
    2)   enabled                   true
    3)   monitor-objectclass       ds-memory-usage-monitor-entry
    4)   include-filter            -
    5)   attribute-to-log          total-bytes-used-by-memory-consumers
    6)   column-name               Memory Consumer Total (GB)
    7)   statistic-type            raw
    8)   header-prefix             -
    9)   header-prefix-attribute   -
    10)  regex-pattern             -
    11)  regex-replacement         -
    12)  divide-value-by           1073741824
    13)  divide-value-by-attribute -
    14)  decimal-format            #.##
    15)  non-zero-implies-not-idle false

    ?)   help
    f)   finish - create the new Custom Logged Stats
    a)   hide advanced properties of the Custom Logged Stats
    d)   display the equivalent dsconfig arguments to create this object
    b)   back
    q)   quit

Enter choice [b]:
```

Result:

A message of `The Custom Logged Stats was created successfully` is returned.

After the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

Configuring a custom stats logger using dsconfig non-interactive

About this task

The following task replicates the previous procedure using `dsconfig` in non-interactive mode.

To create a custom stats logger:

Steps

- Run the `dsconfig` non-interactive command with the `create-custom-logged-stats` option.

  Example:

  In this example, the command produces a column named `Memory Consumer Total (GB)` that contains the value of the of `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
  --stats-name "Memory Usage" --type custom \
  --set monitor-objectclass:ds-memory-usage-monitor-entry \
  --set attribute-to-log:total-bytes-used-by-memory-consumers \
  --set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
  --set divide-value-by:1073741824
```

Enabling and configuring the StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD endpoint type that you can use to transfer metrics data in the StatsD format.

About this task

You can configure the Monitoring Endpoint using the `dsconfig` command or the admin console.

Steps

- To create the StatsD monitoring Endpoint, use either of the following:

  Choose from:

  - To use the command-line, run `dsconfig` with the `create-monitoring-endpoint` option.

    This example configures a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`.

    ```
    dsconfig create-monitoring-endpoint \
        --type statsd \
        --endpoint-name StatsDEndpoint \
        --set enabled:true \
        --set hostname:localhost \
        --set server-port:8125 \
        --set connection-type:unencrypted-udp
    ```

  - To use the admin console:

    1. From the admin console, click Show Advanced Configuration.
    2. In the Logging, Monitoring, and Notifications section, click Monitoring Endpoints.
    3. Click New Monitoring Endpoint.

  When you configure Monitoring Endpoint include:

  - The endpoint's host name
  - The endpoint's port
  - A toggle to use TCP or UDP
  - A toggle to use SSL if you use TCP

You can configure a StatsD Monitoring Endpoint with custom tags using the `additional-tags` property. This adds the defined tags to each metric message sent to the endpoint. Each tag should be created in a "key=value" format. Additional tags are appended to the end of the StatsD message. Here is a sample StatsD message with custom tags:

```
example.metric:123|g|#tag1:value1,tag2:value2
```

> **Note**
>
> You can send data to any number of monitoring endpoints.

Enabling and configuring the Stats Collector Plugin

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint.

About this task

> **Note**
>
> This topic applies only to the PingDirectory server.

To send metrics with the StatsD monitoring endpoint, enable the Stats Collector Plugin and configure the plugin to indicate which metrics to send.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

> **Tip**
>
> For a list of available metrics, use the interactive **`dsconfig`** menu for the Stats Collector Plugin, or in the admin console, edit the Stats Collector plugin, as explained in the second example.

Steps

- To enable and configure the Stats Collector Plugin, use either of the following:

  Choose from:

  - To use the command line, run `dsconfig` with the `set-plugin-prop` option.

    This example enables the Stats Collector Plugin to send host CPU metrics, memory metrics, and server status metrics using `dsconfig`.

```
dsconfig set-plugin-prop \
    --plugin-name "Stats Collector" \
    --set enabled:true \
    --set host-info:cpu \
    --set host-info:disk \
    --set status-summary-info:basic
```

> **Note**
>
> If you are not using Data Metrics Server to monitor your server, you can disable the generation of some unnecessary metrics files for the StatsD Monitoring Endpoint. To do this, set the `generate-collector-files` property on the Stats Collector Plugin to `false`.

- To use the admin console:

  1. In the admin console, click Show Advanced Configuration.
  2. In the LDAP (Administration and Monitoring) section, click Plugin Root.
  3. Edit the Stats Collector plugin and select the configuration options to indicate which metrics to send.

Next steps

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk, as explained in Sending metrics to Splunk with StatsD.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. You can find more information about this configuration in your tool's StatsD documentation.

Sending metrics to Splunk with StatsD

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

Using the StatsD Endpoint type, you can send metric data to a Splunk installation. In Splunk, you can use Secure Sockets Layer (SSL) to secure ports opened for StatsD. You can configure open UDP or TCP ports in Splunk to accept only connections from a certain hostname or IP address.

> **Note**
>
> StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

To securely send UDP or TCP data to Splunk:

Steps

1. Send the data to a Splunk Universal Forwarder.

2. Request that the forwarder use SSL to communicate with the Splunk Indexer.

Troubleshooting the PingDirectory Suite of Products

The PingDirectory Suite of Products provides a highly-reliable service that satisfies your company's objectives. However, if problems do arise, then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

This section provides information about how to perform this analysis to help ensure that the problem is resolved as quickly as possible. This chapter presents the following information:

Troubleshooting the PingDirectory and PingDirectoryProxy servers

There are several ways to troubleshoot issues with the PingDirectory and PingDirectoryProxy servers.

This section contains the following topics:

- Server gauges
- Working with the collect-support-data tool
- PingDirectory server troubleshooting information
- Monitor entries
- Server troubleshooting tools
- Troubleshooting resources for Java applications

Server gauges

The server provides several built-in gauges to monitor server performance. These gauges are listed in the following table.

> **Note**
>
> Some of the gauges described in the following table apply only to the PingDirectory server, and some apply only to the PingDirectoryProxy server. These gauges are indicated as such. The remaining gauges apply to both servers.

Gauge Name	Enabled by default?	Description
Active Cleaner Threads (Percent)	true	PingDirectory server only: Monitors the percentage of database cleaner threads that are active in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. To keep the database from growing on disk, database cleaner threads copy database information from older, mostly obsolete database files to new database files. At a single point in time, 100% of the cleaner threads might be active, but when averaged over time, the percentage of active cleaner threads should remain relatively low. Even environments that sustain a very high write load do not typically see an average cleaner percent busy over 50%. If the percentage exceeds 90% for over an hour, it is a sign that the database cleaner is not progressing and the act of cleaning is producing as much garbage as it cleans. This typically occurs in environments that are not fully cached, and have not given sufficient memory to the database cache. Either increase the memory available to the database cache (by increasing the JVM size or increasing the `db-cache-percent` setting on the backend) or reduce the `db-cleaner-min-utilization` setting, which reduces the burden on the cleaner thread(s).
Authentication Failure Rate	false	Rate of LDAP bind failures per second. A high rate of failures might indicate a misconfigured client application or a malicious attack.
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTORS=12345`. If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring can cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the admin console, for more information about server certificates and how they are managed.

Gauge Name	Enabled by default?	Description
Changelog Database Target Size (Percent)	true	PingDirectory server only: Monitors the size of a changelog database on disk relative to the configured `target-database-size` value for the Replication Server changelog and the LDAP Changelog Backend (cn=changelog). The resource identifier indicates the changelog environment that is being monitored. The server aims to keep the disk usage of the changelog to between 95% and 100% of the target-database-size value. The most common reason that the server exceeds this limit is that there are no more changes that are old enough to purge. This is controlled with the replication-purge-delay setting on the Replication Server configuration object and the `changelog-maximum-age` setting on the 'changelog' Backend configuration object. If this is the case, the effective-purge-delay monitor attribute will match the configured purge delay. To eliminate the alarm in this case reduce the purge delay or increase the target-database-size value. Another reason that the disk usage could exceed this limit is that an export-ldif or online backup of the corresponding backend is running since database files on disk cannot be deleted while this operation is in progress. In practice, this will not occur unless the purge delay and target-database-size setting are configured to very small values and/or the backup is throttled with the `--maxMegabytesPerSecond` option so that it takes an especially long time to complete. The final reason that the limit could be exceeded is that the target-database-size setting is unreasonably small like less than one gigabyte.
Cleaner Backlog (Number Of Files)	true	PingDirectory server only: Monitors the cleaner backlog in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The backlog is the number of database files that need to be cleaned to reach the target level of utilization. The value over time should stay close to zero. If it remains high or continues to grow, then consider updating the backend configuration to increase the `db-num-cleaner-threads` setting or reduce the `db-cleaner-min-utilization` setting. Temporary spikes in cleaner backlog are common during rebuild-index, export-ldif, and backup operations. The backlog should decrease automatically when these commands complete.
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.

Gauge Name	Enabled by default?	Description
Database Cache Full (Percent)	true	PingDirectory server only: Monitors the percentage capacity of the database cache currently populated with entries, per backend. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include-resource and exclude-resource properties respectively. Server performance can drop off dramatically when the database cache can no longer hold the entire data set. Most deployments are designed to keep the database cache usage comfortably within the configured limits. If this server is intentionally disk-bound, this gauge should be disabled.
DB on Disk to DB Cache Size Ratio	true	PingDirectory server only: Monitors the ratio between the sizes of the on-disk database and the in-memory cache database. This gauge relies on the `db-on-disk-to-db-cache-size-ratio` attribute within database environment monitor entries. The ratio can help when troubleshooting performance issues caused by excessive thrashing between memory and disk. If the ratio grows to a size eight times larger than what can be stored in memory, which is the default threshold, there is an increased risk of degraded performance, and the gauge raises an alert. To resolve this issue, consider increasing the amount of RAM on the system or using entry-balancing with the PingDirectoryProxy server. **Note** The alert threshold for the ratio size is configurable and could be larger or smaller than the default.
Data Set Availability	true	PingDirectoryProxy server only: For each data set, indicates whether there is at least one backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the `dsconfig list-load-balancing-algorithms` command to see a list of load balancing algorithms. A data set can be included or excluded from monitoring by specifying its load-balancing algorithm name in the include resource and exclude resource properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Make sure that backend servers are available to fulfill proxy requests.

Gauge Name	Enabled by default?	Description
Data Set Local Availability	true	PingDirectoryProxy server only: For each data set, indicates whether there is at least one local backend server available to fulfill requests. The resource identifier for this gauge is the name of the load-balancing algorithm used to define the set of backend servers fulfilling requests for the data set. Use the `dsconfig list-load-balancing-algorithms` command to see a list of load balancing algorithms. A data set can be included or excluded from monitoring by specifying its load-balancing algorithm name in the `include resource` and `exclude resource` properties respectively. A data set's availability depends upon the availability of the backend servers available to fulfill the PingDirectory server requests. The set of backend servers is defined by the set of servers configured in a data set's load-balancing algorithm. Locations are used to indicate the set of preferred backend servers that should be used to fulfill requests. You can denote that a backend server is local by setting its external server configuration object's location attribute to be the same as this Directory Proxy Server instance's location set in its global configuration. Make sure that backend servers are available to fulfill proxy requests.
Disk Busy (Percent)	true	Monitors disk busy percentage over the update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that Monitor Provider. The resource identifier for this gauge is the disk device name. Use the `iostat` command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk. High disk usage might be indicative of a directory server whose database cache and/or JVM heap size are not large enough to contain the entire data set.
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queueing.
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine memory that is in use. This value naturally fluctuates because of garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Before restarting the server, run collect-support-data and capture the output of 'jmap -histo ' to provide to customer support. The pid of the server can be found from `/logs/server.pid`.

Gauge Name	Enabled by default?	Description
LDAP Operation Average Response Time (Milliseconds)	false	Monitors the average response time across all LDAP operations processed by this server since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall response time of all LDAP operations processed by this server since it was started. High response times can be indicative of several factors including a disk-bound server, network latency, or misconfiguration. Enabling the Stats Logger plugin might help isolate problems. See the administration guide for more information on common problems and solutions.
LDAP Operations Failed (Percent)	false	Monitors the percentage of all LDAP operations processed by this server that have failed since it was started. There is no resource identifier associated with this gauge. The monitored resource is overall number of failed LDAP operations processed by this server since it was started. A high percentage of failed operations might indicate misconfiguration of a client or server in a topology.
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website or contact sales@pingidentity.com. Use the dsconfig tool to update the License configuration's license key property.
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Purge Expired Data Backlog (Number of Entries)	true	PingDirectory server only: Monitors the backlog of entries that need to be purged by a Purge Expired Data Plugin. The resource identifier for this gauge is the name of the configured plugin. Increasing the max-updates-per-second configuration property on the plugin can increase the rate that the plugin purges expired data. It might also be necessary to refine the search that the plugin performs to be more efficient.
Recent Changes Database-to-JVM Heap Size Ratio (Percent)	true	PingDirectory server only: The recent changes database keeps several recent changes made by update operations in changelog change entry form. This database is used by replication and the changelog backends, and unexpected growth affects server start time, memory consumption and space on disk. The ratio of the recent changes database to the overall heap size is used to track the impact on memory consumption. If you expect large changes and the server isn't experiencing issues, increase the alarm threshold. After processing large changes the alarm should clear itself, if not, it might necessary to perform an export and re-import of the data to resolve the issue.

Gauge Name	Enabled by default?	Description
Replication Conflict Growth Rate	false	PingDirectory server only: Growth rate of the number of unresolved conflicts per second over the update interval. The resource identifier for this gauge is the base DN of the replica. Use the `dsreplication status` command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas can be included or excluded from monitoring by specifying a replication base DN in the include resource and exclude resource properties respectively. Updates to directory server entries in a replication topology can happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model means that conflicting changes can be applied at different directory server instances. In most cases, the directory server is able to resolve these conflicts automatically and in a consistent manner. However, in some scenarios, manual administrative action is required. Attention should be paid to the origin of client write requests to prevent conflicts.
Replication Connection Status	false	PingDirectory server only: Indicates the connection status of remote replication servers this servers replication topology. The 'cn=schema' backend as well as the local replication server, are excluded using the include-filter property. For all other remote servers in the topology, separate monitor entries will be created per server and replication base DN. The resource identifier for this gauge is a concatenated string containing the data set name, the host and port of the replication server and the replication server ID. A replicated data set depends upon the availability of servers replicating the data. So long as there are other replicas available in a replication topology, a single replica being unavailable should not affect the overall performance of the replication topology. However, unavailable replicas can increase the likelihood of data loss or performance degradation.
Replication Latency (Milliseconds)	false	PingDirectory server only: Average amount of time it takes a modification on one replica to propagate and commit on another replica, in milliseconds. The resource identifier for this gauge is the base DN of the replica. Use the `dsreplication status` command to see a list of replicated base DNs. A separate gauge monitor entry will be created for each monitored replica. Replicas can be included or excluded from monitoring by specifying its base DN in the include-resource and exclude-resource properties respectively. Replication latency can be reported as high after the server starts, if the global configuration property startup-min-replication-backlog-count is not set. That property limits the number of outstanding changes any replica can have before the server will complete the startup process and begin accepting connections. This limits how out of the sync the server is at start up.

Gauge Name	Enabled by default?	Description
Replication Purge Delay (Hours)	true	PingDirectory server only: For the replication server indicates the effective purge delay. In order to protect against missing changes the effective purge delay should be large enough to accommodate servers that have been offline as well as the need to restore from backups.
Replication Servers Available	false	PingDirectory server only: Strong Encryption Not Available
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.
Undeletable Database Files (Percent)	true	PingDirectory server only: Monitors the percentage of undeletable database files in a Berkeley DB environment. The resource identifier for this gauge is a backend ID. Use the `list-backends` command to see a list of backend IDs. A separate gauge monitor entry will be created for each monitored backend. Backends can be included or excluded from monitoring by specifying its backend ID in the include resource and exclude resource properties respectively. The percentage of undeletable database files tracks the percentage of database files that have been cleaned but cannot be deleted because they are being used by a database maintenance operation. This could be a separate, offline process such as export-ldif or verify-index, or it could be a task running within the server such as a backup or replication initialization. A small percentage of undeletable files is expected when these commands are running, but a high percentage could indicate that one of these operations is having problems and should be canceled and restarted to avoid the database growing too large on disk.
Work Queue Size (Number Of Requests)	true	Number of requests in the server's work queue waiting to be processed, averaged over the update interval. There is no resource identifier associated with this gauge. The monitored resource is the server's work queue. If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available.

Working with the collect-support-data tool

The PingDirectory server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a `.zip` archive that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the `.zip` archive.

The tool can only archive portions of certain log files to conserve space so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target PingDirectory server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Server commands used in the collect-support-data tool

> **Note**
>
> This topic applies only to the PingDirectory server.

The following presents a summary of the data collectors that the `collect-support-data` tool archives in `.zip` format. If an error occurs during processing, you can rerun the specific data collector command and send the results to your authorized support provider.

Data Collector	Description
status	Runs `status -F` to show the full version information of the PingDirectory server (Unix, Windows).
server-state	Runs `server-state` to show the current state of the PingDirectory server process (Unix, Windows).

JDK commands used in the collect-support-data tool

> **Note**
>
> This topic applies only to the PingDirectory server.

Data Collector	Description
jps	Java Virtual Machine Process status tool. Reports information on the JVM (Linux, Windows, Mac OS).
jstack	Java Virtual Machine Stack Trace. Prints the stack traces of threads for the Java process (Linux, Windows, Mac OS).
jstat	Java Virtual Machine Statistics Monitoring Tool. Displays performance statistics for the JVM (Linux, Windows, Mac OS).
jinfo	Displays the Java configuration information for the Java process (Linux, Windows, Mac OS).

Linux commands used in the collect-support-data tool

> **Note**
>
> This topic applies only to the PingDirectory server.

Data Collector	Description
tail	Displays the last few lines of a file. Tails the `/var/logs/messages` directory.
uname	Prints system, machine, and operating system information.
ps	Prints a snapshot of the current active processes.
df	Prints the amount of available disk space for file systems in 1024-byte units.
cat	Concatenates the following files and prints to standard output: • `/proc/cpuinfo` • `/proc/meminfo` • `/etc/hosts` • `/etc/nsswitch.conf` • `/etc/resolv.conf`
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
uptime	Prints the time the server has been up and active.
dmesg	Prints the message buffer of the kernel.
vmstat	Prints information about virtual memory statistics.
iostat	Prints disk I/O and CPU utilization information.
mpstat	Prints performance statistics for all logical processors.
pstack	Prints an execution stack trace on an active processed specified by the pid.
top	Prints a list of active processes and how much CPU and memory each process is using.

MacOS commands used in the collect-support-data tool

> **Note**
>
> This topic applies only to the PingDirectory server.

Data Collector	Description
uname	Prints system, machine, and operating system information.
uptime	Prints the time the server has been up and active.
ps	Prints a snapshot of the current active processes.
system_profiler	Prints system hardware and software configuration.
vm_stat	Prints machine virtual memory statistics.
tail	Displays the last few lines of a file. Tails the `/var/log/system.log` directory.
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
df	Prints the amount of available disk space for file systems in 1024-byte units.
sample	Profiles a process during an interval.

Invoking the collect-support-data tool as an administrative task

> **Note**
>
> This topic applies only to the PingDirectory server.

You can invoke `collect-support-data` as an administrative task, including as a recurring task that can be automatically invoked on a regular basis.

Learn more in About recurring tasks and task chains.

Available tool options

The `collect-support-data` tool has some important options that you should be aware of:

- `--noLdap`: Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- `--pid {pid}`: Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server respectively.
- `--sequential`: Use this option to diagnose "Out of Memory" errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially instead of in parallel. This action reduces the initial memory footprint of this tool at the cost of taking longer to complete.
- `--reportCount {count}`: Specifies the number of reports generated for commands that support sampling, such as `vmstat`, `iostat`, or `mpstat`. A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.

- `--reportInterval {interval}`: Specifies the number of seconds between reports for commands that support sampling, such as `mpstat`. This option must have a value greater than 0 (zero). If this option is not specified, it defaults to 1.
- `--maxJstacks {number}`: Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.
- `--collectExpensiveData`: Specifies that data on expensive or long-running processes be collected. These processes aren't collected by default because they impact the performance of a running server.
- `--comment {comment}`: Provides the ability to submit any additional information about the collected data set. The comment is added to the generated archive as a README file.
- `--includeBinaryFiles`: Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- `--adminPassword {adminPassword}`: Specifies the global administrator password used to obtain `dsreplication status` information.
- `--adminPasswordFile {adminPasswordFile}`: Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.
- `--outputPath`: Specifies the path (and optionally, the name) for the support data archive file. If the path specifies a filename, the archive is written to that file. If the path specifies a directory, the file is written into that directory with a server-generated name.
- `--useRemoteServer`: Invokes the tool against a remote server instance and streams the output and resulting support data archive back to the client. This option can be especially useful when the server instance is running in a container because it might otherwise be difficult to invoke commands or access files in that container. More information: `--proxyToServerAddress` and `--proxyToServerPort`.
- `--proxyToServerAddress` and `--proxyToServerPort`: Use these options with `--useRemoteServer` to indicate that the support data archive should be retrieved from a server that is not directly accessible but can be accessed through a PingDirectoryProxy server.
- `--securityLevel`: Specifies the degree to which the tool will attempt to obscure or omit potentially sensitive information. A value of `none` indicates that the tool won't attempt to obscure or redact any information. A value of `obscure-secrets` indicates that the tool will attempt to obscure secret information (like the values of sensitive configuration properties) and omit log files containing user data (like the data recovery log). A value of `maximum` indicates that the tool will take even more drastic measures, such as omitting access log files and obscuring attribute values in entry DNs and search filters, but at the risk of omitting information that could be useful in investigating the associated issue. If this is not provided, a value of `obscure-secrets` will be used by default.

Running the collect-support-data tool

Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

   Example:

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
```

3. Email the `.zip` archive to your Authorized Support Provider.

PingDirectory server troubleshooting information

> **Note**
>
> This topic applies only to the PingDirectory server.

The PingDirectory server has a comprehensive default set of log files and monitor entries that are useful when troubleshooting a particular server problem.

Error log

By default, this log file is available at `logs/errors` below the server install root, and it provides information about warnings, errors, and other significant events that occur within the server. Several messages are written to this file on startup and shutdown, but while the server is running, there is normally little information written to it. However, if a problem occurs, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887 msg="The Directory Server has
started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include: ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, and VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- `DEBUG`: Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, because the server provides a separate debug logging facility.
- `INFORMATION`: Used for informational messages that can be useful from time to time but aren't normally something that administrators need to see.
- `MILD_WARNING`: Used for problems that the server detects, which can indicate something unusual occurred, but the warning doesn't prevent the server from completing the task it was working on. These warnings aren't normally something that should be of concern to administrators.
- `MILD_ERROR`: Used for problems detected by the server that prevented it from completing some processing normally but that aren't considered to be a significant problem requiring administrative action.
- `NOTICE`: Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.

- `SEVERE_WARNING`: Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- `SEVERE_ERROR`: Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- `FATAL_ERROR`: Used for critical problems that might leave the server unable to continue processing operations normally.

The messages written to the error log can be filtered based on their severities. The error log publisher has a `default-severity` property, which can be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE_WARNING, SEVERE_ERROR, and FATAL_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-warning,severe-error,fatal-error
```

For the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities aren't inherently hierarchical, so enabling the DEBUG severity for a category won't automatically enable logging at the INFORMATION, MILD_WARNING, or MILD_ERROR severities.

The error log configuration can be altered on the fly using tools like **`dsconfig`**, the admin console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger can be activated with a different set of default severities to debug a short-term problem, and then that logger can be removed after the problem is resolved so that the normal error log doesn't contain any of the more verbose information.

server.out log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes several messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

Debug log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- `enabled`: Indicates whether debug logging is enabled. By default, it is disabled.
- `log-file`: Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.

- `default-debug-level`: Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- `default-debug-category`: Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

> **Note**
>
> Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Replication repair log

The replication repair log is written to `logs/replication` by default and records information about processing performed by the replication repair service. This log is used to resolve replication conflicts that can arise. For example, if the same entry is modified at the same time on two different systems, or if an attempt is made to create entries with the same DN at the same time on two different systems, the PingDirectory server records these events.

Config audit log and the configuration archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that can be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and audit log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages can also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1" to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"

[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- `origin=replication`: Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- `message`: Text that was included in the `diagnosticMessage` field of the response sent to the client.
- `additionalInfo`: Additional information about the operation that was not included in the response sent back to the client.
- `authDN – DN` of the user that authenticated to the server (typically only included in bind result messages).
- `authzDN – DN` of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- `authFailureID`: Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- `authFailureReason`: Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- `responseOID`: OID included in an extended response returned to the client.
- `entriesReturned`: Number of matching entries returned to the client for a search operation.

- `unindexed=true`: Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here can also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they can contain.

The server provides a second access log implementation called the audit log, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, and so on.

Setup log

The `setup` command writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log`, although a different name might be used if a file with that name already exists because the `setup` command has already been run. The full path to the setup log file is provided when the `setup` command has completed.

Tool log

Many of the administrative tools provided with the server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, and so on) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, `logs/tools/ import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running using the server tasks interface, log messages generated while the task is running can alternately be written to the server error log file.

je.info and je.config files

The primary datastore used by the PingDirectory server is the Oracle Berkeley DB Java Edition (JE). The PingDirectory server provides two primary sources of information about processing within the database. The first is logging performed by the JE code itself, and is written into the

`je.info.0` file in the server containing the database files (for example, `db/userRoot/je.info.0`). In the event of a problem within JE itself, useful information about the nature of the problem can be written to this log. The level of information written to this log file is controlled by the `db-logging-level` property in the backend configuration object. It uses the standard Java logging framework for logging messages, so the standard SEVERE, WARNING, INFO, CONFIG, FINE, FINER, and FINEST levels are available.

The second is configuration information used when opening the database environment. When the backend database environment is opened, then the PingDirectory server will also write a file named `je.config` in the server containing the database files (for example, `db/userRoot/je.config`) with information about the configuration used.

LDAP SDK debug log

This log can be used to help examine the communication between the PingDirectory server and the PingDirectoryProxy server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

Monitor entries

> **Note**
>
> This topic applies only to the PingDirectory server.

While the server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- General Monitor Entry (cn=monitor) – Provides a basic set of general information about the server.
- Active Operations Monitor Entry (cn=Active Operations,cn=monitor) – Provides information about all operations currently in progress in the server.
- Backend Monitor Entries (cn={id} Backend,cn=monitor) – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- Client Connections Monitor Entry (cn=Client Connections,cn=monitor) – Provides information about all connections currently established to the server.
- Connection Handler Monitor Entry (cn={name},cn=monitor) – Provides information about the configuration of each connection handler and the client connections established to it.
- Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor) – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor) – Provides information about the amount of usable disk space available to server components.
- JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor) – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor) – Provides a stack trace of all threads in the JVM.
- LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor) – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor) – Provides information about the number of percent of operations that completed in various response time categories.
- SSL Context Monitor Entry (cn=SSL Context,cn=monitor) – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.

- System Information Monitor Entry (cn=System Information,cn=monitor) – Provides information about the underlying JVM and system.
- Version Monitor Entry (cn=Version,cn=monitor) – Provides information about the server version.
- Work Queue Monitor Entry (cn=Work Queue,cn=monitor) – Provides information about the state of the server's work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

Server troubleshooting tools

The server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

Server version information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the PingDirectory server software that is in use. If the server is running, then this information can be obtained from the "`cn=Version,cn=monitor`" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs several important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

LDIF connection handler

The PingDirectory server provides an LDIF connection handler that provides a way to request operations that don't require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files in the `config/auto-process-ldif` directory. This directory doesn't exist by default, but if you create it and place an LDIF file in it that contains one or more changes to be processed, the LDIF connection handler applies those changes.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

dbtest tool

> **Note**
>
> This topic applies only to the PingDirectory server.

The `dbtest` tool provides a utility that can be used to obtain general information about the data in a backend database. The tool dumps information about entries or keys, and raw data from the database. It can also find keys that have exceeded the entry limit.

For example, the following command can be used to dump a list of all keys in the `objectClass.equality` that have exceeded the entry threshold:

```
$ bin/dbtest dump-database-container \
  --backendID userRoot \
  --baseDN "dc=example,dc=com" \
  --databaseName objectClass.equality \
  --onlyExceedingLimit
```

On a large database, many `dbtest` operations can take a long time to complete, since every record in the associated database is examined. Use the database name option to list a specific database. The following command displays information about the uid.equality database in the `dc=example,dc=com` entry container in the userRoot backend.

```
$ bin/dbtest list-database-containers -n userRoot -b "dc=example,dc=com" -d uid.equality
```

Index key entry limit

> **Note**
>
> This topic applies only to the PingDirectory server.

Indexes have keys that maintain a list of matching entries, up to the index entry limit. When that limit is reached, the key will not contain or maintain that list, and will just maintain a count of matching entries. To determine if index keys are approaching their limit, use either the `dbtest` tool or the `verify-index` tool.

While the `dbtest` tool can be used to gather general imformation, the `verify-index` tool provides statistical data about the percent of entries covered by the keys.

For example, the following command can be used to retrieve a list of keys that have exceeded the entry threshold:

```
$ bin/verify-index \
  --baseDN dc=example,dc=com \
  --listKeysExceedingIndexEntryLimit
```

The following is a sample of the data returned:

```
[12:06:05]  Checked 6003 entries and found 0 error(s) in 2 seconds (average rate 2453.2/sec)
[12:06:05]  Statistics for records that have exceeded the entry limit:
[12:06:05]  The st.equality index has 48 such record(s) limit=100 min=103 max=152 median=118
[12:06:05]  1. or (152 entries / 2.53% of all entries)
[12:06:05]  2. ma (132 entries / 2.20% of all entries)
 .....
[12:06:05]  The id2subtree index has 2 such record(s) limit=4000 min=6000 max=6002 median=6001
[12:06:05]  1. 1 => dc=example,dc=com (6002 entries / 99.98% of all entries)
 .....
[12:06:05]  The id2children index has 1 such record(s) limit=4000 min=6000 max=6000 median=6000
[12:06:05]  1. 2 => ou=People,dc=example,dc=com (6000 entries / 99.95% of all entries)
[12:06:05]  The objectClass.equality index has 4 such record(s) limit=4000 min=6001 max=6003 median=6001
[12:06:05]  1. top (6003 entries / 100.00% of all entries)
 .....
```

Embedded profiler

If the PingDirectory server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the admin console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- `start`: Indicates that the embedded profiler should start capturing data in the background.
- `stop`: Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- `cancel`: Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

Invoking the profile viewer in text-based mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.

  Example:

  ```
  $ bin/profile-viewer --fileName logs/profile.20110101000000Z
  ```

Invoking the profile viewer in GUI mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

  Example:

  ```
  $ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
  ```

Oracle Berkeley DB Java Edition utilities

> **Note**
>
> This topic applies only to the PingDirectory server.

The Oracle Berkeley DB Java Edition (JE) itself provides several utilities that can be used for performing various types of low-level debugging in the database environment. These utilities should generally not be used unless you are advised to do so by your authorized support provider, but they provide access to information about the underlying database environment that is not available through any other means.

Troubleshooting resources for Java applications

Because the Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the PingDirectory server. In many cases, obtaining the full benefit of these tools requires access to the server source code. These Java tools should be used under the advisement of your authorized support provider.

Java troubleshooting tools

The Java Development Kit provides several very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the Server.

jps

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the PingDirectory server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- `-v`: Includes the arguments passed to the JVM for the processes that are listed.
- `-m`: Includes the arguments passed to the main method for the processes that are listed.

- `-l` (lowercase L): Include the fully qualified name for the main class rather than only the base class name.

jstack

The `jstack` tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the Server), and the frame of the stack trace can include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the `jps` command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where `{pathToJava}` is the path to the java command from which the core file was created, and `{pathToCore}` is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The "`-l`" option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The "`-m`" option can be used to include native frames in the stack trace.

jmap

The `jmap` tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native `pmap` tool provided by many operating systems. As with the `jstack` tool, `jmap` can be invoked against a running Java process by providing the process ID, or against a core file , like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- `-dump:live,format=b,file=filename`: Dump the live heap data to a file that can be examined by the `jhat` tool
- `-heap`: Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- `-histo:live`: Provides a count of the number of objects of each type contained in the heap. If the "`:live`" portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

jhat

The `jhat` (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the PingDirectory server encounters an out of memory error (as a result of the "`-XX:+HeapDumpOnOutOfMemoryError`" JVM option) or from the use of the `jmap` command with the "`-dump`" option.

The `jhat` tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the "`-port`" option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax can be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the PingDirectory server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- `-class`: Provides information about class loading and unloading.
- `-compile`: Provides information about the activity of the JIT complex.
- `-printcompilation`: Provides information about JIT method compilation.
- `-gc`: Provides information about the activity of the garbage collector.
- `-gccapacity`: Provides information about memory region capacities.

Java diagnostic information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

JVM crash diagnostic information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the PingDirectory server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

Garbage collection diagnostic information

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with "`bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

Troubleshooting resources in the operating system

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the PingDirectory server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the server, and in others system, tools can help narrow down the cause of the problem.

Identifying problems with the underlying system

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

Examining CPU utilization

Observing CPU utilization for the server process and the system as a whole provides clues as to the nature of the problem.

System-Wide CPU utilization

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

Per-CPU utilization

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add "`-P ALL`" to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

Per-process utilization

To investigate CPU consumption on a per-process basis, use a command such as the `top` utility on Linux. If a process other than the Java process used to run the PingDirectory server is consuming a significant amount of available CPU, it might be interfering with the ability of the server to run effectively.

Examining disk utilization

If the underlying system has a very high disk utilization, it can adversely impact server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool can be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the "`-x`" argument, like:

```
iostat -x 5
```

Several different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the "%util" column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

Examining process details

There are several tools provided by the operating system that can help examine a process in detail.

ps

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

pstack

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

dbx / gdb

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

pfiles / lsof

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems:

```
lsof -p {processID}
```

Tracing process execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file might be available).

This can be accomplished using the `strace` tool on Linux:

```
strace -f -p {processID}
```

Consult the `strace` manual page for additional information.

Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Examining network communication

Because the server is a network-based application, it can be valuable to observe the network communication that it has with clients. The server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there can be several cases in which it is useful to view information at a much lower level. A network sniffer, like the tcpdump tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using "`-w {path}`" with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore can require root access.

Common problems and potential solutions

This section describes several different types of problems that can occur and common potential causes for them.

General troubleshooting methodology

When a problem is detected, the following general methodology to isolate the problem are recommended.

1. Run the `bin/status` tool or look at the server status in the admin console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
    - logs/errors
    - logs/failed-ops
    - logs/expensive-ops
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the Data Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

> **Important**
>
> Run the **`collect-support-data`** tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

The server will not run setup

If the `setup` tool does not run properly, some of the most common reasons include the following.

A suitable Java environment is not available

The server requires that Java be installed on the system and made available to the server, and it must be installed before running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Oracle Berkeley DB Java Edition is not available

> **Note**
>
> This topic applies only to the PingDirectory server.

If the version of the server that you are using was not provided with the Oracle Berkeley DB Java Edition library, then it must be manually downloaded and the appropriate JAR file placed in the `lib` directory before running setup. See the `lib/downloading-je.txt` file for instructions on obtaining the appropriate library.

Unexpected arguments provided to the JVM

If the `setup` script attempts to launch the java command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running setup, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The server has already been configured or used

The `setup` tool is only intended to provide the initial configuration for the server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the server before running the `setup` tool. This protects an existing server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

The server will not start

If the server does not start, then there are several potential causes.

The server or other administrative tool is already running

Only a single instance of the server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Diretory Server could not acquire an exclusive lock on file
/ds/the/locks/server.lock: The exclusive lock requested for file
/ds/the/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

There is not enough memory available

When the server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are several potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the server, or reconfigure the server to reduce the amount of memory that it attempts to use.
- The server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

An invalid Java Environment or JVM option was used

If an attempt to start the server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value might override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the **`bin/dsjavaproperties`** tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the **`bin/dsjavaproperties`** tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the **`bin/dsjavaproperties`** tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

An invalid command-line option was provided

There are a small number of arguments that are provided when running the **`bin/start-server`** command, but in most cases, none are required. If one or more command-line arguments were provided for the **`bin/start-server`** command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

The server has an invalid configuration

If a change is made to the server configuration using an officially-supported tool like `dsconfig` or the admin console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and several configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

> **Note**
>
> In addition to manually-editing the configuration file, you can look at previous archived configurations to see if the most recent one works. You can also use the **`ldif-diff`** tool to compare the configurations in the archive to the current configuration to see what is different.

You do not have sufficient permissions

The server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the server installation, so that they are owned by the user or role under which the server should run. For example, if the server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/the
```

The server has crashed or shut itself down

You can first check the current server state by using the `bin/server-state` command. If the PingDirectory server was previously running but is no longer active, then the potential reasons include the following:

- The PingDirectory server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The PingDirectory server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The PingDirectory server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The PingDirectory server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.
- The JVM in which the PingDirectory server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

Conditions for automatic server shutdown

All PingDirectory servers will shut down in an out of memory condition, a low disk space error state, or for running out of file descriptors. The server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
            --set unrecoverable-database-error-mode:initiate-server-shutdown
```

The server won't accept client connections

You can first check the current server state by using the `bin/server-state` command. If the server doesn't appear to be accepting connections from clients, then potential reasons include the following:

- The server isn't running.
- The underlying system on which the server is installed isn't running.
- The server is running but isn't reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it doesn't already exist, and then copy the LDIF file into it.

The server is unresponsive

You can first check the current server state by using the `bin/server-state` command. If the server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

If it appears that the problem is with the server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

  A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

> **Note**
>
> If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which might not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (because of garbage collection). The alert will include details of the pause.
- If the JVM in which the server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the server is running are not receiving TCP acknowledgement.
- If the system on which the server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

The server is slow to respond to client requests

If the server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to several potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the server. The Periodic Stats Logger can save the information in csv format for easy viewing in a spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the admin console to see the server's Work Queue information (also see the next bullet point).

- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```
           --- Work Queue ---
           : Recent : Average : Maximum
-----------:--------:---------:--------
Queue Size : 10   : 1       : 10
% Busy     : 17     : 14      : 100
```

  You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.

- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected several pauses and can include tuning recommendations to help alleviate the problem.

- If the server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if swappiness is not set to 0 on Linux. For more information, see Disable File System Swapping.

- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

The server returns error responses to client requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.

- If a portion of the PingDirectory server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update PingDirectoryProxy servers or load balancers or both to route requests away from the affected server. As of PingDirectory version 3.1 or later, the PingDirectory server will indicate that it is in a degraded status and the PingDirectoryProxy server will route around it.
- If the PingDirectory server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and re-opened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

The server must disconnect a client connection

If a client connection must be disconnected because of the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager"  \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for `(description=expensive)`, which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3 msgID=4
     clientIP="10.8.4.21" authDN="cn=app1,ou=applications,dc=example,dc=com" base="dc
     =example,dc=com" scope=wholeSubtree filter="(description=expensive)" attrs="A
     LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1 msgID=2
     clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root DNs,cn=config" base="c
     n=monitor" scope=wholeSubtree filter="(cn=active operations)" attrs="ALL"
     num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named `disconnect6.ldif`.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name: com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to `ds-task-disconnect-connection-id`. The value for `ds-task-id` value does not follow a specific convention. It must be unique among other task entries currently cached by the server.

- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif  \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

The server is experiencing problems with replication

> **Note**
>
> This topic applies only to the PingDirectory server.

If replication does not appear to be functioning properly, then first check the `dsreplication status` command, which shows all of the servers that are replicating and whether they are back-logged or not. Next, you can check the server error log, replication repair log, and replication monitor entries might provide information about the nature of the underlying problem. Potential reasons that replication might not be functioning as expected include the following:

- Replication has not yet been configured between systems or has been disabled.

- If a server has been offline for a period of time or has fallen far enough behind such that it is missing changes, which are no longer present in any of the replication databases, then that server must be re-initialized with an up-to-date copy of the data from another server.
- If the environment is comprised of a heterogeneous set of systems, then it is possible that some of the systems might not be able to keep up with the maximum throughput achieved by other servers in the topology. In such cases, the slower servers might not be fast enough to remain in sync with the other servers in the environment.
- If the environment contains systems in multiple data centers and the network links between the data centers are insufficient for the volume of changes that must be processed, then servers might not be able to remain in sync under a high volume of changes.
- A network or firewall configuration problem has arisen, which prevents or interferes with communication between servers.
- An internal problem within the server has caused replication to stop functioning properly. The PingDirectory server logs the event in the error log in this case. Run the `collect-support-data` tool, so that the details of the problems can be passed to your authorized support provider. Then, try restarting the server.

How to regenerate the server ads-certificate

> **Note**
>
> This topic applies only to the PingDirectory server.

At setup time, the server generates a private key and certificate for use when secure communication between servers is required. This certificate, `ads-certificate`, is stored in `config/ads-truststore` and should typically remain unchanged for the life of the server deployment. If the need arises for a new ads-certificate to be created, say because the server-root has been copied to a new host, then the private key and certificate will be recreated by the startup process if the `config/ads-truststore` and `config/ads-truststore.pin` files are first manually removed while the server is offline. Note that if replication is enabled, the server must have replication disabled before regeneration of the ads-certificate.

For example, the server allows easy copying of its installation, which can then be used to install another server instance. If a server (ldap1.example.com:389) is enabled with its own copy (ldap2.example.com:389), `dsreplication` will exit with the following error message:

```
Replication cannot be enabled between servers ldap1.example.com:389 and ldap2.example.com:389
because they are using the same instance key.
```

The solution is to stop the server, remove `config/adstruststore` and `config/adstruststore.pin` and re-start the server. Upon startup, a new `adstruststore`, containing the server's instance key, will be generated. Then, you can re-run `dsreplication enable` to set up replication between the two servers.

The server behaves differently from Sun/Oracle

> **Note**
>
> This topic applies only to the PingDirectory server.

After migrating from a Sun/Oracle configuration to a PingDirectory server, follow the tuning procedures in Configuring the PingDirectory server for Oracle compatibility if the PingDirectory server behaves differently from the Sun/Oracle server.

Troubleshooting ACI evaluation

> **Note**
>
> This topic applies only to the PingDirectory server.

The server provides the ability to collect debug information related to ACI evaluation for any operation by enabling the Debug ACI Logger. The Debug ACI Logger is highly configurable and can be scoped to trace very specific request operations in order to narrow on any ACI issue that might arise in the field. Parameters for non-request operations, such as `log-connects`, `log-disconnects`, `log-security-negotiation`, `log-results`, `log-assuance-completed`, `log-search-entries`, `log-search-references`, `log-intermediate-responses` are set to `false` by default and should remain so.

Here is an example to enable the Debug ACI Logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set enabled:true
```

Using this debug tracer is often more efficient by limiting the output using request and result criteria to match specific types of operations. An example result criteria for operations that fail because of insufficient access rights can be added to the logger as follows:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set "result-criteria:Insufficient Access Rights"
```

After the logger has been enabled, all matching operations begin writing ACI evaluation traces to the log file. The amount of information is quite large for each evaluation that is done. However, this information is useful if there is an ACI issue that is difficult to resolve. Most operations result in multiple "ACI DEBUG" traces in the log, since it usually requires multiple ACI rights to perform an operation, each of which requires a separate evaluation. In particular, you can expect a lot of debug tracing when dealing with ACIs for controls, extended operations, and proxied authorization.

The ACI DEBUG traces contain the following pieces of information:

Operation

Specifies a dump of the operation object that you can use to correlate to the original request operation.

ACI Container

Specifies the context of the ACI evaluation being performed.

Client Entry

Specifies an LDIF dump of the client request access.

Resource Entry

Specifies an LDIF dump of the target resource.

isProxiedAuth

Specifies if the client is attempting to proxy as another user.

Original Auth

Specifies the original client DN if authorization is currently via the proxy.

Rights

Specifies a list of the ACI rights being requested on the resource entry.

Control

Specifies the OIDs when evaluating ACIs for a control.

ExtOp

Specifies the OIDs when evaluating ACIs for an extended operation.

ACI Candidates

Specifies a list of all the ACIs known to this operation, sorted by origin.

Applicable ACIs

Specifies a list of ACIs relevant to the current evaluation. These ACIs are separated by type into "Denies" and "Allows".

Deny ACI Evaluations

Specifies the results of evaluating each "deny" ACI. If any of these evaluate to TRUE, then the operation will be denied.

Allow ACI Evaluations

Specifies the results of evaluating each "allow" ACI. At least one of these must evaluate to TRUE or the operation will be denied.

For users with the `bypass-acl` privilege, the Debug ACI Logger will not provide any ACI debug tracing since evaluations are not done for those operations. However, you will see the following trace if you have ACI debugging enabled (`debug-aci-enabled` is set to TRUE) for those operations:

```
Bypassing ACL Evaluation for Operation
```

To avoid unnecessary tracing of these operations, the "Debug ACI Logger" uses a "Client Connection Criteria" called "Clients subject to Access Control" that excludes requests from users with the `bypass-acl` privilege. It is recommended that you create and use your own criteria which specifically targets the clients that you are trying to debug in order to make analyzing the tracing output easier.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Restricted Clients" \
  --type simple \
  --set none-included-user-privilege:bypass-acl
```

Note

Do not use Result Criteria with the Debug ACI Logger. Result criteria is evaluated after ACIs, so it will not be taken into consideration for this type of debugging.

Problems with the admin console

If a problem arises when trying to use the admin console, then potential reasons for the problem can include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target PingDirectory server is online. If it is online, then the access log can provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the PingDirectoryProxy server instance using the admin console, then the access and error logs for that PingDirectory server instance might provide additional information about the underlying problem.

Problems with the admin console: JVM memory issues

Console runs out of memory (PermGen). An inadequate PermSize setting in the server, while hosting web applications like the admin console can result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
    severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
    error. Please report this problem and include this log file.
    OutOfMemoryError: PermGen space
    ()\ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
    (DirectoryServer.java:15783)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1057)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.ThreadGroup.uncaughtException
    (ThreadGroup.java:1052)\njava.lang.Thread.dispatchUncaughtException
    (Thread.java:1986)\nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

Troubleshooting global index growing too large

If the global index appears to be growing too large, you can reload from the backend directory servers.

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

Steps

- To override the configuration of the `prime-index-source` property, run the `reload-index` tool with the `--fromDS` subcommand.

  Example:

  You can do this on a one-off basis if the global index appears to be growing too large.

  ```
  $ bin/reload-index \
    --bindPassword password \
    --baseDN "dc=example,dc=com" \
    --fromDS
  ```

Recovering forgotten Proxy User password

If you forget your `cn=Proxy User` password, you can recover it using different methods.

About this task

> **Note**
>
> This topic applies only to the PingDirectoryProxy server.

Steps

- To recover your password, do any of the following:

  Choose from:

  - The PingDirectory server supports a feature called password retirement that allows you to set a new password while allowing the current password to remain usable for a specified period of time. This can be used to set a new password for the account while still allowing the current password to remain temporarily available so that existing PingDirectoryProxy server instances will still be able to use the current password to authenticate until you can update them with the new password. To enable password retirement, update the `password-retirement-behavior` property in the root password policy for all PingDirectory server instances to include a value of `retire-on-administrative-reset`, and set the `max-retired-password-age` property to indicate how long you want the current password to remain valid after setting a new password. Then, reset the Proxy User password for all of the PingDirectory server instances, and update all of the PingDirectoryProxy server instances to use the new password in their LDAP external server configuration.
  - If you do not know the clear-text value for the password but you have other PingDirectoryProxy server instances set up to use that password, then you can use the encoded password value from the LDAP external server configuration entry of one of the existing PingDirectoryProxy servers when creating the LDAP external server for new PingDirectoryProxy server instances.

- Create a new root user in the directory server instances with the appropriate set of privileges and have the new PingDirectoryProxy server instance use that account to authenticate. To use the new account, update all of the other PingDirectoryProxy instances.

Problems with the HTTP Connection Handler

> **Note**
>
> This topic applies only to the PingDirectory server.

When problems with the HTTP Connection Handler occur, first look at the HTTP connection handler log to diagnose the issue. The following section shows HTTP log examples when various errors occur.

- Failed Request Due to a Non-Existent Resource. The server receives a status code 404, which indicates the server could not match the URI.

```
[15/Mar/2012:17:39:39 -0500] RESULT requestID=0 from="10.2.1.113:52958"
method="GET" url="https://10.2.1.113:443/Aleph/Users/uid=user.1,ou=people,
dc=example,dc=com" requestHeader="Host: x2270-11.example.lab"
requestHeader="Accept: / " requestHeader="User-Agent: curl/7.21.6
(i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22
libssh2/1.2.7" authorizationType="Basic" statusCode=404 etime=81.484
responseContentLength=103 responseHeader="Access-Control-Allow-Credentials:true"
responseContentType="application/json"
```

- Failed Request due to a Malformed Request Body. The server receives a status code 400, which indicates that the request had a malformed syntax in its request body.

```
[15/Mar/2012:17:47:23-0500] RESULT requestID=10 from="10.2.1.113:55284"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: / " requestHeader="Content-Type: application/json"
requestHeader="User-Agent: curl/ 7.21.6 (i386-pc-centos2.10) libcurl/7.21.6
OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7" authorizationType="Basic"
requestContentType="application/json" requestContentLength=5564 statusCode=400
etime=15.272 responseContentLength=133 responseContentType="application/json"
```

- Failed Request due to an unsupported HTTP method. The server receives a status code 405, which indicates that the specified method (for example, "PATCH") in the request line is not allowed for the resource identified in the URI.

```
[15/Mar/2012:17:48:59-0500] RESULT requestID=11 from="10.2.1.113:55763"
method="PATCH" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: / " requestHeader="Content-Type:
application/json" requestHeader="User-Agent: curl/7.21.6 (i386-pc-centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorization-Type="Basic" requestContentType="application/json" statusCode=405
etime=6.807 responseContentLength=0 responseHeader="Allow: POST, GET, OPTIONS, HEAD"
```

- Failed Request due to an Unsupported Media Type. The server receives a status code 415, which indicates that the request entity is in a format that is not supported by the requested resource.

```
[15/Mar/2012:17:44:45-0500] RESULT requestID=4 from="10.2.1.113:54493"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: / " requestHeader="Content-Type:
application/atom+xml" requestHeader="User-Agent: curl/7.21.6 (i386-pc-centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/atom+xml"
requestContentLength=3 statusCode=415 etime=6.222 responseContentLength=1402
responseHeader="Cache-Control: must-revalidate,no-cache,no-store"
responseContentType="text/html;charset=ISO-8859-1"
```

- Failed Request due to an Authentication Error. The server receives a status code 401, which indicates that the request requires user authentication.

```
[15/Mar/2012:17:46:06-0500] RESULT requestID=8 from="10.2.1.113:54899"
method="GET" url="https://10.2.1.113:443/Aleph/Schemas" requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: / " requestHeader="User-Agent:
curl/7.21.6 (i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5
libidn/1.22 libssh2/ 1.2.7" authorizationType="Basic" statusCode=401
etime=2.751 responseContentLength=63 responseHeader="WWW-Authenticate: Basic
realm=SCIM" responseHeader="Access-Control-Allow-Credentials: true"
responseContentType="application/json"
```

Virtual process size on RHEL6 Linux is much larger than the heap

> **Note**
>
> This topic applies only to the PingDirectory server.

Red Hat Linux introduced a change in glib 2.11 that creates larger per-thread address spaces aligned at 64MB. This change results in a virtual process size much larger than those seen in previous versions of `glibc`. This is not considered a bug by RedHat, as noted in https://bugzilla.redhat.com/show_bug.cgi?id=640286, and does not affect the physical memory needed by the server process. To see the version of `glibc` on your system, use the command `yum info glibc`.

Providing information for support cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel might need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

Troubleshooting the PingDataSync server

There are several ways to troubleshoot issues with the PingDataSync server.

This section contains the following topics:

PingDataSync gauges

The PingDataSync server provides several built-in gauges to monitor PingDataSync performance. These gauges are listed in the following table:

Directory Server Gauges

Gauge Name	Enabled by default?	Description
Available File Descriptors	true	Monitors the number of file descriptors available to the server process. The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. The number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTORS` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as `NUM_FILE_DESCRIPTORS=12345`. If these are not set, the default of 65535 is used. Running out of available file descriptors can lead to unpredictable behavior and severe system instability.

Gauge Name	Enabled by default?	Description
Certificate Expiration (Days)	true	Monitors the expiration dates of key server certificates. A server certificate expiring can cause server unavailability, degradation, or loss of key server functionality. Certificates nearing the end of their validity should be replaced as soon as possible. See the status tool, or Status in the admin console, for more information about server certificates and how they are managed.
CPU Usage (Percent)	true	Monitors server CPU use and provides an averaged percentage for the interval defined. The monitored resource is the host system's CPU, which does not include a resource identifier. If CPU use is high, check the server's current workload and other processes on this system and make any needed adjustments. Reducing the load on the system will lead to better response times.
Destination Unavailable Seconds	true	Gauge that raises an alarm if the Sync Destination is not available.
Disk Busy (Percent)	true	Monitors the percentage of disk use time averaged over the specified update interval. This gauge requires that the Host System Monitor Provider be enabled and that any monitored disks be registered using the disk-devices property of that configuration object. The resource identifier for this gauge is the disk device name. Use the `iostat` command or a similar system utility to see a list of disk device names. A separate gauge monitor entry will be created for each monitored disk.
HTTP Processing (Percent)	true	Monitors the percentage of time that request handler threads spend processing HTTP requests. This percentage represents the inverse of the server's ability to handle new requests without queuing.
JVM Memory Usage (Percent)	true	Monitors the percentage of Java Virtual Machine (JVM) memory that is in use. This value naturally fluctuates because of garbage collection, so the minimum value within an interval is reported since it is a better indication of overall memory growth. When the memory usage exceeds 90%, this should be reported to customer support since the server is either misconfigured or has a memory leak. As memory usage approaches 100%, the server is more and more likely to experience garbage collection pauses, which leave the server unresponsive for a long time. Restarting the server is likely the only remedy for this situation. Before restarting the server, run `collect-support-data` and capture the output of 'jmap -histo ' to provide to customer support. The pid of the server can be found from `/logs/server.pid`.

Gauge Name	Enabled by default?	Description
License Expiration (Days)	true	Monitors the expiration date of the product license. An expired license will cause warnings to appear in the server's logs and in the status tool output. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com. Use the dsconfig tool to update the License configuration's license key property.
Memory Usage (Percent)	false	Monitors the percentage of memory use averaged over the update interval defined. The monitored resource is the host system's memory use, which does not have a resource identifier. Some operating systems, including Linux, use the majority of memory for file system cache, which is freed as applications need it. If memory use is high, check the applications that are running on the server.
Strong Encryption Not Available	true	The JVM does not appear to support strong encryption algorithms, like 256-bit AES. The server will fall back to using weaker algorithms, like 128-bit AES. To enable support for strong encryption, update your JVM to a newer version that supports it by default, or install or enable the unlimited encryption strength jurisdiction policy files in your Java installation.

PingDataSync log files

The following log files are specific to PingDataSync, and contain details about the synchronization processes:

Sync Log

Provides information about the synchronization operations that occur within the server. Specifically, the Sync Log records all changes applied, detected or failed; dropped operations that were not synchronized; changes dropped because of being out of scope, or no changes needed for synchronization. The log also shows the entries that were involved in the synchronization process.

Sync Failed Operations Log

Provides a list of synchronization operations that have failed.

Resync Log

Provides summaries or details of synchronized entries and any missing entries in the Sync Destination.

Resync Error Log

Provides error information for `resync` operations.

Management tools

Each PingDirectory server provides command-line tools to manage, monitor, and diagnose server operations. Each tool provides a description of the subcommands, arguments, and usage examples needed to run the tool.

> **Note**
>
> For detailed information and examples of the command-line tools, see the Configuration Reference Guide in the `<server-root>/docs` directory, or linked from the admin console.

To view detailed argument options and examples, use `--help` with the each tool:

```
$ bin/dsconfig --help
```

For those utilities that support additional subcommands (such as `dsconfig`), list the subcommands with the following:

```
$ bin/dsconfig --help-subcommands
```

View more detailed subcommand information by using `--help` with the specific subcommand:

```
$ bin/dsconfig list-log-publishers --help
```

The status tool

The `status` tool outputs the health of the server. It polls the current health of the server and displays summary information about the number of operations processed in the network. The tool provides the following information:

Status tool sections

Status section	Description
Server Status	Displays the server start time, operation status, number of connections (open, max, and total).
Server Details	Displays the server details including host name, administrative users, install path, server version, and Java version.
Connection Handlers	Displays the state of the connection handlers including address, port, protocol and current state.
Admin Alerts	Displays the 15 administrative alerts that were generated over the last 48-hour period. Limit the number of displayed alerts using the `--maxAlerts` option. For example, status `-- maxAlerts 0` suppresses all alerts.

The collect-support-data tool

About this task

PingDataSync servers provide information about their current state and any problems encountered. If a problem occurs, run the `collect-support-data` tool in the `/bin` directory. The tool aggregates all relevant support files into a `.zip` file that can be sent to a support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools for the operating system.

The tool might only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool can vary between systems. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Steps

1. Go to the server root directory.
2. Run the `collect-support-data` tool. Include the host, port number, bind distinguished name (DN), and bind password.

```
$ bin/collect-support-data \
--hostname 100.0.0.1 --port 389 \
--bindDN "cn=Directory Manager"
--bindPassword secret
```

3. Email the `.zip` file to a support provider.

The Sync log

The Sync log, located in the logs directory (`<server-root>/logs/sync`), provides useful troubleshooting information on the type of operation that was processed or completed. Most log entries provide the following common elements in their messages.

Sync log elements

Sync log element	Description
category	Indicates the type of operation, which will always be SYNC.
severity	Indicates the severity type of the message: INFORMATION, MILD_WARNING, SEVERE_WARNING, MILD_ERROR, SEVERE_ ERROR, FATAL_ERROR, DEBUG, or NOTICE.
msgID	Specifies the unique ID number assigned to the message.
op	Specifies the operation number specific to PingDataSync.
changeNumber	Specifies the change number from the source server assigned to the modification.

Sync log element	Description
replicationCSN	Specifies the replication change sequence number from the source server. **Note** This only appears if the change on the source server was made through replication.
replicaID	Specifies the replica ID from the source server if there are multiple backend databases.
pipe	Specifies the Sync Pipe that was used for this operation.
msg	Displays the result of this operation.

Sync log example 1

The following example displays an informational message that a modification to an entry was detected on the source server.

```
[17/Nov/2021:15:57:39.562 -0600] category=SYNC severity=INFORMATION msgID=1893728293 op=7
changeNumber=59 pipe="ds1_to_PingOne_Destination" msg="Detected MODIFY of
uid=user.0,ou=People,dc=example,dc=com at ldap://localhost:1389"
```

Sync log example 2

The next example shows another synchronization operation. This was triggered by a `MODIFY` operation on the source server and was successfully synchronized to the destination.

```
[17/Nov/2021:16:22:30.096 -0600] category=SYNC severity=INFORMATION msgID=1893728306 op=8
changeNumber=60 pipe="ds1_to_PingOne_Destination" class="ds1 Users Sync Class"
msg="Synchronized ADD of uid=user.2,ou=People,dc=example,dc=com at ldap://localhost:1389
by modifying entry id=32659530-3c8c-4f9d-be77-390293087532 (after MODDN, new RDN: uid=user.2)
at https://api.pingone.com/v1"
```

Sync log example 3

The next example shows a failed synchronization attempt on a `MODIFY` operation from the source server that could not be synchronized on the destination server. The log displays the LDAP Data Interchange Format (LDIF)-formatted modification that failed, where the source server added two additional `mobilePhone` values for an entry. This would cause a schema violation on the destination server because the destination (in this example, PingOne) only allows a single value for `mobilePhone`.

```
[17/Nov/2021:15:56:39.294 -0600] category=SYNC severity=SEVERE_WARNING msgID=1893859389 op=6
changeNumber=58 pipe="ds1_to_PingOne_Destination" class="ds1 Users Sync Class"
msg="Detected MODIFY of uid=user.0,ou=People,dc=example,dc=com at ldap://localhost:1389,
but failed to apply this change because: Attribute 'mobilePhone' has 3 values in the entry so
the value cannot be constructed since a single value is required
(id=1893859350 ResourceOperationFailedException.java:126 9.0.0.0-20211117202405.000Z-0bc8a906).

Troubleshooting synchronization failures

The majority of synchronization problems involve the connection state of the external servers and the synchronization of the data between the two endpoints. Make sure PingDataSync can properly fail over to another endpoint or server instance if the connection fails on the highest priority external server.

Another factor in troubleshooting synchronization is determining if the distinguished name (DN) and attribute mappings were properly configured and if the information is properly being synchronized across the network. Typical scenarios include checking for any entry failures and mapping issues.

> **Note**
>
> Use the **resync** tool to validate Sync Classes and data mappings from one endpoint to another. The tool provides a `dry-run` option that verifies data operations without actually affecting the data.

While many PingDataSync issues are deployment-related and are directly affected by the hardware, software, and network structure used in the synchronization topology, most failures usually fall into one of the following categories:

Entry Already Exists

When an add operation was attempted on the destination server, an entry with the same DN already exists.

No Match Found

A match was not found at the destination based on the current Sync Classes and correlation rules (DN and attribute mapping). When this value has a high count, correlation rule problems are likely.

Failure at Resource

Indicates that some other error happened during the synchronization process that does not fall into the first two categories. Typically, these errors are communication problems with a source or destination server.

Statistics for these and other types of errors are kept in the `cn=monitor` branch and can be viewed directly using the **status** command.

Troubleshooting "Entry Already Exists" failures

About this task

If there is a count for the `EntryAlready Exists` statistic using the **status** tool, verify the problem in the sync log. For example, the **status** tool displays the following information:

```
          --- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result              : Count
-----------------------:------
Success                : 0
Out Of Scope           : 0
Op Type Not Synced     : 0
No Change Needed       : 0
Entry Already Exists   : 1
No Match Found         : 1
Multiple Matches Found : 0
Failed During Mapping  : 0
Failed At Resource     : 0
Unexpected Exception   : 0
Total                  : 2
```

Verify the change by viewing the `<server-root>/logs/sync` file to see the specific operation, which could be caused by someone manually adding the entry on the target server:

```
op=2 changeNumber=529277 replicationCSN=00000128AD0D9BA01E960008137D
replicaID=7830
pipe="DS1 to DS2" class="DEFAULT" msg="Detected ADD of
uid=user.1001,ou=People,
dc=example,dc=com at ldap://server1.example.com:1389, but cannot create this
entry at the destination because an equivalent entry already exists at
ldap://server3.
example.com:3389. Details: Search using [search-criteria dn:
uid=user.1001,ou=People,
dc=example,dc=com attrsToGet: [*, dn]] returned results;
[uid=user.1001,ou=People,
dc=example,dc=com]. "
```

Perform the following steps to troubleshoot this type of problem:

Steps

1. Assuming that a possible DN mapping is ill-formed, first run the `ldap-diff` utility to compare the entries on the source and destination servers. Then look at the `ldap-diff` results with the mapping rules to determine shy the original search did not find a match.

   ```
   $ bin/ldap-diff \
     --outputLDIF config-difference.ldif \
     --baseDN "dc=example,dc=com" \
     --sourceHost server1.example.com \
     --targetHost server2.example.com \
     --sourcePort 1389 \
     --targetPort 3389 \
     --sourceBindDN "cn=Directory Manager" \
     --sourceBindPassword password \
     --searchFilter "(uid=1234)"
   ```

2. Review the destination server access logs to verify the search and filters used to find the entry. Typically, the key correlation attributes are not synchronized.
3. If the mapping rule attributes are not synchronized, review the Sync Classes and mapping rules, and use the information from the `ldap-diff` results to determine why a specific attribute might not be getting updated. Some questions to answer are as follows:
    - Is there more than one Sync Class that the operation could match?
    - If using an `include-base-dn` or `include-filter` in the mapping rules, does this exclude this operation by mistake?
    - If using an attribute map, are the mappings correct? Usually, the cause of this error is in the destination mapping attribute settings. For example, if a set of correlation attributes is defined as: `dn`, `mobile`, `accountNumber`, and the `accountNumber` changes for some reason, future operations on this entry will fail. To resolve this, either remove `accountNumber` from the rule, or add a second rule as: `dn,mobile`. The second rule is used only if the search using the first set of attributes fails. In this case, the entry is found and the `accountNumber` information is updated.
4. If deletes are being synchronized, check to see if there was a previous delete of this entry that was not synchronized properly. In some cases, simpler logic should be used for deletes because of the available attributes in the change logs. This scenario could cause an entry to not be deleted for some reason, which would cause an issue when a new entry with the same DN is added later. Use this information for mapping rules to see why the original search did not find a match.
5. Look at the destination directory server access logs to verify the search and filters it used to find the entry. Typically, the key attribute mappings are not synchronized.

Troubleshooting "No Match Found" failures

About this task

If there is a count for the No Match Found statistic using the `status` tool, verify the problem in the sync log. For example, if the `status` tool displays the following:

```
           --- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result              : Count
-----------------------:------
Success                : 0
Out Of Scope           : 0
Op Type Not Synced     : 0
No Change Needed       : 0
Entry Already Exists   : 1
No Match Found         : 1
Multiple Matches Found : 0
Failed During Mapping  : 0
Failed At Resource     : 0
Unexpected Exception   : 0
Total                  : 2
```

Verify the change in the `<server-root>/logs/sync` file to see the specific operation:

```
[12/May/2016:10:30:45 -0500] category=SYNC severity=MILD_WARNING
msgID=1893793952
op=4159648 changeNumber=6648922 replicationCSN=4beadaf4002f21150000
replicaID=8469-
ou=test,dc=example,dc=com pipe="DS1 to DS2" class="Others" msg="Detected
DELETE of
'uid=1234,ou=test,dc=example,dc=com' at ldap://server1.example.com:389, but
cannot
DELETE this entry at the destination because no matching entries were found at
ldap://
server2.example.com:389. Details: Search using [search-criteria dn:
uid=1234,ou=test,dc=alu,dc=com filter: (nsUniqueId=3a324c60-5ddb11df-80ffe681-
717b93af) attrsToGet: [*, accountNumber, dn, entryuuid, mobile, nsUniqueId,
object-
Class]] returned no results."
```

Perform the following steps to fix the issue:

Steps

1. Test the search using the filter in the error message, if displayed. For example, if the sync log specifies `filter: (nsUniqueId=3a324c60-5ddb11df-80ffe681-717b93af)`, use the `ldapsearch` tool to test the filter. If it is successful, is there anything in the attribute mappings that would exclude this from working properly?
2. Test the search using the full DN as the base. For example, use `ldapsearch` with the full DN `(uid=1234,ou=People,dc=example,dc=com)`. If it is successful, does the entry contain the attribute used in the mapping rule? If the attribute is not in the entry, determine if there is a reason why this value was not synchronized. Look at the attribute mappings and the filters used in the Sync Classes.

Troubleshooting "Failed at Resource" failures

About this task

If there is a count for the "Failed at Resource" statistic using the `status` tool, verify the problem in the sync log. For example, if the `status` tool displays the following information:

```
            --- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result              : Count
-----------------------:------
Success                : 0
Out Of Scope           : 0
Op Type Not Synced     : 0
No Change Needed       : 0
Entry Already Exists   : 0
No Match Found         : 0
Multiple Matches Found : 0
Failed During Mapping  : 0
Failed At Resource     : 1
Unexpected Exception   : 0
Total :1
```

This will register after a change is detected at the source in any of the following cases:

- If the fetch of the full source entry fails. The entry exists but there is a connection failure, server down, timeout, or something similar.
- If the fetch of the destination entry fails or if the modification to the destination fails for an exceptional reason (but not for "Entry Already Exists," "Multiple Matches Found," or "No Match Found" issues).

Verify the change by viewing the `<server-root>/logs/sync` file to see the specific operation. If any of the following result codes are listed , the server is experiencing timeout errors:

- `resultCode=timeout: errorMessage=A client-side timeout was encountered while waiting 60000ms for a search response from server server1.example.com:1389`
- `resultCode=timeout: errorMessage=An I/O error occurred while trying to read the response from the server`
- `resultCode=server down: errorMessage=An I/O error occurred while trying to read the response from the server`
- `resultCode=server down: errorMessage=The connection to server server1.example.com:1389 was closed while waiting for a response to search request SearchRequest`
- `resultCode=object class violation: errorMessage='Entry device=1234,dc=example,dc=com violates the Directory Server schema configuration because it contains undefined object class`

With these "Failure at Destination" timeout errors, look at the following settings in the PingDirectory server to determine if adjustments are needed:

Steps

1. For External Server Properties, check the connect-timeout property. This property specifies the maximum length of time to wait for a connection to be established before giving up and considering the server unavailable.
2. For the Sync Destination/Sync Source Properties, check the `response-timeout` property. This property specifies the maximum length of time that an operation should be allowed to be blocked while waiting for a response from the server. A value of zero indicates that there should be no client-side timeout. In this case, the server's default will be used.

```
$ bin/dsconfig --no-prompt --port 389 \
  --bindDN "cn=Directory Manager" \
  --bindPassword password list-external-servers \
  --property connect-timeout
```

```
External Server         : Type             : connect-timeout : response-
                                                               timeout
------------------------:------------------:-----------------:-----------
server1.example.com:389 : sundsee-ds       : 10 s            : -
server2.example.com:389 : sundsee-ds       : 10 s            : -
server3.example.com:389 : ping-identity-ds : 10 s            : -
server4.example.com:389 : ping-identity-ds : 10 s            : -
```

3. For Sync Pipe Properties, check the `max-operation-attempts`, `retry-backoff-initialwait`, `retry-backoff-max-wait`, `retry-backoff-increase-by`, `retry-backoff-percentage-increase`. These Sync Pipe properties provide tuning parameters that are used in conjunction with the timeout settings. When a Sync Pipe experiences an error, it will use these settings to determine how often and quickly it will retry the operation.

```
$ bin/dsconfig --no-prompt list-sync-pipes \
  --property max-operation-attempts --property retry-backoff-initial-wait
\
  --property retry-backoff-max-wait --property retry-backoff-increase-by \
  --property retry-backoff-percentage-increase \
  --port 389 --bindDN "cn=Directory Manager" \
  --bindPassword password
```

Installation and maintenance issues

The following are common installation and maintenance issues and possible solutions.

The setup program will not run

If the `setup` tool does not run properly, some of the most common reasons include the following.

A Java environment is not available

The server requires that Java be installed on the system before running the `setup` tool.

If there are multiple instances of Java on the server, run the `setup` tool with an explicitly defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation. For example:

```
$ env JAVA_HOME=/ds/java ./setup
```

Another issue might be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, use the following command to override any other environment variables:

```
$ env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Unexpected arguments provided to the JVM

If the `setup` tool attempts to launch the java command with an invalid set of arguments, it might prevent the Java Virtual Machine (JVM) from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, run the following command:

```
$ unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The server has already been configured or started

The `setup` tool is only intended to provide the initial configuration for the server. It will not run if it detects that it has already been run.

A previous installation should be removed before installing a new one. However, if there is nothing of value in the existing installation, the following steps can be used to run the `setup` program:

- Remove the `config/config.ldiffile` and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories in the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

The server will not start

If the server does not start, then there are several potential causes.

The server or other administrative tool is already running

Only a single instance of the server can run at any time from the same installation root. Other administrative operations can prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The <server> could not acquire an exclusive lock on file
/ds/PingData<server>/locks/server.lock:
The exclusive lock requested for file
/ds/PingData<server>/locks/ server.lock
was not granted, which indicates that another
process already holds a shared or exclusive lock on
that file. This generally means that another instance
of this server is already running.
```

If the server is not running (and is not in the process of starting up or shutting down), and there are no other tools running that could prevent the server from being started, it is possible that a previously held lock was not properly released. Try removing all of the files in the locks directory before attempting to start the server.

There is not enough memory available

When the server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, the server generates an error message indicating that it could not be started.

There are several potential causes for this:

- If the amount of memory in the underlying system has changed, the server might need to be re-configured to use a smaller amount of memory.
- Another process on the system is consuming memory and there is not enough memory to start the server. Either terminate the other process, or reconfigure the server to use a smaller amount of memory.

- The server just shut down and an attempt was made to immediately restart it. If the server is configured to use a significant amount of memory, it can take a few seconds for all of the memory to be released back to the operating system. Run the `vmstat` Installation and maintenance issues command and wait until the amount of free memory stops growing before restarting the server.
- If the system is configured with one or more memory-backed file systems (such as `/tmp`), determine if any large files are consuming a significant amount of memory. If so, remove them or relocate them to a disk-based file system.

An invalid Java environment or JVM option was used

If an attempt to start the server fails with 'no valid Java environment could be found,' or 'the Java environment could not be started,' and memory is not the cause, other causes can include the following:

- The Java installation that was previously used to run the server no longer exists. Update the `config/java.properties` file to reference the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation has been updated, and one or more of the options that had worked with the previous Java version no longer work. Re-configure the server to use the previous Java version, and investigate which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, its value might override the path to the Java installation used to run the server (defined in the `config/java.properties` file). Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before starting the server.

Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, such as:

```
$ env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

An invalid command-line option was used

There are a small number of arguments that can be provided when running the `bin/start-server` command. If arguments were provided and are not valid, the server displays an error message. Correct or remove the invalid argument and try to start the server again.

The server has an invalid configuration

If a change is made to the server configuration using `dsconfig` or the admin console, the server will validate the change before applying it. However, it is possible that a configuration change can appear to be valid, but does not work as expected when the server is restarted.

In most cases, the server displays (and writes to the error log) a message that explains the problem. If the message does not provide enough information to identify the problem, the `logs/config-audit.logfile` provides recent configuration changes, or the `config/archived-configs` directory contains configuration changes not made through a supported configuration interface. The server can be started with the last valid configuration using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

To determine the set of configuration changes made to the server since the installation, use the `config-difftool` with the arguments `--sourceLocal --targetLocal --sourceBaseline`. The `dsconfig --offline` command can be used to make configuration changes.

Proper permissions are missing

The server should only be started by the user or role used to initially install the server. However, if the server was initially installed as a non-root user and then started by the root account, the server can no longer be started as a non-root user. Any new files that are created are owned by root.

If the user account used to run the server needs to change, change ownership of all files in the installation to that new user. For example, if the server should be run as the "ds" user in the "other" group, run the following command as root:

```
$ chown -R ds:other /ds/PingData<server>
```

The server has shutdown

Check the current server state by using the `bin/server-state` command. If the server was previously running but is no longer active, potential reasons can include:

- Shut down by an administrator – Unless the server was forcefully terminated, then messages are written to the error and server logs stating the reason.
- Shut down when the underlying system crashed or was rebooted – Run the `uptime` command on the underlying system to determine what was recently started or stopped.
- Process terminated by the underlying operating system – If this happens, a message is written to the system error log.
- Shut down in response to a serious problem – This can occur if the server has detected that the amount of usable disk space is critically low, or if errors have been encountered during processing that left the server without worker threads. Messages are written to the error and server logs (if disk space is available).
- JVM has crashed – If this happens, then the JVM should provide a fatal error log (a `hs_err_pid<processID>.log` file), and potentially a core file.

The server won't accept client connections

Check the current server state by using the `bin/server-state` command. If the server doesn't appear to be accepting connections from clients, reasons can include the following:

- The server isn't running.
- The underlying system on which the server is installed isn't running.
- The server is running, but isn't reachable as a result of a network or firewall configuration problem. If that is the case, connection attempts should time out rather than be rejected.

- If the server is configured to allow secure communication through Secure Sockets Layer (SSL) or StartTLS, a problem with the key manager or trust manager configuration can cause connection rejections. Messages are written to the server access log for each failed connection attempt.
- The server might have reached its maximum number of allowed connections. Messages should be written to the server access log for each rejected connection attempt.
- If the server is configured to restrict access based on the address of the client, messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, it can stop listening for new requests. A message should be written to the server error log with information about the problem. Restarting the server can also solve the issue. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it doesn't already exist, and then copy the LDIF file into it.

The server is unresponsive

Check the current server state by using the `bin/server-state` command. If the server process is running and appears to be accepting connections but does not respond to requests received on those connections, potential reasons for this include:

- If all worker threads are busy processing other client requests, new requests are forced to wait until a worker thread becomes available. A stack trace can be obtained using the `jstack` command to show the state of the worker threads and the waiting requests.

  If all worker threads are processing the same requests for a long time, the server sends an alert that it might be deadlocked. All threads might be tied up processing unindexed searches.
- If a request handler is busy with a client connection, other requests sent through that request handler are forced to wait until it is able to read data. If there is only one request handler, all connections are impacted. Stack traces obtained using the `jstack` command will show that a request handler thread is continuously blocked.
- If the JVM in which the server is running is not properly configured, it can spend too much time performing garbage collection. The effect on the server is similar to that of a network or firewall configuration problem. A stack trace obtained with the `pstack` utility will show that most threads are idle except the one performing garbage collection. It is also likely that a small number of CPUs is 100% busy while all other CPUs are idle. The server will also issue an alert after detecting a long JVM pause that will include details.
- If the JVM in which the server is running has hung, the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a there is a network or firewall configuration problem, communication attempts with the server will fail. A network sniffer will show that packets sent to the system are not receiving TCP acknowledgment.
- If the host system is hung or lost power with a graceful shutdown, the server will be unresponsive.

Problems with the admin console

If a problem occurs when trying to use the admin console, reasons might include one of the following:

- The web application container that hosts the console is not running. If an error occurs while trying to start it, consult the logs for the web application container.

- If a problem occurs while trying to authenticate, make sure that the target server is online. If it is, the access log might provide information about the authentication failure.
- If a problem occurs while interacting with the server instance using the admin console, the access and error logs for that instance might provide additional information.

Problems with SSL communication

Enable TLS debugging in the server to troubleshoot Secure Sockets Layer (SSL) communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-ds` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Conditions for automatic server shutdown

All PingDirectory servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The PingDirectory server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
  --set unrecoverable-database-error-mode:initiate-server-shutdown
```

Insufficient memory errors

If the server shuts down because of insufficient memory errors, it is possible that the allocated heap size is not enough for the amount of data being returned. Consider increasing the heap size, or reducing the number of request handler threads using the following `dsconfig` command:

```
$ bin/dsconfig set-connection-handler-prop \
         --handler-name "HTTP Connection Handler" \
         --set num-request-handlers:<num-of-threads>
```

Enabling JVM debugging

About this task

Enable the Java Virtual Machine (JVM) debugging options to track garbage collection data for the system. These options can impact JVM performance, but provide valuable data to tune the server. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to provide additional detail, such as:

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

Steps

1. On the server, go to the `config/java.properties` file.
2. Edit the `config/java.properties` file. Add any additional arguments to the end of the line that begins with `start-<server>.java-args`.
3. Save the file.
4. Run the following command for the new arguments to take effect the next time the server is started:

   ```
   $ bin/dsjavaproperties
   ```

FIPS Compliance for PingDirectory

The Federal Risk and Authorization Management Program (FedRAMP) could require that United States government agencies and organizations that work with those agencies ensure that their cloud-based services adhere to either the FIPS 140-2 or FIPS 140-3 specification. These specifications define requirements for cryptographic processing.

Introduction to FIPS compliance

The PingDirectory, PingDirectoryProxy, and PingDataSync servers support running in FIPS-compliant mode using either the FIPS 140-2 or FIPS 140-3 specification.

When setting up in FIPS-compliant mode, the server uses the Bouncy Castle FIPS Java API in approved-only mode, which rejects attempts to use non-FIPS-compliant cryptography.

Differences between FIPS-compliant and non-FIPS-compliant modes

Servers running in FIPS-compliant mode and servers running in non-FIPS-compliant mode differ and have certain incompatibilities.

Some of these are incompatibilities imposed by the specification or the Bouncy Castle FIPS provider. Others allow for better out-of-the-box security in a manner that isn't possible without breaking backward compatibility with existing deployments.

Incompatibilities between FIPS-compliant and non-FIPS-compliant servers

Although the server doesn't have any known substantial cryptographic issues when running in the default non-FIPS-compliant mode, some of the algorithms it uses are either not permitted by the FIPS specification or aren't allowed by the Bouncy Castle FIPS provider.

To preserve backward compatibility with earlier versions, the server still uses those same algorithms when operating in non-FIPS-compliant mode, however it uses a different set of algorithms when set up in FIPS-compliant mode.

> **Note**
>
> Although this shouldn't substantially impact compatibility with clients, it does mean that servers running in FIPS-compliant mode cannot participate in the same topology as servers running in non-FIPS-compliant mode, nor is it possible to directly replicate between servers running in FIPS-compliant mode and servers running in non-FIPS-compliant mode.
> It's also not possible to update or reconfigure an existing server running in non-FIPS-compliant mode to operate in FIPS-compliant mode.

To migrate an existing non-FIPS-compliant topology to one operating in FIPS-compliant mode, you must:

1. Create a second topology in which the servers are set up in FIPS-compliant mode.
2. Migrate the data to the new topology.
3. Start serving client requests from that new topology.

> **Note**
>
> Although you can't replicate data directly between FIPS-compliant and non-FIPS-compliant instances, the PingDataSync server supports synchronizing changes between the topologies.

> **Note**
>
> If you're not using automatic backend server discovery for both types of servers, the PingDirectoryProxy server can forward requests to a mix of FIPS-compliant and non-FIPS-compliant servers. This allows you to migrate from one topology to another in a manner that's transparent to clients.

Changes in supported key store types

The server uses key stores to hold certificates needed for TLS negotiation and authentication. Historically, it supported the Java KeyStore (JKS) and PKCS #12 (a standard format described in RFC 7292) file-based key store types. However, these key store types could use cryptographic algorithms that aren't permitted in FIPS-compliant mode. Instead, use the Bouncy Castle FIPS-compliant Key Store (BCFKS) format. BCFKS is similar to PKCS #12 but relies only on cryptographic algorithms that are allowed by the Bouncy Castle FIPS provider in approved-only mode.

The `manage-certificates` tool has been updated to provide support for BCFKS key store types. For servers operating in non-FIPS-compliant mode, it can interact with any of the JKS, PKCS #12 or BCFKS key store types, and the `copy-keystore` subcommand is used to convert a JKS or PKCS #12 key store to a BCFKS key store.

> **Note**
>
> For servers operating in FIPS-compliant mode, only the BCFKS key store format is allowed.

The server also supports the standard PKCS #11 cryptographic API that can be used to interact with tokens like hardware security modules (HSMs). PKCS #11 tokens can be used in either FIPS-compliant mode or non-FIPS-compliant mode, however you should use a FIPS-compliant HSM when running in FIPS-compliant mode. The `manage-certificates` tool also supports interacting with PKCS #11 tokens.

TLS for network communication

When running in non-FIPS-compliant mode, you can configure the server to accept only encrypted, only unencrypted, or a mix of encrypted and unencrypted network communication.

When setting up the server in FIPS-compliant mode, you must enable TLS encryption. Unencrypted communication won't be enabled. The server can optionally accept connections that are initially unencrypted, but the StartTLS extended request must be used to secure communication on those connections before other types of requests are allowed.

Because secure communication is required, you must configure the server with appropriate certificate key and trust stores during setup. Learn more in Setting up certificate key and trust stores.

Data encryption

Using data encryption to protect data at rest is optional in non-FIPS-compliant mode but is required when setting up the server in FIPS-compliant mode.

You must configure the server with at least one encryption settings definition. Learn more in Setting up data encryption.

> **Note**
>
> When creating an encryption settings definition from a passphrase (whether user-supplied or automatically generated), servers running in non-FIPS-compliant mode default to using a 128-bit AES encryption key. When setting up a server in FIPS-compliant mode, `setup` uses a 256-bit AES encryption key.

Strong administrative passwords

When setting up the server in non-FIPS-compliant mode, you should choose a strong password for the initial root user that conforms to the following requirements:

- The password must be at least 12 characters long.
- The password must not be contained in a dictionary of words from a variety of languages.
- The password must not be contained in a dictionary of commonly used passwords.

In non-FIPS-compliant mode, you can ignore those rules and choose a weaker password through the `--allowWeakRootUserPassword` argument. You can't use this argument when setting up the server in FIPS-compliant mode, and you will be required to provide what the server considers a strong password.

The minimum password length requirement is increased from 12 characters to 14 characters because this is the minimum length required by the Bouncy Castle FIPS-compliant PBKDF2 implementation when running in approved-only mode.

Reduced available password storage schemes in FIPS-compliant mode

More password storage schemes are available in the out-of-the-box configuration when setting up a server in non-FIPS-compliant mode than in FIPS-compliant mode.

The only schemes available in the out-of-the-box configuration for a FIPS-compliant server are:

- AES256
- PBKDF2
- SSHA256
- SSHA384
- SSHA512

The PBKDF2 password storage scheme is the default scheme for root users and topology administrators. The SSHA256 password scheme is the default scheme for non-administrative users.

> **Note**
>
> In FIPS-compliant mode, the server defaults to the PBKDF2WithHmacSHA256 algorithm rather than PBKDF2WithHmacSHA1, which is used by default for backwards compatibility in non-FIPS-compliant mode. The SSHA256, SSHA384, and SSHA512 schemes use a default salt length of 128 bits in FIPS-compliant mode as opposed to the default length of 64 bits in non-FIPS-compliant mode.

The following password storage schemes aren't available in FIPS-compliant mode because they depend on the non-FIPS-compliant Bouncy Castle library, which is not compatible with the FIPS-compliant library:

- ARGON2
- BCRYPT
- SCRYPT

The following schemes are available in the default configuration for non-FIPS-compliant mode for the purpose of backward compatibility and are excluded from the out-of-the-box configuration for a FIPS-compliant server:

- AES
- BASE64
- BLOWFISH
- CLEAR
- CRYPT
- MD5
- SHA
- SMD5
- SSHA

> **Note**
>
> You should avoid using these password storage schemes whenever possible.

Reduced available SASL mechanisms

When running in non-FIPS-compliant mode, the server has some non-recommended Simple Authentication and Security Layer (SASL) mechanisms available in the out-of-the-box configuration for purposes of backward compatibility that aren't included in the FIPS-compliant mode default configuration.

These mechanisms include:

- ANONYMOUS
- CRAM-MD5
- DIGEST-MD5

Setting up the server in FIPS-compliant mode

You can't have both FIPS-compliant and non-FIPS-compliant servers in the same topology, and you can't update an existing non-FIPS-compliant server to run in FIPS-compliant mode.

Because of this, if you want to run a server in FIPS-compliant mode, you must set up a new instance. This can be done in the following two ways:

- Use `setup` with an appropriate set of arguments.
- Use `manage-profile setup` with a profile that includes the necessary setup arguments, along with any other configuration changes, extensions, and other files that you might want included in the installation.

> **Note**
>
> You can run servers with different levels of FIPS compliance in the same topology.

Ensure sufficient entropy

Strong cryptography requires a reliable source of high-quality random data.

On some systems, the OS-provided random number generator, such as `/dev/random` on Linux systems, might block if there's not enough entropy available to keep up with the demand for strong random data, which can severely impede server performance. This is especially likely when running the server in a virtual machine or in a container because it's less likely to have access to the entropy stream from the underlying host system.

When running in non-FIPS-compliant mode, the server can work around this problem by using an alternative random number generator, such as `/dev/urandom` on Linux, that uses cryptographic techniques to ensure that it can still provide a high-quality stream of random data that won't block even when available entropy is exhausted on the underlying system. However, the Bouncy Castle FIPS-compliant random number generator doesn't support this alternative, and it's likely to block for long periods of time if the server is installed in a container or virtual machine.

This isn't a problem that's likely to go unnoticed because the server is likely to appear completely unresponsive for many minutes at a time if the random number generator blocks because of a lack of entropy. It's likely to block for long periods of time, especially if the server is installed in a container or virtual machine.

Resolve entropy exhaustion

To help diagnose the problem, the installer attempts to monitor available system entropy when setting up the server in FIPS-compliant mode and displays a warning message if entropy drops too low. Similarly, if the server is running in FIPS-compliant mode, it continuously monitors available system entropy and logs a warning message and raises an alarm if entropy drops low enough that the server is likely to become unresponsive.

If entropy exhaustion is a problem, the best options to address it include:

- If the server is running in a virtual machine or container, you might be able to configure it with access to the underlying host system's entropy pool if that's not already the case.
- Install a hardware random number generator on the system and ensure that the server can access it even when running in a container or virtual machine.
- Install an entropy-supplementing daemon, such as rngd, to keep the OS-provided random number generator topped off and able to generate high-quality random data without blocking.

Setting up certificate key and trust stores

About this task

Because FIPS-compliant mode requires secure communication, you must provide arguments that indicate how the server should obtain the certificate chain, private key, and trusted certificate information that it should use during TLS negotiation.

Steps

- Configure the server with appropriate key and trust stores during setup. Choose from:

  Choose from:

  - If you have existing key and trust stores in the BCFKS format:
  - Use the `--useBCFKSKeyStore` and `--useBCFKSTrustStore` arguments to provide the paths to those stores.
  - Use either the `--keyStorePassword` or `--keyStorePasswordFile` argument to specify the PIN needed to access the contents of the key store.
  - Use either the `--trustStorePassword` or `--trustStorePasswordFile` argument to specify the PIN needed to access the contents of the trust store.

    > **Note**
    >
    > Unlike the JKS format, a PIN is always required when using a BCFKS key store, even if you don't need to access the private key.

  - If you have existing key and trust stores in a non-BCFKS format:
  - Convert the non-BCFKS files using `manage-certificates copy-keystore` with the `--destination-key-store-type BCFKS` argument.
  - Follow the steps for existing key and trust stores in the BCFKS format.
  - If you have PEM files containing the certificate chain and private key from a certificate authority, and you want to use them to generate new BCFKS key and trust stores:
  - Use the `--certificateChainPEMFile` and `--certificatePrivateKeyPEMFile` arguments to specify the paths to those files.
  - If you have PEM files containing trusted certificates that you want to include in a new BCFKS trust store, you can use the `--trustedCertificatePEMFile` argument to provide the paths to those files.
  - If the listener certificate chain and private key that you want to use reside in a PKCS #11 token:
  - Use the `--usePKCS11KeyStore` argument to enable that support for creating a BCFKS key store.

    > **Important**
    >
    > PingDirectory only supports key store creation using PKCS #11 tokens. In order to create a trust store, you must use either the `--useBCFKSTrustStore` or `--trustedCertificatePEMFile` arguments in conjunction with `--usePKCS11KeyStore`.

  - If the Java virtual machine (JVM) has not been pre-configured with the necessary PKCS #11 provider, then use the `--pkcs11ProviderConfigFile` argument to specify the path to the necessary provider configuration file.
  - Use either the `--keyStorePassword` or `--keyStorePasswordFile` argument to specify the PIN needed to access the token.

- If you want the server to generate a self-signed certificate and use it to create BCFKS key and trust stores, use the `--generateSelfSignedCertificate` argument.

  > **Important**
  >
  > Self-signed certificates are convenient for testing or evaluation purposes, but they aren't trusted by any clients (by default) and shouldn't be used in production environments.

Setting up data encryption

About this task

Setting up the server in FIPS-compliant mode requires that you enable data encryption.

Steps

- Configure the server with at least one encryption settings definition. Choose from:

  Choose from:

  - If you want the server to generate an encryption settings definition from a passphrase that you provide, use the `--encryptDataWithPassphraseFromFile` argument to specify the path to a file containing that passphrase.

    > **Note**
    >
    > If you provide the same passphrase to each instance, they will generate the same encryption settings definition and will encrypt data in the same way. Also, in many cases, if you know the passphrase used to generate an encryption settings definition, you can use that passphrase to decrypt encrypted data even if the encryption settings definition isn't available.

  - If you have one or more encryption settings definitions that have been exported from another instance:

    1. Use the `--encryptDataWithSettingsImportedFromFile` argument to specify the path to that export file.
    2. Provide the `--encryptionSettingsExportPassphraseFile` argument to specify the path to a file containing the passphrase used to protect the contents of that export.

  - If you want the server to generate an encryption settings definition with a randomly generated passphrase, use the `--encryptDataWithRandomPassphrase` argument.

    > **Note**
    >
    > If you use this argument when setting up multiple instances, then each instance will have a different encryption settings definition, and data encrypted on one instance might not be accessible to other instances. However, you can use it when setting up the first instance in a topology and then export the generated definition and use the `--encryptDataWithSettingsImportedFromFile` argument to import it when setting up additional instances.
    > Because the random passphrase the server generated when creating the definition will not be exposed, you can't use it to decrypt data if that encryption settings definition is not available.

Installing the server in FIPS-compliant mode

Install the server in FIPS-compliant mode with TLS negotiation and data encryption.

About this task

Interactive setup doesn't provide an option to enable FIPS-compliant mode, and there are currently no other supported providers that can be used to enable FIPS-compliant mode.

Steps

- Install the server with one of the supported FIPS specifications.

  Choose from:

  - To set up the server for FIPS 140-2 compliance, add `--fips-provider BCFIPS1` to the set of arguments used when running setup in non-interactive mode or to the server profile's `setup-arguments.txt` file when using `manage-profile setup`.

    Example:

    The following example provides a sample command line that demonstrates the process for setting up the server in FIPS 140-2-compliant mode. The server only accepts TLS-encrypted LDAP on port 636 and TLS-encrypted HTTP on port 443, but doesn't allow unencrypted connections from either LDAP or HTTP clients. BCFKS key and trust stores are generated from information provided in PEM files, and an encryption settings definition is generated from a specified passphrase.

    ```
    ./setup \
      --fips-provider BCFIPS1 \
      --no-prompt \
      --acceptLicense \
      --localHostName ds1.example.com \
      --ldapsPort 636 \
      --httpsPort 443 \
      --baseDN "dc=example,dc=com" \
      --rootUserDN "cn=Directory Manager" \
      --rootUserPasswordFile /path/to/root-pw.txt \
      --maxHeapSize 2g \
      --primeDB \
      --sampleData 10001 \
      --certificateChainPEMFile /path/to/server-cert.pem \
      --certificateChainPEMFile /path/to/ca-cert.pem \
      --certificatePrivateKeyPEMFile /path/to/server-key.pem \
      --trustedCertificatePEMFile /path/to/ca-cert.pem \
      --encryptDataWithPassphraseFromFile /path/to/encryption-passphrase.txt \
      --instanceName ds1 \
      --location example-location \
      --noPropertiesFile
    ```

  - To set up the server for FIPS 140-3 compliance, add `--fips-provider BCFIPS2` to the set of arguments used when running setup in non-interactive mode or to the server profile's `setup-arguments.txt` file when using `manage-profile setup`.

Checking the level of FIPS compliance

You can check a server's level of FIPS compliance by reviewing the properties of its `cn=Version,cn=monitor` entry.

About this task

The following table details the properties to review within the monitor entry:

Property	Values
`fips-compliant-mode`	• `true` indicates that the server is installed in FIPS-compliant mode (using any supported specification). • `false` indicates that the server isn't installed in FIPS-compliant mode.
`fips-140-2-compliant-mode`	• `true` indicates that the server is configured with the FIPS 140-2 specification. • `false` indicates that the server isn't configured with the FIPS 140-2 specification.
`fips-140-3-compliant-mode`	• `true` indicates that the server is configured with the FIPS 140-3 specification. • `false` indicates that the server isn't configured with the FIPS 140-3 specification.

Note

A FIPS-compliant server returns a value of `true` for the `fips-compliant-mode` property and one of the FIPS specification properties. It returns `false` for all other FIPS specification properties.

Steps

- Run `ldapsearch` to return the `cn=Version,cn=monitor` entry.

  Example:

  The following example includes an `ldapsearch` and the resulting entry, which indicates that the server is installed in FIPS 140-2-compliant mode:

```
$ bin/ldapsearch \
  --hostname <hostname> --port <port> --useSSL --trustAll \
  --bindDN "cn=Directory Manager" --bindPasswordFile <password_file> \
  --baseDN cn=Version,cn=monitor "(&)" fips-compliant-mode fips-140-2-compliant-mode fips-140-3-
compliant-mode

  dn: cn=Version,cn=monitor
  fips-compliant-mode: true
  fips-140-2-compliant-mode: true
  fips-140-3-compliant-mode: false

  # Result Code:  0 (success)
  # Number of Entries Returned:  1
```

Changing the level of FIPS compliance

You can change the level of FIPS compliance for an existing FIPS-compliant server.

About this task

You can update a server's FIPS compliance level to any supported FIPS specification. For example, your organization might be required by regulation to update an existing topology of FIPS 140-2-compliant servers to FIPS 140-3 compliance. Alternatively, you might need to transition a FIPS 140-3-compliant server to the FIPS 140-2 specification for technical reasons.

Before you begin

To update the FIPS specification on a FIPS-compliant server, you need to know the following:

- The server's current FIPS specification
- The server's installation method:
  - Using `manage-profile setup`
  - Using `setup`
- The encoded value of the target FIPS specfication:
  - `BCFIPS1` for FIPS 140-2
  - `BCFIPS2` for FIPS 140-3

Steps

- Follow the appropriate steps based upon the type of server installation method:

  Choose from:

  - For servers installed using `manage-profile setup`, run `manage-profile replace-profile`. Supply the `--fips-provider` argument using the encoded value of the target FIPS specification. Learn more about the `manage-profile` tool.

- For servers installed using `setup`:

  1. In `config/java.properties`, edit the value of `-Dcom.unboundid.crypto.FIPS_PROVIDER` to the encoded value of the target FIPS specification.
  2. Run `bin/dsjavaproperties`.
  3. Restart the server.

Troubleshooting:

If the server doesn't operate as expected after the update, revert the server to the previous FIPS compliance level.

PingDirectory Security Guide

The PingDirectory Security Guide provides concepts and procedures to secure and manage the PingDirectory platform.

Introduction

This guide is intended for administrators responsible for installing and managing servers in an enterprise or consumer-facing identity environment. Storing and handling consumer identity data requires taking appropriate steps to safeguard it while continuing to provide fast, real-time, and available services for the consumers who consent to its use.

Administrators should already know the following:

- Identity platforms and LDAP concepts
- General system administration and networking practices
- Java Virtual Machine (JVM) compromise
- Application performance monitoring

Threat vectors in an identity environment

The PingDirectory platform serves as the authentication repository for a wide variety of network applications, and it often stores sensitive user information and application data.

Hackers that obtain user credentials can cause extensive damage to individuals, systems, and businesses.

Business costs to secure and monitor identity deployments can be large, but the total cost is small compared to the cost of a security breach. A security breach requires resources to investigate the incident, assess the scope of the damage, identify any compromised data, and revert any changes. Affected users must be notified and must be compensated for downtime and for any costs incurred from the exposure of their personal data. However, the damage to a company's reputation is often the most costly result.

Directories are the central component within identity management systems. They streamline authentication and authorization across system boundaries. Whether for user, account, or subscriber provisioning, directory services must be properly secured so that sensitive information is not accessible by unauthorized individuals externally or internally. If the directory service is compromised, attackers can gain access to the data that it contains and to other systems that rely on the directory service for authentication and authorization.

In securing the directory service, several threat vectors must be considered:

- Compromise of:
  - The underlying host system on which the PingDirectory server is running
  - Peripheral systems that might have access to server data, including backups, LDIF exports, log files, or monitor data
  - Systems used in setting up new instances including orchestration frameworks and configuration-as-code repositories
- Access to network communication

This includes not only the ability to observe traffic passing between clients and servers, but also the potential to intercept and alter that communication, or impersonate a legitimate server.

- Attacks that involve communication with the server over the intended protocols, including LDAP, SCIM, and the Directory REST API, whether by unauthenticated clients, regular and administrative users using legitimately obtained credentials, or attackers who might be able to obtain compromised credentials

  This includes denial of service attacks and attempts to access unauthorized data.

Securing the host system

The process of securing the underlying systems used to run the PingDirectory server or that might have access to server data is outside the scope of this document but is covered in other security references. However, it is important to rely on several best practices, as outlined in the following sections.

Minimize installed software

Each application or command on a system is potentially a security hole that could provide unauthorized users a way to get into the system.

The PingDirectory software has a minimal set of dependencies. As a pure Java application, its primary dependency is the Java Virtual Machine (JVM). However, troubleshooting and support data collection tools might rely on other operating system utilities to obtain information about the state of the underlying system. On Linux, these tools include:

- `cat`
- `crontab`
- `df`
- `dmesg`
- `dstat`
- `ethtool`
- `gstack`
- `ifconfig`
- `iostat`
- `ip`
- `jinfo`
- `jmap`
- `journalctl`
- `jps`
- `jstack`

- `ls`
- `mpstat`
- `netstat`
- `pidstat`
- `pmap`
- `ps`
- `pstack`
- `sar`
- `sh`
- `ss`
- `sysctl`
- `systemctl`
- `tail`
- `top`
- `tuned-adm`
- `udevadm`
- `uname`
- `uptime`
- `vmstat`

Consider removing software that is not a critical part of the operating system, such as not needed to run the JVM, and that is not needed to run the previous troubleshooting and data collection tools.

Keep systems patched

Keep any software that cannot be removed from the system up to date.

Install all operating system security patches and software updates in a timely manner.

Operating system and software updates do have the potential to cause unforeseen problems. Thoroughly test all updates in a staging environment before production.

Monitor security-related mailing lists and news feeds, and consider following security experts on social media. The sooner you know about operating system or software vulnerabilities, the sooner you can take action to minimize the exposure while waiting for and testing the appropriate patches.

Minimize network services

Take steps to reduce the potential for compromise of network services.

Steps include:

- Disable any unnecessary network services.
- If there are network daemons that must run on the system but are only accessed over the loopback interface, such as a local SMTP server for relaying email messages, configure them so that they are not accessible to external clients.
- Use firewall software to ensure that only the minimum number of ports are exposed to external systems.
- When possible, configure services to run as a non-root user with as few rights as possible.

Configure filesystem security

The most basic forms of filesystem protection are file permissions and filesystem encryption.

Any portion of the filesystem that contains sensitive data should be accessible only to the account used to run the server. In a default PingDirectory software installation, all components of the server reside within the instance root. When the software is extracted, which should be done using the account that will be used to run the software, the instance root directory will have filesystem permissions of 0700, preventing any access by other accounts on the system other than those exempt from file permission restrictions, like the root account. Directories used to hold database files are also given permissions of 0700 by default, and log files are written with default permissions of 0600. If the server is configured to access other areas of the filesystem outside of the instance root, take care to set file permissions and ownership on the paths that contain that content.

Some operating systems offer mechanisms beyond the basic file permissions. For example, Linux systems offer `getfacl` and `setfacl` commands that can define more fine-grained access controls for files and directories. Consider using those mechanisms to provide greater protection from unauthorized access.

Filesystem auditing software can help identify questionable use of file permissions. It can also keep a record of all filesystem permission and content changes. Although this is not useful for content that changes frequently like database and log files, it can be very helpful for detecting changes to other content, like server binaries and configuration. We also recommend using this auditing for the operating system binaries and configuration.

PingDirectory software provides support for encrypting database contents, backups, LDIF exports, and other content. You can also gain additional protection by enabling filesystem encryption to help protect against unauthorized access to the underlying storage.

> **Note**
>
> The use of filesystem encryption might not offer much additional protection for a mounted filesystem because it appears unencrypted to the users and applications that interact with it.

Enable time synchronization

Always set the system clock to the right time.

There are several reasons for this, including:

- It ensures that logging and auditing timestamps are accurate.
- It is useful when correlating events across multiple systems.
- It is essential to ensure correct behavior if replication conflicts arise.
- It is necessary for time-sensitive authentication mechanisms like GSSAPI and UNBOUNDID-TOTP.
- It is important for time-related password policy processing.

Apply recommended OS-level tuning

The PingDirectory Server Administration Guide makes several tuning recommendations to help ensure software runs smoothly.

These include:

- Configure file descriptor limits.
- Configure process limits.
- Apply recommended filesystem tuning.
- Disable filesystem swapping.
- Configure filesystem event monitoring limits.
- Tune the I/O scheduler.
- Tune memory management.
- Manage OS-level environment variables.
- Configure the system to allow the PingDirectory software to listen on privileged ports while running as a non-root user.

Run the PingDirectory software in a container

Consider running the PingDirectory software in a Docker image or some other type of container.

This can help isolate the server from other software and processes on the system. It also encourages adopting a DevOps philosophy, which streamlines the process for deploying new instances of the software using a reliable and repeatable process. This is good for disaster recovery because it allows a new instance to be quickly created if an existing instance should fail for any reason.

Containerization can also offer other security-related benefits. For example, containers frequently do not provide direct shell access to the instance, reducing the chance that an attacker can gain access to server data through that avenue. If you subscribe to the DevOps blue-green strategy, in which configuration changes are applied by spinning up new instances with the desired settings rather than updating existing instances, unauthorized configuration changes are easier to detect and revert.

Maintain the Java Virtual Machine

Keep the Java Virtual Machine (JVM) up to date with the latest patches.

Run the most recent major release of the JVM that the PingDirectory software supports because it can offer support for additional security features that are not available in older versions.

In some cases, you might want to run the PingDirectory software on a standalone JVM installation rather than one provided through the operating system's package management system. This might not be necessary when using the DevOps configuration-as-code practice because the process of updating the JVM or applying operating system patches typically involves spinning up a new container using the updated software. However, if you use a more traditional deployment model in which the software is installed on long-lived systems that are updated over time, then relying on a JVM provided by the operating system vendor might cause it to be updated unexpectedly. By maintaining a dedicated Java installation for the PingDirectory software, you have better control over when the JVM is updated and the specific version that is in use.

Maintain a support contract with your JVM vendor to ensure that they will be able to assist with any issues that you encounter in the Java runtime itself.

Minimize access to the underlying system

If administrators can access the underlying system, then the mechanism they use to do so should be as secure as possible.

All shell access must occur over an encrypted session that uses strong authentication, such as relying on SSH keys rather than passwords, and ideally using a second authentication factor like TOTP or U2F.

Keep the number of users authorized to access the system to a minimum, and ensure each authorized user has their own account rather than sharing accounts across multiple individuals. This makes it easier to audit access and identify which administrator made a given change. Using separate accounts also avoids problems that might arise whenever the credentials need to be changed. With a separate account per administrator, each has their own distinct credentials.

The account used to run and manage the PingDirectory software itself should not be able to directly authenticate to the underlying system. Instead, each user authorized to interact with the PingDirectory software on the underlying system must authenticate with their own account before using some mechanism, such as su or sudo on UNIX-based systems, to interact with the server software.

The accounts for the users who manage the PingDirectory software and the account used to run that software should be configured with the minimum set of capabilities required to perform their duties. Those who manage the underlying system might require full access, but those who just maintain the PingDirectory software can be given restricted access. If possible, restrict the set of commands that those users can invoke and their access to other running processes and areas of the filesystem.

If a system account becomes compromised or its owner leaves, terminate that account as quickly as possible. While managing system accounts is usually best left to a centralized naming service like LDAP, this is not recommended for the accounts used to manage the PingDirectory software itself because an issue with the server might prevent users from authenticating to the system to address it. Local file-based accounts are the most reliable, but it is important to keep a current list of all users with access to these systems and of all systems they can access with those credentials so that the credentials can quickly be revoked if necessary.

Managing the server without shell access to the underlying system

Even if PingDirectory server administrators are not granted shell access to the underlying system, it is still possible to manage the server.

Most administrative functions can be performed remotely over secure LDAP or HTTP connections.

The web-based administration console provides support for managing the server configuration and schema. It also provides access to a variety of status information, including monitor entries, active alarms, and administrative alerts.

If you extract the PingDirectory software onto your local system, then you will also have access to a variety of command-line tools that can interact with the server remotely. Some of the most useful tools include:

`status`

Retrieve a variety of status information from the server.

`dsconfig`

Manage the server configuration.

`dsreplication`

Manage and monitor replication.

`collect-support-data`

Collect a wide variety of information that is useful for troubleshooting problems and understanding the server configuration and status. The resulting support data archive can be securely streamed back to the client system.

`backup`

Back up the contents of one or more server backends. The backup files will be written onto the server filesystem.

`restore`

Restore a backup stored on the server filesystem.

`export-ldif`

Export the contents of a specified backend to LDIF. The LDIF file will be written onto the server filesystem.

`import-ldif`

Import LDIF data stored on the server filesystem into a specified backend.

`config-diff`

Compares server configurations, whether of two different servers or different versions of the configuration from the same instance, to identify differences.

`ldapsearch`

Search for information stored in the server.

`ldapmodify`

Update information stored in the server, including creating new entries or updating or removing existing entries.

`ldappasswordmodify`

Reset user passwords.

`manage-account`

Manage password policy state for users.

`ldap-diff`

Compare the data between multiple servers to identify differences.

`audit-data-security`

Examine and report on various security-related aspects of data stored in the server.

`schedule-exec-task`

Schedule an administrative task that can be used to execute a specified command on the server system. This task is not enabled by default, and it provides several safeguards to ensure that it cannot be invoked by unauthorized users and that authorized users are not allowed to invoke unauthorized commands.

You might also need to access files on the server filesystem, especially for things like backups, LDIF exports, and log files. There are options for this that do not require shell access:

- Consider using a secure shared filesystem that is accessible from other trusted systems. Even if you don't want to place the server root itself on a shared filesystem, you could write backups, LDIF exports, and rotated log files to it so that they are more readily available.
- Use the file servlet that is provided as part of the PingDirectory server installation. If you go to https://*server-address*:*server-https-port*/instance-root/ and authenticate as a user with the `file-servlet-access` privilege, which is included in the default set of root privileges, you can see a listing of all files and directories in the server instance root and you can download any files of interest to your desktop.

Use system logging and auditing

Auditing provides vital information for diagnosing problems or investigating security breaches.

Most operating systems provide an audit mechanism that records information about system events. This can include basic information like keeping a record of sign on attempts, but it might also be possible to capture more detailed information like recording each command that is invoked or each file that is accessed.

Make sure that logging and auditing are properly tuned to record an appropriate amount of information without impeding system performance. You might also want to ensure that system logs are recorded locally and sent to a remote system to ensure higher availability and to reduce the likelihood that an attacker who gains access to the system will be able to cover their tracks.

Configuring data encryption

While attackers ideally won't be able to gain access to any of the systems running the PingDirectory software or to systems that contain data generated by the PingDirectory software, you should still take additional measures to protect the data.

One of the best ways to accomplish this is to encrypt all sensitive data. The PingDirectory software provides extensive support for data encryption. It is possible to encrypt the backend databases, both entry contents and index data, as well as the replication database and the LDAP-accessible changelog if enabled. It is also easy to encrypt backups, LDIF exports, log files, and support data archives.

Enabling data encryption during setup

Data encryption should be enabled when running setup, which ensures that all data added to the server is encrypted and also configures the server to automatically encrypt backups and LDIF exports.

The interactive setup process, which is started when setup is run without any arguments, guides you through the process of enabling data encryption, but if you're using non-interactive setup or manage-profile setup, then data encryption can be enabled by providing one of the following arguments.

Argument	Description
`--encryptDataWithPassphraseFromFile`	Specifies the path to a file that contains the passphrase to use to generate the encryption settings definition that encrypt the data. If you provide the same passphrase when setting up multiple instances of the server, then each generates the same encryption settings definition, and each instance can access data encrypted by the other instances.
`--encryptDataWithSettingsImportedFromFile`	Specifies the path to a file that contains one or more encryption settings definitions to be imported into the newly created encryption settings database. Use the `--encryptionSettingsExportPassphraseFile` argument to provide the path to a file containing the passphrase used to encrypt those definitions. If you import the same encryption settings definitions into all servers in the topology, then each instance can access data encrypted by the other instances. See the Exporting encryption settings definitions section for more information on exporting the contents of the encryption settings database.

Argument	Description
`--encryptDataWithRandomPassphrase`	Indicates that the server should enable data encryption with an encryption settings definition created from a randomly generated passphrase. If you use this option to set up multiple instances, then they will not have the same encryption settings definitions, and data encrypted by one instance is not accessible on other instances unless the encryption settings definitions are synchronized across all of those instances.
`--encryptDataWithPreExistingEncryptionSettingsDatabase`	Indicates that the server should enable data encryption using the definitions from a pre-existing encryption settings database. This database can be protected with any cipher stream provider supported by the server, configured with data encryption restrictions, and frozen so that its contents are immutable. If you set up the server with a pre-existing encryption settings database, you should use the `manage-profile setup` tool. The server profile must meet the following requirements: • The `setup-arguments.txt` file must include the `--encryptDataWithPreExistingEncryptionSettingsDatabase` argument. • The server profile must contain the `server-root/pre-setup/config/encryption-settings/encryption-settings-db` file, which represents the encryption settings database to use for the new server instance. • The `pre-setup-dsconfig` directory must exist and it must contain one or more `dsconfig` batch files with the changes needed to set up and enable the cipher stream provider to use with the encryption settings database. • The `server-root/pre-setup` directory should include any metadata files that the cipher stream provider needs to access the encryption settings database.

Managing the encryption settings database

If data encryption is enabled in the PingDirectory software, the server use a secret key to actually perform that encryption. Without that encryption key, the encrypted data is worthless.

The PingDirectory software uses an encryption settings database to manage the keys that it uses for data encryption. Each encryption settings definition includes not only the key used to perform the encryption, but also specifies the cipher transformation that is used for that encryption. The encryption settings database can include multiple definitions, but only one of those definitions is marked as the preferred definition, and that is the one that is used for encrypting new data that is written to the database.

The PingDirectory server provides an `encryption-settings` tool that can manage the contents of the encryption settings database.

Listing encryption settings definitions

Use the `encryption-settings list` command to obtain a list of the definitions in the server's encryption settings database.

This command does not require any arguments.

Example

```
$ bin/encryption-settings list
Encryption Settings Definition ID:  125480AFA3300CD8E48CDF53AF3A0D4DDC8760E115C5B986530F1FE438B19DBD
     Alternate ID:  3D21C37492A2AE8D28BBB7A39A238987005AA4DC
     Description:  Generated during setup on 'test' using a passphrase read from a file
     Create Time:  Wed Aug 26 15:04:12 CDT 2020
     Cipher Transformation:  AES/CBC/PKCS5Padding
     Key Length (bits):  128
     Preferred for New Encryption:  true

Encryption Settings Definition ID:  CA8A76C13DD5CC3F85A437119D9DC0867396910F64E228962A30FF80B36C3B63
     Alternate ID:  7AF6A51673D0BC10915B23370448C1592905E8E2
     Description:  Generated during setup on 'test' using a passphrase read from a file
     Create Time:  Wed Aug 26 15:04:12 CDT 2020
     Cipher Transformation:  AES/CBC/PKCS5Padding
     Key Length (bits):  256
     Preferred for New Encryption:  false
```

Creating encryption settings definitions

To create a new encryption settings definition, use the `encryption-settings create` command, which takes the following arguments.

Argument	Description
`--cipher-algorithm`	A required argument that specifies the base cipher that should be used for encryption and decryption. The value for this argument must be the name of a valid symmetric encryption algorithm that is supported by the Java Virtual Machine (JVM). We recommend using AES.

Argument	Description
`--cipher-transformation`	An optional argument that allows you to specify the complete cipher transformation for encryption performed using this definition. If provided, the cipher transformation should consist of three components separated by forward slashes: the cipher algorithm, the cipher mode, and the padding algorithm, such as "AES/CBC/PKCS5Padding". If this is not provided, the server automatically selects the transformation based on the specified cipher algorithm.
`--key-factory-iteration-count <count>`	Specifies the PBKDF2iteration count to use in deriving the encryption key for the encryption settings definition. You should use this argument when creating a new encryption settings definition. The current OWASP recommendation is to use a PBKDF2 iteration count value of at least 600,000.
`--key-length-bits`	The length, in bits, to use for the encryption key. When using the AES cipher, this should generally be either 128 or 256.
`--prompt-for-passphrase`	An optional argument that indicates that the tool should interactively prompt for the passphrase to use when generating the encryption key.
`--passphrase-file-path`	An optional argument that provides the path to a file containing the passphrase that should be used when generating the encryption key.
`--description`	An optional argument that can be used to provide a human-readable description for the new encryption settings definition.
`--set-preferred`	An optional argument that indicates that the new definition should be the preferred definition used for subsequent encryption operations.

The following is an example of the command with some of the arguments included.

```
$ bin/encryption-settings create \
     --cipher-algorithm AES \
     --cipher-transformation AES/GCM/PKCS5Padding \
     --key-factory-iteration-count 60000 \
     --key-length-bits 256 \
     --prompt-for-passphrase \
     --description "An example encryption settings definition"
Enter the encryption passphrase:
Confirm the encryption passphrase:

Successfully created a new encryption settings definition with ID
494DCE52DE58D0A44E56B9E80FC62B257870F2FC7CEEDCA150F4EF51829D7B20.
```

Each encryption settings definition has an underlying passphrase that is used to generate the encryption key. If you provide the `--prompt-for-passphrase` argument, then the tool interactively prompts you for that passphrase. If you provide the `--passphrase-file-path` argument, then it reads the passphrase from a file. If you do not provide either argument, then the tool generates a strong random passphrase for use by that definition.

We generally recommend that you explicitly specify the passphrase for new encryption settings definitions rather than allowing the tool to generate a random passphrase. If you want to create the encryption settings definition across multiple instances, then providing the same passphrase for each instance ensures that the same definition is created everywhere. Further, if you need to decrypt a file that was encrypted with a key from the encryption settings database, like a backup, LDIF export, or log file, then you can decrypt the file (using the `encrypt-file` tool or using the PassphraseEncryptedInputStream class provided in the UnboundID LDAP SDK for Java) if you know the passphrase, even if you're on a system that doesn't have access to the server's encryption settings database.

Removing encryption settings definitions

To remove an encryption settings definition, use the `encryption-settings delete` command.

This command takes the following arguments.

Argument	Description
`--id`	A required argument that indicates which encryption settings definition should be removed.
`--no-prompt`	An optional argument that indicates that the specified definition should be removed without prompting for confirmation.

The following is an example of the command with one of the arguments included.

```
$ bin/encryption-settings delete \
     --id 494DCE52DE58D0A44E56B9E80FC62B257870F2FC7CEEDCA150F4EF51829D7B20
If the encryption definition is being used to encrypt existing objects in the system,
then those objects will no longer be able to be decrypted. In certain cases, the
server may not be able to be restarted until those objects are deleted. Are you sure
about deleting it (yes/no)?  yes
Successfully deleted encryption settings definition
494DCE52DE58D0A44E56B9E80FC62B257870F2FC7CEEDCA150F4EF51829D7B20.
```

Before you delete an encryption settings definition, you should make sure that it is not still in use. If you remove an encryption settings definition that is still in use within the database, then any data encrypted with that key becomes inaccessible and operations that attempt to access it fail. See Re-encrypting data in the database for more information about this.

Also note that the tool will not allow you to remove the preferred encryption settings definition. If you want to remove the preferred definition, then you must make another definition the preferred definition. See the Setting the preferred encryption settings definition for more information.

Exporting encryption settings definitions

To use the same set of encryption settings definitions, ensure that all servers in the topology are configured.

There are two ways to accomplish this:

- Use the `encryption-settings create` command on each instance with the same passphrase. Alternatively, if you're enabling data encryption when running setup, provide the same passphrase file to each instance.
- Create the desired definitions on one instance, export them from that instance, and import them into the other instances or provide the export file when running setup.

To export one or more encryption settings definitions, use the `encryption-settings export` command, which supports the following arguments.

Argument	Description
`--output-file`	A required argument that specifies the path to the export file to be written.
`--pin-file`	An optional argument that specifies the path to a file containing the passphrase to use to encrypt the contents of the export. If this is not provided, the tool interactively prompts for the passphrase. Because this passphrase is used to protect the contents of the export, it must be strong and it should not match the passphrase used to create any of the definitions.
`--id`	An optional argument that can be used to explicitly specify the IDs of the definitions to include in the export. If this is not provided, then all definitions are included.

Argument	Description
`--use-legacy-export-format`	Indicates that the tool should use a legacy export format that was supported by older versions of the server. You might need to use this argument if you are exporting definitions from a newer version for import into an older version. The legacy export format can only hold a single encryption settings definition, so the `--id` argument must be used to specify the ID of the definition to include.

The following is an example of the command with one of the arguments included.

```
$ bin/encryption-settings export \
     --output-file exported-definitions.esd
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
Successfully exported encryption settings data to file exported-definitions.esd.
```

Importing encryption settings definitions

The `encryption-settings import` command with the `import` subcommand provides you with a mechanism to import definitions into the encryption settings database.

About this task
Steps

- To import definitions into the encryption settings database, use the `encryption-settings` command with the `import` subcommand.

  The `import` subcommand supports the following arguments.

Argument	Description
`--input-file` (required)	Specifies the path to the file containing the exported encryption settings definitions.
`--pin-file` (optional)	Specifies the path to a file containing the passphrase used to protect the contents of the encryption settings definitions. If this is not provided, the tool interactively prompts for the passphrase.
`--set-preferred` (optional)	An optional argument that indicates that if the export file contains a definition that is marked as preferred, then it becomes the new preferred definition for the instance.

> **Note**
>
> When importing definitions into a non-empty encryption settings database, the existing definitions are preserved and the new definitions are added alongside them. If any of the definitions from the import file already exist in the database, they are skipped when processing the import.

The following is an example of the command with one of the arguments included.

```
$ bin/encryption-settings import \
     --input-file exported-definitions.esd
Enter the PIN used to encrypt the definition:
Successfully imported encryption settings definition
125480AFA3300CD8E48CDF53AF3A0D4DDC8760E115C5B986530F1FE438B19DBD from file
/ds/{pingdir}/exported-definitions.esd.
Successfully imported encryption settings definition
CA8A76C13DD5CC3F85A437119D9DC0867396910F64E228962A30FF80B36C3B63 from file
/ds/{pingdir}/exported-definitions.esd.
```

Setting the preferred encryption settings definition

To choose a different definition to be the one that is preferred for new encryption operations, use the `encryption-settings set-preferred` command.

This command supports the following arguments.

Argument	Description
`--id`	A required argument that specifies the ID of the encryption settings definition that should become the new preferred definition.

The following is an example of the command with one of the arguments included.

```
$ bin/encryption-settings set-preferred \
     --id CA8A76C13DD5CC3F85A437119D9DC0867396910F64E228962A30FF80B36C3B63
Encryption settings definition
CA8A76C13DD5CC3F85A437119D9DC0867396910F64E228962A30FF80B36C3B63 was successfully set
as the preferred definition for subsequent encryption operations.
```

When creating a new definition that is used across multiple instances, you might want to omit the `--set-preferred` argument when running `encryption-settings create`. Instead, you should ensure that the definition is created across all instances first, and then use `encryption-settings set-preferred` to make it the new preferred definition. This helps avoid the chance that an instance that has not yet been updated with the new definition encounters an error when trying to decrypt data from another instance that is already using that definition.

Configuring data encryption restrictions

The PingDirectory server supports several data encryption restrictions that make it harder for unauthorized individuals to access data in an unencrypted form.

About this task

> **Note**
>
> By default, none of the available data encryption restrictions are active in the server.

Steps

- To configure data encryption restrictions, use the `encryption-settings set-data-encryption-restrictions` command with one of the following arguments.

Arguments	Description
`--add-restriction <restriction-name>`	Activates the specified encryption restriction in the server. You can provide this argument multiple times with a single command to add multiple restrictions.
`--remove-restriction <restriction-name>`	Removes the specified encryption restriction from the server. You can provide this argument multiple times with a single command to remove multiple restrictions.
`--remove-all-restrictions`	Removes any data encryption restrictions that are currently in place.
`--add-all-restrictions`	Activates all supported data encryption restrictions that are not already active.

Example:

```
$ bin/encryption-settings set-data-encryption-restrictions \
    --add-all-restrictions
```

After the successful completion of the previous command, you receive a message like the following:

```
Successfully updated the set of active data encryption restrictions.

The updated set of active data encryption restrictions is:
* prevent-disabling-data-encryption.
* prevent-changing-cipher-stream-provider.
* prevent-encryption-settings-export.
* prevent-unencrypted-ldif-export.
* prevent-passphrase-encrypted-ldif-export.
* prevent-unencrypted-backup.
* prevent-passphrase-encrypted-backup.
* prevent-decrypt-file.
```

- To determine which data encryption restrictions are active in the server, use the `encryption-settings get-data-encryption-restrictions` command.

> **Note**
>
> If you are defining data encryption restrictions in the server, freeze the encryption settings database so that these restrictions cannot be modified by anyone without the appropriate passphrase. For more information, see Freezing the encryption settings database.

Freezing the encryption settings database

You can freeze the encryption settings database with a specified passphrase. While it is frozen, the database operates in read-only mode.

About this task

If the encryption settings database is frozen, the server can use the database for data encryption processing but will not allow any of the following:

- Creating new encryption settings definitions
- Importing encryption settings definitions from an exported set
- Removing encryption settings definitions
- Specifying which definition is preferred for new encryption operations
- Adding or removing data encryption restrictions

To make changes to a frozen database, you must unfreeze it by providing the passphrase originally used to freeze it.

Steps

- To freeze the encryption settings database, use the `encryption-settings freeze` command.

  This command supports the `--passphrase-file <path>` argument, which specifies the path to a file containing the passphrase to use for freezing the encryption settings database. If the argument is not provided, the `encryption-settings freeze` command prompts the user for the passphrase.

  Example:

```
$ bin/encryption-settings freeze
Enter the passphrase to use to freeze the encryption settings database:
Confirm the freeze passphrase:
Successfully froze the encryption settings database.
```

- To unfreeze the encryption settings database, use the `encryption-settings unfreeze` command and provide the passphrase originally used to freeze the database.

  This command supports the `--passphrase-file <path>` argument, which specifies the path to a file containing the passphrase to use for unfreezing the encryption settings database. If this argument is not provided, the `encryption-settings unfreeze` command prompts the user for the passphrase.

  Example:

  ```
  $ bin/encryption-settings unfreeze
  Enter the passphrase used to freeze the encryption settings database:
  Successfully unfroze the encryption settings database.
  ```

- To determine whether the encryption settings database is currently frozen, use the `encryption-settings is-frozen` command.

  This command does not require any arguments.

  Example:

  ```
  $ bin/encryption-settings is-frozen
  The encryption settings database was frozen at Mon Mar 06 22:42:10 UTC 2023.
  ```

Re-encrypting data in the database

If you update the server to use a new preferred encryption settings definition, that new definition is used for all subsequent data encryption, but existing data remains encrypted with an older key.

In many cases, this can be acceptable. Records in the replication database or the LDAP changelog that were encrypted with an old key are eventually removed in accordance with the configured purge settings, and entries in backends are upgraded to use the new key as they are updated by clients.

However, there can be cases, such as if you suspect that an existing key might have been compromised, in which you want to immediately transition to using a new definition. To do this, you must use the `encryption-settings create` command to add the desired new encryption settings definition to the settings database on all servers or alternatively, create the new definition on one server, export it from that instance, and import it into all of the other instances. You can then use the `encryption-settings set-preferred` command to make the new definition the preferred definition across all instances.

Important

Before removing a compromised encryption settings definition, you should run the **`encrypt-file --find-encrypted-files`** command to search for encrypted files on the server. If any files are encrypted with a key tied to the compromised encryption settings definition, those files will no longer be accessible after you remove the definition, potentially preventing the server from starting or from functioning properly. If any encrypted files are found, run **`encrypt-file --re-encrypt`** to re-encrypt the files with a different definition before removing the compromised definition.

Complete the following process for each instance, one instance at a time, in the topology:

1. To disable replication for all backends and remove the server from the replication topology, use **`dsreplication disable`**.
2. Stop the instance so that its data will not change during the process of converting to the new key.
3. To export the contents of all encrypted backends, those backed by the Berkeley DB Java Edition database, to LDIF, use the **`export-ldif`** command. If the LDAP changelog is enabled, then also export its contents to LDIF using the same process. Make sure that the LDIF exports are encrypted (see Encrypting LDIF exports) to keep them secure.
4. To re-import the LDIF data into the appropriate backends, use the **`import-ldif`** command.
5. Remove the `changelgoDb` directory in the server instance root, which holds the replication database not the `db/changelog` directory, which holds the database for the LDAP changelog.
6. Start the server.
7. To add the server back into the replication topology and verify that changes are properly replicated between that instance and other servers in the topology, use **`dsreplication enable`**.

Managing data encryption in the global configuration

If data encryption is not enabled during setup, you can enable it at any time by ensuring that the server is configured with an appropriate encryption settings definition and updating the following properties in the global configuration.

Property	Description
`encrypt-data`	Indicates whether data encryption should be enabled. Upon enablement, any writes to backends, the replication database, and the LDAP changelog are encrypted, but existing data remains unencrypted. Any unencrypted data in the replication database and LDAP changelog is eventually removed in accordance to their purging configuration, but we recommend exporting backends to LDIF and re-importing to ensure that all of the data that they contain is encrypted.
`encryption-settings-cipher-stream-provider`	The cipher stream provider that should be used to protect the contents of the encryption settings database. See the Configuring cipher stream providers topic for more detail.

Property	Description
`encrypt-backups-by-default`	Indicates whether any new backups that are created should automatically be encrypted with a key from the encryption settings database. If you want to create a backup that is not encrypted, then you can provide the `--doNotEncrypt` argument to the backup command. If you want to create a backup that is encrypted with a different key, then use one of the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, or `--encryptionSettingsDefinitionID` arguments.
`backup-encryption-settings-definition-id`	The ID of the encryption settings definition that is used when encrypting backups by default. If this is not specified, then the server's preferred encryption settings definition is used.
`encrypt-ldif-exports-by-default`	Indicates whether any new LDIF exports that are created should be automatically encrypted with a key from the encryption settings database. As with the backup tool, the export-ldif tool offers the `--doNotEncrypt`, `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to change its encryption behavior.
`ldif-export-encryption-settings-definition-id`	The ID of the encryption settings definition that is used when encrypting LDIF exports by default. If this is not specified, then the server's preferred encryption settings definition is used.
`automatically-compress-encrypted-ldif-exports`	Indicates whether the server should automatically compress LDIF exports that are encrypted.

Configuring cipher stream providers

Cipher stream providers are used to protect the keys stored in the encryption settings database.

By default, setup generates a strong, random passphrase and writes it to a file. The server then uses a file-based cipher stream provider to read the passphrase and generate a key for encrypting the contents of the encryption settings database. However, the server supports additional cipher stream providers that use alternative means for unlocking the encryption settings database. Options include:

- Require a passphrase to be interactively provided when the server is started, or any time an external process needs access to the encryption settings database.
- Use a key stored in the Amazon Key Management Service (KMS).

- Use a key stored in a HashiCorp Vault instance.
- Use a key generated from a passphrase stored in the Amazon Secrets Manager service.
- Use a key generated from a passphrase stored in the Azure Key Vault service.
- Use a key generated from a passphrase stored in a CyberArk Conjur instance.
- Use a key generated from a certificate stored in a PKCS #11 token.

It is also possible to use the Server SDK to create cipher stream providers that use custom logic to protect the contents of the encryption settings database.

If you want to configure the server to use a different cipher stream provider, first ensure that the desired cipher stream provider is defined and enabled in the configuration and then update the global configuration to use that cipher stream provider to protect the encryption settings database. You should do this with the server online so that it can automatically re-encrypt the encryption settings database with the new key.

For example, to configure the server to use the Amazon KMS cipher stream provider, first create an Amazon AWS external server configuration definition that provides information needed to interact with the AWS service, including which region to use, the type of authentication to use, and whether to access AWS through an HTTP proxy server:

```
$ bin/dsconfig create-external-server \
  --server-name AWS \
  --type amazon-aws \
  --set authentication-method:access-key \
  --set aws-access-key-id:[KMS_ACCESS_KEY_ID] \
  --set aws-secret-access-key:[KMS_SECRET_ACCESS_KEY] \
  --set region-name:us-east-1
```

Then, create a cipher stream provider with the configured external server and specify which key to use to protect the encryption settings database:

```
dsconfig create-cipher-stream-provider \
     --provider-name "Amazon KMS" \
     --type amazon-key-management-service \
     --set enabled:true \
     --set "aws-access-key-id:[KMS_ACCESS_KEY_ID]" \
     --set "aws-secret-access-key:[KMS_SECRET_ACCESS_KEY]" \
     --set "kms-encryption-key-arn:[KMS_KEY_ARN]"
```

Finally, update the global configuration to use the new cipher stream provider. This should be done with the server online to ensure that the existing encryption settings database is re-encrypted with the cipher stream provider:

```
dsconfig set-global-configuration-prop \
     --set "encryption-settings-cipher-stream-provider:Amazon KMS"
```

See the `use-the-amazon-kms-cipher-stream-provider.dsconfig` and `use-the-vault-cipher-stream-provider.dsconfig` batch files in the `config/sample-dsconfig-batch-files` directory for more information about the KMS and Vault cipher stream providers.

Encrypting backups

Even if the data stored in a backend's database is encrypted, there is additional benefit in encrypting backups of that database.

The encryption covers additional database metadata that is not encrypted, and it also serves as a kind of integrity check to ensure that the backup hasn't been altered or corrupted since it was created.

If you enable data encryption when running setup, then the server is automatically configured to encrypt backups by default. If encryption is enabled after setup, you can use the `encrypt-backups-by-default global` configuration property to configure this. In either case, the default behavior is to use the preferred encryption settings definition to obtain the encryption key, but you can explicitly specify an alternative definition for backups using the backup-encryption-settings-definition-id property.

The backup tool offers the following arguments related to encryption.

Argument	Description
`--encrypt`	Indicates that the backup should be encrypted. This can be used to explicitly enable encryption if the `encrypt-backups-by-default global` configuration property is set to false. This argument is also required if you use one of the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, or `--encryptionSettingsDefinitionID` arguments. If encryption is not enabled by default in the global configuration and this argument is provided without one of the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, or `--encryptionSettingsDefinitionID` arguments, then the server's preferred encryption settings definition is used.
`--promptForEncryptionPassphrase`	Indicates that the backup tool should interactively prompt for the passphrase used to generate the encryption key. If this is provided, then the backup is encrypted with that key rather than one obtained from an encryption settings definition.
`--encryptionPassphraseFile`	Specifies the path to a file that contains the passphrase that should be used to generate the encryption key. If this is provided, then the backup is encrypted with that key rather than one obtained from an encryption settings definition.
`--encryptionSettingsDefinitionID`	Specifies the identifier for the encryption settings definition that should be used to encrypt the data. This can override the logic that the server would otherwise use to select the encryption settings definition.

Argument	Description
`--doNotEncrypt`	Indicates that the backup should not be encrypted. This can be used to explicitly obtain an unencrypted backup if `encrypt-backups-by-default` is set to true in the global configuration.

Each backup directory includes a descriptor file with information about all of the backups contained in that directory. This descriptor indicates whether the backup is encrypted, and if it was encrypted with a definition from the encryption settings database, then it includes its ID. In such cases, the restore tool automatically obtains the necessary key from the encryption settings database.

However, if the backup was encrypted with a passphrase rather than an encryption settings definition or if the definition is not included in the encryption settings database but you know the passphrase used to create that definition, then you can use one of the following arguments to provide the necessary passphrase.

Argument	Description
`--promptForEncryptionPassphrase`	Indicates that the restore tool should interactively prompt for the passphrase used to generate the encryption key.
`--encryptionPassphraseFile`	Indicates that the restore tool should interactively prompt for the passphrase used to generate the encryption key.

Encrypting LDIF exports

Each backup is essentially an archive that includes all of the necessary database files. It can be quickly restored in a PingDirectory server if the need arises, but the data is not accessible for any other purpose.

LDIF is a standard plain-text representation of LDAP data. While it might take somewhat longer to import data from an LDIF file than it does to restore a backup, the PingDirectory server can generally import entries at a very high rate. Because LDIF is a standard format, the data can be easily parsed with a wide variety of libraries (including the UnboundID LDAP SDK for Java) or viewed in a text editor. It is also highly compressible, and a gzipped LDIF file can take up substantially less space than a backup (which includes additional data beyond the entries, like indexes and database structure). As such, there are compelling reasons to use LDIF exports as a backup mechanism instead of or in addition to backup archives. However, because it is a plain-text format, it is essential that LDIF exports be encrypted to prevent their content from being readily available to anyone who gains access to them.

The `encrypt-ldif-exports-by-default` property in the global configuration can automatically encrypt LDIF exports by default. The `ldif-export-encryption-settings-definition-id` property can specify the encryption settings definition to protect the data, or the server can fall back to using the preferred definition. Further, the `automatically-compress-encrypted-ldif-exports` property can be used to compress the data as it is encrypted for substantial space savings.

If the global configuration is not set up to encrypt LDIF exports by default, or if you want to encrypt the data with a different key, the **`export-ldif`** tool provides the following arguments which are largely the same as those offered by the backup tool:

- `--encryptLDIF`
- `--promptForEncryptionPassphrase`

- `--encryptionPassphraseFile`
- `--encryptionSettingsDefinitionID`
- `--doNotEncrypt`

When importing an LDIF file, the server can automatically determine whether the data is encrypted or compressed, and if the file was encrypted with a key from the encryption settings database, the encryption header includes the ID of the definition that was used. However, if the LDIF data was encrypted with a passphrase rather than an encryption settings definition, then one of the following arguments can be used to provide that passphrase:

- `--promptForEncryptionPassphrase`
- `--encryptionPassphraseFile`

Encrypting, sanitizing, and signing log files

Log files are useful for understanding server usage patterns and troubleshooting problems, but they can also contain sensitive data like attribute values that might appear in entry DNs or search filters. To protect against this, the server can log to encrypted files.

File-based loggers include the following configuration properties to control this.

Property	Description
`encrypt-log`	Indicates whether the log file should be encrypted.
`encryption-settings-definition-id`	Specifies the ID of the encryption settings definition that should be used to obtain the encryption key. If this is not specified, then the preferred definition is used.

If you need to access data in an encrypted log file, then the **`encrypt-file`** tool can be used to decrypt its content. This tool is discussed in more detail in the encrypt-file tool section. However, it might not be necessary to decrypt log files to be able to use them. Both the **`search-logs`** and **`summarize-access-log`** tools both provide support for operating on encrypted and compressed log files.

In most cases, no special handling is needed, because the log data is encrypted with a definition from the server's encryption settings database, and the tool can obtain the appropriate definition from that database. However, if the encryption settings database is not available, such as if the tool is run from a system other than the one on which the server is running, or no longer contains the definition that was used to encrypt the log file, then the `--encryptionPassphraseFile` argument can be used to specify the passphrase used to generate that definition.

For additional information, see the `config/sample-dsconfig-batch-files/create-encrypted-loggers.dsconfig` batch file.

Sanitizing log files

Another way to prevent unauthorized access to sensitive information in log files is to remove or obscure that information.

The **`sanitize-log`** tool can be used to accomplish this. It classifies each log field into one of three categories found in the following table.

> **Note**
>
> To sanitize log content as it's being written, see Log sanitization.

Category	Description
Preserve	The value of the field is preserved as it appeared in the log message. The `sanitize-log` tool is preconfigured with a set of log fields that should not contain any sensitive information and are considered safe to preserve, but you can add additional fields to this set using the `--preserveField` argument.
Tokenize	The value of the field is converted into a token, which is a number surrounded by curly braces (for example, the first tokenized value is "{1}", the second is "{2}", and so on). If the field value appears to be a DN or search filter, then only attribute values in that DN or filter are tokenized; otherwise, the entire value is tokenized. The same token is used for the same value every time it appears in a log file, which can make it easier to correlate information across operations without revealing what the value actually is. The tool is preconfigured with a set of log fields that are appropriate for tokenization, but you can add additional fields to this set with the `--tokenizeField` argument.
Redact	The entire value of the field will be replaced with the string `---REDACTED---`. Any field that is not marked for preservation or tokenization is automatically redacted. If you want to redact a field whose value would otherwise be preserved or tokenzied by default, you can use the `--redactField` argument.

The `sanitize-log` tool automatically detects whether the log file is encrypted or compressed, and you can also optionally encrypt or compress the output. It provides the following arguments in support of this.

Argument	Description
`--inputEncryptionPassphraseFile`	Specifies the path to a file containing the passphrase needed to decrypt the contents of the log file. This is generally not needed, as log files are encrypted with a key from the encryption settings database and the `sanitize-log` tool can automatically obtain the appropriate key from that database. However, if that key is not available for some reason, you can use this argument to provide the necessary passphrase.
`--compressOutput`	Indicates that the sanitized output should be compressed.

Argument	Description
`--encryptOutput`	Indicates that the sanitized output should be encrypted.
`--outputEncryptionPassphraseFile`	Specifies the path to a file containing the passphrase that is used to encrypt the sanitized output. If this argument is not provided but the `-encryptOutput` argument is given, then the tool interactively prompts for the passphrase.

Signing log files

Regardless of whether they are encrypted, the server can digitally sign log files to provide a means of verifying that the content has not been altered in any way. This can be controlled by the `sign-log` property in the configuration for each logger.

Rather than signing log files as a whole, the server signs groups of one or more messages. Each time it writes a set of log messages to disk, a signature is generated for that set of messages. In the event that log messages are altered, or a set of messages are removed from the file, this provides a more fine-grained method for determining which content is trustworthy and which is not. Signature information can also carry over between rotated log files, so it is possible to determine if an entire log file has been removed.

The `validate-file-signature` tool can be used to verify the signatures in a log file to confirm that the content has not been altered. This tool supports the following arguments.

Argument	Description
`--file`	Specifies the path to the file whose signature should be validated. If a chain of log files should be validated, then this should be the most recent file in the chain.
`--encryptionPassphraseFile`	Specifies the path to a file containing the passphrase that was used to encrypt the file contents. This should not be necessary if the file was encrypted with a key from the encryption settings database and that key is still accessible. If this argument is not provided and the encryption passphrase cannot be automatically retrieved, then the tool interactively prompts for the passphrase.

Argument	Description
`--validateLogChain`	Indicates that the tool should validate a chain of log files. It starts with the file specified by the `--file` argument, but if that file was created after rotating from a previous file, then it works its way backwards through the chain of log files. **Note** When the server is restarted, it cannot continue using the same signature chain that it was using before the restart, so the process of validating a chain automatically stops when it encounters a server restart.
`--numFiles`	Specifies the maximum number of log files in the chain that should be validated. By default, the tool attempts to verify as much of the chain as possible.
`--logDuration`	Specifies the minimum length of the time span that should be covered by the log content when validating a chain of files. If this is specified, then its value should be given as an integer followed by a time unit (for example, "10 minutes" or "1 day"), and the tool tries to iterate backwards through files in the chain until at least this length of time has been covered.
`--ignoreMultipleSignedBlocks`	Indicates that the tool should ignore errors that can arise if a log file contains multiple signed blocks. This can happen if the server was restarted and the logger is configured to append to any existing log file rather than rotating it and starting with a fresh log file.
`--ignoreMissingEndOfSignature`	Indicates that the tool should ignore an error if the target log file does not end with valid signature information. This might happen when trying to validate the active log file with the server still online.
`--ignoreMissingFile`	Indicates that the tool should ignore an error caused by attempting to follow a log file chain when a file indicates that it was created after rotating from an earlier log file, but that earlier log file does not exist. This might happen if the older log file has been deleted by log retention processing.

Encrypting TOTP secrets and delivered tokens

The server might sometimes need to store authentication-related data in the user's entry in reversible form.

This includes:

- Shared secrets that are needed to generate time-based passwords for use by the UNBOUNDID-TOTP Simple Authentication and Security Layer (SASL) mechanism. It might also need to store the last TOTP password that the client used to prevent it from being reused.
- One-time passwords that have been generated by the server and delivered to the user for use by the UNBOUNDID-DELIVERED-OTP SASL mechanism.
- Password reset tokens that can be used to allow a user to recover access to their account even if they have forgotten their password, if their password is expired, or if the account has been locked.

This information needs to be stored in the server in a form that allows the server to obtain its clear-text value. Although these values can actually be stored in the clear, the Encrypt TOTP Secrets and Delivered Tokens plugin can be used to encrypt their values so that they are not available to anyone who gains access to the corresponding operational attributes in the user's entry.

For more information, see the `config/sample-dsconfig-batch-files/enable-encryption-for-shared-secrets-and-one-time-passwords.dsconfig` sample batch file.

Encrypting support data archives

The `collect-support-data` tool is a vital resource for support personnel to use when trying to diagnose issues with a PingDirectory server.

It collects a range of information about the server installation and the underlying system, including:

- The current server configuration and configuration changes made over time
- The server schema
- Portions of log files
- Server monitor data
- The server root DSE
- The output of the status command
- A list of all of the access control rules defined in the server
- Information about all third-party extensions that have been installed
- Stack traces of all threads running in the server
- Information about JVM garbage collection and memory usage
- A listing of all processes running on the system
- Information about the underlying performance of the system, including CPU utilization, memory consumption, disk I/O
- Other system-related information, including networking and storage configuration

The `collect-support-data` tool attempts to redact sensitive information (like encoded passwords and other credentials) as it's collecting data, and you can use the `--securityLevel` argument to configure how aggressive it is when deciding what to obscure or remove. However, even at the highest security level, the resulting support data archive likely has information that you want to protect.

One way that you can do this is by encrypting the support data archive before you provide it to support personnel. You can encrypt the contents with a passphrase, and then provide the passphrase to the support engineer through a different channel than was used to transmit the archive. The `collect-support-data` tool offers the following arguments related to encrypting the archive.

Argument	Description
`--encrypt`	Indicates that the support data archive file should be encrypted.
`--passphraseFile`	Specifies the path to a file containing the passphrase to use to encrypt or decrypt the file. If this argument is not provided, then the tool interactively prompts for the passphrase.
`--generatePassphrase`	Indicates that the tool should generate a random encryption passphrase and write it to the specified passphrase file. This argument should only be used in conjunction with both the `--encrypt` and `--passphraseFile` arguments.
`--decrypt`	Indicates that the tool should decrypt the support data archive at the specified path.

Other files that can be encrypted

The PingDirectory server and accompanying tools support interacting with a variety of other types of encrypted files.

Examples of this include:

- The files containing the PIN needed to access a certificate key or trust store, such as the `ads-truststore.pin`, `keystore.pin`, and `truststore.pin` files in the server's config directory, can be encrypted.
- If a command-line tool needs to read a password from a file, such as when using the `--bindPasswordFile`, `--keyStorePasswordFile`, or `--trustStorePasswordFile` arguments offered by LDAP-enabled tools, it should be able to read from encrypted files.
- If a command-line tool supports obtaining default argument values from a properties file, such as from `config/tools.properties`, that properties file can be encrypted.
- When writing its output to one or more files, the `ldapsearch` tool can encrypt the data as it is written.
- When reading the set of changes to process, the `ldapmodify` and `parallel-update` tools can read those changes from encrypted LDIF files.
- LDIF tools like `ldifsearch`, `ldifmodify`, and `ldif-diff` support reading from and writing to encrypted LDIF files.

The encrypt-file tool

The PingDirectory server includes a command-line tool that can be used to encrypt and decrypt files using keys from the server's encryption settings database or using a passphrase that you provide interactively or in a file.

This tool offers the following arguments.

Argument	Description
`--input-file`	Specifies the path to the file containing the data to be encrypted or decrypted. If this is not provided, then the data can be read from standard input, such as entered interactively or piped from another command.
`--output-file`	Specifies the path to the file to which the encrypted or decrypted data is written. If this is not provided, the data is written to standard output.
`--decrypt`	Indicates that input is expected to be encrypted, and the tool should decrypt it. If this argument is not provided, then the tool encrypts the input data.
`--prompt-for-passphrase`	Indicates that the tool should interactively prompt for the passphrase to use to encrypt or decrypt the input data. If this is provided, then the `--input-file` argument must also be provided because the tool does not support both prompting for a passphrase and reading the data to process from standard input.
`--passphrase-file`	Specifies the path to a file containing the passphrase to use to encrypt or decrypt the input data.
`--encryption-settings-id`	Specifies the identifier for an encryption settings definition that is used to encrypt or decrypt the input data.
`--use-topology-key`	Indicates that the data should be encrypted or decrypted using a key that is generated by and shared among servers in the replication topology. This is a legacy encryption mechanism that is no longer used by modern versions of the server, and it is only needed when encrypting data that might need to be decrypted by older instances in the same topology.
`--compress-output`	Indicates that the output should be gzip-compressed as it is written. When the tool is operating in encrypt mode, the data is compressed before it is encrypted.

Argument	Description
`--decompress-input`	Indicates that the input data is gzip-compressed. When operating in decrypt mode, the data is decompressed after it has been decrypted.
`max-megabytes-per-second`	The maximum rate at which the tool should write the encrypted or decrypted data. This can be helpful when operating on large files as a way of avoiding excessive disk I/O that might impact the performance of other I/O operations on a busy server.

The `--prompt-for-passphrase`, `--passphrase-file`, `--encryption-settings-id`, and `--use-topology-key` arguments are all mutually exclusive and cannot be used together. If none of these arguments is provided, then the tool uses a key from the encryption settings database. When encrypting data, it uses the preferred definition. When decrypting data that was encrypted with an encryption settings definition, the encryption header at the beginning of the file should contain the identifier for the appropriate definition.

Centralized logging

By default, the PingDirectory server logs to files on the server filesystem. This provides the best option for performance and reliability of the logging mechanism itself.

However, this also has the following disadvantages:

- If the system crashes in an unrecoverable manner, such as if the storage becomes corrupted, then the log data might be lost.
- If an attacker is able to gain access to the underlying system, they might be able to alter or delete log files to cover their tracks. Even if the log files are signed so that you can tell that log files have been modified, that doesn't help you determine what the original content was.
- It requires more effort to analyze log files and aggregate results when they are spread across multiple systems.
- In some cases, such as when running in a container like Docker, it might not be easy or possible to get direct access to the instance filesystem.

These issues can be addressed by centralizing log content, and PingDirectory software offers several options to assist with this.

> **Note**
>
> Because PingDirectory server allows you to define multiple loggers of the same type, you can both log to local files and to one or more centralized locations. This can provide the best combination of usefulness and availability.

Logging to a shared filesystem

One simple option for centralizing log content is to have the server log to a shared filesystem.

This is the simplest option, but it only addresses some of the issues outlined previously. While a shared filesystem reduces the need for access to the instance filesystem, it does not necessarily help prevent attackers from altering the files. If attackers gain access to the underlying system and that system has access to files from other instances, they might be able to cause greater disruption than if the content had been kept local to each instance.

Copying files to a centralized system

Another option to centralize logging is to continue to write log files to the local filesystem, but to periodically copy them to a centralized system.

For greater security, the centralized system can pull the files from the instances rather than having the instances push the content, which avoids allowing the server instances to write data to the centralized system.

However, this option still has some security risk associated with it. If an attacker is able to alter log files, then those altered versions will be copied to the centralized system. This can be mitigated to an extent by copying the content more frequently and using versioning when the same copy is copied multiple times, but there is still a window of time in which an attacker can alter the file before it is copied.

Ingesting logs into a log management system

Many organizations use a centralized log management system, such as Splunk or DataDog. In these cases, product log messages can be ingested into that system to make them accessible from a common location, and to provide improved support for analytics and taking other actions upon log content.

There are several ways that log content can make it into the log management system. Some of these options include:

- Most log management software provides agent software that can read data from log files and send it to the centralized system. In some cases, the agent can stream log data as it is written, which reduces the chance that an attacker has a chance to alter it. In other cases, it can copy the data at configured intervals.
- For cases in which the target application is running in a container like Docker, a common practice is to have that application write log messages to standard output or standard error, and to forward those streams to the log management software. To help support this, the PingDirectory server provides an option to write access and error log messages, with each message formatted as a JSON object for greater parsability, to standard output or standard error. For more information about logging to standard output or standard error, see the `config/sample-dsconfig-batch-files/enable-console-based-logging.dsconfig` batch file.
- The log management software can provide an API that applications can use to write log messages directly to that service. Although the PingDirectory software does not provide support for this out of the box, it is possible to use the Server SDK to write a custom log publisher to take advantage of this API.

Logging with syslog

The PingDirectory server can write log messages using the syslog protocol for both access and error logs.

This allows messages to be aggregated at the system level and potentially forwarded to a centralized system. The messages are written to syslog as they are generated, so attackers do not have a chance to alter these log messages.

If you want to use syslog-based logging, configure the server to log to a syslog server running on the local server over the loopback interface. The local syslog server can then forward the messages to a remote server over a secure connection.

Logging over TCP for improved reliability is supported.

UDP-based communication is in the clear, so a network observer can see all of the log messages. You should only use syslog to log to a local syslog server and have it forward messages to a remote server in a secure manner. TLS encryption for TCP-based communication is optionally supported, so you can safely configure the server to log directly to a remote syslog server.

UDP does not provide any feedback about whether messages are successfully delivered, but TCP does provide this feedback. When using TCP-based logging, you can optionally specify information about multiple syslog servers. If the primary syslog server becomes unavailable, the logger can fail over to an alternative syslog server.

Logging access and error log messages can be logged as JSON objects or in legacy space-delimited text format.

In addition to access and error logging over syslog, loggers that can write JSON-formatted audit and HTTP operation log messages are also provided.

Logging to a remote database

The PingDirectory server can write log messages to a relational database.

This should work with any database that provides a driver that allows it to integrate with the Java Database Connectivity (JDBC) framework. As with syslog, these log messages are written to the database as they are generated in the server, so attackers do not have a chance to alter them before they are written.

Communication with the database can be secured using whatever facilities are provided by the JDBC driver. In most cases, this includes support for TLS encryption.

Custom loggers created with the Server SDK

The UnboundID Server SDK provides support for creating custom access, error, and HTTP operation loggers.

If necessary, you can create a custom logger that handles these log messages in whatever way you want.

TLS overview

TLS is a popular protocol for securing network communication.

It is the successor to the SSL, and those terms are sometimes used interchangeably. For legacy compatibility purposes, the PingDirectory server and client tools often use the term SSL in reference to TLS.

TLS can sit below other network protocols in the communication stack to allow those protocols to communicate in a secure manner. The PingDirectory server supports TLS to secure communication with many types of systems, but clients most often use it in conjunction with LDAP, where LDAP secured with TLS is often referred to as LDAPS, and HTTP, referred to as HTTPS.

The security that TLS provides comes in the form of two main components: encryption and trust. It provides a way for two systems to communicate over a secure channel that cannot be deciphered or altered by observers, and it also provides mechanisms for clients to have assurance that they are actually communicating with the intended system.

TLS relies on certificates. This section provides a baseline understanding of certificates, the TLS protocol, the manage-certificates tool, and configuring and using TLS encryption in conjunction with the PingDirectory software.

Understanding X.509 certificates

Although other types of certificates exist, X.509 certificates are the most common type and the only type that the PingDirectory server supports.

The current version of the specification is X.509v3, which is described in RFC 5280. An X.509v3 certificate includes the following components:

- The X.509 encoding version, which makes it possible to differentiate between an X.509v3 certificate or one that conforms to an earlier or future version of the specification.
- The certificate's serial number, which is an integer value that uniquely identifies a certificate as issued by a certification authority. While they were often generated in sequential order in the past, they are now required to be unpredictable with at least 20 bits of entropy.
- A subject DN, which is the distinguished name for the certificate that often provides information about the context in which the certificate is to be used. Certificate subject DNs are discussed in more detail later.
- An issuer DN, which is the distinguished name for the issuer certificate (that is, the certificate used to sign the certificate). For a self-signed certificate, this matches the subject DN.
- A validity window, which indicates the time frame that the certificate should be considered valid. This includes a "notBefore" element, which is the earliest time that the certificate should be considered valid, and a "notAfter" element, which is the latest time that the certificate should be considered valid.
- A public key, which is the public portion of a pair of two cryptographically linked keys. Certificate key pairs are discussed in more detail later.
- An optional subject unique ID, which is intended to uniquely identify the certificate. This has been deprecated in favor of the subject key identifier extension and is generally omitted from X.509v3 certificates.
- An optional issuer unique ID, which is the subject unique ID of the issuer certificate (if it had one). This has been deprecated in favor of the authority key identifier extension.
- An optional set of extensions that provide additional context for the certificate and how it can be used. Certificate extensions are discussed in more detail later.
- A signature, which is a type of cryptographic proof that the certificate really did come from the issuer and has not been altered in any way. As its name implies, a self-signed certificate is signed with its own private key; otherwise, it is signed with the issuer's private key.

Certificate subject DNs

A certificate's subject distinguished name (DN) is a name that provides information about the certificate and how it is intended to be used.

Like an LDAP DN, it is comprised of a comma-delimited series of attribute-value pairs, but the attribute names in a certificate subject DN are typically written in all uppercase, whereas they are typically lowercase or camelCase in LDAP DNs.

Attributes that commonly appear in certificate subjects include:

CN

A common name. For a listener certificate, this is often a hostname that clients use to access the certificate, although the subject alternative name extension provides a better mechanism for accomplishing that. Most certificate subject DNs include at least the CN attribute.

E

An email address.

OU

An organizational unit (department) name.

O

An organization (company) name.

L

A locality (city) name.

ST

A state or province name.

> **Note**
>
> This should be the full name of the state or province, not an abbreviation.

C

An ISO 3166 country code (not the full country name).

A certificate subject should include at least one attribute-value pair, and the CN attribute is typically present. Other attributes can be omitted, but the O and C attributes are also fairly common. For example, a listener certificate for a server with an address of ldap.example.com run by the US-based company Example Corp might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate key pairs

Each certificate has a key pair, which consists of two keys that are cryptographically linked so that if you encrypt data with one of those keys, then it can only be decrypted with the other key.

While it is a relatively simple mechanism to come up with a key pair when generating both keys at the same time, it is extremely difficult (in cryptographic terms, computationally infeasible) to derive one key from the other.

When generating a key pair, one of these keys is designated the public key, and the other is designated the private key. The public key can be made widely available, but the private key should be kept secret and not shared with anyone. As long as that is the case, then you can use this key pair to perform two different functions.

Function	Description
Encryption (also called confidentiality)	If someone wants to send you a secret message and doesn't want anyone else to be able to read it, they can encrypt it with your public key, and since you are the only one with the private key, only you can decrypt it.
Digital signatures	If you encrypt data with your private key, then it can only be decrypted with your public key. Since your public key can be made widely available, then this encryption doesn't actually protect the content, but it does prove that the message came from you because only your private key could have generated it. **Note** When generating a digital signature, you typically don't encrypt the entire message, but rather a hash of the message such as using a digest algorithm like SHA-256. This can also provide integrity protection because if the decrypted signature matches the digest of the original message, then it guarantees that not only the message came from you, but that it hasn't been altered since you signed it.

There are two primary public key algorithms that are used in certificates used for TLS communication: RSA and EC. RSA is based on multiplying really big prime numbers together, while EC is based on computations involving special types of elliptic curves.

RSA is more widely supported, but it's slower and requires bigger keys to achieve the same level of security as EC. If you need to support legacy clients, then you probably need to use an RSA certificate, and you should choose a key size of at least 2048 bits. But if all of your clients support elliptic curve certificates, then EC might be the better choice, with a key size of at least 256 bits.

Certificate extensions

Extensions provide additional context for a certificate.

There are several types of extensions, but some of the most common include.

Extension	Description
Subject key identifier	Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.
Authority key identifier	Holds the subject key identifier for the issuer certificate. It can help identify the issuer certificate, especially when presented with an incomplete certificate chain.

Extension	Description
Subject alternative name	Holds a list of ways that clients are expected to reference a server when establishing a connection to it. Clients should take this information into account when deciding whether to trust a server's certificate. There are several types of values, but the most common are DNS names, IP addresses, and URIs. **Note** DNS names should be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component, For example, "*.example.com" could match "www.example.com" or "ldap.example.com", but would not match "ldap.east.example.com" or "example.com".
Key usage	Provides information about the way in which the certificate is expected to be used. Allowed key usages include: *digitalSignature* Indicates that the certificate can be used for digitally signing data, excluding certificates and CRLs. *nonRepudiation (also known as contentCommitment)* Indicates that the certificate can be used to prevent denying the authenticity of a message. *keyEncipherment* Indicates that the certificate can be used to protect encryption keys, such as symmetric keys derived during TLS key agreement. *keyAgreement* Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key used to protect TLS communication. *keyCertSign* Indicates that the certificate can be used for signing other certificates. For example, it can act as a certification authority. *cRLSign* Indicates that the certificate can be used to sign certificate revocation lists (CRLs). *encipherOnly* When used in conjunction with the keyEncipherment usage, this indicates that the public key can only be used for encrypting data during key agreement. *decipherOnly* When used in conjunction with the keyEncipherment usage, this indicates that the public key can only be used for decrypting data during key agreement

Extension	Description
Extended key usage	Acts as an alternative to the key usage extension and provides additional high-level functionality. Allowed extended key usages include: *serverAuth* Indicates that the server might present the certificate to the client during TLS negotiation. *clientAuth* Indicates that the client might present the certificate to the server during TLS negotiation. *codeSigning* Indicates that the certificate can be used to sign source and compiled code. *emailProtection* Indicates that the certificate can be used to sign or encrypt email messages. *timeStamping* Indicates that the certificate can be used to assert the time that an event occurred. *ocspSigning* Indicates that the certificate can be used to sign an OCSP (online certificate status protocol) response.
Basic constraints	Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that might appear beneath it in a certificate chain.

Certificate chains

A certificate chain is an ordered list of one or more certificates, in which each subsequent certificate is the issuer of the previous certificate.

During TLS negotiation, the server presents a certificate chain to the client so that the client can determine whether it should trust that chain and continue with the negotiation. The client can optionally present its own certificate chain to the server.

If a certificate is self-signed, then its chain contains only that one certificate. If a certificate was signed by a root certificate authority (CA), that is, a self-signed certification authority certificate, then the chain contains two certificates: the server certificate followed by the CA certificate. If there is a single intermediate CA, then the chain contains the server certificate, followed by the intermediate CA, and finally the root CA, and so on.

Intermediate certification authorities are useful security purposes, especially for commercial CAs or other widely trusted authorities. If a client trusts a root CA certificate, then it likely trusts anything that has that root CA certificate at the base of its chain. This means that it's critical to keep the root CA certificate secure, because if it is compromised, then any certificate signed by it (whether directly or indirectly) can no longer be trusted. With intermediate CA certificates, the root certificate

can be kept offline in very secure storage and only used whenever it is necessary to sign a new intermediate CA certificate. The intermediate CA certificates can be the ones to sign end-entity certificates. They should also be extremely well-guarded because it would be disastrous if one of them were compromised requiring it and all certificates it signed had to be revoked, but at least the root CA could be used to sign a new intermediate CA certificate, and that could then be used to sign replacements for all certificates that had been issued by the former CA certificate.

> **Note**
>
> The certificate chain that the server presents to the client (or that the client presents to the server) during TLS negotiation does not necessarily have to be the complete chain.

If the root CA at the end of the chain is widely trusted, then the server might assume that the client already has that root CA in its default set of trusted certificates and leave it off the chain with the assumption that the client will retrieve it from its default trust store. While the same could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. Upon receiving such an incomplete chain, the client should look in its default trust store to see if it contains the issuer certificate which it can identify using things like the issuer DN or an authority key identifier extension.

The certificate at the head of a certificate chain (the first one in the list) is often called the end-entity certificate. If it's at the head of a chain presented by a server during TLS negotiation, then it can also be called the server certificate, whereas if it's at the head of a chain presented by a client, then it can also be called a client certificate. The certificate at the tail of the complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both of those roles.

Representing certificates, private keys, and certificate signing requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which is a binary format. When writing a certificate to a file, it can use this raw DER format, or it can use a plain-text format called PEM.

The PEM encoding consists of a line containing the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines containing the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line containing the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The encoding for private keys is described in the PKCS #8 specification in RFC 5958. This also uses a DER encoding, with a PEM variant that uses `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----`, rather than `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----`. RFC 5958 also describes an encrypted representation of the private key although PingDirectory tools do not currently support that format.

The certificate signing request (CSR) format is described in the PKCS #10 specification in RFC 2986. It uses a DER encoding with a PEM variant. The PEM variant uses a header of `-----BEGIN CERTIFICATE REQUEST-----` and a footer of `-----END CERTIFICATE REQUEST-----` although some implementations use the alternate, nonstandard forms `-----BEGIN NEW CERTIFICATE REQUEST-----` and `-----END NEW CERTIFICATE REQUEST-----`.

Understanding certificate trust

Whenever the server presents its certificate chain to the client during TLS negotiation, the client needs to decide whether it wants to trust that certificate chain and believes that it's actually talking to the legitimate server and not an impostor.

If a client is tricked into communicating with a rogue application instead of the real server, such as through DNS hijacking, then that application could steal the client's credentials or trick the client into believing that it has performed some action that it really hasn't. If the rogue application forwards client communication on to the legitimate server, then it could be even harder for the client to detect the trickery, and even easier for that application to steal data or alter communication. This is why it's vital to avoid using "trust all" or "blind trust" options in a production environment.

The steps that a client should take when determining whether to trust a server certificate chain include:

- The client should ensure that it has the complete certificate chain. If the server presented an incomplete chain, then the client should ensure that it can complete the chain with information in an explicitly provided trust store or a default trust store. If the client can't complete the certificate chain, then it should not be trusted.
- The client should ensure that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it. If a certificate chain contains extraneous certificates, or if a subsequent certificate was not the issuer for the certificate that precedes it, in which case the certificate's signature would not match the expected value, then the chain should not be trusted.
- The client should ensure that it has a reason to trust the certificate at the root of the chain. This is generally done by ensuring that the root certificate authority (CA) certificate can be found in either a trust store configured for use by that client or a default trust store provided by the operating system, Java Virtual Machine (JVM), browser software, or other trusted source. If the client does not have any prior knowledge of the root CA certificate, then the chain should not be trusted.
- The client should verify that the current time is within the validity window for each certificate in the chain. If any certificate in the chain has a notBefore value that is later than the current time or a notAfter value that is earlier than the current time, then the chain should not be trusted.
- The client should verify that the server certificate, the one at the head of the chain, is suitable for the server that the client thinks it's communicating with. It should verify that the address it used to establish the connection matches an address contained in the certificate's subject alternative name extension or in the CN attribute of the certificate's subject.

> **Note**
>
> The client can perform additional types of validation. For example, if any of the root or intermediate certification authorities maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), then the client should verify that none of the certificates in the chain has been revoked. It can verify that the CA certificates include the basic constraints extension and that the server certificate isn't too many levels deep. Other checks, like those using certificate policy extensions, can also be performed.

Understanding key and trust stores

A key store, or keystore, is a type of database for holding certificates.

Key stores come in multiple forms, but the most common include:

- A file using the Java-specific Java Key Store (JKS) format.
- A file using the standard PKCS #12 format, as described in RFC 7292.
- A collection of files that hold certificates and private keys, typically in PEM or DER format.
- A hardware security module (HSM) that makes the certificate information through an interface like PKCS #11.

The PingDirectory server supports file-based key stores using the Java KeyStore (JKS) and PKCS #12 formats and also hardware security modules that are accessible through PKCS #11. It does not directly support a key store format that is comprised of individual certificate and private key files, but the manage-certificates tool can be used to import these files into a JKS or PKCS #12 key store.

A key store is a collection of entries, each of which is identified by an alias, sometimes called a nickname. Key stores can have three types of entries:

Private key entries

Contain both a certificate chain and a private key. When a server is performing TLS negotiation, it uses a private key entry to obtain the certificate chain to present to the client, and it can use the private key from that same entry for its key agreement processing. Similarly, if a client presents its own certificate chain to the server, then it uses a private key entry for that.

Trusted certificate entries

Contain a single certificate without a private key. As the name implies, these entries are primarily intended to be used in the course of determining whether to trust a certificate chain that has been presented during TLS negotiation.

Secret key entries

Contain just a secret key without any associated certificate. These types of entries are not used for TLS processing, but rather hold symmetric encryption keys or other types of secrets.

The contents of a key store are protected with a password or passphrase, sometimes called a PIN. In some cases, like with JKS key stores, some of the content can be accessible without a password, and a password might only be required when trying to access private keys or secret keys. In other cases, like with PKCS #12 key stores, you might need a password for any interaction with the key store.

Further, private keys can also be protected with an additional password. This is often the same as the key store password, but it can also be different. This could be useful, for example, if a single key store is shared for multiple purposes, and merely having access to the key store isn't sufficient to have access to all of the data that it contains.

A trust store, or truststore, is another name for a key store that is primarily intended for use in determining whether to trust a certificate chain that has been presented. Trust stores generally contain just trusted certificate entries, but there is no requirement for that to be the case.

Java runtime environments typically include a default trust store, often `jre/lib/security/cacerts or lib/security/cacerts`, that is pre-populated with several widely trusted certification authority certificates. When presented with a certificate signed by one of these authorities, this default trust store could allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate signed by an issuer that is not in this default trust store, such as a private corporate CA, a separate trust store is needed.

Understanding TLS

TLS provides support for both trust and encryption.

Here are two types of encryption that make up a TLS session:

Symmetric encryption

Uses the same key for both encryption and decryption. Anyone who has the key can decipher encrypted data and can encrypt new data. The most common symmetric algorithms used in modern TLS cipher suites are AES and ChaCha20. Older cipher suites that are no longer considered secure used additional algorithms like DES, 3DES, and RC4.

Asymmetric encryption (also called public key encryption)

Uses different keys for encryption and decryption. Data encrypted with the public key can only be decrypted with the private key, and data encrypted with the private key can only be decrypted with the public key. The most common asymmetric encryption algorithms used in TLS are RSA and elliptic curve (EC).

Symmetric encryption is generally much faster than asymmetric encryption, but it's only secure if the sender and receiver are the only parties that have the symmetric key. Anyone else who has the key could covertly decrypt the information being transferred, and if they can interject themselves into the middle of the communication, they could transparently alter its content. As such, it's only safe to use if the two parties have previously agreed upon a symmetric key that they use only for communication with each other.

The payload data that is transferred in a TLS session is encrypted with a symmetric cipher. However, this can only happen after a negotiation process that allows the client and server to decide upon which symmetric algorithm to use and what key to use with it.

TLS handshake

There are several steps in the TLS negotiation process, which is also called the handshake.

The process varies somewhat based on the TLS version that is ultimately chosen. The basic components of a TLS 1.2 handshake are as follows:

1. The client sends a client hello message, which tells the server the highest version of the TLS protocol that the client supports and what cipher suites it's willing to use. It also includes a set of extensions with additional information, like the address the client is using to communicate with the server, which signature algorithms and elliptic curves the client supports, and whether it supports secure renegotiation.
2. The server returns a server hello message, which tells the client which TLS protocol version it uses and the cipher suite that it has selected. The server can also provide its own extensions to the client.
3. The server sends a certificate message, in which it provides its certificate chain to the client.
4. The server can optionally send a server key exchange message with additional information that the client might need to help it securely derive the same symmetric encryption key that the server comes up with.
5. The server can optionally send a certificate request message, asking the client to present its own certificate chain to the server.
6. The server sends a server `hello done` message to tell the client that it has completed its hello sequence.
7. The client can optionally send a certificate message to the server with its own certificate chain. It should only do this if the server sent a certificate request.

> **Note**
>
> Even if the client got such a request, it can decide not to send a certificate chain and in most cases, it won't. It is up to the server to decide whether it will require a client certificate chain, or whether it is merely optional.

In LDAP, it's very common for the server to ask the client to present a certificate, but to continue with TLS negotiation even if the client doesn't present one. This makes it possible to support authentication methods like SASL EXTERNAL in which the client can use the certificate chain it presented during TLS negotiation as proof of its identity at the LDAP layer.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and then sends a client key exchange message to the server that includes the information that the server needs to come up with the same key. This is done in such a way that only the client and the server know what that key is, even if someone else can observe all the communication that passes between the client and the server.
9. If the client presented a certificate chain to the server, then it also sends a certificate verify message to prove that it has the private key for the certificate at the head of the chain.
10. The client sends a change cipher spec message to the server, which tells the server that it is going to start encrypting everything else that it sends to the server with the symmetric key that they have agreed upon.
11. The client sends a finished message to the server, indicating that it has completed its portion of the handshake.
12. The server sends a change cipher spec message to the client, which tells the client that it is going to start encrypting everything else that it sends to the client with the agreed-upon symmetric key.
13. The server sends a finished message to the client, indicating that it has completed its portion of the handshake.

TLS 1.3 uses a dramatically different handshake sequence that might only require a single round trip to exchange all the necessary information between the client and the server as opposed to the two round trips that TLS 1.2 uses. It does this by trying to guess the type of key agreement that the server wants to use and sending the necessary information to the server up front instead of waiting to hear from the server.

> **Note**
>
> The elimination of an extra round of communication between the client and the server does mean that the server now finishes its portion of the negotiation before the client, whereas it was previously the other way around.

This means that the server has to assume that the client trusts its certificate chain, while it would have previously known that before completing negotiation. This can make certain types of troubleshooting a little more complicated, because the server can log a successful negotiation, only to later find (though a TLS alert) that the client rejected the certificate.

Key agreement

Key agreement processing is a critical component of TLS negotiation because it allows the client and server to pick the symmetric key that is used to encrypt the remainder of the communication, but without letting anyone else know what that key is.

There are a several different key agreement algorithms, but the most common ones use RSA or variants on Diffie-Hellman.

In RSA key exchange, the client generates some random data, encrypts it using the server's public key, and provides that encrypted data to the server. The server uses its private key to decrypt it and get the random data that the client originally generated. Both the client and the server then derive the encryption key from that random data.

In Diffie-Hellman (DH) key exchange, the client and server publicly agree on a pair of mathematically linked numbers, and then each chooses its own secret value. Through a special computation, they come up with a key that is only known to someone who knows one of the secret values. There are a few different variants of the Diffie-Hellman algorithm that are used in key exchange, but ECDHE and DHE are the recommended versions because they use ephemeral keys without any relation to the server's certificate, and of the two, ECDHE is preferred because it is faster and can use smaller keys without compromising security.

If possible, you should prefer ECHDE over DHE, and either of those over RSA. The Diffie-Hellman algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data used to generate the symmetric key, if that certificate's private key is ever compromised, then the encryption can be broken. This includes not only communication on new TLS connections, but also any data that might have been captured in the past. On the other hand, the use of ephemeral keys in ECDHE and DHE ensure that even if the certificate's private key is compromised, any encrypted communication is still indecipherable to anyone but the client and server although anyone with the private key could still pretend to be the legitimate server.

The LDAP StartTLS extended operation

In some cases, it might be possible to establish a non-secure connection and then convert it to a secure one. In LDAP, this can be accomplished with the StartTLS extended operation.

In most cases, when a client wants to use TLS, they establish a connection to a port dedicated to its use, like 636, which is the standard port for LDAPS, or 443, which is the standard port for HTTPS, and the client immediately sends a client hello message over that connection to begin the TLS negotiation process.

There are potential advantages to using the StartTLS extended operation over a dedicated LDAPS connection. It does mean that only one port needs to be opened through a firewall for both secure and insecure communication. It also means that a client can use opportunistic encryption, whereby the client can first query the root DSE to determine whether the server supports StartTLS and then secure the connection if possible. This can be useful in cases like following referrals because LDAP URLs do not officially support "ldaps" as a scheme.

However, we recommend using LDAPS to ensure that the communication is always secure, rather than establishing an initially insecure connection and then securing it with the StartTLS extended operation. If you enable support for unencrypted LDAP communication, which is required for StartTLS, then you run the risk that a client might send sensitive data, such as a bind request containing a password, over that unencrypted connection. The server can be configured to reject any unencrypted communication, but it can't prevent the client from sending the unencrypted request in the first place.

> **Note**
>
> While it is theoretically possible to use StartTLS to temporarily secure a connection and then drop back to using unencrypted LDAP communication, this is not a recommended practice, and the PingDirectory server does not support it.

Managing certificates

Because certificates are critical to providing secure communication, it is vital to understand how to manage them in the PingDirectory server.

The manage-certificates tool

The PingDirectory server offers a manage-certificates tool that can interact with Java KeyStore (JKS) and PKCS #12 key stores.

It is similar to the `keytool` utility that accompanies most Java distributions, but `manage-certificates` is easier to use, provides better usage information, and offers some additional functionality.

Available subcommands

The `manage-certificates` tool uses subcommands to indicate which function you want to invoke.

The subcommands that it offers include the following.

Subcommand	Description
`list-certificates`	Lists the certificates in a key store.
`import-certificate`	Imports a certificate into a trusted certificate entry, or imports a certificate chain and private key into a private key entry.
`export-certificate`	Exports a certificate from a key store.
`export-private-key`	Exports a private key from a key store.
`generate-self-signed-certificate`	Generates a self-signed certificate.
`generate-certificate-signing-request`	Generates a certificate signing request that can be provided to a certification authority.
`sign-certificate-signing-request`	Signs a certificate signing request with a specified issuer certificate.
`check-certificate-usability`	Checks a specified certificate in a key store to verify whether it is suitable for use as a listener certificate.
`trust-server-certificate`	Initiates the TLS negotiation process with a specified server to obtain its certificate chain to update a trust store with information needed to trust that chain.
`display-certificate-file`	Displays the contents of a file containing one or more PEM-encoded or DER-encoded X.509 certificates.

Subcommand	Description
`display-certificate-signing-request-file`	Displays the contents of a file containing a PEM-encoded or DER-encoded PKCS #10 certificate signing request (CSR).
`change-certificate-alias`	Changes the alias for an entry in a key store.
`change-keystore-password`	Changes the password for a key store.
`change-private-key-password`	Changes the password used to protect the private key for a specified entry in a key store.

Commonly used arguments

Most of the `manage-certificates` subcommands require access to a Java KeyStore (JKS) or PKCS #12 key store. In such cases, you must specify path to that key store using the `--keystore` argument.

If the key store already exists, then the tool automatically detects whether it is a JKS or PKCS #12 key store. If the operation creates a new key store, then you can explicitly specify the type using the `--keystore-type` argument followed by a value of either `JKS` or `PKCS12`. If you do not specify the key store type, a default value of "JKS" is used.

In some cases, you might also be required to provide the password needed to access the key store. For a JKS key store, you might only need to provide a key store password for operations that involve creating a key store or accessing a private key, but you might need to provide the password for all operations involving a PKCS #12 key store. If you need to provide a key store password, there are three ways that you can do so:

- Using the `--keystore-password` argument followed by the clear-text password for the key store.
- Using the `--keystore-password-file` argument followed by the path to a file containing the password for the key store. The file can contain the password in the clear, or it can be encrypted with a definition from the server's encryption settings database.
- Using the `--prompt-for-keystore-password` argument. If this argument is provided, the tool interactively prompts for the password.

Private keys can also be protected with a different password than the key store itself. If that is the case, then the private key password can be given in one of the following ways:

- Using the `--private-key-password` argument followed by the clear-text password.
- Using the `--private-key-password-file` argument followed by the path to a file containing the clear-text or encrypted password.
- Using the `--prompt-for-private-key-password` argument, which causes the tool to interactively prompt for the password.

Several operations require you to specify which key store entry you want to target. In such cases, you can provide the `--alias` argument followed by the name of the alias for that entry.

Listing the certificates in a key store

Use the `list-certificates` subcommand to list the certificates in a key store.

You must specify the path to the key store file, and possibly the password needed to access the key store. Other options that are available include:

`--alias` *{alias}*

Specifies the alias of the certificate to display. If this is not provided, then all certificates are displayed. This can be provided multiple times to list multiple specific certificates.

`--display-pem-certificate`

Indicates that a PEM-encoded representation of each certificate should also be included as part of the output.

`--verbose`

Indicates that the listing should include more detailed information about each of the certificates.

For example, the following command demonstrates a basic listing of a key store containing a single certificate chain.

```
$ bin/manage-certificates list-certificates \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin

Alias:  server-cert (Certificate 1 of 2 in a chain)
Subject DN:  CN=ds1.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time:  Saturday, November 9, 2019 at 11:26:09 AM CST (8 minutes, 15 seconds ago)
Validity End Time:  Sunday, November 8, 2020 at 11:26:09 AM CST (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:81:23:a3
SHA-256 Fingerprint:  4f:be:47:ed:36:68:13:38:ba:e8:c0:c5:6c:85:51:97:8b:40:1b:76:10:c0:be:80:15:62:06:96:c5:71:30:df
Private Key Available:  Yes
The certificate has a valid signature.

Alias:  server-cert (Certificate 2 of 2 in a chain)
Subject DN:  CN=Example Certification Authority,O=Example Corp,C=US
Issuer DN:  CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time:  Saturday, November 9, 2019 at 11:26:08 AM CST (8 minutes, 16 seconds ago)
Validity End Time:  Friday, November 4, 2039 at 12:26:08 PM CDT (7299 days, 23 hours, 51 minutes, 43 seconds from
now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  b8:d0:16:9b:5d:f2:e7:a1:80:79:95:a2:64:b5:aa:ad:80:23:64:16
SHA-256 Fingerprint:  cf:98:2a:66:35:6e:6d:f9:5d:25:c6:68:68:04:5a:a8:88:43:ca:b5:c8:e5:c9:95:09:e9:fc:ab:b9:41:ec:71
The certificate has a valid signature.
```

The following is the verbose version of the previous command.

```
$ bin/manage-certificates list-certificates \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --verbose

Alias:  server-cert (Certificate 1 of 2 in a chain)
X.509 Certificate Version:  v3
Subject DN:  CN=ds1.example.com,O=Example Corp,C=US

Generating self-signed certificates

A self-signed certificate claims itself as its own issuer, so it is a straightforward process to create one. It's convenient for testing, but because no clients trust it by default, it's not recommended as a listener certificate for production use.

The manage-certificates tool offers a generate-self-signed-certificate subcommand that can be used to create one. In addition to the arguments used to provide information about the key store, certificate alias, and optional private key password, the following arguments are also available.

Argument	Description
`--subject-dn <subject>`	The subject distinguished name (DN) for the certificate to create. This must be provided.
`--days-valid <number>`	The number of days that the certificate is valid. If this is not provided, a default value of 365 is used.

Argument	Description
`--validity-start-time <timestamp>`	A timestamp that indicates when the certificate should begin its validity window. The value should be in the form YYYYMMDDhhmmss (for example, 20190102030405 indicates January 2, 2019 at 3:04:05 a.m.) and is assumed to be in the local time zone. If this is not provided, then the current time is used.
`--key-algorithm <name>`	The name of the algorithm to use to generate the key pair. For a listener certificate, the value is typically either "RSA" or "EC". This cannot be used in conjunction with the `--replace-existing-certificate` argument. If neither that argument nor this argument is provided, a default value of "RSA" is used.
`--key-size-bits <number>`	The length of the key to generate, in bits. This must be provided if the `--key-algorithm` argument is also given, and it must not be provided if the `--replace-existing-certificate` argument is given. Typical key sizes are 2048 or 4096 bits when using an RSA key, and 256 or 384 bits for an elliptic curve key. If a default RSA key is used and this argument is not provided, then a default key size of 2048 bits is used.
`--signature-algorithm <name>`	The name of the algorithm to use to sign the certificate. Typical signature algorithms are SHA256withRSA for certificates with RSA keys, or SHA256withECDSA for certificates with elliptic curve keys. This must not be provided if the `--replace-existing-certificate` argument is used, but it must be given if the `--key-algorithm` argument is used to specify an algorithm other than RSA. If a default key algorithm is used and this argument is not provided, then a default value of SHA256withRSA is used.
`--replace-existing-certificate`	Indicates that the new certificate should replace an existing certificate in the key store (in the same alias) and that the key for that certificate should be re-used.
`--inherit-extensions`	Indicates that when replacing an existing certificate, the new certificate should have the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided but this argument is omitted, then the new certificate only has the arguments that are explicitly provided.

Argument	Description
`--subject-alternative-name-dns <name>`	Indicates that the certificate should have a subject alternative name extension with the provided DNS name. The given name should be fully qualified, although it can contain an asterisk as a wildcard in the leftmost component. This argument can be provided multiple times if multiple DNS names are to be included in the subject alternative name extension.
`--subject-alternative-name-ip-address <address>`	Indicates that the certificate should have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address, with no wildcards allowed. This argument can be provided multiple times if multiple IP addresses are to be included in the subject alternative name extension.
`--subject-alternative-name-email-address <address>`	Indicates that the certificate should have a subject alternative name extension with the provided email address. This argument can be provided multiple times if multiple email addresses are to be included in the subject alternative name extension.
`--subject-alternative-name-uri <uri>`	Indicates that the certificate should have a subject alternative name extension with the provided URI. This argument can be provided multiple times if multiple URIs are to be included in the subject alternative name extension.
`--subject-alternative-name-oid <oid>`	Indicates that the certificate should have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. This argument can be provided multiple times if multiple OIDs are to be included in the subject alternative name extension.
`--basic-constraints-is-ca <value>`	Indicates that the certificate should have a basic constraints extension with the specified value (which must be either `true` or `false`) for the flag indicating whether the certificate should be considered a certification authority and can therefore be used to sign other certificates. This should be present with a value of `true` for root and intermediate CA certificates. It can optionally be present with a value of `false` for end-entity certificates. It's probably a good idea for it to be present with a value of `false` for self-signed certificates to indicate that it should not be considered a CA certificate.

Argument	Description
`--basic-constraints-maximum-path-length <number>`	Indicates that the basic constraints extension should include a path length constraint element with the specified value. This can only be used if `--basic-constraints-is-ca` is provided with a value of true. A path length constraint value of zero indicates that the certificate can only be used to issue end-entity certificates. If it has a value of one, then it can be used to sign intermediate CA certificates that can only be used to sign end-entity certificates (although it could also be used to sign end-entity certificates). If it has a value that is greater than one, then that means there can be that many intermediate CA certificates between it and the end-entity certificate at the head of the chain.
`--key-usage <value>`	Indicates that the certificate should have a key usage extension with the specified value. Allowed values include `digital-signature`, `non-repudiation`, `key-encipherment`, `data-encipherment`, `key-agreement`, `key-cert-sign`, `crl-sign`, `encipher-only`, and `decipher-only`. This argument can be provided multiple times to include multiple key usages.
`--extended-key-usage <value>`	Indicates that the certificate should have an extended key usage extension with the specified value. Allowed values include `server-auth`, `client-auth`, `code-signing`, `email-protection`, `time-stamping`, and `ocsp-signing`. This argument can be provided multiple times to include multiple extended key usages.

For example, a command like the following can be used to generate a self-signed server certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Generating certificate signing requests

A certificate signing request (CSR) contains all of the information needed for a certification authority to issue a certificate.

The request format (also known as PKCS #10) is defined in RFC 2986 and includes the following elements:

- The certificate signing request version.
- The requested subject distinguished name (DN) for the certificate.
- The public key for the requested certificate.
- The requested set of extensions for the certificate.
- A signature that proves the requester has the private key for the given public key.

The `manage-certificates generate-certificate-signing-request` command can be used to create a certificate signing request. It generates a public and private key pair and store it in a key store with a given alias, and it also outputs the certificate signing request to the terminal and optionally write it to a file. Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. However, the following arguments are not available when generating a CSR:

- `--replace-existing-certificate`

- `--days-valid <number>`
- `--validity-start-time <timestamp>`

The following arguments are available when generating a certificate signing request but not a self-signed certificate.

Argument	Description
`--output-file <path>`	The path to a file to which the certificate signing request should be written. If this is not provided, then the request is only written to the terminal in PEM form.
`--output-format <value>`	The format to use when writing the certificate signing request. The value can be either PEM or DER, but the DER format can only be used in conjunction with the `--output-file` argument. If this argument is not provided, the PEM format is used by default.
`--use-existing-key-pair`	Indicates that the certificate signing request should use a key pair that already exists in the key store with the given alias rather than generating a new key pair, in which case the given alias must not already be in use in the key store.

For example, a command like the following can be used to create a certificate signing request.

```
$ bin/manage-certificates generate-certificate-signing-request \
     --output-file ds1-cert.csr \
     --output-format PEM \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --keystore-type JKS \
     --alias server-cert \
     --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
     --key-algorithm EC \
     --key-length-bits 256 \
     --signature-algorithm SHA256withECDSA \
     --subject-alternative-name-dns ds.example.com \
     --subject-alternative-name-dns ds1.example.com \
     --subject-alternative-name-ip-address 1.2.3.4 \
     --key-usage digital-signature \
     --key-usage key-encipherment \
     --key-usage key-agreement \
     --extended-key-usage server-auth \
     --extended-key-usage client-auth

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ds/build/package/{pingdir}/ds1-cert.csr'.
```

The contents of the resulting certificate signing request file can be provided to a certification authority to be signed, and the resulting signed certificate can be imported into the key store as described in Importing signed and trusted certificates.

You can also print out the contents of a certificate signing request file using the `display-certificate-signing-request-file` subcommand. This subcommand only supports a couple of arguments.

Argument	Description
`--certificate-signing-request-file <path>`	The path to the file containing the certificate signing request to be displayed.
`--verbose`	Indicates that the command should display verbose information about the request rather than just a basic set of information.

For example, the following demonstrates the basic output from the command.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
```

The following demonstrates the verbose output.

```
$ bin/manage-certificates display-certificate-signing-request-file \
     --certificate-signing-request-file ds1-cert.csr \
     --verbose

PKCS #10 Certificate Signing Request Version:  v1

```

Importing signed and trusted certificates

Use the manage-certificates import-certificate command to import certificates into a key store.

There are three primary uses for this command:

- To import a certificate that has been signed by a certification authority into the key store in which the key pair was generated. It is imported into a private key entry, and it should be imported as a certificate chain rather than just the end-entity certificate.
- To import a trusted issuer certificate into a trust store. It is imported into a trusted certificate entry and is a single certificate rather than a chain.
- To import a certificate chain along with the private key for the end-entity certificate. This can be used to import certificates that were generated through some other library like OpenSSL.

In addition to the arguments used to provide information about the key store and the alias into which the certificate (or certificate chain), this command accepts the following arguments.

Argument	Description
`--certificate-file <path>`	The path to the file containing the certificate to be imported. The certificate can be in either PEM or DER format, and it can be a single certificate or a certificate chain. This argument can also be provided multiple times when importing a certificate chain if the certificates in the chain are in separate files.
`--private-key-file <path>`	The path to a file containing the private key that corresponds to the certificate at the head of the chain that is being imported. The private key can be in either PEM or DER format.
`--no-prompt`	Indicates that the certificate should be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you actually want to import it.

For example, you can use the following command to import a signed certificate into the key store used to generate the certificate signing request.

```
$ bin/manage-certificates import-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --certificate-file ds1-cert.pem \
     --certificate-file ca-cert.pem

The following certificate chain will be imported into the keystore into alias 'server-cert', preserving the existing
private key
associated with that alias:

Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time:  Sunday, November 10, 2019 at 09:09:23 PM CST (4 minutes, 16 seconds ago)
Validity End Time:  Monday, November 9, 2020 at 09:09:23 PM CST (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:  1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:86:1f:5d:79:c3:93

Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time:  Sunday, November 10, 2019 at 09:00:07 PM CST (13 minutes, 32 seconds ago)
Validity End Time:  Saturday, November 5, 2039 at 10:00:07 PM CDT (7299 days, 23 hours, 46 minutes, 27 seconds from
now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP384r1)
SHA-1 Fingerprint:  0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:  77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.
```

Although the tool displays information about the certificates to be imported if you don't provide the `--no-prompt` argument, you might want to see more information about the certificate before it is imported. You can do so with the `display-certificate-file` subcommand, which offers the following arguments.

Argument	Description
`--certificate-file <path>`	The path to the file containing the certificate to view.
`--verbose`	Indicates that verbose information about the certificate should be displayed.

The output of this subcommand has the same format and content as the `list-certificates` subcommand.

Exporting certificates

The `export-certificate` subcommand can be used to export a single certificate or a certificate chain from a key store to a file in either PEM or DER format.

It supports the usual arguments about the key store and the certificate alias, as well as the following additional arguments.

Argument	Description
`--output-file <path>`	The path to the file to which the exported certificates will be written. If this is not provided, then the certificates are written to standard output rather than a file.
`--output-format <format>`	The format in which the exported certificates are written. The value can be one of PEM or DER, but the DER format can only be used if the output is to be written to a file. If this is not provided, PEM is used as the default format.
`--export-certificate-chain`	Indicates that a certificate chain should be exported rather than just the end-entity certificate.
`--separate-file-per-certificate`	Indicates that a separate output file should be used for each certificate that is exported rather than placing them all in one file. If this argument is provided and multiple certificates are to be exported, then ".1" is appended to the path for the indicated output file for the first certificate in the chain, ".2" is appended for the second certificate, and so on.

For example, something like the following could be used to export a certificate chain.

```
$ bin/manage-certificates export-certificate \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert \
     --output-file server-cert.pem \
     --output-format PEM \
     --export-certificate-chain \
     --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN:  CN=ds.example.com,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time:  Sunday, November 10, 2019 at 09:09:23 PM CST (3 hours, 26 minutes, 23 seconds ago)
Validity End Time:  Monday, November 9, 2020 at 09:09:23 PM CST (364 days, 20 hours, 33 minutes, 36 seconds from now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with ECDSA
Public Key Algorithm:  EC (secP256r1)
SHA-1 Fingerprint:  02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb

```

The `export-certificate` subcommand only exports the public portion of a certificate and does not include its private key. If you want to export the private key, then you can use the `export-private-key` subcommand, which supports the following arguments in addition to the usual key store and alias arguments.

Argument	Description
`--output-file <path>`	The path to the file to which the exported private key is written. If this is not provided, then the key is written to standard output rather than a file.
`--output-format <format>`	The format in which the exported private key is written. The value can be one of PEM or DER, but the DER format can only be used if the output is to be written to a file. If this is not provided, PEM is used as the default format.

The following example includes some of the arguments defined previously.

```
$ bin/manage-certificates export-private-key \
        --keystore config/keystore \
        --keystore-password-file config/keystore.pin \
        --alias server-cert \
        --output-file server-cert-key.pem \
        --output-format PEM

Successfully exported the private key.
```

Using manage-certificates as a simple certification authority

If your server instances need to support an arbitrary or unknown set of clients, then it's probably best to configure them with certificates from a trusted issuer, like a commercial authority or the free Let's Encrypt service.

However, if you control all of the clients that will access the servers, then you might want to create your own internal certification authority. This allows you to have a common issuer for all servers so that clients just need to trust certificates signed by that issuer. There are commercial and open-source software packages that provide full-featured certification authority functionality, but you can also use the manage-certificates tool to create a certificate authority (CA) certificate and use it to sign certificate signing requests.

The first thing that you need to do is to create a certification authority certificate. This is a self-signed certificate that should have a key usage extension that includes at least the KeyCertSign usage, and a basic constraints extension that indicates that it's a CA certificate. If you don't plan to have an intermediate CA certificate, then the basic constraints extension should have a path length constraint of zero. If you do plan to have an intermediate CA certificate, then the path length constraint should be one to account for it. The CA certificate should also have a long life span because any certificates that it signs is only valid as long as all certificates in the chain are valid.

For example, you can use the following to create a new root CA certificate.

```
$ bin/manage-certificates generate-self-signed-certificate \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --keystore-type JKS \
     --alias root-ca-cert \
     --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
     --days-valid 7300 \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 1 \
     --key-usage key-cert-sign \
     --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:  CN=Example Root CA,O=Example Corp,C=US
Validity Start Time:  Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)
Validity End Time:  Sunday, January 22, 2040 at 03:47:29 PM CST (7299 days, 23 hours, 59 minutes, 59 seconds from
now)
Validity State:  The certificate is currently within the validity window.
Signature Algorithm:  SHA-256 with RSA
Public Key Algorithm:  RSA (4096-bit)
SHA-1 Fingerprint:  bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:  d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:61:e2:aa:40:08:3a:ff
```

You should then export the public portion of that root CA certificate so that you have it for reference, and so that it can be imported as a standalone certificate into trust stores and as part of a certificate chain when importing signed certificates.

If you want to create an intermediate CA certificate, then you should create a new certificate signing request for that certificate. It should essentially use the same settings as for the root CA, although if we assume that there is only a single intermediate CA, then its basic constraints extension should have a path length constraint of zero rather than one to indicate that it can only be used to sign end-entity certificates and cannot itself create subordinate CA certificates. That certificate signing request can be created with a command like the following.

```
$ bin/manage-certificates generate-certificate-signing-request \
     --keystore /ca/intermediate-ca-keystore \
     --keystore-password-file /ca/intermediate-ca-keystore.pin \
     --keystore-type JKS \
     --alias intermediate-ca-cert \
     --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
     --key-algorithm RSA \
     --key-size-bits 4096 \
     --signature-algorithm SHA256withRSA \
     --basic-constraints-is-ca true \
     --basic-constraints-maximum-path-length 0 \
     --key-usage key-cert-sign \
     --key-usage crl-sign \
     --output-file /ca/intermediate-ca-cert.csr \
     --output-format PEM

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing
request.

Successfully wrote the certificate signing request to file
'/ca/intermediate-ca-cert.csr'.
```

Next, we need to use the root CA certificate to sign the certificate signing request for the intermediate CA certificate. That can be done with the sign-certificate-signing-request subcommand, which takes most of the same arguments as generating a self-signed certificate. The primary differences include:

- The key store arguments provided should be for the key store containing the certificate to use to sign the request. The `--signing-certificate-alias` argument must be used to specify the name of the certificate to use to sign the request.
- You must provide a `--request-input-file argument` to specify the path to the file containing the certificate signing request file to generate.
- You can optionally provide a `--certificate-output-file` argument to specify the path to the file to which the signed certificate should be written. If this argument is omitted, then the PEM representation of the certificate is written to standard output.
- You can optionally provide an `--output-format` argument to specify the format (PEM or DER) in which the certificate should be written to the output file.
- You can optionally use the `--subject-dn` argument to specify the subject that should be used for the signed certificate, but you can omit it to indicate that the subject DN from the certificate signing request should be used.
- You cannot specify the key algorithm or key length, because the requester generated the key. You can, however, use the `--signature-algorithm` argument to specify the name of the signature algorithm.
- The `--include-requested-extensions` argument can be used to indicate that the signed certificate should include all of the extensions listed in the certificate signing request. If this argument is not provided, then you must explicitly specify the set of extensions that should be included.

For example, you can use a command like the following to sign the certificate signing request for an intermediate CA certificate.

```
$ bin/manage-certificates sign-certificate-signing-request \
     --keystore /ca/root-ca-keystore \
     --keystore-password-file /ca/root-ca-keystore.pin \
     --signing-certificate-alias root-ca-cert \
     --days-valid 7300 \
     --include-requested-extensions \
     --request-input-file /ca/intermediate-ca-cert.csr \
     --certificate-output-file /ca/intermediate-ca-cert.pem \
     --output-format PEM

Read the following certificate signing request:

PKCS #10 Certificate Signing Request Version:  v1
Subject DN:  CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm:  SHA-256 with RSA
Public Key Algorithm:  RSA (4096-bit)

Do you really want to sign this request? yes

Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.
```

After you have the intermediate CA certificate, you should create secure, offline backups of the root CA certificate, and then remove it (or at least its private key) from all systems. All of the end-entity certificates should be signed with the intermediate CA certificate, and that process is identical to the example given above. The only reason that you should need to pull the root CA certificate out of cold storage is if you need to sign another intermediate CA certificate.

The PingDirectory server's use of certificates

The PingDirectory server uses two main types of certificates: listener certificates and an inter-server certificate.

Listener certificates

Listener certificates are those that are used to secure communication through TLS.

Whenever a client initiates TLS negotiation with the server, it presents a certificate chain to the client, and the certificate at the head of that chain will be a listener certificate. The client must decide whether to trust the certificate chain, so it is beneficial to ensure that it is signed by an issuer that the client is likely to trust or at least, that the client can be easily configured to trust.

While you can create self-signed certificates with very long life spans, any certificate that you have signed by a certification authority is likely to have a relatively short life span. Commercial authorities are only likely to issue certificates that are valid for up to one or two years, and some use much shorter validity windows. For example, the nonprofit Let's Encrypt service, which can be used to obtain trusted certificates for free as long as you can prove that you control the domains for which they are to be issued, only issues certificates that are valid for up to three months.

While short certificate life spans can be inconvenient for administrators who need to replace them, they do offer some security benefits. In particular, because most clients don't make any attempt to check whether a certificate has been revoked, a relatively short validity window minimizes the time that a compromised certificate can be used. And if the process for replacing certificates is automated or least streamlined, then the inconvenience can be kept to a minimum.

Listener certificates are stored in key stores, and those key stores are referenced by key manager providers, which provide the logic and configuration needed to access the key stores. If a server component, for example, a connection handler, needs to have access to a certificate that it presents to a peer during the TLS negotiation process, then that component should reference the key manager provider that points to the key store containing the desired certificate. If the key store has more than one certificate, and if the component referencing it includes a property that specifies the nickname of the certificate to use, then the certificate with that alias is selected. Otherwise, the server leaves it up to the JVM to select a certificate, and which one it chooses is not well defined.

The server also provides trust manager providers that can determine whether to trust any presented certificate chains. A trust manager provider can reference a specified trust store file, but other options include the JVM-default trust store which uses the Java installation's default set of trusted issuers and the blind trust manager provider which blindly trusts any certificate chain that is presented to it. Do not use the blind trust manager in a production environment because it leaves the server vulnerable to impersonation and interception attacks, but it can be convenient in test environments to troubleshoot certain types of problems.

The inter-server certificate

Use the inter-server certificate to authenticate to other server instances in the topology.

Each instance has a unique inter-server certificate that is generated during the setup process. This certificate is not exposed to clients, so there is no need for it to be signed by a trusted issuer. The topology registry, a mirrored portion of the configuration with information about all of the PingDirectory server instances in the environment, has all of the information that each instance needs to trust the inter-server certificates for all of the other instances.

Inter-server certificates can also be used to protect certain secrets that are shared among servers within the topology, like those used to digitally sign log files, backups, or LDIF exports. It also includes the encryption keys used by reversible password storage schemes.

The inter-server certificate is generated with a very long life span and should not ever need to be replaced unless you suspect that its private key has been compromised.

Replacing listener certificates

In production environments, you should use listener certificates issued by a certification authority, not self-signed certificates. Certification authorities typically use restricted life spans for the certificates that they sign, and you might need to replace those certificates on a regular basis.

This includes obtaining a new certificate chain, making any necessary updates to the key manager provider and connection handler configuration, and updating the server instance listener configuration with the new certificate. This is something that can be done manually, but the `replace-certificate` tool can help automate that process. Updating the server instance listener configuration can be onerous because it should provide information about multiple listener certificates, at least during the transitional phase when the new certificate is being installed.

The `replace-certificate` tool offers both interactive and non-interactive modes of operation. The interactive mode is convenient because it walks you through the process of obtaining a new certificate and installing it in the server, while the non-interactive mode is better suited for scripting the process of replacing the certificate. The interactive mode is also useful for learning the tool because it displays the non-interactive commands needed to achieve the same result.

The `replace-listener-certificate` subcommand handles all the work involved in replacing a listener certificate. In addition to arguments needed to authenticate to the server (for example, `--bindDN` and `--bindPasswordFile`), this subcommand takes arguments that provide information about the key store, PEM, or DER file containing the new certificate, which key and trust manager provider updates should be made, and whether to signal the HTTP connection handler to reload its certificates after the update is complete. The available arguments are listed in the following table.

Argument	Description
`--source-certificate-file` *<path>*``	The path to the PEM or DER file that contains the new certificate chain. Either this argument or `--source-key-store-file <path>` must be provided. If you are providing a certificate chain with multiple certificates, order the chain with the server certificate first. Each subsequent certificate should be the issuer for the previous certificate. You can provide `--source-certificate-file` multiple times if the certificates in the chain are in separate files rather than one file.
`--source-private-key-file` *<path>*``	The path to the PEM or DER file that contains the private key that correlates to the new PEM or DER server certificate. This argument must be provided when including `--source-certificate-file <path>`.
`--source-key-store-file <path>`	The path to the Java KeyStore (JKS) or PKCS #12 file that contains the private key entry with the new certificate chain. Either this argument or `--source-certificate-file <path>` must be provided.
`--source-key-store-password <password>`	The clear-text password needed to access the contents of the source key store.
`--source-key-store-password-file <path>`	The path to a file containing the password needed to access the contents of the source key store. The file can contain the password in the clear, or it can be encrypted with a definition from the server's encryption settings database.
`--source-certificate-alias <alias>`	The alias of the private key entry in the source key store that contains the certificate chain for the new listener certificate. If the source key store has more than one private key entry, then this argument must be provided to indicate which one to use.
`--source-private-key-password <password>`	The password needed to access the appropriate private key in the source key store, PEM, or DER file. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, then the key store password is also used as the private key password.

Argument	Description
`--source-private-key-password-file <path>`	The path to a file containing the password needed to access the appropriate private key in the source key store, PEM, or DER file. The file can contain the password in the clear, or it can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, then the key store password is also used as the private key password.
`--key-manager-provider <name>`	The name of the key manager provider that will be updated to use the new certificate chain. It must be a file-based key manager provider, and it must be enabled. If this argument is not provided, a default value of "JKS" is assumed.
`--trust-manager-provider <name>`	The name of the trust manager provider that will be updated with the information needed to trust the new certificate chain. It must be a file-based trust manager provider, and it must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, then the tool assumes that the trust manager provider has the same name as the key manager provider, though these providers remain separate and distinct.
`--use-jvm-default-trust-manager-provider`	Indicates that the server should be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the cacerts trust store provided with the JVM, rather than updating an existing trust manager provider.
`--target-certificate-alias <alias>`	The alias to use for the new certificate in the key manager provider's key store and also for any appropriate updates in the trust manager provider's trust store. If this is not provided, a default alias of "server-cert" is used. **Note** If the key manager provider's key store or the trust manager provider's trust store already contains an entry with the given alias, the existing entry will be renamed.

Argument	Description
`--reload-http-connection-handler-certificates`	**Indicates that the tool should request that the server cause any HTTPS-based connection handlers to reload their certificates so that they will start using the updated certificate. LDAP connection handlers reacts to the change right away and start presenting the new certificate chain during any subsequent TLS negotiations, but HTTPS connection handlers will continue using the former certificate until the connection handler is restarted or until it is specifically asked to reload its certificates.** **Note** Using this option can prevent clients with existing TLS sessions negotiated with the former certificate from being resumed.

The following example illustrates what you see when you run the `replace-certificate replace-listener-certificate` command with the `--help` argument:

```
replace-certificate replace-listener-certificate \
     --bindDN uid=admin,dc=example,dc=com \
     --bindPasswordFile admin-password.txt \
     --source-key-store-file new-listener-certificate-keystore.jks \
     --source-key-store-type JKS \
     --source-key-store-password-file new-listener-certificate-keystore.pin \
     --source-certificate-alias new-listener-cert \
     --key-manager-provider JKS \
     --trust-manager-provider JKS \
     --target-certificate-alias server-cert
```

The following example illustrates replacing a PEM-encoded listener certificate:

```
replace-certificate replace-listener-certificate \
     --bindDN cn=Directory Manager \
     --bindPasswordFile admin-password.txt \
     --source-certificate-file new-listener-certificate-chain.pem \
     --source-private-key-file new-private-key.pem \
     --source-private-key-password-file encrypted-private-key-password.txt \
     --key-manager-provider JKS \
     --trust-manager-provider JKS \
     --target-certificate-alias server-cert
```

The following example demonstrates using the `replace-certificate` tool in interactive mode to replace the listener certificate chain. The output also includes the non-interactive commands needed to perform the corresponding operations.

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses forTLS
        communication
2 - Replace the inter-server certificate that the server uses to
        authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
        topology registry
4 - Purge any retired inter-server certificates for this server from the
        topology registry
q - Quit without doing anything

Enter your choice: 1

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

NOTE:  'JKS' is the only key manager provider that is suitable to be
updated with a new listener certificate.  Automatically selecting that
provider

Which trust manager provider do you wish to update with information needed
to trust the new listener certificate?

1 - JKS
d - Use the JVM-default trust manager provider to trust any certificate
        signed by an authority in the JVM's default set of trusted issuers

Enter your choice [1]: 1

How would you like to obtain the new listener certificate?

1 - Generate a new self-signed certificate
2 - Generate a request for a certificate to be signed by a certification
    authority
3 - Use a certificate in an existing key store
q - Quit without doing anything

Enter your choice: 2

Enter the subject DN that you would like to use for the new certificate.
The subject DN typically includes some or all of the following components:

* CN -- The common name for the certificate.  This is typically the
  fully-qualified name (not an IP address) that most clients will use to
  connect to the server (alternate names and IP addresses may be provided
  later).  We strongly recommend including a CN attribute in the
  certificate subject
* OU -- Typically the name of the department or organizational unit that
  manages the server
```

```
* O -- Typically the name of the company or organization that manages the
  server
* L -- Typically the name of the city or locality in which the server is
  located
* ST -- Typically the full name (NOT an abbreviation) of the state or
  province in which the server is located
* ST -- Typically the two-character ISO 3166 country code for the country
  in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory
Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: CN=ds1.example.com,O=Example Corp,C=US

Enter the complete set of resolvable names (not IP addresses) that clients
are expected to use to access the server.  These names will be included in
the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk
as a wildcard in the leftmost component that will match any host name in
that component.  For example, '.example.com' indicates that the
certificate may be used in any server whose fully-qualified name consists of
exactly three components, and in which the last two components are
'example.com'

The current set of DNS names to include in the set of subject alternative
names is:

* ds1.example.com
* ip6-localhost
* localhost

What would you like to do?

1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: 2

Enter the new DNS name to include: ds.example.com

The current set of DNS names to include in the set of subject alternative
names is:

* ds.example.com
* ds1.example.com
* ip6-localhost
* localhost

What would you like to do?

1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: 1
```

```
Enter the complete set of IPv4 and IPv6 addresses that clients are
expected to use to access the server.  These addresses will be included in
the certificate's subject alternative name extension.  Wildcards are not
allowed

The current set of IP addresses to include in the set of subject
alternative names is:

* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:fe1d:811d

What would you like to do?

1 - Use the current set of IP addresses
2 - Add another IP address
3 - Remove a specific IP address
4 - Clear the current set of IP addresses
5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: 1

Generating a certificate signing request with the following command:

     manage-certificates \
          generate-certificate-signing-request \
          --output-file /ds/tmp/replace-certificate-certificate-signing-request-6730986100632343057.pem \
          --output-format PEM \
          --keystore /ds/tmp/replace-certificate-temporary-key-store-281484917294163222.jks \
          --keystore-password-file 'REDACTED' \
          --keystore-type JKS \
          --alias generated-certificate \
          --subject-dn "CN=ds1.example.com,O=Example Corp,C=US" \
          --key-algorithm RSA \

-----END CERTIFICATE REQUEST-----

How would you like to import the signed certificate into the key store?

1 - I expect to get the signed certificate back right away.  Walk me
        through the process of importing it into the key store
2 - I will manually import the signed certificate

Enter your choice [1]: 1
Enter the path to the file containing the signed certificate (and
optionally any necessary issuer certificates): /ca/server-cert.pem

NOTICE:  Certificate file '/ca/server-cert.pem' ends with certificate
'CN=ds1.example.com,O=Example Corp,C=US' that was signed by issuer
'CN=Example Intermediate CA,O=Example Corp,C=US', but that issuer
certificate could not be found in the JVM-default trust store

Enter the path to a file containing the
'CN=Example Intermediate CA,O=Example Corp,C=US' certificate (and
optionally its issuer chain): /ca/intermediate-ca-cert.pem

NOTICE:  Certificate file '/ca/intermediate-ca-cert.pem' ends with
certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' that was
signed by issuer 'CN=Example Root CA,O=Example Corp,C=US', but that issuer
certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Root CA,O=Example
Corp,C=US' certificate (and optionally its issuer chain): /ca/root-ca-cert.pem

Would you like to request that the server reload any certificates
associated with HTTP connection handlers configured with support for HTTPS
so that they will start using the new certificate right away?  Note that
```

```
this may prevent clients from resuming TLS sessions created before the
reload

1 - Yes.  Reload the certificates associated with any HTTPS-enabled HTTP
        connection handlers
2 - No.  Do not reload the certificates.  HTTPS connection handlers will
        continue to use their current certificates until the server (or at
        least the connection handler) is restarted, or until the
        reload-http-connection-handler-certificates tool is run
q - Quit without doing anything else

Enter your choice [1]: 1

About to invoke the following command:

     replace-certificate \
          replace-listener-certificate \
          --bindDN "cn=Directory Manager" \
          --bindPassword 'REDACTED*' \
          --key-manager-provider JKS \
          --trust-manager-provider JKS \
          --source-key-store-file /ds/tmp/replace-certificate-temporary-key-store-281484917294163222.jks \
          --source-key-store-password-file /ds/config/ads-truststore.pin \
          --source-certificate-alias generated-certificate \
          --reload-http-connection-handler-certificates

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No.  Quit without doing anything else

Enter your choice [1]: 1
Successfully replaced the listener certificate
```

As part of its processing, the `replace-certificate` tool updates the server instance listener configuration object to include the new listener certificate. It will merge that new certificate with any existing certificates in that configuration object rather than replacing them. If you want to remove any older certificates from the server instance listener configuration, you can do that with the `purge-retired-listener-certificates` subcommand, which doesn't take any arguments other than those needed to authenticate to the server, as in the following example.

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses for TLS
        communication
2 - Replace the inter-server certificate that the server uses to
        authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
        topology registry
4 - Purge any retired inter-server certificates for this server from the
        topology registry
q - Quit without doing anything

Enter your choice: 3

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

About to invoke the following command:

        replace-certificate \
        purge-retired-listener-certificates \
        --bindDN "cn=Directory Manager" \
        --bindPassword 'REDACTED'

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No.  Quit without doing anything else

Enter your choice [1]: 1

Successfully purged one retired listener certificate
```

For help fixing replication issues related to broken certificate trust in a topology, see Repairing broken listener certificate trust in replication.

Replacing the inter-server certificate

The inter-server certificate is only intended for use between instances within the same topology.

It is not exposed to normal clients, so it doesn't need to be trusted. It is generated at install time with along life span, so it should not need to be replaced under normal circumstances. In fact, we discourage replacing the inter-server certificate unless you have reason to suspect that its private key has been compromised.

If you do need to replace the inter-server certificate, the `replace-certificate replace-inter-server-certificate` command can be used to accomplish this. As when replacing a listener certificate, it takes the new inter-server certificate from a provided Java KeyStore (JKS) or PKCS #12 key store, and it makes the necessary updates to the appropriate server key store, and in the case of the inter-server certificate, that is the one in the `config/ads-truststore` file. It also updates the server instance configuration object to include the new inter-server certificate.

> **Note**
>
> The server currently requires the inter-server certificate to use an RSA key pair, and the key size must be between 2048 bits and 3072 bits. Certificates with an elliptic curve key pair are not allowed, nor are certificates with an RSA key smaller than 2048 bits or larger than 3072 bits.

Use a self-signed certificate with a long life span so that it does not need to be replaced on a regular basis. Each instance should have its own unique inter-server certificate.

The `replace-inter-server-certificate` subcommand takes a subset of the arguments used in conjunction with the replace-listener-certificate subcommand. The available arguments include:

- `--source-key-store-file <path>`
- `--source-key-store-password <password>`
- `--source-key-store-password-file <path>`
- `--source-certificate-alias <alias>`
- `--source-private-key-password <password>`
- `--source-private-key-password-file <path>`

The following example illustrates what you see when you run `replace-certificate replace-inter-server-certificate` with the `--help` argument:

```
replace-certificate replace-inter-server-certificate \
     --bindDN uid=admin,dc=example,dc=com \
     --bindPasswordFile admin-password.txt \
     --source-key-store-file new-inter-server-certificate-keystore.jks \
     --source-key-store-type JKS \
     --source-key-store-password-file new-inter-server-certificate-keystore.pin \
     --source-certificate-alias new-inter-server-cert
```

The following example demonstrates the process for replacing the inter-server certificate in interactive mode, but includes the non-interactive command needed to achieve the same result.

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses for TLS
        communication
2 - Replace the inter-server certificate that the server uses to
        authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
        topology registry
4 - Purge any retired inter-server certificates for this server from the
        topology registry
q - Quit without doing anything

Enter your choice: 2

WARNING:  The inter-server certificate is used only for the purpose of
authenticating this server instance to other servers in the topology, and
to encrypt some legacy secrets.  It is NOT used to encrypt communication
(listener certificates are used for that purpose), and the trust mechanism
that we use for authenticating inter-server certificates is stronger when
using self-signed certificates than when using certificates signed by a
publicly trusted authority

We strongly discourage replacing the inter-server certificate unless you
believe that the key has been compromised.  Any errors in the process of
replacing the certificate could render the server unable to authenticate
to other instances in the topology, and may interfere with replication or
other forms of inter-server communication, and also the server's ability
to perform certain types of encryption and digital signing

Are you sure you want to replace the inter-server certificate?

1 - No.  Do not replace the inter-server certificate
2 - Yes.  Proceed with replacing the inter-server certificate

Enter your choice [1]: 2

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

How would you like to obtain the new inter-server certificate?

1 - Generate a new self-signed certificate
2 - Generate a request for a certificate to be signed by a certification
        authority
3 - Use a certificate in an existing key store.  Note that each server
        instance must have a unique inter-server certificate, and we do not
        recommend using the same certificate as both a listener certificate
        and an inter-server certificate
q - Quit without doing anything

Enter your choice: 1

Enter the subject DN that you would like to use for the new certificate.
The subject DN typically includes some or all of the following components:
```

```
* CN -- The common name for the certificate.  This is typically the
  fully-qualified name (not an IP address) that most clients will use to
  connect to the server (alternate names and IP addresses may be provided
  later).  We strongly recommend including a CN attribute in the
  certificate subject
* OU -- Typically the name of the department or organizational unit that
  manages the server
* O -- Typically the name of the company or organization that manages the
  server
* L -- Typically the name of the city or locality in which the server is
  located
* ST -- Typically the full name (NOT an abbreviation) of the state or
  province in which the server is located
* ST -- Typically the two-character ISO 3166 country code for the country
  in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory
Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: CN=ds1,O=Example Corp,C=US

Enter the complete set of resolvable names (not IP addresses) that clients
are expected to use to access the server.  These names will be included in
the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk
as a wildcard in the leftmost component that will match any host name in
that component.  For example, '.example.com' indicates that the
certificate may be used in any server whose fully-qualified name consists
of exactly three components, and in which the last two components are
'example.com'

The current set of DNS names to include in the set of subject alternative
names is:

* ds1.example.com
* ip6-localhost
* localhost

What would you like to do?

1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: 1

Enter the complete set of IPv4 and IPv6 addresses that clients are
expected to use to access the server.  These addresses will be included in
the certificate's subject alternative name extension.  Wildcards are not
allowed

The current set of IP addresses to include in the set of subject
alternative names is:

* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
```

```
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:fe1d:811d

What would you like to do?

1 - Use the current set of IP addresses
2 - Add another IP address
3 - Remove a specific IP address
4 - Clear the current set of IP addresses
5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: 1

Generating a self-signed certificate with the following command:

     manage-certificates \
          generate-self-signed-certificate \
          --keystore /ds/tmp/replace-certificate-temporary-key-store-12068302381295037387.jks \
          --keystore-password-file 'REDACTED' \
          --keystore-type JKS \
          --alias generated-certificate \
          --subject-dn "CN=ds1,O=Example Corp,C=US" \
          --validity-start-time 20191111120632 \
          --days-valid 7300 \

registry
```

PKCS #11 support in the PingDirectory server

PKCS #11 is a standard that defines an API (also known as cryptoki) for interacting with cryptographic tokens.

They can interact with things including:

- Hardware security modules (HSMs)
- Smart cards
- Cryptographic accelerators

> **Note**
>
> Cryptographic accelerators aren't used as much now because most CPUs include their own native support.

Many PKCS #11 tokens provide the ability to store certificates, and the PingDirectory server supports using these types of PKCS #11 tokens as an alternative to a Java KeyStore (JKS) or PKCS #12 file-based key store. While the PKCS #11 tokens used in production environments are typically associated with hardware devices, it's possible to emulate a PKCS #11 token in software.

Using PKCS #11 in the PingDirectory server

There are two ways to configure the PingDirectory server to use a PKCS #11 token to access the listener certificate.

You can either:

- Set up the PingDirectory server with PKCS #11 support enabled during setup.
- Enable PKCS #11 support after setup.

Regardless of the method, you must perform some initial preparation.

Preparing for PCKS #11 support in the PingDirectory server

Steps

1. Extract the PingDirectory server `.zip` file onto the system.

   In this example, it's assumed that it's in `/demo/PingDirectory`.

2. Make `/demo/PingDirectory` your current working directory.

3. Create a provider configuration file that tells Java how to interact with the PKCS #11 token.

   > **Note**
   >
   > If you use a different type of PKCS #11 token, like an actual hardware security module (HSM), then you must specify the appropriate path to its driver library.

   Consult the documentation for the token that you're using for details, but the provider configuration file will generally look something like the following:

   Example:

   ```
   name = pkcs11
   library = /path/to/provider/library.so
   slotListIndex = 0
   ```

4. Create a file with the user PIN needed to access the token.
5. Ensure that the PKCS #11 token has an appropriate certificate chain to present to clients during TLS negotiation.

   In many cases, you can use the `manage-certificates` tool to accomplish this. When interacting with a PKCS #11 token with `manage-certificates`, you must use the `--keystore` argument to specify the path to the provider configuration file, the `--keystore-type` argument with a value of `PKCS11`, and one of the `--keystore-password`, `--keystore-password-file`, or `--prompt-for-keystore-password` arguments to supply the user PIN.

   Example:

   ```
   $ bin/manage-certificates generate-certificate-signing-request \
        --keystore /path/to/provider.conf \
        --keystore-password-file /path/to/pkcs11/user.pin \
        --keystore-type PKCS11 \
        --alias server-cert \
        --subject-dn "CN=demo.example.com,O=Example Corp,C=US" \
        --key-algorithm EC \
        --key-size-bits 256 \
        --signature-algorithm SHA256withECDSA \
        --subject-alternative-name-dns demo.example.com \
        --subject-alternative-name-ip-address 1.2.3.4 \
        --extended-key-usage server-auth \
        --extended-key-usage client-auth \
        --output-file server-cert.csr \
        --output-format PEM
   ```

   After you have the signed certificate, use the `manage-certificates import-certificate` command to import the certificate chain (the signed certificate, any intermediate authority certificates, and the root authority certificate).

Enabling PKCS #11 support during setup

About this task

If you know that you're going to be using a PKCS #11, you can enable PKCS #11 support when running `setup` or `manage-profile setup`.

Steps

- Run `setup` or `manage-profile setup` with the following important arguments:

  `--usePKCS11KeyStore`

  Indicates that you want to configure the server to use a PKCS #11 token to access the listener certificate.

  `--pkcs11ProviderConfigFile <path>`

  Specifies the path to the provider configuration file that tells the JVM how to access the PKCS #11 token.

  `--keyStorePasswordFile <path>`

  Specifies the path to the file containing the user PIN needed to interact with the PKCS #11 token.

  Example:

```
$ ./setup \
     --no-prompt \
     --noPropertiesFile \
     --acceptLicense \
     --localHostName demo.example.com \
     --ldapPort 1389 \
     --ldapsPort 1636 \
     --httpsPort 1443 \
     --usePKCS11KeyStore \
     --pkcs11ProviderConfigFile config/path/to/provider.conf \
     --keyStorePasswordFile /path/to/pkcs11/user.pin \
     --encryptDataWithPassphraseFromFile config/encryption-settings.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile config/pre-encoded-root-user-password.txt \
     --instanceName demo-instance \
     --location demo-location

settings in java.properties and run dsjavaproperties for the changes to take effect.

Configuring Directory Server ..... Done
Configuring Certificates ..... Done
Starting Directory Server ..... Done

Access product documentation from docs/index.html
```

Note

If you don't specify any trust store-related properties, then `setup` automatically generates a trust store populated with just the listener certificate, which works if the token is configured with a self-signed certificate, or if you're using a certificate signed by an authority that is already included in the JVM's default trust store.

However, if you're using a certificate signed by a private authority, then you likely want to either provide an existing trust store, such as in JKS or PKCS #12 format, or you want to use the `--trustedCertificatePEMFile` argument to specify the paths to PEM files for any appropriate issuer certificates that you want to include in the trust store.

Enabling PKCS #11 support after setup

Before you begin

- Make sure that the token already includes a suitable certificate and that the PKCS #11 provider configuration files and user PIN files exist as described in Preparing for PCKS #11 support in the PingDirectory server.
- Make sure that the trust store has the appropriate trust information for the certificate in the PKCS #11 token. If that certificate is signed by an authority in the Java virtual machine (JVM)'s default set of trusted issuers, or if it's signed by the same private internal authority as the certificate in the current file-based key store, then you can skip this.

But if the certificate in the PKCS #11 token is self-signed, or if it's signed by an authority that the server isn't currently configured to trust, then you must update the trust store with the necessary certificates.

About this task

If you already have an existing PingDirectory server set up with some other type of key store, you can update it to use a PKCS #11 token without needing to set up a whole new instance.

Steps

- Update the server to use the PKCS #11 token instead of the file-based key store.

  1. Enable the PKCS11 key manager provider and give it the appropriate provider configuration file and user PIN file.
  2. Update any appropriate connection handlers to use the PKCS11 key manager provider.

     Example:

     The following batch file demonstrates the configuration changes that you can use to accomplish this.

```
dsconfig set-key-manager-provider-prop \
     --provider-name PKCS11 \
     --set enabled:true \
     --set pkcs11-provider-configuration-file:config/path/to/provider.conf \
     --set key-store-pin-file:config/path/to/pkcs11/user.pin

dsconfig set-connection-handler-prop \
     --handler-name "LDAPS Connection Handler" \
     --set key-manager-provider:PKCS11

dsconfig set-connection-handler-prop \
     --handler-name "LDAP Connection Handler" \
     --set key-manager-provider:PKCS11

dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set key-manager-provider:PKCS11

dsconfig set-connection-handler-prop \
     --handler-name "JMX Connection Handler" \
     --set key-manager-provider:PKCS11
```

Note

If you change the key type that the certificate uses, for example, from an RSA key pair to an elliptic curve key pair, you might need to restart the server or disable and re-enable the connection handler.
If you don't do this, attempts to establish new secure connections could fail during TLS negotiation, and the server-side error might indicate that it can't handle the new key type.

Enabling TLS in the PingDirectory server

You can enable support for TLS when initially setting up the server. If you already have a server instance without TLS support, you can enable it after the fact.

Enabling TLS support during setup

The easiest way to enable TLS support in the server is to do so during setup. You can do so by either providing a key store containing the certificate you want to use or by having the installer generate a self-signed certificate for you.

If you are running `setup` in interactive mode, then it prompts you for all of the questions needed to configure secure communication.

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, Instance Root File, SCIM2, and Swagger UI) and Administrative
Console over HTTPS?  After setup, you can selectively enable or disable
individual services and applications by configuring the HTTPS Connection
Handler (yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

Do you want to accept unencrypted LDAP connections?

        1)  Do not accept unencrypted LDAP connections
        2)  Accept unencrypted LDAP connections, but require StartTLS to secure all
        communication on those connections
        3)  Accept unencrypted LDAP connections, but optionally allow StartTLS to
        secure communication on those connections
        4)  Accept unencrypted LDAP connections and do not enable support for
        StartTLS

Enter option [3]: 3

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Certificate server options:

        1)  Generate self-signed certificate (recommended for testing purposes
        only)
        2)  Use an existing certificate located on a Java Keystore (JKS)
        3)  Use an existing certificate located on a PKCS12 keystore
        4)  Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

        1)  Generate a default JKS truststore
        2)  Use an existing JKS truststore
        3)  Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}
```

When using `setup` in non-interactive mode, use the following arguments to configure TLS support.

Argument	Description
`--ldapPort <port>`	Indicates that the server should enable support for unencrypted LDAP connections on the specified TCP port. If this argument is not provided, then the server does not accept unencrypted LDAP connections.
`--ldapsPort <port>`	Indicates that the server should enable support for LDAPS (LDAP over TLS) on the specified TCP port.
`--httpsPort <port>`	Indicates that the server should enable support for HTTPS (for things like SCIM, the Directory REST API, the web-based administration console, etc.) on the specified TCP port.
`--enableStartTLS`	Indicates that the LDAP connection handler should enable support for the StartTLS extended operation. This argument should only be provided if the `--ldapPort` argument is also given.
`--generateSelfSignedCertificate`	Indicates that setup should generate a self-signed certificate to be presented to clients using LDAPS, HTTPS, and the StartTLS extended operation.
`--useJavaKeyStore <path>`	Indicates that the server should use the specified Java KeyStore (JKS) key store to obtain the certificate chain to be presented to clients using LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS12KeyStore <path>`	Indicates that the server should use the specified PKCS #12 key store to obtain the certificate chain to be presented to clients using LDAPS, HTTPS, and the StartTLS extended operation.
`--usePKCS11KeyStore`	Indicates that the server should use a PKCS #11 key store (for example, a hardware security module) to obtain the certificate chain to be presented to clients using LDAPS, HTTPS, and the StartTLS extended operation. The Java virtual machine (JVM) must already be configured to access the desired key store via PKCS #11.
`--keyStorePassword <password>`	The password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store. Note that setup assumes that the private key password matches the key store password.
`--keyStorePasswordFile <path>`	The path to a file containing the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 key store.

Argument	Description
`--certNickname <alias>`	The alias of the private key entry in the specified key store that contains the certificate chain to present to clients during TLS negotiation. This argument is optional, but it is recommended if the key store has multiple certificates.
`--useJavaTrustStore <path>`	Indicates that the server should use the specified JKS trust store to determine whether to trust any certificate chains that are presented to it during TLS negotiation.
`--usePKCS12TrustStore <path>`	Indicates that the server should use the specified PKCS #12 trust store to determine whether to trust any certificate chains that are presented to it during TLS negotiation.
`--trustStorePassword <password>`	The password needed to interact with the specified JKS or PKCS #11 trust store.
`--trustStorePasswordFile <path>`	The path to a file containing the password needed to interact with the specified JKS or PKCS #11 trust store.
`--rejectInsecureRequests`	Indicates that the server should be configured to reject requests received over insecure connections. This argument can be used in conjunction with the `--ldapPort` argument to allow clients to establish connections that are initially insecure, but requires those connections to be secured with the StartTLS extended operation before they can issue other types of requests.

For example, the following command could be used to set up the server in non-interactive mode with an existing certificate.

```
$ ./setup \
     --no-prompt \
     --acceptLicense \
     --ldapPort 389 \
     --ldapsPort 636 \
     --httpsPort 443 \
     --enableStartTLS \
     --useJavaKeyStore config/keystore \
     --keyStorePasswordFile config/keystore.pin \
     --certNickname server-cert \
     --useJavaTrustStore config/truststore \
     --trustStorePasswordFile config/truststore.pin \
     --baseDN dc=example,dc=com \
     --rootUserDN "cn=Directory Manager" \
     --rootUserPasswordFile root-pw.txt \
     --maxHeapSize 10g \
     --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
     --instanceName ds1 \
     --location Austin \
     --noPropertiesFile

Enabling TLS support after setup

If the server has been set up without support for TLS, you can enable it after the fact by obtaining a certificate chain, configuring key and trust manager providers, and configuring connection handlers.

The process for obtaining a certificate has already been discussed in depth. Use `manage-certificates` (or some other tool) to prepare a Java KeyStore (JKS) or PKCS #12 key store with an appropriate certificate chain and private key. You should also create a trust store for use by the server.

Configuring key and trust manager providers

After you have a key store, configure a key manager provider to access it.

The server is preconfigured with key manager providers, `JKS` and `PKCS12`, that you can use with JKS or PKCS #12 key stores, respectively. In most cases, you can update the appropriate key manager provider to reference the key store that you plan to use, as shown in the following example:

```
dsconfig set-key-manager-provider-prop \
    --provider-name JKS \
    --set enabled:true \
    --set key-store-file:config/keystore \
    --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate trust store, as shown in the following example:

```
dsconfig set-trust-manager-provider-prop \
    --provider-name JKS \
    --set enabled:true \
    --set include-jvm-default-issuers:true \
    --set trust-store-file:config/truststore \
    --set trust-store-pin-file:config/truststore.pin
```

> **Note**
>
> If all clients and servers use certificates that are signed by issuers and are included in the JVM's default trust store, you can use the `JVM-Default` trust manager provider to accomplish this task.

Caching key and trust managers

When you create key and trust manager providers, caching is enabled by default, allowing the manager providers to avoid loading key store and trust store files from disk when establishing connections to process requests.

Invalidating the cache

The manager provider reloads files from the configured key store or trust store and refreshes the cache under any of the following conditions:

- The cached manager for the configured store has a `null` value.
- The path to the cached store doesn't match the path of the configured store.
- The length of the cached store doesn't match the length of the configured store.
- The last-updated time for the cached store doesn't match the last-updated time for the configured store.

Enabling or disabling caching (optional)

You can define whether caching is enabled by using the `enable-key-manager-caching` or `enable-trust-manager-caching` properties. Supply a value of `false` to disable caching, causing manager providers to load managers for each connection. Supply a value of `true` to re-enable caching.

To create a key manager provider with caching disabled, supply the `enable-key-manager-caching` property with a value of `false`, as shown in the following example:

```
dsconfig create-key-manager-provider \
    --provider-name JKS \
    --type file-based \
    --set enabled:true \
    --set key-store-file:config/keystore \
    --set key-store-type:JKS \
    --set key-store-pin-file:config/keystore.pin \
    --set enable-key-manager-caching:false
```

To create a trust manager provider with caching disabled, supply the `enable-trust-manager-caching` property with a value of `false`, as shown in the following example:

```
dsconfig create-trust-manager-provider \
    --provider-name JKS \
    --type file-based \
    --set enabled:true \
    --set trust-store-file:config/truststore \
    --set trust-store-type:JKS \
    --set enable-trust-manager-caching:false
```

To re-enable caching, set a value of `true` for the same caching property used to create the manager provider, as shown in the following example:

```
dsconfig set-trust-manager-provider-prop \
    --provider-name JKS \
    --set enable-trust-manager-caching:true
```

Configuring connection handlers

After you have configured the key and trust manager providers, you can update the connection handlers to use them.

For the LDAP connection handler, which accepts non-secure connections by default, you can enable StartTLS with a configuration change as in the following example.

```
dsconfig set-connection-handler-prop \
     --handler-name "LDAP Connection Handler" \
     --set allow-start-tls:true \
     --set key-manager-provider:JKS \
     --set trust-manager-provider:JKS \
     --set ssl-cert-nickname:server-cert \
     --set ssl-client-auth-policy:optional
```

If you want to require that clients use StartTLS when connected to the LDAP connection handler, use the reject-insecure-requests global configuration property.

```
dsconfig set-global-configuration-prop \
     --set reject-insecure-requests:true
```

If you did not configure secure communication during setup, then the LDAPS connection handler is disabled. Configuring LDAPS support requires enabling that connection handler and configuring most of the same settings. except `allow-start-tls` must be false and `use-ssl` must be true.

```
dsconfig set-connection-handler-prop \
     --handler-name "LDAPS Connection Handler" \
     --set enabled:true \
     --set key-manager-provider:JKS \
     --set trust-manager-provider:JKS \
     --set ssl-cert-nickname:server-cert \
     --set ssl-client-auth-policy:optional
```

Use a similar configuration change to enable the HTTPS connection handler.

```
dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set enabled:true \
     --set listen-port:443 \
     --set key-manager-provider:JKS \
     --set trust-manager-provider:JKS \
     --set ssl-cert-nickname:server-cert
```

Updating the topology registry

After you update the server connection handlers to enable TLS, you should also update the topology registry to provide information about the new configuration.

The topology registry holds information about server instances that are part of the environment and helps facilitate inter-server communication, like replication, mirroring portions of the configuration, and the PingDirectoryProxy server's automatic backend server discovery functionality.

There are two types of entries that need to be updated: the server instance listener configuration, which provides information needed to trust the TLS certificates presented by instances in the topology, and the server instance configuration, which provides information about options for communicating with those instances.

The server instance listener configuration needs to include the server certificate (that is, the certificate at the head of the chain). This should be the multi-line PEM-formatted representation of the certificate. When using `dsconfig`, this is easiest to import from a file.

```
bin/dsconfig set-server-instance-listener-prop \
        --instance-name ds1 \
        --listener-name ldap-listener-mirrored-config \
        --set server-ldap-port:636 \
        --set connection-security:ssl \
        --set 'listener-certificate</ca/ds1-cert.pem'
```

> **Note**
>
> The use of the less-than operator in the last line indicates that the value should be read from a file rather than provided directly. Also, the property name and path might need to be enclosed in single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

The server instance configuration object should also be updated to reflect the new methods that are available to communicate with that instance, and the preferred-security property indicates what mechanism other instances in the topology should try to use when communicating with that instance. The following example demonstrates setting the LDAPS and HTTPS ports to indicate that StartTLS support has been enabled and to indicate that other instances should use SSL (LDAPS) when communicating with this instance.

```
dsconfig set-server-instance-prop \
     --instance-name ds1 \
     --set ldaps-port:636 \
     --set https-port:443 \
     --set preferred-security:ssl \
     --set start-tls-enabled:true
```

Configuring supported TLS protocols and cipher suites

By default, the PingDirectory server enables support for the following TLS protocol versions:

- TLS 1.2
- TLS 1.3 (if supported by the underlying Java Virtual Machine (JVM))

This attempts to strike a good balance between providing the best security and maintaining compatibility with legacy clients.

Modern security best practices recommend only enabling support for TLS 1.2 and TLS 1.3, but some legacy LDAP clients can only support older versions. However, if you are confident that your LDAP clients support the more modern protocols, you can configure the server to only support those versions.

The server also tries to select an appropriate set of cipher suites to use for the TLS communication. It excludes suites that use known-weak key exchange, encryption, and digest algorithms and prioritizes key exchange algorithms that support forward secrecy over those that do not. However, as with the TLS protocol you can also explicitly customize the set of cipher suites that you wish to support.

The set of TLS protocols and cipher suites can be customized on a per-connection-handler basis using the connection handler's `ssl-protocol` and `ssl-cipher-suite` configuration properties. You should also customize those properties in the crypto manager configuration, as the server uses that for other purposes like securing replication traffic.

```
dsconfig set-crypto-manager-prop \
     --set ssl-protocol:TLSv1.2 \
     --set ssl-protocol:TLSv1.3 \
     --set ssl-cipher-suite:TLS_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA \
     --set ssl-cipher-suite:TLS_EMPTY_RENEGOTIATION_INFO_SCSV

dsconfig set-connection-handler-prop \
     --handler-name "LDAPS Connection Handler" \
     --set ssl-protocol:TLSv1.2 \
     --set ssl-protocol:TLSv1.3 \
     --set ssl-cipher-suite:TLS_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA \
     --set ssl-cipher-suite:TLS_EMPTY_RENEGOTIATION_INFO_SCSV

dsconfig set-connection-handler-prop \
     --handler-name "LDAP Connection Handler" \
     --set ssl-protocol:TLSv1.2 \
     --set ssl-protocol:TLSv1.3 \
     --set ssl-cipher-suite:TLS_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA \
     --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 \
```

```
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA \
      --set ssl-cipher-suite:TLS_EMPTY_RENEGOTIATION_INFO_SCSV

dsconfig set-connection-handler-prop \
      --handler-name "HTTPS Connection Handler" \
      --set ssl-protocol:TLSv1.2 \
      --set ssl-protocol:TLSv1.3 \
      --set ssl-cipher-suite:TLS_AES_256_GCM_SHA384 \
      --set ssl-cipher-suite:TLS_AES_128_GCM_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384 \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA384 \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA384 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256 \
      --set ssl-cipher-suite:TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA \
      --set ssl-cipher-suite:TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA \
      --set ssl-cipher-suite:TLS_EMPTY_RENEGOTIATION_INFO_SCSV
```

See the `configure-enabled-tls-protocols.dsconfig` and `configure-enabled-tls-cipher-suites.dsconfig` files in the `config/sample-dsconfig-batch-files` directory for more information.

Using TLS in command-line tools

The PingDirectory software includes a wide variety of command-line tools that can help manage and interact with the server.

Many of these tools communicate with the server over LDAP, and it is important to understand how to secure that communication with TLS.

Common arguments for TLS communication

The most useful TLS-related arguments our LDAP tools offer include the following.

Argument	Description
`--hostname <address>`	The address of the server to which the connection should be established.

Argument	Description
`--port <port>`	The TCP port of the server to which the connection should be established. 389 is the standard port for non-secure LDAP (or LDAP to be secured with StartTLS) and 636 is the standard port for secure LDAPS, but many deployments use alternate ports (especially non-privileged ports above 1024).
`--useSSL`	Indicates that the tool should establish an LDAPS connection that is secured with TLS.
`--useStartTLS`	Indicates that the tool should establish an initially insecure LDAP connection that is then secured with the StartTLS extended operation.
`--trustStorePath <path>`	The path to a trust store that should be used in the course of determining whether to trust the certificate chain presented by the server during TLS negotiation. If neither this argument nor the `--trustAll` argument is provided, then the tool interactively prompts about whether to trust the server certificate if it is not signed by an issuer in the Java Virtual Machine (JVM's) default trust store.
`--trustStoreFormat <format>`	The format for the trust store. This is typically be Java KeyStore (JKS) or PKCS12.
`--trustStorePassword <password>`	The password needed to access the contents of the trust store.
`--trustStorePasswordFile <path>`	The path to a file containing the password needed to access the contents of the trust store.
`--trustAll`	Indicates that the tool should blindly trust any TLS certificate chain that is presented to it. This is not recommended for general use, but it can be useful for troubleshooting purposes.
`--keyStorePath <path>`	The path to a key store that should be used if a client certificate chain should be presented to the server. This should typically be omitted unless the server has been configured to require clients to present a certificate or unless you want to use the certificate to authenticate using SASL EXTERNAL.
`--keyStoreFormat <format>`	The format for the key store. It is typically JKS or PKCS12.
`--keyStorePassword <password>`	The password needed to access the key store.

Argument	Description
`--keyStorePasswordFile <path>`	The path to a file containing the password needed to access the key store.
`--certNickname <alias>`	The alias of the private key entry in the key store that should be used to obtain the certificate chain to present to the server.
`--useSASLExternal`	Indicates that the client should authenticate using the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that was presented during TLS negotiation.
`--enableSSLDebugging`	Indicates that the tool should enable low-level TLS debugging provided by the JVM.

The easiest way to test TLS communication with the PingDirectory server is to use a command like ldapsearch.

```
$ bin/ldapsearch \
        --hostname ds1.example.com \
        --port 636 \
        --useSSL \
        --trustStorePath config/truststore \
        --baseDN "" \
        --scope base \
        "(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse

If you don't provide any trust-related arguments, then the tool automatically checks each of the following to determine whether it can trust the certificate chain that the server presented:

- The `config/truststore` file for the local instance
- The certificates defined in the local instance's topology registry
- The JVM's default trust store

If the presented certificate chain can be trusted through one of those mechanisms, then the tool establishes the connection without the need for any further interaction. However, if the certificate chain is still not trusted after checking each of those locations, then the tool displays information about that certificate chain and interactively prompts to determine if it should be trusted.

If you want to ensure that the tool does not prompt about whether to trust the certificate chain, then provide trust-related arguments like `--trustStorePath`. If the certificate chain cannot be trusted using the information in the provided trust store, then the tool exits with an error.

If you want to present a client certificate chain to the server (for example, because the server's connection handler has been configured with an `ssl-client-auth-policy` value of required, or because you want to use the certificate to authenticate using the SASL EXTERNAL mechanism), then you must provide at least the key store and its corresponding password. You can also specify the alias of the certificate chain to present, which you should probably do if your client key store contains multiple certificates.

```
$ bin/ldapsearch \
     --hostname ds1.example.com \
     --port 636 \
     --useSSL \
     --trustStorePath config/truststore.p12 \
     --trustStorePasswordFile config/truststore.pin \
     --trustStoreFormat PKCS12 \
     --keyStorePath client-keystore \
     --keyStorePasswordFile client-keystore.pin \
     --certNickname client-cert \
     --saslOption mech=EXTERNAL \
     --baseDN "" \
     --scope base \
     "(objectClass=*)"

If at any point you encounter a TLS-related problem that you can't figure out by looking at the `ldapsearch` output or server logs, then you can try using the `--enableSSLDebugging` option. This enables the JVM's support for low-level debugging of TLS processing, as described in the next section.

Troubleshooting TLS-related problems

Ideally, the TLS configuration functions properly and all clients can communicate securely with the PingDirectory server. If errors occur, there are several things you can do to help troubleshoot the problem.

Log Messages

The first place to check is the server's access log.

If the client can successfully establish a TCP connection to the server, which must happen before TLS negotiation can begin, the access log should show a `CONNECT` message with the source and destination address and port for the connection, the protocol, and the selected client connection policy. If you don't see that `CONNECT` message, then that suggests that the client might not be able to communicate at all with the server. That might mean there is a network problem, that a firewall is blocking the communication, or something as simple as the client is trying to use the wrong address or port.

If you see the `CONNECT` message in the access log, then that message should include a `conn` element that provides the connection ID for that connection. You can then use the `search-logs` tool to see if there are any other log messages for that client connection. For example, if the connection ID is 12345, then the following command can show the complete set of log messages for that connection.

```
$ bin/search-logs --logFile logs/access conn=12345
```

When trying to use LDAPS, the next log message that you see should either be a `SECURITY-NEGOTIATION` or a `DISCONNECT` message. `SECURITY-NEGOTIATION` messages should indicate that the client and server successfully completed the negotiation process and should include details about that negotiation, like the TLS protocol and selected cipher suite. If you see a `SECURITY-NEGOTIATION` message, then it indicates that the problem likely happened after the TLS session was established.

On the other hand, if the `CONNECT` message is immediately followed by a `DISCONNECT` message, then that suggests that the problem is likely a failure in the TLS negotiation process. In such cases, the message should include a `reason` element that provides more information about the reason for the disconnect. If the failure occurred during TLS negotiation, then how useful that message is depends at least in part on whether the failure occurred on the client or the server. If the server decided to abort the negotiation, then the message ideally contains the exact reason. If the problem occurred on the client, then the log message likely only contains the general category for the failure. That is because the TLS protocol does not provide a mechanism for conveying detailed error messages but only offers a basic alert mechanism with a fixed set of alert types. For example, if the problem is that the client did not trust the certificate chain that the server presented to it, the client might know exactly why it rejected the chain, but the server probably only gets an alert like `certificate_unknown`. In such cases, you might need to see if the client provides any more detail about the problem.

If the access log does not appear to provide any useful information, then you might also want to check the server error log. The error log won't normally include information about problems related to client communication, but it can offer useful information in certain circumstances, such as if an internal error within the server is interfering with the communication attempt.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand that can be used to examine a specified entry in a key store and identify any potential problems with it that might interfere with secure communication.

Some of the things it checks include:

- It makes sure the specified entry in the key store includes a private key and a complete certificate chain.
- It checks whether the certificate at the root of the chain is found in the JVM's default set of trusted certificates.
- It makes sure that the current time is within the validity window for all of the certificates in the chain.
- It validates the signatures for all certificates in the chain.
- It warns if the end-entity certificate is self-signed.
- It warns if the end-entity certificate does not contain an extended key usage extension with the "serverAuth" usage.
- It warns if any of the issuer certificates does not have a key usage extension with the "keyCertSign" usage.
- It warns if any of the issuer certificates does not have a basic constraints extension indicating that it can operate as a certification authority. It reports an error if the chain violates a path length constraint.

- It ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256. It reports an error for weak digest algorithms like MD5 or SHA-1, and a warning for unrecognized digest algorithms.
- It ensures that none of the certificates using an RSA key pair have a key size less than 2048 bits.

The following example demonstrates the usage for this command and its output when no problems are identified.

```
$ bin/manage-certificates check-certificate-usability \
     --keystore config/keystore \
     --keystore-password-file config/keystore.pin \
     --alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23
hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' at the head of
the chain includes an extended key usage extension, and that extension
includes the serverAuth usage.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a basic constraints extension, and the certificate chain
satisfies those constraints.

OK:  Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
includes a key usage extension with the keyCertSign usage flag set to
true.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a basic constraints extension, and the certificate chain satisfies those
constraints.

OK:  Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes
a key usage extension with the keyCertSign usage flag set to true.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a
signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature
algorithm of 'SHA-256 with RSA', which is is considered strong.

OK:  Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a 2048-bit
RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
4096-bit RSA public key, which is considered strong.

OK:  Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit
RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the
certificate chain.
```

If any usability issues are identified, they might be responsible for the communication problems.

Low-level TLS debugging

If nothing else helps, then you might need to resort to low-level debugging options.

In this case, the best option is probably to enable the Java Virtual Machine (JVM's) support for TLS debugging. Many of the command-line tools provided with the PingDirectory server, like ldapsearch, offer an `--enableSSLDebugging` argument that can simplify this process, but for other tools, you can edit the `config/java.properties` file to add `-Djavax.net.debug=all` to the set of properties for the desired tool and then run the `bin/dsjavaproperties` command to make the change take effect. The next time you run the tool, you will get voluminous output detailing all of the TLS-related processing that the JVM is performing. Something in that output should allow you or our support personnel to identify the issue.

This low-level debugging is also available within the server by adding `-Djavax.net.debug=all` to the `start-server.java-args` property in the `config/java.properties` file, running `bin/dsjavaproperties`, and restarting the server. Because this requires a server restart (and then another one when you want to turn off the debugging), it is not a very attractive option. You might be able to obtain more information about the problem without a restart by using the debugging support built into the server. You can do that with the following configuration changes.

```
dsconfig create-debug-target \
     --publisher-name "File-Based Debug Logger" \
     --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
     --set debug-level:verbose

dsconfig set-log-publisher-prop \
     --publisher-name "File-Based Debug Logger" \
     --set enabled:true
```

After these changes, the `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. It won't have quite as much detail as the debugging information built into the JVM, but it can still allow pinpointing the cause of the problem and identifying the solution. When this debugging is no longer needed, the debug log publisher can be disabled, and the debug target can be removed.

```
dsconfig set-log-publisher-prop \
     --publisher-name "File-Based Debug Logger" \
     --set enabled:false

dsconfig delete-debug-target \
     --publisher-name "File-Based Debug Logger" \
     --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
```

If you need to troubleshoot TLS communication with a non-Java client that doesn't offer its own TLS debugging mechanism, and if the server-side debugging support is not sufficient, then the best remaining option can be to use a network protocol analyzer to capture the communication between the client and the server and examine its content. The free and open source Wireshark utility, available at https://www.wireshark.org/, is an excellent graphical tool that runs on a variety of platforms and provides excellent support for understanding TLS communication. Even if you're unable to decipher the encrypted content, you can see at least some of the handshake messages. Unfortunately, when using TLS version 1.3, more of the handshake is now encrypted than with earlier versions of the protocol. This is terrific for security and privacy but unfortunately can interfere with troubleshooting attempts.

Additional mechanisms for securing communication

TLS provides a strong way to ensure that unauthorized observers aren't able to interpret the network communication to and from the PingDirectory server.

It also includes a trust mechanism to help clients ensure that they are communicating with a legitimate server and not an impostor. However, there are additional steps you can take to secure network communication.

Secure name service configuration

If possible, you should use a secure name service like DNS over TLS or DNS over HTTPS. Regular DNS, especially DNS over UDP connections, is vulnerable to hijacking attacks.

If an attacker is able to run their own DNS server, and if that server is able to respond more quickly than the legitimate DNS server, then clients can be tricked into establishing connections to the wrong server.

If a secure DNS option is not available, then another option can be to use host files for name resolution. However, this option can be difficult to maintain in dynamic environments in which server addresses might change. It is also not a feasible option if you do not have control over the client systems.

Name service caching

If name resolution is slow, then it can adversely affect server performance.

If the server is unable to resolve a host name to the corresponding address, then it might be unable to establish a connection to an external system. In some cases, it can also affect the ability to accept client connections or evaluate access control rules.

The server logs a message if attempts to resolve a host name to an IP address fail or take a long time to complete. This can help make it easier to diagnose problems related to name resolution, but it would be better to prevent those problems in the first place.

The JVM provides its own address caching facility that can help with this. It maintains its own internal cache that maps host names to IP addresses, and each mapping is associated with a Time To Live (TTL) value that indicates how long it should be used. If the mapping between host names and IP addresses is stable in your environment, then you might want to configure the JVM to use a large TTL value to reduce its dependency on the underlying name service. From a security perspective, this is primarily useful for cases in which you cannot rely on a secure name service or host file, but it can also help mitigate the possibility of problems that could arise in the event of a name service outage. You can use the `network-address-cache-ttl` property in the global configuration to tune this value.

You might also want to consider running a caching name server on the same system as the server to provide an additional layer of protection against name service outages and to reduce network latency for name service requests.

Strong TCP sequence numbers

Use strong TCP sequence numbers to prevent already-established TCP connections from being hijacked.

Reject source-routed packets

Source-routed packets allow a packet's sender to specify which route it should take to its destination.

An attacker might be able to use this capability to trick the client into communicating with the wrong system. Source-routed packets are rarely used for legitimate communication.

Reject ICMP redirects

The Internet Control Message Protocol (ICMP) offers features that can ensure that traffic gets from its source to its destination as efficiently as possible, but it can also help attackers hijack existing sessions.

ICMP redirects are intended to provide a mechanism for a router to let a client know about a better way to reach the target system, but they are rarely needed in private networks, and attackers can use them to trick the client into communicating with the wrong system.

Encrypt all inter-system communication

Any communication that the PingDirectory server itself has with other systems should be encrypted to resist observation and interception.

This also applies to any communication that the underlying system needs to perform, including name service resolution, use of network-based filesystems, remote logging, shell access, and file transfer.

Restricting client access

One way to prevent clients from gaining unauthorized access to the data is to prevent unauthorized clients from establishing connections or to terminate connections if conditions change in a way that the server determines is no longer acceptable.

Restricting access through network access controls

One common and effective way to prevent connections from unauthorized clients is to prevent those clients from reaching the server.

This can be accomplished using firewall software on the underlying system or through access controls in network hardware like firewalls and routers.

Restricting access through connection handlers

For connection attempts that are able to reach the PingDirectory server, the server itself can make decisions about whether those connections should be accepted.

The first layer of defense is at the connection handler that accepts the connection. Connection handlers offer the following configuration properties for determining which clients should be accepted and which should be rejected:

`allowed-client`

> An optional set of address masks that indicate which clients are allowed to establish connections to that connection handler. If one or more allowed-client values are defined, then only clients whose address matches one of those patterns are permitted.

`denied-client`

An optional set of address masks that indicate which clients are not allowed to establish connections to that connection handler. If one or more denied-client values are defined, then any connection from a client whose address matches one of those patterns are terminated.

Any values provided for the `allowed-client` and `denied-client` properties should be formatted as address masks. These address masks can take several forms, including:

- They can be raw IPv4 addresses, like `1.2.3.4`.
- They can be raw IPv6 addresses. These addresses can use the full hexadecimal representation, such as `2001:fecd:ba23:cd1f:dcb1:1010:9234:4088` optionally surrounded by square brackets. They can also use the shorthand notation when appropriate, such as `::1` and IPv6 representations of IPv4 addresses can end with the dotted IPv4 representation, such as `0:0:0:0:0:ffff:1.2.3.4`.
- They can be IPv4 addresses that use the asterisk as a wildcard character in one or more of the octets, such as `1.2.3.` or `...*`.
- They can be an IPv4 or IPv6 address using CIDR notation to indicate the number of bits that are required to match, such as `1.2.3.0/24` or `::1/128`.
- They can be IPv4 addresses followed by a slash and a subnet mask, such as `1.2.3.4/255.255.255.0`.
- They can use resolvable host names, whether complete or using asterisks as wildcards, such as `client.example.com` or `*.example.com`.

For example, to configure the LDAP connection handler so that it only accepts client connections from the 192.168.0.0/24 subnet, you can use a change as in the following example.

```
dsconfig set-connection-handler-prop \
     --handler-name "LDAP Connection Handler" \
     --set allowed-client:192.168.0.0/24
```

Using an `allowed-client` value of either `192.168.0.0/255.255.255.0` or `192.168.0.*` would also achieve the same result since they are equivalent ways to express the same range of client addresses.

Restricting access through client connection policies

Whenever a client establishes a connection to the PingDirectory server, that connection is associated with a client connection policy, which can restrict the kinds of requests that the client can issue and impose resource limits for that connection.

The server uses the following properties to determine which client connection policy should be associated with a client connection:

`evaluation-order-index`

An integer value that specifies the order in which the client connection policy will be evaluated relative to other policies. Each client connection policy must have a unique evaluation-order-index value.

`connection-criteria`

An optional set of criteria that indicates which connections are allowed to be associated with the client connection policy. That criteria can take several things into account, including the address of the client, the connection handler that accepted the connection, whether it is communicating with the server over a secure connection, whether the client is authenticated, the authentication mechanism, the location or content of the authenticated user's entry, the groups in which that user is a member, and the set of privileges that they have. If the client connection policy is not associated with any connection criteria, then it matches any connection. See the Connection criteria section of this document for more information.

`terminate-connection`

A Boolean value that indicates whether to terminate any client connection in which the client connection policy is the first one to match the client connection.

Whenever the server accepts a connection, it iterates through all enabled client connection policies in order from lowest `evaluation-order-index` value to highest. The first policy that the server encounters that either does not have connection criteria or that has connection criteria that matches the client connection is assigned to that connection. If the connection cannot be associated with any client connection policy because all enabled policies have criteria that do not match the client connection, or if the first matching policy has a `terminate-connection` value of true, then the connection is terminated.

After processing each bind operation (which might change the authentication state for the client connection) as well as after each StartTLS extended operation (which might change the communication security for the connection) the server re-selects the client connection policy to use for that connection. It might assign the same policy or a different policy to that connection, or it might terminate the connection.

Restricting access through operational attributes in user entries

The PingDirectory server also defines several operational attributes that can be placed in user entries to indicate the context in which their account can be used.

These attributes include the following.

Attribute	Description
`ds-auth-allowed-address`	Can be used to provide a set of address masks in the same format used by the allowed-client property in the connection handler configuration to indicate which clients are allowed to authenticate as the user. If any allowed addresses are defined and a client attempts to authenticate as the user from a client whose address does not match one of these patterns, then the bind attempt is rejected.

Attribute	Description
`ds-auth-allowed-authentication-type`	Can be used to restrict the ways in which the user can authenticate to the server. Values can be either `simple` to indicate that the user can authenticate with LDAP simple authentication or " `sasl <mechanism>` " such as " `sasl EXTERNAL` " to indicate that the user can authenticate with the specified SASL mechanism. If any allowed authentication types are defined and a client attempts to authenticate using a mechanism that is not included in this list, then the bind attempt is rejected.
`ds-auth-require-secure-authentication`	Can be used to indicate whether the user is required to authenticate to the server in a secure manner that does not reveal the credentials to a network observer whether by authenticating over a secure connection or by using an authentication mechanism that protects the credentials in transit. If this is set to true and a client attempts to authenticate as the user in an insecure manner, then the bind attempt is rejected.
`ds-auth-require-secure-connection`	Can be used to indicate whether the user is required to communicate with the server over an encrypted connection. While this is similar to the `ds-auth-require-secure-authentication` property, if it is set to true, then the user is only allowed to authenticate over a secure connection: it will not allow the client to authenticate over an insecure connection even if the authentication mechanism does not reveal the user's credentials to an external observer.

Attribute	Description
`ds-auth-is-proxyable`	Indicates whether the user's account can be used as an alternate authorization identity, such as using the proxied authorization request control, or as the authorization identity of a SASL bind. Values of this attribute can be one of the following: **`allowed`** Indicates that the account can optionally be used as an alternate authorization identity. This is the default behavior used for accounts that do not include the `ds-auth-is-proxyable` attribute. **`prohibited`** Indicates that the account cannot be used as an alternate authorization identity. Operations can only be processed as this user by clients that have directly authenticated as that user. **`required`** Indicates that the account can only be used as an alternate authorization identity and is not allowed to directly authenticate to the server.
`ds-auth-is-proxyable-by`	The distinguished names (DNs) of the users that are allowed to request this account as an alternate authorization identity. If one or more ds-auth-is-proxyable-by values are configured, then any attempt to proxy as the user from some account whose DN is not listed is rejected.
`ds-auth-is-proxyable-by-group`	The DNs of the groups whose members are allowed to request this account as an alternate authorization identity. If one or more group DNs are provided, then any attempt to proxy as the user from an account that is not a member of any of those groups is rejected.
`ds-auth-is-proxyable-by-url`	A set of LDAP URLs that can be used to identify users that will be allowed to request this account as an alternate authorization identity. If one or more LDAP URLs are provided, then any attempt to proxy as the user from an account that does not match the criteria represented by any of those URLs is rejected.
`ds-auth-may-proxy-as`	The DNs of the accounts that the user can request as an alternate authorization identity. If one or more `ds-auth-may-proxy-as` values are provided and the client attempts to proxy as any user whose DN is not listed, then that attempt is rejected.

Attribute	Description
`ds-auth-may-proxy-as-group`	The DNs of the groups whose members can be used as alternate authorization identities by the user. If one or more group DNs are provided and the user attempts to proxy as a user that is not a member of any of those groups, then that attempt is rejected.
`ds-auth-may-proxy-as-url`	A set of LDAP URLs that can be used to identify accounts that the user can request as an alternate authorization identity. If one or more LDAP URLs are provided, then an attempt to proxy as an account whose entry does not match the criteria from any of those LDAP URLs is rejected.

These operational attributes can be set as real or virtual attributes in the target user's entry.

Restricting access with plugins

The UnboundID Server SDK provides support for creating a wide range of extensions that can be configured to run in the server. One of the available extension types is `Plugin`, which can be used to invoke custom code at various points in server processing.

If a custom plugin is configured in the server with a `postconnect` plugin type, then its `doPostConnect` method is invoked for any new connection that is established. This method can examine information that the server has about the client connection, and if it determines that the connection should not be allowed, then it can terminate the connection.

Plugins can also intercept operation requests and responses to invoke custom processing for them. If a client requests an operation that a plugin decides should not be allowed, then the plugin can reject the operation or terminate the connection.

Lockdown mode

The PingDirectory server offers a lockdown mode in which it reports itself as unavailable and only allows requests from clients with the `lockdown-mode` privilege.

Lockdown mode provides a way for the server to be online so that administrators can investigate a problem or perform some disruptive administrative action, but in a manner that causes it to be unavailable to most clients.

The PingDirectory server can automatically place itself in lockdown mode under certain circumstances. Some of these include:

- If the access control handler encounters a malformed access control rule on startup. The server does its best to prevent invalid access control rules from being created, but if one does make it through, the server enters lockdown mode rather than running with a potentially incomplete access control policy.
- If an unrecoverable error occurs while interacting with a backend database based on the `unrecoverable-database-error-mode` global configuration property.
- If available disk space gets too low, as determined by the disk space usage monitor provider's low-space-error-size-threshold and low-space-error-percent-threshold properties.

- If an error occurs while attempting to log a message based on the `logging-error-behavior` property in the log publisher configuration.

The server can also be placed in lockdown mode at any time using the `enter-lockdown-mode` command-line tool, or the enter lockdown mode administrative task that the tool uses behind the scenes. The start-server command also provides a `--lockdownMode` argument that can be used to make the server enter lockdown mode before startup completes.

After the server enters lockdown mode, that mode stays in effect until the server is restarted or until the `leave-lockdown-mode` command or the underlying administrative task is used. Lockdown mode does not persist across server restarts unless it is automatically triggered by a condition that still exists after the restart.

Criteria

The PingDirectory server provides a powerful criteria subsystem that allows it to match connections, requests, responses, entries, and references based on a wide variety of characteristics.

Criteria can be used in many ways in the server. Some of these include:

- When determining which client connection policy should be assigned to a connection
- When determining which log messages should be recorded in an access log
- When determining which types of requests should be allowed over an insecure connection if the `reject-insecure-requests` global configuration property is set to true
- When determining which types of requests should be allowed over an unauthenticated connection if the `reject-unauthenticated-requests` global configuration property is set to true
- When determining which types of bind requests should be forwarded to another server when pass-through authentication is enabled
- When determining which operations should automatically use assured replication.
- When determining which entries should be automatically updated to use entryUUID as the naming attribute
- When determining which types of delete operations should be processed as soft deletes.
- When determining which types of add and modify operations should result in "account created" and "account updated" account status notifications
- When determining the types of operations for which a custom plugin should be invoked

Connection criteria

You can use connection criteria to match client connections based on what the server knows about the connection.

Simple connection criteria

Simple connection criteria is used to match client connections based on a broad set of properties.

These properties include the following.

Property	Description
`included-client-address`	An optional set of address masks (in the form used by the connection handler's `allowed-client` property) that can be used to identify connections that can match this criteria based on the client address.
`excluded-client-address`	An optional set of address masks (in the form used by the connection handler's `allowed-client` property) that can be used to identify connections that do not match this criteria based on the client address.
`included-connection-handler`	An optional set of connection handlers whose connections are allowed to accept connections that can match this criteria.
`excluded-connection-handler`	An optional set of connection handlers whose connections do not match this criteria.
`included-protocol`	An optional set of the communication protocols for connections that might match this criteria.
`excluded-protocol`	An optional set of the communication protocols for connections that do not match this criteria.
`communication-security-level`	The communication security level that can be used by connections that might match this criteria. Possible values include: **`secure-only`** Indicates that this criteria only matches clients that are communicating with the server over a secure connection. **`insecure-only`** Indicates that this criteria only matches clients that are communicating with the server over an insecure connection. **`any`** Indicates that this criteria can match both secure and insecure connections. This is the default value that is used for this property.

Property	Description
`use-auth-type`	The types of authentication that can be used by connections that might match this criteria. By default, this property includes all of the following allowed values: **none** Indicates that this criteria can match connections that are not authenticated. **Note** If this value is included, then any authentication-related properties defined in the criteria are ignored for unauthenticated connections. **simple** Indicates that this criteria can match connections that are authenticated using LDAP simple authentication. **sasl** Indicates that this criteria can match connections that are authenticated using SASL authentication. The `included-user-sasl-mechanism` and `excluded-user-sasl-mechanism` properties can be used to further refine which SASL mechanisms can be used by matching connections. **internal** Indicates that this criteria can match connections that were authenticated through an internal mechanism (for example, internal connections created by Server SDK extensions).
`authentication-security-level`	The types of authentication security that can be used by connections that might match this criteria. This property is ignored for unauthenticated connections. Possible values include: **secure-only** Indicates that this criteria can only match connections in which the authentication was performed in a secure manner. This can include authentication that was processed over a secure connection or in which the authentication can be processed securely even over an insecure connection. **insecure-only** Indicates that this criteria can only match connections in which the authentication was performed in an insecure manner. **any** Indicates that this criteria can match connections in which the authentication was performed in either a secure or insecure manner.
`included-user-sasl-mechanism`	An optional set of the SASL mechanisms used by clients that can match this criteria. This property is ignored for unauthenticated connections, or connections that did not authenticate with SASL.

Property	Description
`excluded-user-sasl-mechanism`	An optional set of the SASL mechanisms used by clients that do not match this criteria. This property is ignored for unauthenticated connections, or connections that did not authenticate with SASL.
`included-user-base-dn`	An optional set of the authenticated user entry base DNs for connections that might match this criteria. This property is ignored for unauthenticated connections.
`excluded-user-base-dn`	An optional set of the authenticated user entry base DNs for connections that do not match this criteria. This property is ignored for unauthenticated connections.
`all-included-user-group-dn`	An optional set of the group DNs in which the authenticated user must be a member for connections that might match this criteria. If multiple group DNs are specified, then the authenticated user must be a member of all of those groups. This property will be ignored for unauthenticated connections.
`any-included-user-group-dn`	An optional set of the group DNs in which the authenticated user must be a member for connections that might match this criteria. If multiple group DNs are specified, then the authenticated user must be a member of at least one of those groups. This property is ignored for unauthenticated connections.
`not-all-included-user-group-dn`	An optional set of the group DNs in which the authenticated user should not be a member for connections that might match this criteria. If multiple group DNs are specified, then the authenticated user can optionally be a member of one or more of those groups as long as they are not a member of all of them. This property is ignored for unauthenticated connections.
`none-included-user-group-dn`	An optional set of the group DNs in which the authenticated user must not be a member for connections that might match this criteria. If multiple group DNs are specified, then the authenticated user must not be a member of any of those groups. This property is ignored for unauthenticated connections.
`all-included-user-filter`	An optional set of filters that must match the authenticated user entry for connections that might match this criteria. If multiple filters are specified, then the user entry must match all of them. This property is ignored for unauthenticated connections.
`any-included-user-filter`	An optional set of filters that must match the authenticated user entry for connections that might match this criteria. If multiple filters are specified, then the user entry must match at least one of them. This property is ignored for unauthenticated connections.
`not-all-included-user-filter`	An optional set of filters that should not match the authenticated user entry for connections that might match this criteria. If multiple filters are specified, then the user entry can optionally match one or more of them as long as it does not match all of them. This property is ignored for unauthenticated connections.

Property	Description
`none-included-user-filter`	An optional set of filters that must not match the authenticated user entry for connections that might match this criteria. If multiple filters are specified, then the user entry must not match any of them. This property is ignored for unauthenticated connections.
`all-included-user-privilege`	An optional set of privileges that authenticated users should have for connections that might match this criteria. If multiple privileges are specified, then the user must have all of them. This property is ignored for unauthenticated connections.
`any-included-user-privilege`	An optional set of privileges that authenticated users should have for connections that might match this criteria. If multiple privileges are specified, then the user must have at least one of them. This property is ignored for unauthenticated connections.
`not-all-included-user-privilege`	An optional set of privileges that authenticated users should not have for connections that might match this criteria. If multiple privileges are specified, then the user can optionally have one or more of them as long as it does not have all of them. This property is ignored for unauthenticated connections.
`none-included-user-privilege`	An optional set of privileges that authenticated users should not have for connections that might match this criteria. If multiple privileges are specified, then the user must not have any of them. This property ise ignored for unauthenticated connections.

The default settings for the simple connection criteria match any connection. If you set values for multiple properties, then it essentially behaves as a logical AND, and the criteria only match connections that match all of those properties.

> **Note**
>
> A common pitfall encountered with the simple connection criteria is that if the `use-auth-type` property includes none as one of the values, then any properties that pertain to authenticated users are ignored for unauthenticated clients.
> A client connection is initially unauthenticated when it is first established and previously authenticated connections might become unauthenticated again if they perform an anonymous bind or if a bind attempt fails.

Aggregate connection criteria

Aggregate connection criteria can be used to create a single connection criteria that combines multiple other connection criteria objects.

It offers the following properties.

Property	Description
`all-included-connection-criteria`	An optional set of the connection criteria objects that must all match the client connection for this aggregate criteria to match.
`any-included-connection-criteria`	An optional set of the connection criteria objects in which at least one of those criteria objects must match the connection for this aggregate criteria to match.
`not-all-included-connection-criteria`	An optional set of the connection criteria objects in which at least one of those criteria objects must not match the connection for this aggregate criteria to match.
`none-included-connection-criteria`	An optional set of the connection criteria objects in which none of those objects can match the connection for this aggregate criteria to match.

Third-party connection criteria

You can use the UnboundID Server SDK to create your own custom connection criteria implementations.

Request Criteria

Use request criteria to match operations based on the content of the request or on the connection on which it was received.

Simple request criteria

Use simple request criteria to match requests based on a broad set of properties.

These properties include the following.

Property	Description
`operation-type`	The set of operation types for requests that might match this criteria. By default, all of the following operation types are included: • `abandon` • `add` • `bind` • `compare` • `delete` • `extended` • `modify` • `modify-dn` • `search` • `unbind`
`operation-origin`	Specifies the origin for operations that might match this criteria. By default, all of the following operation types are included: **`external-request`** Indicates that the criteria can match requests from external clients. **`internal-operation`** Indicates that the criteria can match internal operations, such as those created by Server SDK extensions. **`replicated-operation`** Indicates that the criteria can match operations received from replication.
`connection-criteria`	An optional reference to a connection criteria object that must match the connection associated with requests that might match this criteria.
`all-included-request-control`	An optional set of the OIDs of controls that can be included in requests that might match this criteria. If multiple OIDs are specified, then the request must include all of those controls.
`any-included-request-control`	An optional set of the OIDs of controls that can be included in requests that might match this criteria. If multiple OIDs are specified, then the request must include at least one of those controls.
`not-all-included-request-control`	An optional set of the OIDs of controls that should not be included in requests that might match this criteria. If multiple OIDs are specified, then the request can optionally include one or more of those controls as long as it does not have all of them.
`none-included-request-control`	An optional set of the OIDs of controls that should not be included in requests that might match this criteria. If multiple OIDs are specified, then the request must not include any of them.

Property	Description
`included-target-entry-dn`	An optional set of base distinguished names (DNs) for entries targeted by requests that match this criteria.
`excluded-target-entry-dn`	An optional set of base DNs for entries targeted by requests that will not match this criteria.
`all-included-target-entry-filter`	An optional set of filters that should match the target entry for requests that match this criteria. If multiple filters are specified, then the target entry must match all of them.
`any-included-target-entry-filter`	An optional set of filters that should match the target entry for requests that match this criteria. If multiple filters are specified, then the target entry must match at least one of them.
`not-all-included-target-entry-filter`	An optional set of filters that should not match the target entry for requests that match this criteria. If multiple filters are specified, then the target entry can optionally match one or more of them as long as it does not match all of them.
`none-included-target-entry-filter`	An optional set of filters that should not match the target entry for requests that match this criteria. If multiple filters are specified, then the target entry must not match any of them.
`all-included-target-entry-group-dn`	An optional set of the DNs of groups in which the target entry should be a member for requests that match this criteria. If multiple group DNs are specified, then the target entry must be a member of all of them.
`any-included-target-entry-group-dn`	An optional set of the DNs of groups in which the target entry should be a member for requests that match this criteria. If multiple group DNs are specified, then the target entry must be a member of at least one of them.
`not-all-included-target-entry-group-dn`	An optional set of the DNs of groups in which the target entry should not be a member for requests that match this criteria. If multiple group DNs are specified, then the target entry can optionally be a member of one or more of them as long as it is not a member of all of them.
`none-included-target-entry-group-dn`	An optional set of the DNs of groups in which the target entry should not be a member for requests that match this criteria. If multiple group DNs are specified, then the target entry must not be a member of any of them.

Property	Description
`target-bind-type`	The authentication types for bind requests that can match this criteria. This property is ignored for non-bind requests. By default, this includes both of the following values: **`simple`** Indicates that this criteria can match simple bind requests. **`sasl`** Indicates that this criteria can match SASL bind requests. The `included-target-sasl-mechanism` and `excluded-target-sasl-mechanism` properties can be used to further restrict it to specific mechanisms.
`included-target-sasl-mechanism`	An optional set of the names of SASL mechanisms for SASL bind requests that might match this criteria. This is ignored for all requests other than SASL bind requests.
`excluded-target-sasl-mechanism`	An optional set of the names of SASL mechanisms for SASL bind requests that do not match this criteria. This is ignored for all requests other than SASL bind requests.
`included-target-attribute`	An optional set of the target attributes for requests that might match this criteria. For add requests, the entry to add must include at least one of the target attributes. For compare requests, one of the target attributes must be used in the assertion. For modify requests, at least one modification must include one of the target attributes. For modify DN requests, at least one of the target attributes must be included in the new RDN. For search requests, at least one of the target attributes must be used in the filter. This property is ignored for other types of requests.
`excluded-target-attribute`	An optional set of the target attributes for requests that do not match this criteria.
`included-extended-operation-oid`	An optional set of the OIDs for extended requests that might match this criteria. This is ignored for all requests other than extended requests.
`excluded-extended-operation-oid`	An optional set of the OIDs for extended requests that might not match this criteria. This is ignored for all requests other than extended requests.
`included-search-scope`	The allowed scope values for search requests that might match this criteria. This is ignored for all requests other than search. By default, this includes all of the following values: • `base-object` • `single-level` • `whole-subtree` • `subordinate-subtree`

Property	Description
`using-administrative-session-worker-thread`	Indicates whether to match requests based on their use of a worker thread from the administrative thread pool. The value can be one of the following: **`true`** Indicates that this criteria might only match requests that are processed on an administrative worker thread. **`false`** Indicates that this criteria might only match requests that are not processed on an administrative worker thread. **`any`** Indicates that this criteria can match any type of request, regardless of whether they are processed using an administrative worker thread.
`included-application-name`	An optional set of application names for requests that might match this criteria. The application name for a request can either be specified by either the operation purpose request control or the intermediate client request control. Requests without an application name do not match.
`excluded-application-name`	An optional set of application names for requests that do not match this criteria. Requests with an application name might match this criteria.

The default settings for the simple request criteria match any request. If you set values for multiple properties, then it essentially behaves as a logical `AND`, and the criteria only matches requests that match all of those properties.

> **Note**
>
> Properties that are based on the target entry for the request are ignored for abandon and unbind requests, since they do not target a specific entry. They are also ignored for SASL bind and extended requests because the process for determining the target entry, if there is one, depends on decoding that is specific to the type of SASL mechanism or extended request. For search requests, the target entry DN is the search base DN.

Root DSE request criteria

Use the root DSE request criteria type to match requests that target the server root DSE.

The root DSE request criteria type includes the following configuration property:

`operation-type`

Specifies the types of operations that matches the criteria. By default, only the compare and base-object-search types are included. Available values include:

- `compare` — Indicates that the criteria matches compare requests that use the null DN.
- `base-object-search` — Indicates that the criteria matches search requests that use a null base DN with a baseObject scope.

- `single-level-search` — Indicates that the criteria matches search requests that use a null base DN with a singleLevel scope.
- `whole-subtree-search` — Indicates that the criteria matches search requests that use a null base DN with a wholeSubtree scope.
- `subordinate-subtree-search` — Indicates that the criteria matches search requests that use a null base DN with a subordinateSubtree scope.

Aggregate request criteria

Use aggregate request criteria to create a single request criteria that combines multiple other request criteria objects.

Aggregate request criteria offers the following properties.

Property	Description
`all-included-request-criteria`	An optional set of the request criteria objects that must all match the request for this aggregate criteria to match.
`any-included-request-criteria`	An optional set of the request criteria objects in which at least one of those criteria objects must match the request for this aggregate criteria to match.
`not-all-included-request-criteria`	An optional set of the request criteria objects in which at least one of those criteria objects must not match the request for this aggregate criteria to match.
`none-included-request-criteria`	An optional set of the request criteria objects in which none of those objects can match the request for this aggregate criteria to match.

Third-party request criteria

Use the UnboundID Server SDK to create your own custom request criteria implementations.

Result criteria

Use result criteria to match operations based on the content of the result or the associated request or client connection.

Simple result criteria

Use simple result criteria to match results based on a broad set of properties.

These properties include the following.

Property	Description
`request-criteria`	An optional reference to a request criteria object that must match the operation for this criteria to match.
`result-code-criteria`	Specifies the criteria that the operation's result code must match for this criteria to match. Allowed values include: **`all-result-codes`** Any result code can match. This is the default behavior. **`non-failure-result-codes`** Only operations with non-failure result codes (success, compareFalse, compareTrue, referral, saslBindInProgress, and noOperation) can match this criteria. **`failure-result-codes`** Only operations with failure result codes (all result codes other than the non-failure result codes) can match this criteria. **`selected-result-codes`** Only operations with one of the result codes listed in the `result-code-value` property can match this criteria.
`result-code-value`	The set of result codes that an operation might have to match this criteria. This is only used if the `result-code-criteria` property has a value of `selected-result-codes`. Values can include any result code that the PingDirectory server can use.
`processing-time-criteria`	Specifies the criteria that the operation's processing time must satisfy for this criteria to match. Allowed values include: **`less-than-or-equal-to`** Indicates that only operations with a processing time that is less than or equal to the value of the `processing-time-value` property can match this criteria. **`greater-than-or-equal-to`** Indicates that only operations with a processing time that is greater than or equal to the value of the processing-time-value property can match this criteria. **`any`** Indicates that operations with any processing time can match this criteria. This is the default value for this property.
`processing-time-value`	The duration to use in conjunction with the `processing-time-criteria` property. This property is ignored if the `processing-time-criteria` property has a value of `any`.

Property	Description
`queue-time-criteria`	Specifies the criteria that the operation's queue time (the time that it spent waiting in the work queue before it was picked up by a worker thread) must satisfy for this criteria to match. Allowed values include: **`less-than-or-equal-to`** Indicates that only operations with a processing time that is less than or equal to the value of the `processing-time-value` property can match this criteria. **`greater-than-or-equal-to`** Indicates that only operations with a processing time that is greater than or equal to the value of the processing-time-value property can match this criteria. **`any`** Indicates that operations with any processing time can match this criteria. This is the default value for this property.
`queue-time-value`	The duration to use in conjunction with the `queue-time-criteria` property. This property is ignored if the `queue-time-criteria` property has a value of `any`.
`referral-returned`	Indicates whether this criteria should match operations that included one or more referral URLs. Allowed values include: **`required`** Indicates that this criteria only matches operations that include one or more referral URLs. **`prohibited`** Indicates that this criteria does not match operations that include any referral URLs. **`optional`** Indicates that this criteria can match operations regardless of whether they contain referral URLs. This is the default value for this property.
`all-included-response-control`	An optional set of the OIDs of controls that might be included in responses that can match this criteria. If multiple OIDs are specified, then the operation must include all of those response controls.
`any-included-response-control`	An optional set of the OIDs of controls that might be included in responses that can match this criteria. If multiple OIDs are specified, then the operation must include at least one of those response controls.
`not-all-included-response-control`	An optional set of the OIDs of controls that should not be included in responses that might match this criteria. If multiple OIDs are specified, then the operation can optionally include one or more of those controls as long as it does not include all of them.

Property	Description
`none-included-response-control`	An optional set of the OIDs of controls that should not be included in responses that can match this criteria. If multiple OIDs are specified, then the operation must not include any of those response controls.
`used-alternate-authzid`	Indicates whether this criteria should match operations that used an authorization identity that is different from the authentication identity (for example, as a result of the proxied authorization request control). Allowed values include: **`required`** Indicates that this criteria only matches operations that include one or more referral URLs. **`prohibited`** Indicates that this criteria does not match operations that include any referral URLs. **`optional`** Indicates that this criteria can match operations regardless of whether they contain referral URLs. This is the default value for this property.
`used-any-privilege`	Indicates whether this criteria should match operations in which the requester used one or more privileges. **`required`** Indicates that this criteria only matches operations in which the requester used one or more privileges. **`prohibited`** Indicates that this criteria only matches operations in which the requester did not use any privileges. **`optional`** Indicates that this criteria can match operations regardless of whether the requester used any privileges.
`used-privilege`	An optional set of the privileges that the requester might have used for this criteria to match the operation. If multiple privileges are specified, then the requester must have used at least one of those privileges.

Property	Description
`missing-any-privilege`	Indicates whether this criteria should match operations in which the requester was missing one or more required privileges. **`required`** Indicates that this criteria only matches operations in which the requester was missing one or more privileges. **`prohibited`** Indicates that this criteria only matches operations in which the requester was not missing any privileges. **`optional`** Indicates that this criteria can match operations regardless of whether the requester was missing any required privileges.
`missing-privilege`	An optional set of the privileges that were required for the associated operation that the requester must have been missing for this criteria to match. If multiple privileges are specified, then the requester must have been missing at least one of those privileges.
`retired-password-used-for-bind`	Indicates whether this criteria should match bind operations based on whether the client authenticated with a retired password. This property is ignored for all operations other than bind. Allowed values include: **`retired-password-used`** Indicates that this criteria only matches bind operations in which the user authenticated with a retired password. **`retired-password-not-used`** Indicates that this criteria only matches bind operations in which the user did not authenticate with a retired password. **`any`** Indicates that this criteria can match bind operations regardless of whether the user authenticated with a retired password. This is the default value for the property.

Property	Description
`search-entry-returned-criteria`	Specifies the criteria for the number of entries returned in response to a search operation that operations matching this criteria should use. This property is ignored for all operations other than search. Allowed values include: **`equal-to`** Indicates that this criteria only matches search operations in which the number of entries returned matches the value of the `search-entry-returned-count` property. **`not-equal-to`** Indicates that this criteria only matches search operations in which the number of entries returned does not match the value of the `search-entry-returned-count` property. **`greater-than-or-equal-to`** Indicates that this criteria only matches search operations in which the number of entries returned is greater than or equal to the value of the `search-entry-returned-count` property. **`less-than-or-equal-to`** Indicates that this criteria only matches search operations in which the number of entries returned is less than or equal to the value of the `search-entry-returned-count` property. **`any`** Indicates that this criteria can match search operations regardless of the number of entries that were returned. This is the default value for the property.
`included-authz-user-base-dn`	An optional set of base DNs below which the operation's authorization identity might exist for the criteria to match.
`excluded-authz-user-base-dn`	An optional set of base DNs below which the operation's authorization identity must not exist for the criteria to match.
`all-included-authz-user-group-dn`	An optional set of the DNs of groups in which the operation's authorization identity must be a member for this criteria to match. If multiple group DNs are specified, then the user must be a member of all of those groups.
`any-included-authz-user-group-dn`	An optional set of the DNs of groups in which the operation's authorization identity must be a member for this criteria to match. If multiple group DNs are specified, then the user must be a member of at least one of those groups.
`not-all-included-authz-user-group-dn`	An optional set of the DNs of groups in which the operation's authorization identity should not be a member for this criteria to match. If multiple group DNs are specified, then the user can optionally be a member of one or more of those groups as long as it is not a member of all of them.

Property	Description
`none-included-authz-user-group-dn`	An optional set of the DNs of groups in which the operation's authorization identity should not be a member for this criteria to match. If multiple group DNs are specified, then the user must not be a member of any of them.

The default settings for the simple result criteria matches any operation. If you set values for multiple properties, then it essentially behaves as a logical `AND`, and the criteria only matches operations that match all of those properties.

Replication assurance result criteria

Use replication assurance result criteria to match operations based on their use of assured replication, whether based on a request control or criteria, and whether the constraints were satisfied.

Property	Description
`local-assurance-level`	The set of local replication assurance levels that can be in use for the criteria to match. By default, this property has all three of the following possible values: **`none`** Indicates that the criteria should match if the operation does not expect any degree of local assurance. **`received-any-server`** Indicates that the criteria should match if the operation expects that the change will be received by at least one other local server before the response is returned to the client. **`processed-all-servers`** Indicates that the criteria should match if the operation expects that the change will be processed by all other available local servers before the response is returned to the client.

Property	Description
`remote-assurance-level`	The set of remote replication assurance levels that might be in use for the criteria to match. By default, this property has all four of the following possible values: **none** Indicates that the criteria should match if the operation does not expect any degree of remote assurance. **`received-any-remote-location`** Indicates that the criteria should match if the operation expects that the change will be received by at least one server in at least one remote location before the response is returned to the client. **`received-all-remote-locations`** Indicates that the criteria should match if the operation expects that the change will be received by at least one server in all of the remote locations before the response is returned to the client. **`processed-all-remote-servers`** Indicates that the criteria should match if the operation expects that the change will be processed by all available servers in all remote locations before the response is returned to the client.
`assurance-timeout-criteria`	Indicates the criteria that should be used to match the assurance timeout. Allowed values include: ***less-than-or-equal-to*** Indicates that the criteria can match if the assurance timeout is less than or equal to the value contained in the `assurance-timeout-value` property. **`greater-than-or-equal-to`** Indicates that the criteria can match if the assurance timeout is greater than or equal to the value contained in the assurance-timeout-value property. **any** Indicates that the assurance timeout is not considered when deciding whether the criteria matches the operation. This is the default value for the property.
`assurance-timeout-value`	The duration value used in conjunction with the `assurance-timeout-criteria`. This is ignored if the assurance-timeout-criteria value is any.

Property	Description
`response-delayed-by-assurance`	Indicates whether the criteria should match an operation based on whether the operation response was delayed by replication assurance processing. Allowed values include: **`true`** Indicates that the criteria can match if the operation response was delayed by assurance processing. **`false`** Indicates that the criteria does not match if the operation response was delayed by assurance processing. **`any`** Indicates that the criteria does not depend on whether the response was delayed by replication assurance processing. This is the default value for the property.
`assurance-behavior-altered-by-control`	Indicates whether the criteria should match an operation based on whether it included an assured replication request control that used different assurance criteria than the server would have otherwise used for the operation. **`true`** Indicates that the criteria can match if the operation included an assured replication request control with different criteria than would otherwise be used. **`false`** Indicates that the criteria can match if the operation did not include an assured replication request control or if it included a control with the same behavior that the server would have used without the control. **`any`** Indicates that the criteria does not depend on whether the assurance behavior was altered by a control. This is the default value for the property.

Property	Description
`assurance-satisfied`	Indicates whether the criteria should match the operation based on whether the assurance constraints were satisfied. **`both-satisfied`** Indicates that the criteria can match if both the local and remote assurance requirements were satisfied. **`either-satisfied`** Indicates that the criteria can match if one or both of the local and remote assurance requirements were satisfied. **`at-least-local-satisfied`** Indicates that the criteria can match if the local assurance requirements were satisfied, regardless of whether the remote requirements were satisfied. **`at-least-remote-satisfied`** Indicates that the criteria can match if the remote assurance requirements were satisfied, regardless of whether the local requirements were satisfied. **`only-local-satisfied`** Indicates that the criteria can match if the local assurance requirements were satisfied, but the remote requirements were not satisfied. **`only-remote-satisfied`** Indicates that the criteria can match if the remote assurance requirements were satisfied, but the local requirements were not satisfied. **`either-not-satisfied`** Indicates that the criteria can match if one or both of the local or remote requirements were not satisfied. **`at-least-local-not-satisfied`** Indicates that the criteria can match if the local assurance requirements were not satisfied, regardless of whether the remote requirements were satisfied. **`at-least-remote-not-satisfied`** Indicates that the criteria can match if the remote assurance requirements were not satisfied, regardless of whether the local requirements were satisfied. **`neither-satisfied`** Indicates that the criteria can match if neither the local nor the remote criteria were satisfied. **`any`** Indicates that the criteria does not depend on whether the assurance constraints were satisfied. This is the default value for the property.

Aggregate result criteria

Use aggregate result criteria to create a single result criteria that combines multiple other result criteria objects.

Aggregate result criteria offers the following properties.

Property	Description
`all-included-result-criteria`	An optional set of the result criteria objects that must all match the result for this aggregate criteria to match.
`any-included-result-criteria`	An optional set of the result criteria objects in which at least one of those criteria objects must match the result for this aggregate criteria to match.
`not-all-included-result-criteria`	An optional set of the result criteria objects in which at least one of those criteria objects must not match the result for this aggregate criteria to match.
`none-included-result-criteria`	An optional set of the result criteria objects in which none of those objects might match the result for this aggregate criteria to match.

Third-party result critera

Use the UnboundID Server SDK to create your own custom result criteria implementations.

Search entry criteria

Use search entry criteria when matching search result entries, which are entries that match search criteria and are intended to be returned to the client.

They contain the DN and set of attributes that you typically find in an entry, and they can also optionally include a set of controls.

Simple search entry criteria

Simple search entry criteria objects provide support for matching search result entries based on the following properties.

Property	Description
`request-criteria`	An optional reference to request criteria that is expected to match the search request for this entry criteria to match.

Property	Description
`all-included-entry-control`	An optional set of OIDs of controls that must be included with the search result entry to match this criteria. If multiple OIDs are specified, then the entry must have all of those controls.
`any-included-entry-control`	An optional set of OIDs of controls that must be included with the search result entry to match this criteria. If multiple OIDs are specified, then the entry must have at least one of those controls.
`not-all-included-entry-control`	An optional set of OIDs of controls that should not be included with the search result entry to match this criteria. If multiple OIDs are specified, then the entry can optionally have one or more of those controls as long as it does not have all of them.
`none-included-entry-control`	An optional set of OIDs of controls that should not be included with the search result entry to match this criteria. If multiple OIDs are specified, then the entry must not have any of those controls.
`included-entry-base-dn`	An optional set of base DNs for entries that might match this criteria.
`excluded-entry-base-dn`	An optional set of base DNs for entries that do not match this criteria.
`all-included-entry-filter`	An optional set of OIDs of search filters that must match the entry for this criteria to match. If multiple filters are specified, then the entry must match all of them.
`any-included-entry-filter`	An optional set of OIDs of search filters that must match the entry for this criteria to match. If multiple filters are specified, then the entry must match at least one of them.
`not-all-included-entry-filter`	An optional set of OIDs of search filters that should not match the entry for this criteria to match. If multiple filters are specified, then the entry can optionally match one or more of them as long as it does not match all of them.
`none-included-entry-filter`	An optional set of OIDs of search filters that should not match the entry for this criteria to match. If multiple filters are specified, then the entry must not match any of them.

Property	Description
`all-included-entry-group-dn`	An optional set of the DNs of groups in which the entry must be a member for this criteria to match. If multiple groups are specified, then the entry must be a member of all of them.
`any-included-entry-group-dn`	An optional set of the DNs of groups in which the entry must be a member for this criteria to match. If multiple groups are specified, then the entry must be a member of at least one of them.
`not-all-included-entry-group-dn`	An optional set of the DNs of groups in which the entry should not be a member for this criteria to match. If multiple groups are specified, then the entry can optionally be a member of one or more of them as long as it is not a member of all of them.
`none-included-entry-group-dn`	An optional set of the DNs of groups in which the entry should not be a member for this criteria to match. If multiple groups are specified, then the entry must not be a member of any of them.

Aggregate search entry criteria

Use aggregate search entry criteria to create a single search entry criteria that combines multiple other search entry criteria objects.

It offers the following properties.

Property	Description
`all-included-search-entry-criteria`	An optional set of the search entry criteria objects that must all match the entry for this aggregate criteria to match.
`any-included-search-entry-criteria`	An optional set of the search entry criteria objects in which at least one of those criteria objects must match the entry for this aggregate criteria to match.
`not-all-included-search-entry-criteria`	An optional set of the search entry criteria objects in which at least one of those criteria objects must not match the entry for this aggregate criteria to match.
`none-included-search-entry-criteria`	An optional set of the search entry criteria objects in which none of those objects can match the entry for this aggregate criteria to match.

Third-party search entry criteria

Use the UnboundID Server SDK to create your own custom search entry criteria implementations.

Search reference criteria

Use search reference criteria when matching search result references, which provide information about other servers or different portions of the DIT in which the client can continue the search. They contain a set of referral URLs and an optional set of controls.

Simple search reference criteria

Simple search reference criteria objects provide support for matching search result references based on the following properties.

Property	Description
`request-criteria`	An optional reference to request criteria that is expected to match the search request for this reference criteria to match.
`all-included-reference-control`	An optional set of OIDs of controls that must be included with the search result reference to match this criteria. If multiple OIDs are specified, then the reference must have all of those controls.
`any-included-reference-control`	An optional set of OIDs of controls that must be included with the search result reference to match this criteria. If multiple OIDs are specified, then the reference must have at least one of those controls.
`not-all-included-reference-control`	An optional set of OIDs of controls that should not be included with the search result reference to match this criteria. If multiple OIDs are specified, then the reference can optionally have one or more of those controls as long as it does not have all of them.
`none-included-reference-control`	An optional set of OIDs of controls that should not be included with the search result reference to match this criteria. If multiple OIDs are specified, then the reference must not have any of those controls.

Aggregate search reference criteria

Use aggregate search reference criteria to create a single search reference criteria that combines multiple other search reference criteria objects.

It offers the following properties.

Property	Description
`all-included-search-reference-criteria`	An optional set of the search reference criteria objects that must all match the reference for this aggregate criteria to match.
`any-included-search-reference-criteria`	An optional set of the search reference criteria objects in which at least one of those criteria objects must match the reference for this aggregate criteria to match.
`not-all-included-search-reference-criteria`	An optional set of the search reference criteria objects in which at least one of those criteria objects must not match the reference for this aggregate criteria to match.
`none-included-search-reference-criteria`	An optional set of the search reference criteria objects in which none of those objects can match the reference for this aggregate criteria to match.

Third-party search reference criteria

Use the UnboundID Server SDK to create your own custom search reference criteria implementations.

Authentication

Authentication is the process that a client uses to identify themselves to the server.

This includes three basic components:

- Identify the account that is trying to authenticate. This is often provided in the form of a DN or username, but it can come in other forms like a Kerberos principal or information in a certificate or OAuth bearer token.
- Provide proof of that identity. This can include a password, optionally combined with a second factor like a one-time password, a certificate, or interaction with a trusted system like a Kerberos KDC or an OAuth introspection endpoint.
- Optionally specify an alternate authorization identity. Usually, when a client authenticates, subsequent operations on that connection are processed using the authority of the authenticated user. However, in some cases, it might be possible for the client to request that subsequent operations be processed under the authority of a different user.

For LDAP clients, the PingDirectory server supports both simple authentication and several SASL mechanisms. For HTTP clients, the server supports basic authentication and OAuth 2.0.

This section covers the set of authentication mechanisms that the PingDirectory server supports. It also provides information about its extensive support for password policy functionality, some of which also applies to non-password-based authentication.

LDAP simple authentication

The most common type of authentication for LDAP clients is the simple bind.

When using simple authentication, clients identify themselves by providing the distinguished name (DN) of the entry for their account, and they prove their identity with a password.

The password is provided to the server in the clear, so it is especially vital to protect the communication using TLS. Because simple binds are a single-factor authentication mechanism relying only on the password as proof of identity, it is important to ensure that the password is strong and stored in a secure manner.

It is also possible to perform anonymous authentication with an LDAP simple bind. In this case, the bind DN and password should both be empty. Although the original LDAPv3 specification, RFC 2251, indicated that it was possible to perform an anonymous simple bind with just an empty password, allowing for a non-empty DN, this resulted in many security problems in LDAP-based applications that didn't verify that the password was non-empty. The revised LDAPv3 specification, RFC 4511, discourages allowing a non-empty DN with an empty password. By default, the PingDirectory server rejects bind attempts with an empty password but non-empty DN.

SASL authentication

Simple Authentication and Security Layer (SASL) is a standard authentication framework described in RFC 4422.

It isn't any one type of authentication, but it is an extensible framework that allows for just about any type of authentication. The type of authentication is identified with a mechanism name, and the credentials can be encoded in a manner that is specific to that mechanism.

Some SASL mechanisms provide support for specifying an alternate authorization identity that should be used for processing subsequent operations on the connection. Some mechanisms also provide support for adding integrity (digital signatures) or confidentiality (encryption) to any communication that occurs over the connection after the authentication has completed.

Standard SASL mechanisms

There are several Simple Authentication and Security Layer (SASL) mechanisms defined in various RFCs and IETF drafts. This section details the standard mechanisms that the PingDirectory server supports.

PLAIN

The PLAIN mechanism is a password-based authentication mechanism that is described in RFC 4616 and is similar to Lightweight Directory Access Protocol (LDAP) simple authentication. However, it provides two advantages that simple authentication doesn't:

- LDAP simple authentication only allows you to identify the client by providing the distinguished name (DN) of the entry for their account. The PLAIN SASL mechanism allows you to identify the client with either a username or a DN.
- The PLAIN mechanism optionally allows you to specify an alternate authorization identity that should be used to authorize subsequent requests on the connection.

If you want to authenticate by a username, then you should prefix that username with "`u:`" such as `u:jdoe` for a username of `jdoe`. The server uses an identity mapper to identify the entry that corresponds to that username. If you want to authenticate with a DN, then you should prefix the DN with `dn:`, such as `dn:uid=jdoe, ou=People, dc=example, dc=com`.

As when using LDAP simple authentication, the PLAIN mechanism provides the password to the server in the clear. It should therefore only be used over a secure connection.

CRAM-MD5 and DIGEST-MD5

CRAM-MD5 and DIGEST-MD5 are password-based authentication mechanisms that allow the client to identify themselves with either a username prefixed by `u:` or a DN prefixed by `dn:`.

The primary benefit that these mechanisms offer over the PLAIN mechanism is that they do not send the password to the server in the clear. Instead, they send an MD5 digest that combines the username, password, and some randomly generated data. The DIGEST-MD5 mechanism optionally also allows you to specify a realm and an alternate authorization identity.

While this might initially seem like an improvement over the PLAIN mechanism, there are two key reasons that these mechanisms are discouraged:

- They rely on the MD5 message digest algorithm, which has long been considered weak and should no longer be relied upon to secure communication.
- Even though the bind request doesn't include the clear-text password, it requires that both the client and the server have access to the clear-text password. This means that the password must be stored in the server in a reversible form, which greatly increases the risk of exposure in the event of a data breach.

Because of these security concerns, both of these mechanisms have officially declared historic through draft-ietf-sasl-crammd5-to-historic for CRAM-MD5 and RFC 6331 for DIGEST-MD5) and should no longer be used. Although the PingDirectory server supports them, we strongly discourage their use.

EXTERNAL

The EXTERNAL SASL mechanism described in RFC 4422 authenticates a client based on information that is available for that client outside of information transmitted over LDAP. To do this, the PingDirectory server uses a certificate chain that the client presents to the server during TLS negotiation. The server uses a certificate mapper to identify the user that is authenticating. It can optionally also require the public portion of the certificate to be present in the user's entry.

Because the EXTERNAL mechanism in the PingDirectory server can only occur over a TLS-encrypted connection, it is a secure mechanism. Although it only uses a single authentication factor, as long as the server is configured with an appropriate trust manager to properly validate the client certificate chain, it is a much stronger form of authentication than a password.

GSSAPI

The GSSAPI SASL mechanism described in RFC 4752 allows clients to authenticate with a Kerberos KDC. The credentials, typically either a password or a key read from a keytab file, are validated by the KDC and are not exposed to the PingDirectory server. The PingDirectory server does need to have an account for the user (and an identity mapper is used to map the Kerberos principal to an entry in the server), but that account does not need to include a password if you are only going to authenticate with GSSAPI.

The Kerberos authentication process protects the credentials in transit so that they are not exposed to network observers. Further, it provides an option to protect communication on the connection that occurs after authentication with either integrity protection that digitally signs the communication to protect it from being altered in transit but does not prevent it from being observed, or confidentiality protection, that encrypts the communication so that it cannot be observed or altered. Alternatively, GSSAPI authentication can occur over a TLS-encrypted connection to protect all communication on that connection.

See the `config/sample-dsconfig-scripts/enable-gssapi-authentication.dsconfig` batch file for more information about configuring GSSAPI authentication in the PingDirectory server.

OAUTHBEARER

The OAUTHBEARER SASL mechanism described in RFC 7628 allows a client to authenticate using an OAuth 2.0 bearer token. The access token can be obtained from an OAuth authorization server, which can authenticate the client through a variety of means, such as a username and password, a two-factor mechanism that combines a static password with a one-time password, or a FIDO hardware token. The PingDirectory server uses an access token validator to ensure that the token is authentic and to map it to an entry in the server.

The token can also be associated with one or more OAuth scopes. These are associated with the user's authentication state and can be used in conjunction with the `oauthscope` access control bind rule to grant or deny access control rights to the user.

ANONYMOUS

As its name implies, the ANONYMOUS mechanism described in RFC 4505 only performs anonymous authentication. That is, it does not identify any account, and it does not provide any proof of identity.

The bind request can include an optional trace string in the SASL credentials, which can provide additional information about the context for the bind (for example, the application that is associated with the connection), but this should be taken with a grain of salt because without any proof of identity, there is nothing to prevent the client from lying about what it includes in the trace string.

The PingDirectory server supports the ANONYMOUS SASL mechanism although it is disabled by default because it provides very little benefit over anonymous simple authentication.

Proprietary SASL mechanisms

In addition to the standard SASL mechanisms listed earlier, the PingDirectory server provides support for several proprietary mechanisms.

UNBOUNDID-CERTIFICATE-PLUS-PASSWORD

The UNBOUNDID-CERTIFICATE-PLUS-PASSWORD mechanism is similar to the EXTERNAL mechanism in that it allows a client to authenticate with a certificate presented during TLS negotiation. However, it adds a second authentication factor in the form of a static password. This makes it a two-factor mechanism that adds an additional layer of protection in the event that the user's client certificate is compromised or if an attacker is somehow able to get a trusted certificate that maps to the user entry.

UNBOUNDID-DELIVERED-OTP

The UNBOUNDID-DELIVERED-OTP mechanism allows a user to authenticate with the combination of a static password and a one-time password (OTP) that is generated by the server and delivered to the user through some out-of-band mechanism. The PingDirectory server provides out-of-the-box support for delivering the one-time password through an SMS, through the Twilio service, text message, or in an email message, but you can create custom OTP delivery mechanisms using the UnboundID Server SDK.

When using the UNBOUNDID-DELIVERED-OTP mechanism, the client first uses the deliver one-time password extended request, which sends a username and static password to the server as preliminary proof of identity. The server then generates a one-time password and deliver it to the user through an appropriate means. Finally, the client includes the authentication ID, the delivered one-time password, and an optional authorization identity in an UNBOUNDID-DELIVERED-OTP bind request to complete the authentication process.

The one-time password that the server generates is only valid for a limited period of time, five minutes by default. After they are generated, these one-time passwords are stored in the user's entry. The "Encrypt TOTP Secrets and Delivered Tokens" plugin can be used to ensure that these values are encrypted when stored in the server.

See the `config/sample-dsconfig-batch-files/enable-delivered-otp-authentication.dsconfig` batch file for more information about configuring the UNBOUNDID-DELIVERED-OTP SASL mechanism.

UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION

The UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION mechanism is unusual in that it doesn't actually change the authentication state of the underlying client connection. The connection must already be authenticated as a user that has either the `permit-externally-processed-authentication` privilege or the `proxied-auth` privilege, and it remains authenticated as that user regardless of the outcome of the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION bind attempt.

The real benefit of the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION mechanism is that it allows an application to authenticate a user through some external means, but still verify that authentication in the PingDirectory server. It can ensure that the user's account is in a usable state, such as not disabled or locked, and it can also update the user's password policy state to do things like update the user's login history and increment the set of failed attempts and possibly lock the account in the event that the external authentication attempt failed.

UNBOUNDID-TOTP

The UNBOUNDID-TOTP mechanism is a two-factor authentication scheme that allows a user to identify themselves with a username or DN and verify that identity with both a static password and a time-based one-time password generated using the TOTP algorithm described in RFC 6238. The bind request can optionally include an alternate authorization identity.

Time-based one-time passwords are generated using a variety of free software, including phone apps like Google Authenticator and Authy as well as desktop software. The software used to generate TOTP passwords depends only on the current time and a secret key that is shared between the client and the server. There is no need to communicate with any other system, so it's an especially good choice for administrative accounts because it allows them to use strong authentication that work even if the server is unable to communicate with other systems. TOTP authentication does require that the client and server both agree on what time it is, but it does allow for some leeway. By default, the server allows the TOTP generator's clock to be at least a minute head of or a minute behind the server's clock.

The client and server need to be using the same shared secret to generate the time-based one-time passwords. The "generate TOTP shared secret" extended operation can be used to generate a suitable secret value, store it in the user's entry, and return it to the client to allow them to configure it for use with their authenticator app. The "revoke TOTP shared secret" extended operation can be used to revoke a secret if it is no longer needed or if you are concerned that it might have been compromised.

In some cases, the client might want to verify a time-based one-time password without using the UNBOUNDID-TOTP SALS mechanism. For example, the client can implement its own kind of "step up" authentication in which a simple password might be sufficient for some operations but additional proof of identity might be required when performing other operations. To help with this, the server offers a "validate TOTP password" extended operation that allows the client to provide the user's DN and TOTP password to verify for that user.

> **Note**
>
> This extended operation does not actually change the authentication state for the underlying connection.

The shared secret that the server uses to generate TOTP shared secrets needs to be stored in a reversible form so that the server can use it to verify the values that the client provides. The server can also store the last TOTP password that the client used to prevent it from being used more than once. The "Encrypt TOTP Secrets and Delivered Tokens" plugin can be used to ensure that these values are encrypted when stored in the server.

UNBOUNDID-YUBIKEY-OTP

The UNBOUNDID-YUBIKEY-OTP mechanism is a two-factor authentication scheme that allows a user to identify themselves with a username or DN and verify their identity with the combination of a static password and a one-time password generated by a YubiKey device offered by Yubico.

The one-time password that is generated can be sent to the public validation servers that Yubico maintains or you can run your own local authentication servers. Although running your own servers requires additional effort, it eliminates a dependency on a third-party service and also allows you to use YubiKey devices that have been updated to use a different private key than was initially assigned to them.

The "register YubiKey OTP device" extended operation can be used to register a device with the server and associate it with a user account. The server also offers a corresponding "deregister Yubikey OTP device" extended operation that can remove information about the device from the user's entry.

See the `config/sample-dsconfig-batch-files/enable-yubikey-otp-authentication.dsconfig` batch file for more information on this SASL mechanism.

Third-Party SASL Mechanisms

Use the UnboundID Server SDK to develop support for custom SASL mechanisms that the server should support.

HTTP client authentication

Clients that are communicating with the server over HTTP can authenticate in one of two ways:

HTTP basic authentication

> The client provides a simple username and password. An identity mapper is used to identify the entry, and the password is used to prove that identity.

An OAuth bearer token

> The client provides the server with an OAuth 2.0 bearer token and the server uses an access token validator to verify that the token is authentic and map it to a user's entry.

The set of authentication methods used depends on the endpoint with which the client is communicating.

Pass-through authentication

The PingDirectory server also provides support for pass-through authentication in which the client sends a simple bind request to the local server, and the server can forward the request to another server to actually verify the credentials.

The server allows the authentication attempt to be passed through to two different types of servers:

Another LDAP directory server

This can be useful when migrating to the PingDirectory server from another type of directory server, especially if that server does not provide any way to export the authentication credentials from that server. This can be enabled through the pass-through authentication plugin.

The cloud-based PingOne service

This can be useful when migrating between an on-premise PingDirectory server and the PingOne service. This can be enabled through the PingOne pass-through authentication plugin.

Both of these pass-through authentication mechanisms offer a similar set of options, including:

- The bind attempt can be tried locally first, or you can have it always pass through the authentication attempt to the backend service.
- The plugin can optionally update the password in the user's entry if the local authentication attempt fails, but the credentials are accepted by the service to which the request is passed through.
- You can use criteria to indicate which bind requests should be passed through to the backend service.

> **Note**
>
> Only one pass-through authentication plugin instance can be enabled in the server at any one time.

Identity mapping

The PingDirectory server provides an identity mapper framework that allows it to identify the user entry that corresponds to a provided identifier such as a username or a Kerberos principal.

Out-of-the-box support is provided for two types of identity mappers:

Exact Match

The server performs an internal search to find entries in which the provided identifier exactly matches the value of one of a specified set of attributes in the user's entry. The default instance of the exact match identity mapper is configured to match any user entry whose `uid` or `mail` attribute contains a value that matches the provided identifier. For example, if the provided identifier is "`jdoe`", then the identity mapper would perform an internal search with a filter of "`(|(uid=jdoe)(mail=jdoe))`".

Regular Expression

The server uses a regular expression to transform the provided identifier in some way, and then looks for an entry that contains the resulting value in one of a specified set of attributes. The default instance of the regular expression identity mapper is configured to strip off an at sign and anything after it in the provided username, and then to search for any entries that have the resulting string as a value for the `uid` attribute. For example, if the provided identifier is "`jdoe@EXAMPLE.COM`", then the mapper would perform an internal search with a filter of "`(uid=jdoe)`".

It is also possible to use the UnboundID Server SDK to create custom identity mapper implementations if those provided by the server are not sufficient.

The identity mapper must be able to identify exactly one entry that corresponds to the given identifier. If it cannot find any appropriate entries, or if it finds multiple matching entries, then the identity mapping attempt fails.

Certificate mapping

The PingDirectory server uses a component called a certificate mapper to identify the user entry that corresponds to a given certificate, such as in the course of processing a bind using the EXTERNAL or UNBOUNDID-CERTIFICATE-PLUS-PASSWORD SASL mechanism.

The types of certificate mappers that it offers by default include:

Subject Equals DN

This certificate mapper expects the subject DN of the certificate to match the distinguished name (DN) of the corresponding user entry.

Subject Attribute to User Attribute

This certificate mapper extracts the values of a specified set of attributes from the certificate subject and search for an entry containing those values in a corresponding set of attributes. The default instance of this certificate mapper tries to map the CN attribute from the certificate's subject to the `cn` attribute in the user's entry, or the `E` attribute in the certificate's subject to the mail attribute in the user's entry.

Subject DN to User Attribute

This certificate mapper expects the user's entry to contain a specified attribute whose value matches the subject DN of the presented certificate.

Fingerprint

This certificate mapper expects the user's entry to contain a specified attribute whose value matches the SHA-256, SHA-1, or MD5 fingerprint of the presented certificate.

You can also use the UnboundID Server SDK to create custom certificate mapper implementations.

Using alternate authorization identities

Under certain conditions, a client that is authenticated as one user can request that the server process operations under the authority of a different user.

The most common ways to accomplish this include:

- The client can use the proxied authorization request control. The server supports two variants of this control:
  - A version that is described in draft-weltman-ldapv3-proxy-04, in which the target user is identified by a distinguished name (DN).
  - A version that is described in RFC 4370, in which the target user is identified by an authorization ID that can include either a username (prefixed by `u:`) or a DN (prefixed by `dn:`).
- The client can include an intermediate client request control that contains a value in the clientIdentity field. This value should be an authorization ID that starts with either `u:` or `dn:`.
- Some SASL mechanisms allow the user to request an alternate authorization identity that will automatically be used for all subsequent operations requested on that connection. This includes the DIGEST-MD5, GSSAPI, OAUTHBEARER, PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP mechanisms.

This is a very powerful mechanism, and it allows applications to efficiently support multiple concurrent users over a common set of pooled connections. These pooled connections can be authenticated with an account that is specific to that application, and then each time that application needs to perform an operation on behalf of one of its end users, it can include the proxied authorization or intermediate client control in the request.

However, there are also obvious security concerns associated with this ability. If any user could impersonate any other user, then access controls would be irrelevant. PingDirectory server offers several forms of protection to ensure that alternate authorization identities can be used safely. These include:

- Only clients who have the `proxied-auth` privilege are permitted to use an alternate authorization identity. This privilege is not granted to any user by default (even root users).
- The use of the proxied authorization and intermediate client controls can be restricted by access control.
- Operational attributes in user entries can be used to restrict the use of alternate authorization identities. See Restricting access through operational attributes in user entries for more information about these operational attributes.
- Only accounts with a usable password policy state can be used as alternate authorization identities. For example, if an account is administratively disabled, locked because of too many failed authentication attempts, has an expired password, or has any other state that would prevent them from authenticating to the server, then the server does not allow operations to be processed under the authority of that user.

The retain identity request control

Bind operations alter the authentication state of the underlying client connection. If the bind attempt succeeds, then subsequent operations are processed under the authority of the authenticated user or possibly an alternate authorization identity for some SASL mechanisms.

If the bind attempt fails, then the connection reverts to an unauthenticated state. This behavior is dictated by LDAP specifications, and it is the appropriate behavior in most circumstances.

However, it might not be ideal for some applications, and especially those that support multiple concurrent users and use the PingDirectory server to authenticate those users. In such cases, connection pooling allows existing connections to be reused for multiple operations (and even operations that need to be processed under the authority of different users), which is much more efficient and resource-friendly than establishing a new connection for each request or maintaining a separate connection for each authenticated user. In such cases, performing a bind operation to verify a user's identity might affect the application's ability to reuse the connection for other purposes.

The most common way to address this in applications is to maintain two pools of connections. One that is used for only processing bind operations to verify user credentials, and a second that is used to process all other types of operations. However, the PingDirectory server offers an alternative that only requires the application to maintain a single pool: the retain identity request control. If this control is included in a bind request, then the server performs all of the usual processing for the bind operation, including identifying the user, verifying their credentials, and applying any necessary updates to their password policy state, but it does not affect the authentication state of the underlying connection. Regardless of whether the bind attempt succeeds or fails, the connection remains authenticated as the same account with the same authorization identity that it had before the bind was attempted.

Delaying responses to failed bind attempts

Configure PingDirectory server to delay the response to bind requests as a way of rate-limiting online password guessing attacks.

This can be done in two different ways:

- The LDAP connection handler offers a `failed-bind-response-delay` configuration property. If this is set to a nonzero duration, then the server automatically delays the response to any failed bind attempt by the specified length of time. The server does not delay the response to successful bind attempts.
- The password policy offers a `failure-lockout-action` configuration property that can be used to indicate what action should be taken after too many failed authentication attempts, and one possible action is delaying the bind response. For more information, see This will be covered in more detail in the Failure lockout section in the discussion on password policies.

The option to delay bind responses in the connection handler was available before the corresponding option in the password policy. However, the latter option is the recommended approach because it also delays the response to the first successful bind following several failed attempts, which makes it more difficult for an attacker to use the delay to identify a failed attempt and to abort early without waiting for the full failure duration. You can also configure the password policy approach to work for non-LDAP clients.

Password policies

Because password policies govern many aspects of the server's behavior, especially with regard to authentication and password management, it is critical to configure them appropriately.

Assigning password policies to users

Each user is associated with a password policy that governs their activity in the server, and different users can have different password policies.

Whenever the server processes an operation that attempts to authenticate a user, change their password, or interact with their password policy state in some way, it needs to select an appropriate password policy to use for that processing.

A user can be associated with a password policy through the `ds-pwp-password-policy-dn` operational attribute. If this attribute exists in the user's entry and refers to a valid password policy, then the user is subject to that password policy. If that attribute exists but refers to a nonexistent policy, then that user is unable to authenticate or be used as an alternate authorization identity. If a user's entry does not include the `ds-pwp-password-policy-dn` operational attribute, then that user is subject to the server's default password policy, which is specified by the default-password-policy property in the global configuration.

The `ds-pwp-password-policy-dn` operational attribute can be either real or virtual. You can explicitly set a value for the attribute in a user's entry, but it is also possible to have the server generate a value for that attribute based on some criteria using the virtual attribute subsystem. For example, you could use a virtual attribute to automatically assign the same password policy to all members of a specified group or to all users in a specified portion of the DIT.

> **Note**
>
> A user should not be conditionally subjected to different password policies under different circumstances. While it is technically possible to use virtual attributes that assign different values to the same attribute under different conditions, this capability should not be used for the `ds-pwp-password-policy-dn` attribute.

For example, you should not attempt to detect which application has issued a request and select a password policy based on that application. The server only maintains one set of password policy state for each user, and attempting to access the same user under different password policies might have unexpected adverse effects and can introduce security risks.

Maintaining password policies in user data

While password policies are typically defined in the server configuration, it is also possible to define them in user data.

This is particularly useful when the PingDirectory server is used to back a multi-tenant application, in which information about many different organizations is maintained in the same server instance, typically with a separate branch for each organization. You can configure password policies on a per-organization basis.

Each password policy must be defined in an entry containing the `ds-cfg-password-policy` structural object class. The definition of this object class can be found by querying the server schema over LDAP, by retrieving the "`cn=schema`" entry, or by looking in the `config/schema/02-config.ldif` schema definition file. The names of the LDAP attribute types which should correspond to names of the password policy configuration properties that are available in dsconfig or the administration console with a "`ds-cfg-`" prefix.

For example, the following entry represents a minimal password policy that might be defined in user data.

```
dn: cn=Org X Password Policy,ou=Org X,ou=tenants,dc=example,dc=com
objectClass: top
objectClass: ds-cfg-password-policy
cn: Org X Password Policy
ds-cfg-password-attribute: userPassword
ds-cfg-default-password-storage-scheme: cn=Salted SHA-256,cn=Password Storage
  Schemes,cn=config
```

Assign users to password policies contained in the user data in the same way that you assign them to policies in the configuration. Include the `ds-pwp-password-policy-dn` operational attribute in their entry as either a real or a virtual attribute.

> **Note**
>
> While password policies can reside in user data, any other configuration elements that they reference, including password storage schemes, password validators, password generators, account status notification handlers, and failure lockout actions, must reside within the configuration.

For improved performance, the PingDirectory server maintains a cache of password policy entries that are defined in the user data. This cache holds up to 500 policies by default, but you can tune that through the `maximum-user-data-password-policies-to-cache` property in the global configuration.

Password policy tips to improve performance

Consider these best practices for server performance when configuring your password policies.

For your environment, you might configure password policies for different account types and operations so that your policies apply beyond user password changes. For example, when a user signs on, these policies could be triggered to update the `last-login-timestamp` or validate a password during a bind operation.

Given that password policies can affect many server operations, they can also affect server performance. Poorly configured password policies can lead to some of the following issues:

- Slow password binds, replication, or replication topology changes
- A growing replication backlog
- Timing out of replication topology changes
- Excessive use of heap memory indicated by unexpected garbage collection cycles

> **Tip**
>
> Create explicit password policies scoped to groups of users or organizations and be careful when changing the default password policy.

The following table describes password policy configurations that can limit server performance and corresponding recommendations to avoid these limitations:

Limiting configuration	Recommended configuration
Creating a `last-login-timestamp` that includes milliseconds. This can limit performance as follows: • Every bind triggers an update of the entry. ◦ The updated entry has to be replicated. ◦ The change to the entry gets recorded in the `ds-sync-hist` operational attribute. • If a service account is within the scope of the policy (for example, the default policy or a group for a virtual attribute), and the service account binds frequently, replication or memory garbage collection could affect service availability.	• Limit the resolution of any `last-login-timestamp` attributes using the `yyyymmdd` format. ◦ If you need more precise time resolution, limit the bytes of `replication-history-limit` or the duration of `sync-hist-purge-delay`. • Create special password policies for service accounts and keep updates to a minimum.
Creating a bind scoped validator that accesses an external service (such as a pwned password validator). Every bind validation is as slow as the response of the external service. While this configuration might not have a large impact in many cases, it can limit performance where bind password validation frequency is high. The server performs bind password validation according to the `minimum-bind-password-validation-frequency` configuration property, which is set to 30 days by default. Learn more in Configuring password validators for binds.	Avoid external validation services if you set a high frequency for bind password validation.
Creating a password policy for a large number of users that uses a key derivation function. This can limit performance by significantly increasing the CPU capacity required to process binds. **Tip** While the processing cost for first-time user binds that use expensive password storage schemes is high, subsequent bind attempts by users who have previously authenticated since the server started could be significantly reduced by Encoded password caching.	Consider reducing widespread use of key derivation function password storage schemes.
Creating a password policy that relies on interacting with external services such as HashiCorp Vault, CyberArk Conjur, AWS Secrets Manager, or Azure Key Vault. This can limit performance because each bind authentication is as slow as the response of the external service and can't be mitigated by encoded password caching.	Limit password polices that require external services to sensitive accounts.

Limiting configuration	Recommended configuration
Creating a password policy that updates root user or topology administrator entries, which are stored in the `config.ldif` file. This can limit performance because every bind operation triggers the following: • The `config.ldif` file gets completely rewritten. • The `config.ldif` file gets backed up. ◦ Backups can slow down the completion of `dsreplication` subcommands including `enable`, `disable`, and `remove-defunct-server`. • The server raises an alert. Changes to topology administrator entries are mirrored to other servers in the topology, further affecting performance.	Don't add policy constraints that update the entry for root user or topology administrator accounts.

Password storage schemes

The PingDirectory server does not store passwords in the clear.

Whenever a password is set through an add operation, a modify operation, or a password modify extended operation, and when clear-text passwords are included in entries imported from LDIF, the server uses a component called a password storage scheme to encode that password. Whenever a client attempts a password-based bind, the password storage scheme determines whether the password included in the bind request matches one stored in the user's entry.

The server allows users to authenticate with passwords encoded using any scheme that the server supports. However, when storing new passwords, it uses the `default-password-storage-scheme` property in the password policy configuration to determine which scheme to use when encoding that password. Although it is technically possible to have multiple default schemes enabled simultaneously within the same password policy, only enable one scheme at a time unless you need to synchronize encoded passwords to multiple different systems that require different encodings.

Supported password storage schemes

The PingDirectory server supports many password storage schemes. The most notable of these schemes are described here.

Salted variants of the SHA-2 digest

The SHA-2 algorithms described in RFC 6234 are a suite of cryptographic one-way digest algorithms that can be used to generate 256-bit, 384-bit, and 512-bit hashes of arbitrary amounts of data. One-way digests means that there is no known way to examine the resulting hash and determine the clear-text value used to generate it, other than simply trying every possible combination of clear-text values until you find one that matches. It is also computationally infeasible to generate collisions, that is, to find two different clear-text values that result in the same hash.

The SHA-2 digest algorithms are considered secure although there are two issues that can make them suboptimal on their own. The first is that providing the same clear-text input to the digest algorithm consistently yields the same hash. This makes it vulnerable to precomputed dictionary attacks in which attackers might use a dictionary that maps hashes to the clear-text values used to generate them and also makes it possible to determine whether two different users have the same password. This weakness can be addressed by combining the passwords with some amount of randomly generated data (called a salt) before computing the digest and then making the salt available in addition to the digest. The PingDirectory server only offers support for salted versions of the SHA-2 password storage schemes.

The second issue is that SHA-2 digests are fast to compute on their own. It is not unreasonable for an attacker to have access to hardware capable of generating billions of SHA-2 digests per second. This means that it can be faster to try large numbers of possibilities in an attempt to guess the password used to generate a digest through brute force. While strong passwords can still be highly resistant to this form of attack, weak passwords (for example, those using a smaller number or range of characters, and especially those based on dictionary words) can be quickly broken. Some other password storage schemes attempt to address this by requiring multiple rounds of digest computation, requiring parallel processing, or requiring large amounts of memory, but even in those cases, the best defense is still a strong password and ideally one that is combined with a second factor like a one-time password.

The PingDirectory server uses the salted 256-bit SHA-2 digest as the default password storage scheme for regular users, that is, for users other than root users and topology administrators.

Salted and unsalted variants of the SHA-1 digest

The SHA-1 algorithm described in RFC 3174 is a cryptographic one-way digest algorithm that was in widespread use for many years as a leading mechanism for encoding passwords, and some directory servers in widespread use can still use it as the basis for their default password storage schemes. However, researchers have been able to devise attacks against the SHA-1 digest that make it possible to generate collisions under some circumstances (albeit with considerable computational effort). As such, it is no longer recommended for use in encoding new passwords.The PingDirectory server supports both salted and unsalted variants of the SHA-1 digest. Support for the salted variant is enabled by default, but you should only use it as a deprecated scheme for the purpose of migrating passwords to a more secure alternative, like one of the SHA-2 digests or one of the PBKDF2, Argon2, bcrypt, or scrypt key derivation functions. Support for the unsalted SHA-1 digest is disabled by default and should only be enabled if needed for compatibility with legacy systems.

The PBKDF2 key derivation function

The PBKDF2 (password-based key derivation function, version 2, as described in RFC 2898) is a standard algorithm for encoding passwords and generating cryptographic keys from passwords. The PBKDF2 algorithm uses a salt to make it resistant to precomputed dictionary attacks, and it also uses multiple rounds of computation to increase the amount of processing required to compute the encoded representation for the password and slow down the rate at which attackers can make guesses in brute-force attacks.

> **Important**
>
> The PBKDF2 storage scheme is inherently slow. Avoid using this scheme for service accounts unless you have evaluated the computational processing costs involved.

While the PBKDF2 function is a well-defined standard, the specification only covers the algorithm used to derive a key using the password, salt, and number of rounds as inputs. There is no standard encoding that combines the resulting digest with the salt and number of rounds used to generate that digest. This means that while multiple products can support using the PBKDF2 algorithm to encode passwords, the way they represent the encoded passwords might be different.

The PingDirectory server uses an encoding that attempts to be as compact as possible, helping to minimize the on-disk and in-memory footprint for the data, and as a result it is very likely to be different from the encoding used by any other product. The encoding that we use is constructed as follows:

1. The first byte represents the encoding version and the message digest algorithm. Possible values include:
    - 0x00 — The SHA-1 digest (PBDKDF2WithHmacSHA1)
    - 0x01 — The 256-bit SHA-2 digest (PBDKDF2WithHmacSHA256)
    - 0x02 — The 384-bit SHA-2 digest (PBDKDF2WithHmacSHA384)
    - 0x03 — The 512-bit SHA-2 digest (PBDKDF2WithHmacSHA512)
2. The second byte represents the number of bytes used to hold the salt. The storage scheme supports salts from 8–127 bytes (64–1016 bits). By default, the server generates 16-byte (128-bit) salts.
3. The byte used to indicate the salt length is followed immediately by the bytes that comprise the salt.
4. The next two or four bytes holds the iteration count used for the algorithm. If the iteration count is less than or equal to 32,767, then it is encoded in two bytes. If the iteration count is greater than or equal to 32,768, then it is encoded in four bytes, and the most significant bit of the first byte is set to 1.
5. The remainder of the encoded password is the output of the PBKDF2 algorithm generated from the clear-text password and salt using the indicated algorithm and iteration count.

The bytes resulting from the above steps are base64-encoded, and the whole string is preceded by a prefix of "`{PBKDF2}`".

> **Note**
>
> Even though the encoding that the PingDirectory server uses might differ from that of other servers, as long as those other servers use the same standard algorithm to derive the key, it should still be possible to convert between their encoded representations and the one that the PingDirectory server uses. It should therefore be possible to migrate PBKDF2-encoded passwords between systems.

The PingDirectory server uses the PBKDF2 password storage scheme by default for root users and topology administrators.

See the `config/sample-dsconfig-batch-files/use-pbkdf2-password-storage-scheme.dsconfig` batch file for more information on configuring and using the PBKDF2 password storage scheme.

The Argon2, bcrypt, and scrypt key derivation functions

The Argon2, bcrypt, and scrypt key derivation functions are strong, highly regarded functions for encoding passwords. They are all intentionally expensive as a means of making them more resistant to password guessing attacks. The bcrypt algorithm uses a cost factor to increase the amount of processing required. The script and Argon2 algorithms also employ memory access and parallel processing as additional techniques for increasing the cost of generating large numbers of passwords.

Unlike the PBKDF2, the Argon2, bcrypt, and scrypt algorithms do have predefined encodings that combine all of the necessary metadata like the salt, cost factors, and other settings used to compute the resulting key. As such, the format that the PingDirectory server uses for passwords encoded with these schemes should be compatible with the format used by other servers that support them.

See the `use-argon2-password-storage-scheme.dsconfig`, `use-argon2-password-storage-scheme.dsconfig`, and `use-scrypt-password-storage-scheme.dsconfig` files in the `config/sample-dsconfig-batch-files` directory for more information about configuring and using these password storage schemes.

The crypt password storage scheme

The PingDirectory server also provides support for a suite of password encodings that match those often used by Linux and UNIX-based systems. This includes the legacy UNIX crypt algorithm which uses the DES encryption algorithm and an extremely small 12-bit salt, as well as stronger, multi-round variants that are based on the MD5 and SHA-2 digests. It can support authentication with any of these variants, but it only uses one of them when encoding new passwords.

Only the 256-bit and 512-bit SHA-2 variants are considered secure, and they are the only ones that should be used for encoding new passwords. The 256-bit SHA-2 variant is used by default. However, because of the potential to support the weak DES-based and MD5-based algorithms, we discourage the use of the crypt password storage scheme unless absolutely required for compatibility.

The AES encryption algorithm

The PingDirectory server also supports storing passwords in a reversibly encrypted form using the AES cipher algorithm. Because this storage scheme uses reversible encryption, there is a much greater risk that passwords encoded with this scheme could be exposed in the event of a data breach. As such, use of this password storage scheme is highly discouraged unless you need to use an authentication mechanism that requires access to the clear-text password, such as the CRAM-MD5 or DIGEST-MD5 SASL mechanisms.

Custom password storage schemes

Use the UnboundID Server SDK to implement support for custom password storage schemes using whatever encoding you want. The Server SDK provides two types of extensions for this purpose:

- The `PasswordStorageScheme` class provides support for encoding and validating passwords using only the clear-text password and information in the configuration for that storage scheme.
- The `EnhancedPasswordStorageScheme` class also provides access to other information in the user's entry, as well as a potential set of updates that are being applied to that entry. This option might be required if the password encoding depends on other information stored in the user's entry, such as if the salt or other encoding metadata is stored separately from the encoded password.

A custom password storage scheme might be required if you need to migrate data from another system into a PingDirectory server instance, and the migrated data includes passwords encoded in a format that the PingDirectory server does not support.

Fast algorithms versus expensive algorithms

Some password encoding algorithms, like the SHA-1 and SHA-2 schemes, can be cheap to compute, while others like PBKDF2, Argon2, bcrypt, and scrypt can be expensive to compute.

The more expensive a password storage scheme is, the more effort that an attacker must expend when trying to crack passwords encoded with that scheme.

However, the higher resistance to password cracking attacks does not come for free. If it is more expensive for attackers to generate encoded password representations, it is also more expensive for the server to generate them in response to legitimate requests. Because the server has to generate these encoded representations whenever it is processing a bind request to authenticate a user, or when processing an add, modify, or password modify request used to set a new password, using these storage schemes can significantly affect server performance.

You can tune each of these expensive schemes in some way to adjust the performance impact that it will have. If you plan to use one of them, determine what level of authentication and password change performance (in terms of number of operations per second) that you will need, and the minimum cost factor that you are willing to accept for the password storage scheme. Then, benchmark the system to make sure that your environment can meet those demands or to determine how much additional hardware you might require to do so.

This performance impact can be even more significant when importing data that contains clear-text passwords. Ideally, if you're migrating data from another system, that system also has been storing passwords in a relatively secure manner, and you will therefore not have access to their clear-text representations. However, if you do have access to the clear-text passwords, or if you're importing sample data for testing purposes, then you can find the import proceeding at a crawl because of the expensive password processing. If you're just using sample data for testing purposes, then pre-encode the passwords so that the import can proceed as quickly as possible. If you're using real-world data, then you might want to use a faster password storage scheme (like one of the SHA-2 schemes) for the import, and then configure that scheme as deprecated (as described in the next section) so that the passwords are gradually migrated to the preferred encoding.

Alternatively, you might decide that the potential benefit you get from using an expensive password storage scheme as increased resistance to password cracking attacks is not worth the added processing cost that it incurs for legitimate processing. This can be a completely valid conclusion to reach in some environments, especially if you take steps to help ensure that users are required to choose strong passwords and continue to monitor the strength of those passwords over time. Using a more expensive encoding might require an attacker to expend thousands of times more resources to crack passwords than if they had used a fast encoding, but this additional cost is largely irrelevant if users have weak passwords that can be quickly guessed by attackers.

On the other hand, using a very fast algorithm might not incur that much risk for sufficiently strong passwords. For example, if a ten-character password is comprised of a random combination of uppercase and lowercase letters, numeric digits, and ASCII symbols, a set of 95 characters, then there are 9510 = 59,873,693,923,837,890,625 possible combinations of those characters. Even if an attacker can make one hundred billion guesses per second, it would still take nearly nineteen years for them to try every option. Realistically, users probably aren't going to have ten-character completely random passwords, but you can still do things like encourage password managers, encourage passphrases, discourage password reuse, and prohibit known-weak passwords. You can also use two-factor authentication so that gaining access to a user's account requires more than just cracking their password.

Ideally, you might find that the constraints of your budget and performance requirements do not prohibit the use of expensive encoding and that you can enjoy the best of both worlds: strong passwords encoded in a secure manner and protected by an additional authentication factor

Deprecated password storage schemes

PingDirectory server provides support for deprecating password storage schemes.

If a storage scheme is configured as deprecated, which can be done using the `deprecated-password-storage-scheme` property in the password policy configuration, any user who authenticates using a password encoded with that scheme using a mechanism that provides the server with access to the clear-text representation of that password automatically has their password re-encoded using the default scheme. This provides an excellent way to transparently migrate user passwords from weaker encodings to stronger ones without requiring users to change their passwords.

See the `config/sample-dsconfig-batch-files/deprecate-weak-password-storage-schemes.dsconfig` batch file for more information about deprecating password storage schemes.

Pre-encoded passwords

Whenever possible, passwords to be stored in PingDirectory server should be provided in the clear.

This is likely not an option when migrating data from an existing system into PingDirectory server, as passwords from those systems are likely already encoded in a non-reversible form. However, passwords included in add, modify, and password modify operations should be provided in the clear. If users are allowed to provide passwords in pre-encoded form, then they might be able to exempt themselves from some of the server's password quality constraints, including:

- The server cannot validate a pre-encoded password to ensure that it meets password quality requirements. Allowing pre-encoded passwords can therefore allow users to choose weak passwords.
- The server cannot ensure that a pre-encoded password is not just an alternative representation of the same password that they are currently using (for example, one that just uses a different salt), or a password that is already in their history. Allowing pre-encoded passwords can therefore allow users to circumvent restrictions around password expiration and password reuse.
- The server cannot ensure that passwords are encoded using the desired scheme. Allowing pre-encoded passwords can permit clients to use encodings that are not as resistant to password cracking attacks, and can also make it harder to migrate to migrate to stronger schemes in the future.

By default, PingDirectory server does not permit clients to provide pre-encoded passwords. While this restriction can be lifted using the `allow-pre-encoded-passwords` in the password policy configuration, we discourage this for the reasons listed above. In the event that there are legitimate use cases in which some applications might need to set pre-encoded passwords, such as when synchronizing passwords from another system into the PingDirectory server, there are a couple of better alternatives:

- You can update the account used by any such applications to grant them the `bypass-pw-policy` privilege. This privilege exempts the user from certain password policy restrictions when setting new passwords for other users, but not when changing the password for their own account. This includes:
  - They are permitted to set pre-encoded passwords.
  - They are permitted to set passwords that would otherwise fail password validation.
  - They are permitted to set passwords that are already in the user's password history.
- The client can use the password update behavior request control to customize the behavior that the server exhibits for the associated operation.

Encoded password caching

By default, the server can cache passwords encoded with PBKDF2, bcrypt, scrypt, or Argon2 to help improve authentication performance for passwords encoded with those schemes.

How encoded password caching works

The PingDirectory, PingDirectoryProxy, and PingDataSync servers support several computationally expensive password storage schemes. The encoded password cache can speed up repeated authentication attempts for users with these schemes, as follows:

1. The first time that a user authenticates, the server verifies the provided plaintext password using the expensive storage scheme.
2. The server then caches the encoded representation of the password in memory, along with an alternative salted SHA-256-encoded representation.
3. For all following authentication attempts as the same user, if the server finds their encoded password in the cache, it can attempt to verify their provided plaintext password using the faster SHA-256 algorithm.
4. The server automatically clears the cache whenever you change the configuration for the associated password storage scheme.

This cache can significantly reduce the performance impact of attempting to authenticate multiple connections as the same user in a short period of time, as could happen when a client creates a connection pool. This cost savings might be seen when the PingDirectoryProxy server makes its connections to the PingDirectory server because the Proxy User account has a PBKDF2-encoded password by default, as do the accounts for other root users and topology administrators.

Configuring the cache

The encoded password cache is enabled by default for expensive password storage schemes. The server maintains a separate cache with a default size of 10,000 passwords for each of these schemes.

You can change the size of the cache or disable it entirely by setting the value of the `encoded-password-cache-size` property for the applicable password storage schemes.

For example, the following command sets the cache size to 2000 passwords:

```
$ bin/dsconfig set-password-storage-scheme-prop \
    --scheme-name <password_storage_scheme_name> \
    --set encoded-password-cache-size:2000
```

> **Important**
>
> To disable the cache for a given password storage scheme, set the value of `encoded-password-cache-size` to 0.

Security considerations

The following security considerations apply to encoded password caching:

- The cache doesn't hold the plaintext representations of passwords. All cached passwords are stored in both their original encodings and as a cryptographically secure SHA-256 digest generated from a combination of the provided password and a securely generated 128-bit salt.
- The cache isn't persisted. It's only held in memory. Passwords that are persisted are encoded only with their configured storage schemes.

- The cache only holds encoded passwords. It doesn't include any other information that might be able to associate an encoded password with a user account.
- The cache can't become stale in any way that would affect the accuracy of authentication processing. For example, if a user changes their password, the cache won't allow them to continue authenticating with a former password. It also won't allow a user to continue authenticating after their account has become locked or disabled, or after their password has expired.

Password validators

Password validators ensure that user passwords are of sufficient quality.

When processing an add operation, a modify operation, or a password modify extended operation that attempts to set a new password, the server can reject that operation if the password is deemed too weak by one or more of the password validators. It is also possible to invoke password validators when users authenticate in a manner that provides the server with access to their clear-text password as an ongoing means of ensuring password quality.

Supported password validators

The PingDirectory server provides support for a wide variety of commonly used password validators.

The attribute value password validator

The attribute value password validator can be used to help ensure that users are not allowed to choose passwords that match other information in their entry. For example, a user might want to make their password the same as their username or email address. If an attacker gains access to information in a user's entry, then they can use that information to customize attacks gained at cracking that user's password.

The attribute value password validator offers the following configuration options:

`match-attribute`

The names of the other attributes to check when validating the password. If this is not provided, then all attributes are used by default.

`test-password-substring-of-attribute-value`

Indicates whether to reject passwords that are a substring of the value of another attribute in the user's entry. By default, only exact matches are rejected.

`test-attribute-value-substring-of-password`

Indicates whether to reject passwords that contain the value of another attribute in the user's entry as a substring. By default, only exact matches are rejected.

`minimum-attribute-value-length-for-substring-matches`

An integer value that specifies the minimum attribute value length that will be checked if `test-attribute-value-substring-of-password` is set to true. This can help prevent inappropriately rejecting passwords that happen to contain short attribute values. For example, if you have an attribute whose values can be just a single character, you probably don't want to prevent passwords that happen to contain that character. By default, only attributes values that contain at least four characters are checked.

`test-reversed-password`

Indicates whether to check attribute values in reverse order in addition to the order in which the values are stored. For example, if an attribute has value of "jdoe", then this could cause the server to also check for a value of "eodj". This is true by default.

See the `config/sample-dsconfig-batch-files/use-the-attribute-value-password-validator.dsconfig` batch file for more information about using the attribute value password validator.

The character set password validator

The character set password validator can be used to ensure that passwords contain an appropriate combination of characters. For example, you might want to require that a password contain at least one lowercase letter, one uppercase letter, one digit, and one symbol. Or you might want to ensure that a password contains characters from at least three of those four sets.

The character set password validator offers the following configuration properties:

`character-set`

Defines the sets of characters that are validated. Each of these sets should be defined as an integer followed by a colon and the characters contained in that set. The integer defines the minimum number of characters from that set that must be present in passwords. For example, a `character-set` value of "`1:abcdefghijklmnopqrstuvwxyz`" indicates that passwords will be required to have at least one lowercase letter. The integer value can be zero to indicate that characters from that set are permitted to be included in passwords but are not required. By default, the validator is configured with sets containing all lowercase letters, all uppercase letters, all numeric digits, and a range of ASCII symbols, and to require passwords to contain at least one character from each of those sets.

`allow-unclassified-characters`

Indicates whether to allow passwords to contain characters that are not contained in any of the defined character sets. This is true by default.

`minimum-required-character-sets`

Specifies the minimum number of character sets that are required to be included in passwords. This is useful, for example, if you want to require passwords to contain characters from at least three of the four predefined sets of lowercase letters, uppercase letters, digits, and symbols. In this case, all of the character sets should be updated to have a minimum required count (the value before the colon) of zero to indicate that they are all optional. If any character set has a nonzero minimum required count, then at least that many characters from that set are required in passwords, even if they would otherwise have contained characters from enough of the other sets.

> **Note**
>
> While this has been and still is a common practice, it is discouraged by modern password guidelines, such as those in NIST Special Publication 800-63B section 5.1.1.2. Studies have shown that these types of constraints annoy users without significantly improving password security, or even giving the false impression of security.

See the `config/sample-dsconfig-batch-files/use-the-character-set-password-validator.dsconfig` batch file for more information about using the character set password validator.

The dictionary password validator

The dictionary password validator can be used to prevent passwords that are known to be weak. The server comes predefined with two instances of the dictionary password validator:

- One that contains a dictionary of common words from a variety of languages
- One that contains a dictionary of strings that are known to be the most commonly used passwords

We also recommend that you provide your own dictionary that includes additional words not included in either of the included word lists. In particular, we recommend prohibiting words that are related to your company's name or products or services that you provide.

The dictionary password validator offers the following configuration properties:

`dictionary-file`

The path to a file containing the list of prohibited passwords. Each line of the file represents a prohibited password.

`case-sensitive-validation`

Indicates whether differences in capitalization should not be ignored when checking passwords against the dictionary file. By default, the validator uses case-insensitive validation.

`test-reversed-password`

Indicates whether to test passwords in reversed order when checking them against the dictionary file. For example, to prohibit a password of "terces" if the dictionary contains the word "secret". Reversed passwords are not checked by default.

`ignore-leading-non-alphabetic-characters`

Indicates whether to ignore any non-alphabetic characters that might appear at the start of the password when checking passwords against the dictionary file. For example, "123secret" could be rejected if the dictionary contains the word "secret". By default, all leading characters are considered significant.

`ignore-trailing-non-alphabetic-characters`

Indicates whether to ignore any non-alphabetic characters that might appear at the end of the password when checking passwords against the dictionary file. For example "secret123" could be rejected if the dictionary contains the word "secret". By default, all trailing characters are considered significant.

`strip-diacritical-marks`

Indicates whether to strip diacritical marks, such as accents, cedillas, circumflexes, diaereses, tildes, and umlauts, off of characters before checking passwords against the dictionary. For example, "sèçrét" could be rejected if the dictionary contains the word "secret". By default, diacritical marks are preserved.

`alternative-password-character-mapping`

Specifies a set of alternative characters that might be substituted in when checking passwords against a dictionary. For example, if a dollar sign is a substitute for the letter s, the number 3 is a substitute for the letter e, and the number 7 is a substitute for the letter t, then "$3cr37" could be rejected if the dictionary contains the word "secret". By default, no character substitutions are defined.

`maximum-allowed-percent-of-password`

Indicates that the proposed password should be rejected if it makes up at least a given percentage of a dictionary word . For example, if this threshold is set to 70%, then "mysecret" could be rejected if the dictionary contains the word "secret" because the word "secret" makes up 75% of "mysecret". By default, this is set to 100%, so values are ony rejected if they match complete dictionary words (after performing any other configured processing, like stripping of leading or trailing non-alphabetic characters).

See the `config/sample-dsconfig-batch-files/use-the-dictionary-password-validator.dsconfig` batch file for more information about using the dictionary password validator.

The haystack password validator

The haystack password validator is based on the concept of password haystacks as described at https://www.grc.com/haystack.htm. It is based on the premise that a password's resistance to brute-force attacks comes from a combination of two factors:

- The number of characters contained in the password. Longer passwords require more effort to crack than shorter passwords.
- The types of characters contained in the password. Passwords containing a wider range of characters might require more effort to crack than shorter passwords. For example, a password containing a mix of lowercase and uppercase letters might take longer to crack than a password containing just lowercase letters (at least, if an attacker crafts their attack to prioritize passwords that contain characters from only one set over those that contain passwords from multiple sets)

Because this cost is a combination of two factors, an increase in one of them can make up for a deficiency in another. For example, a password containing only lowercase letters can be very strong if it is long enough, while a shorter password might be acceptable if it contains a wider mix of characters.

This is a useful metric to offer because it can reject passwords that are legitimately easy to crack while not flatly rejecting passwords purely based on the types of characters that they contain. Unfortunately, it can be a difficult concept to succinctly convey to users when describing the requirements that their password will have to satisfy, which might ultimately make it undesirable for use.

The haystack password validator offers the following configuration properties:

`assumed-password-guesses-per-second`

The assumed rate at which an attacker can make password guessing attempts. By default, the validator assumes a rate of one hundred billion guesses per second.

`minimum-acceptable-time-to-exhaust-search-space`

The minimum acceptable length of time required to try all possible combinations of characters in the sets that make up the proposed password at the configured maximum rate. By default, the minimum acceptable time is one week.

See the `config/sample-dsconfig-batch-files/use-the-haystack-password-validator.dsconfig` batch file for more information about using the haystack password validator.

The length-based password validator

The length-based password validator can be used to impose restrictions on the allowed number of characters that a password can contain. Available configuration properties include:

`min-password-length`

The minimum number of characters that passwords are allowed to contain. Passwords that contain fewer characters than this limit are rejected.

`max-password-length`

The maximum number of characters that passwords are allowed to contain. Passwords that contain more characters than this limit are rejected. A value of zero indicates that no limit is enforced.

In some cases, it might be useful to impose a maximum length to prevent the server from spending too much processing power on extremely long passwords, but we strongly discourage setting a maximum length that is too short and unnecessarily limits the strength that a password can have. NIST Special Publication 800-63B section 5.1.1.2 recommends allowing passwords to be at least 64 characters long.

The PingDirectory server includes two length-based dictionary validator definitions by default: one with a minimum length of six characters and another with a minimum length of twelve characters. The NIST guidelines referenced above recommend requiring that passwords contain at least 8 characters.

See the `config/sample-dsconfig-batch-files/use-the-length-based-password-validator.dsconfig` batch file for more information about using the length-based password validator.

The Pwned Passwords password validator

The Pwned Passwords validator can be used to prevent users from choosing passwords that are known to have been compromised. By default, it checks with the free Pwned Passwords service, which includes a database of hundreds of millions of compromised passwords although it can be used with any other service that uses a compatible API.

The Pwned Passwords service uses the k-Anonymity algorithm to allow a client to securely determine whether a password has been compromised without revealing what the proposed password actually is. It does this by first computing an unsalted SHA-1 digest of the proposed password, and then only sending the first five characters of the hexadecimal representation of that digest to the service. The service then identifies all compromised passwords whose hex-encoded SHA-1 digest starts with those five characters and return the remaining 35 characters for all of those digests back to the client. If that returned set includes the last 35 characters in the digest for the proposed password, then it is one that has been known to be compromised.

The Pwned Passwords validator offers the following configuration properties:

`pwned-passwords-base-url`

The base URL to use for the service with which to communicate. By default, this is `https://api.pwnedpasswords.com/range/`.

`invoke-for-add`

Indicates whether the validator should be invoked for passwords set in add requests. Thisis true by default.

`invoke-for-self-change`

Indicates whether the validator should be invoked for new passwords chosen by the end user. This is true by default.

`invoke-for-admin-reset`

Indicates whether the validator should be invoked for new passwords set by an administrator. This is true by default.

`accept-password-on-service-error`

Indicates whether the validator should consider the password acceptable if it cannot communicate with the target service, or if that service returns an error response. By default, the password is considered acceptable although it might still be rejected if it fails to satisfy one or more of the other configured validators.

`key-manager-provider`

A key manager provider that should be used for HTTPS communication with the target service. This can be omitted, which is the case by default, if no key store is required because the client does not need to present its own client certificate chain to the server.

`trust-manager-provider`

A trust manager that should be used for HTTPS communication to determine whether to trust the server's certificate chain. This can be omitted if the server should use the JVM's default trust store.

See the `config/sample-dsconfig-batch-files/use-the-pwned-passwords-validator.dsconfig` batch file for more information about using the Pwned Passwords password validator.

The regular expression password validator

The regular expression password validator can be used to require passwords to match a given regular expression, or to reject passwords that do not match a given regular expression. It offers the following configuration properties:

`match-pattern`

The regular expression pattern to use when evaluating proposed passwords.

`match-behavior`

The behavior to exhibit if the given pattern matches a proposed password. Allowed values include:

- `require-match` — Indicates that the validator should accept passwords that match the provided pattern and reject passwords that do not.

- `reject-match` — Indicates that the validator should reject passwords that match the provided pattern and accept passwords that do not.

The repeated characters password validator

The repeated characters password validator can be used to reject passwords that have the same character more than a specified number of times in a row. This can help prevent passwords that contain stretches of the same character repeated several times, such as "aaaaaaaa".

The repeated characters password validator offers the following configuration properties:

`max-consecutive-length`

The maximum number of times that the character is allowed to be present consecutively within a proposed password. The default value is 2, which means that it is acceptable for the same character to appear twice in a row, but not three times or more.

`case-sensitive-validation`

Indicates whether to treat uppercase and lowercase versions of the same letter as different. By default, the validator uses case-insensitive validation, which means that it would reject a password containing the string "aAa" if the validator is configured with a max-consecutive-length of 2.

`character-set`

An optional set of characters that should be considered equivalent for the purpose of this password validator. For example, you could use this to define a set of numeric digits, and then reject passwords that contain too many consecutive digits.

Although many organizations might use a requirement that rejects passwords with repeated characters, we do not recommend using this validator unless it is configured with a longer limit than the default (for example, four characters rather than two). A limit that is too small might unnecessarily prevent very strong long randomly generated passwords (for example, one created by a password manager) just because the same character happened to occur a few times in a row. However, the unique characters password validator can be used to achieve the same result in a better way, so its use is recommended over the repeated characters validator.

The similarity-based password validator

The similarity-based password validator can be used to prevent users from choosing new passwords that are too similar to their current password. It uses the Levenshtein distance algorithm to compute the minimum number of changes (characters added to, removed from, or replaced in) to convert the current password into the new password.

This password validator is only invoked for self-changes. It is not invoked for add operations or administrative password resets. Further, because it requires access to the user's current password, it should only be used if the `password-change-requires-current-password` property is set to true in the password policy configuration.

This password validator offers the following configuration properties:

`min-password-difference`

The minimum number of changes (character insertions, removals, or replacements) required to convert the user's current password into the proposed new password for that new password to be considered acceptable. The default value is 3.

See the `config/sample-dsconfig-batch-files/use-the-similarity-based-password-validator.dsconfig` batch file for more information about using the similarity-based password validator.

The unique characters password validator

The unique characters password validator can be used to reject passwords that contain fewer than a specified minimum number of unique characters. This can help prevent users from choosing passwords that only contain a few different characters, such as "abababab".

This password validator supports the following configuration properties:

`min-unique-characters`

The minimum number of different characters that can appear in an acceptable password. Passwords that contain fewer than this number of unique characters are rejected.

`case-sensitive-validation`

Indicates whether to perform case-sensitive validation, in which uppercase and lowercase versions of the same letter are treated as different characters. By default, the validator uses case-insensitive validation.

See the `config/sample-dsconfig-batch-files/use-the-unique-characters-password-validator.dsconfig` batch file for more information about using the unique characters password validator.

Custom password validators

The UnboundID Server SDK can be used to create custom password validators using whatever logic you want.

Configuring password validators for updates

Password policies contain the following properties for configuring the set of password validators that are invoked for add operations, modify operations, and password modify extended operations.

`password-validator`

The set of password validators that should be invoked. Zero or more validators can be configured.

`skip-validation-for-administrators`

Indicates whether to allow administrators to set passwords that do not satisfy the password validation requirements.

No validators are included in the out-of-the-box configuration for the default password validator. Unless the `--allowWeakRootUserPassword` argument is provided when running setup, or the equivalent option is chosen when setting up the server in interactive mode, the passwords for root users and topology administrators are subject to the following requirements:

- The password must contain at least 12 characters.
- The password must not be contained in a dictionary of common words in various languages
- The password must not be contained in a dictionary of commonly used passwords

The `skip-validation-for-administrators` property is false by default in both the default password policy and the policy for root users and topology administrators.

Configuring password validators for binds

The PingDirectory server also provides support for invoking password validators while processing bind operations in which the server has access to the user's clear-text password.

This can be useful in at least a couple of key circumstances:

- If you use a service like Pwned Passwords that is regularly updated with information from new data breaches
- If you maintain one or more dictionaries of banned passwords and update them with new values
- If you enable a new validator or change the configuration of an existing validator

> **Note**
>
> The set of password validators that are configured for add, modify, and password modify operations is not automatically used for bind operations. Rather, you can explicitly configure which validators (if any) should be invoked for binds.

Similarly, password validators do not have to be invoked for every bind. In many cases, it might be better to only periodically invoke validators to reduce the potential impact on performance. This is especially true for cases in which validation might interact with external systems like the Pwned Passwords service.

Password policies provide the following configuration properties related to invoking password validators on bind:

`bind-password-validator`

The set of password validators to invoke for bind operations. Zero or more validators can be configured, and none are configured by default.

`minimum-bind-password-validation-frequency`

The minimum frequency that can be used when invoking validators for users. If this is set to zero seconds, then password validators will be invoked for each bind. If it is set to a value that is greater than zero, then the server keeps track of the last time it invoked bind password validators for that user and only invokes the validators if at least that much time has passed since the last set of validation. The default validation frequency is 30 days.

`bind-password-validation-failure-action`

The action that the server should take if a user's password fails validation during a bind. Allowed values include:

- f`orce-password-change` — Indicates that the bind attempt should succeed, but the user will be forced to choose a new password before they are allowed to perform any other operations in the server. The bind response includes a password expired response control and a diagnostic message that describes the problems identified with the password. This is the default behavior.
- r`eject-bind` — Indicates that the bind attempt should fail and the user's account should be locked. An administrative password reset is required to restore access to the user's account.

- `generate-account-status-notification` — Indicates that the bind attempt should succeed, but that the server should generate an account status notification to make the user or server administrators aware of the weakness, or potentially to take custom action in response to it.

See the `config/sample-dsconfig-batch-files/enable-password-validation-for-binds.dsconfig` batch file for more information about enabling password validators for binds.

Recommended password validator configuration

To help ensure that users choose strong passwords, configure the following password validators for add, modify, and password modify operations.

- A length-based password validator with a minimum length of ten characters.
- A dictionary password validator configured to use `config/wordlist.txtA`.
- A dictionary password validator configured to use `config/commonly-used-passwords.txt`.
- A dictionary password validator configured to use a custom dictionary with banned words that relate to the company and its products or services, as well as any other banned passwords that are not included in dictionaries shipped with the PingDirectory server.
- The Pwned Passwords validator that prohibits passwords from known data breaches.
- An attribute value password validator that rejects passwords matching attribute values.
- A similarity-based password validator that rejects new passwords that are too similar to the current password.
- A unique characters password validator that requires passwords to contain at least five unique characters.

We also recommend periodically invoking the following password validators for bind operations:

- The Pwned Passwords validator that prohibits passwords from known data breaches.
- The dictionary validator that uses the custom banned password file if you intend to update it on a regular basis with new banned passwords.

Consider forcing users to change their passwords if validation fails during a bind operation.

Password history

Configure PingDirectory server to maintain a history of former passwords to prevent them from reusing the password multiple times.

Use the following password policy configuration properties to enable a password history:

`password-history-count`

The maximum number of former passwords to maintain in the history.

`password-history-duration`

The maximum length of time that former passwords should be stored in the history.

If either of these properties is configured with a nonzero value, then the server maintains a password history for users associated with that password policy.

If a password history is to be maintained, then you might want to also impose a limit on how frequently users are allowed to change their password. Without such a limit, some crafty users might attempt to change their passwords several times in quick succession to purge the password they want to keep from the history so they can re-use it. Configure this limit with the following configuration property:

`min-password-age`

The minimum length of time that must pass between self password changes. If a user attempts to change their password multiple times within this duration, then the latter attempts are rejected.

> **Note**
>
> Administrators are able to reset user passwords at any time, regardless of how long it has been since a user has changed their password. It also does not prevent a user from choosing a new password following an administrative reset.

See the `config/sample-dsconfig-batch-files/enable-password-history.dsconfig` batch file for more information about enabling password history.

Password expiration

While it was once a common practice, and still is in some environments, password expiration is no longer recommended.

You should force a user to change their password if you have reason to believe that it is weak or has been exposed in a data breach, but forcing arbitrary password changes is frustrating for users and does not meaningfully improve security.

Nevertheless, PingDirectory server provides full support for password expiration. Use the following configuration properties to enable password expiration and customize its behavior:

`max-password-age`

The maximum length of time that a user can continue using the same password. If this is configured with a value of zero seconds (which is the default), then password expiration is disabled.

`password-expiration-warning-interval`

The length of time before an upcoming password expiration that the server should start warning about that expiration. A value of zero seconds disables the warning. By default, the server starts warning about an upcoming expiration five days in advance.

`expire-passwords-without-warning`

Indicates whether the server should allow a user's password to expire even if they have not been warned about an upcoming expiration. If this is false (which is the default), then the server ensures that the user receives at least one warning about the upcoming expiration, even if the expiration time has already passed. After it has issued the warning, the server grants the user the full duration of the password expiration warning interval before the password actually expires.

`allow-expired-password-changes`

Indicates whether the server allows a user to change their password even after it has expired. This is false by default, and an administrator is required to reset the user's password before the account becomes usable again. However, if this is changed to true, then the user is allowed to use the password modify extended operation over an unauthenticated connection, providing their current password in addition to the desired new password.

`grace-login-count`

The maximum number of grace logins that the server grants to a user. A grace login allows a user to authenticate with an expired user, but only for the purpose of changing their password. Any other operations that they attempt are rejected. By default, the server does not allow any grace logins.

The server offers a pair of response controls that are related to password expiration, both of which are described in draft-vchu-ldap-pwd-policy:

- The password expiring response control is included in the response to a successful bind operation in cases where the user's password is about to expire.
- The password expired response control is included in the response to a bind operation in cases where the user's password has expired. If the bind response includes a result code of success, then the user is permitted to change their password, but is not be allowed to do anything else until they have done that. If the bind response has a non-success result code, then an administrative password reset is required to restore access to the user's account.

> **Note**
>
> If the user includes the password policy request control, as described in draft-behera-ldap-password-policy in the bind request, then the server includes the password policy response control in the bind response instead of the password expiring or password expired control. The password policy response control value can be used to indicate whether the user's password is expired or is about to expire, so the additional control is not necessary.

See the `config/sample-dsconfig-batch-files/enable-password-expiration.dsconfig` batch file for more information about enabling password expiration.

Failure lockout

PingDirectory server provides the ability to lock a user's account after too many consecutive failed authentication attempts.

The lockout can be temporary, automatically expiring after a specified length of time, or permanent. In either case, an administrative password reset can be used to immediately restore access to the account.

However, actually locking a user's account after too many failed authentication attempts can be problematic because it has the potential to block legitimate access to the server. If the password policy is configured with a lockout failure count value that is too low, then it is possible for a user to legitimately mistype their password enough times in a row to trigger the lockout. However, the bigger risk is that an attacker could purposefully lock a user's account by intentionally making repeated failed bind attempts, denying the legitimate user access to their own account. To help protect against this, PingDirectory server offers support for alternative failure lockout actions. Rather than locking the account, the server can be configured to delay bind responses as a rate-limiting mechanism, or it can be configured to generate an account status notification to alert administrators to the problem or invoke custom processing.

The password policy configuration offers the following properties related to failure lockout:

`lockout-failure-count`

The number of consecutive authentication failures required to trigger the failure lockout action. This is zero by default to indicate that failure lockout is disabled, but if it is set to a nonzero value, then the appropriate failure lockout action is taken after that number of consecutive failed attempts. If the user binds successfully before the failure count is reached, then the record of failed attempts is cleared. The set of failed attempts is also cleared by an administrative password reset.

`lockout-duration`

The length of time that the failure lockout should be in effect. A value of zero seconds (which is the default) indicates that the lockout should be permanent, and that an administrative password reset is required to restore access to the user's account. A value that is greater than zero indicates that the account is automatically unlocked after that length of time, although an administrative password reset can be used to restore access before that lockout period has expired.

`lockout-failure-expiration-interval`

The maximum length of time that the server should preserve information about a failed authentication attempt even if there is no intervening successful attempt or password reset. The default value of zero seconds indicates that failed attempts never expire, and they are preserved until enough failed attempts are accumulated to lock an account, or until a successful bind or an administrative reset clears the record of failed attempts.

`ignore-duplicate-password-failures`

Indicates that repeated failed authentication attempts that try the same wrong password should just be considered a single wrong attempt. If this is true (which is the default), then a client that repeatedly tries to bind with the same wrong password only accumulates a single failed attempt toward account lockout, regardless of the number of bind failures that actually occur. This is a safeguard to prevent issues that might arise if an account's password is changed but there are applications still configured to use the old password. Using this option does not constitute an additional security risk because someone attempting an online guessing attack will try different passwords rather than repeatedly trying the same wrong password.

`failure-lockout-action`

Specifies the action that the server should take if the necessary number of failed attempts is reached.

See the `config/sample-dsconfig-batch-files/enable-failure-lockout.dsconfig` batch file for more information about enabling failure lockout.

Alternative failure lockout actions

As stated earlier, you can configure the server to take a variety of actions if the failure lockout count is reached.

Lock account

As its name implies, the lock account failure lockout action can be used to lock a user's account. Any attempts to authenticate are rejected while the lockout is active, regardless of whether the correct credentials were provided. If a lockout-duration is configured in the password policy, then the lockout automatically expires after that length of time. Otherwise, it persists until an administrative password reset.

This lockout failure action does not offer any configurable properties.

Delay bind response

The delay bind response lockout failure action can be used to delay the response to bind attempts after the lockout failure count has been reached. Once the threshold has been reached, then subsequent bind attempts are delayed until the user successfully authenticates or until the password is reset.

> **Note**
>
> If the server has delayed the response to any failed attempts, then the response to the next successful attempt will also be delayed. This helps prevent clients from using the presence of a delay as an indication of whether the password was correct.

Without this additional delay, an attacker could terminate the connection and establish a new one to make another attempt as soon as they detect the delay, rather than having to wait for the full duration of the delay.

The delay bind response failure lockout action offers the following configuration properties:

`delay`

The duration to use when delaying the response to the failed bind attempt. By default, a delay of one second is used.

`allow-blocking-delay`

Indicates whether the server should delay the bind response even doing so could block the thread being used to process the operation. This option applies to operations requested by non-LDAP clients. When delaying the response to an LDAP bind, the server is able to do so in a way that does not tie up any threads that could be used for processing operations. For other clients, like those using HTTP to communicate, the only option that the server has for performing the delay is to sleep on the thread that is processing the operation, which makes that thread unavailable for processing other requests until it's done sleeping. This property is set to false by default, and if you want to delay the response to HTTP clients, then you should make sure to adjust the number of HTTP request handler threads to reduce the potential that all of them could be tied up sleeping on failed bind attempts.

`generate-account-status-notification`

Indicates whether the server should generate an account status notification if it delays a bind response. The account status notification uses a notification type of either `account-temporarily-locked` or `account-permanently-locked`, depending on whether the password policy is configured with a lockout duration. By default, no notification is generated.

No operation

The no operation failure lockout action does not take any client-visible action in response to reaching the lockout failure count. It offers a single configuration property:

`generate-account-status-notification`

Indicates whether the server should generate an account status notification, of type `account-temporarily-locked` or `account-permanently-locked`, if the failure lockout count is reached. This can potentially be used to notify administrators or optionally take some custom action using an account status notification handler created with the UnboundID Server SDK in the event of a failure lockout.

Sign on history tracking and idle account lockout

You can configure PingDirectory server to maintain a record of previous authentication attempts. It can also lock an account if it has been too long since the user last successfully authenticated.

Recent sign on history

PingDirectory server can maintain a history of recent successful and failed sign on attempts.

If enabled, it maintains the following information about each recorded attempt:

- A Boolean value indicating whether the attempt was successful
- A timestamp, formatted in the ISO 8601 format described in RFC 3339, indicating when the attempt occurred
- The name of the authentication method that was attempted (for example, "simple" or "SASL PLAIN")
- The IP address of the client that made the attempt, if available
- A general reason that the authentication attempt failed for failed attempts
- An optional additional attempt count that can be used to indicate how many other attempts with the same properties (successful, authentication method, client IP address, and failure reason) occurred on the same date

Enabling recent login history

The following password policy configuration properties are used to manage recent login history tracking:

`maximum-recent-login-history-successful-authentication-count`

The maximum number of successful attempts to maintain in the recent login history.

`maximum-recent-login-history-successful-authentication-duration`

The maximum length of time to retain successful login attempts in the recent login history.

`maximum-recent-login-history-failed-authentication-count`

The maximum number of failed attempts to maintain in the recent login history.

`maximum-recent-login-history-failed-authentication-duration`

The maximum length of time to retain failed attempts in the recent login history.

`recent-login-history-similar-attempt-behavior`

The behavior to exhibit for clients with multiple similar attempts (with the same values for the successful, authentication method, client IP address, and failure reason fields) on the same date (within the UTC time zone). Allowed values include:

- `collapse-similar-attempts-on-the-same-date` — Indicates that multiple similar attempts should be collapsed into a single record. The timestamp of that record reflects the most recent attempt on that date, and the additional attempt count reflects the number of additional similar attempts that were collapsed. This is the default behavior.
- `maintain-every-attempt` — Indicates that the server should not collapse multiple similar attempts and that each attempt is maintained as a separate record in the recent login history. Clients that authenticate multiple times per day can have multiple records per day.
- `update-at-most-once-per-day` — Indicates that the server should not collapse multiple similar attempts and that only the first such attempt on any given day is recorded. This can reduce the number of writes required to maintain the recent login history.

If either the `maximum-recent-login-history-successful-authentication-count` or the `maximum-recent-login-history-successful-authentication-duration` properties has a value, then the server maintains a history of recent successful attempts. If both properties are configured, then the server can purge information about successful attempts that match the criteria for either. This is useful, for example, if you usually want to keep records based on a duration, but want to add protection against the history growing too large from an excessive number of records created within that duration.

Similarly, the server maintains a record of recent failed authentication attempts if either or both the `maximum-recent-login-history-failed-authentication-count` and `maximum-recent-login-history-failed-authentication-duration` properties are configured. It is possible to maintain a record of successful attempts without a record of failed attempts, to maintain a record of failed attempts without successful attempts, or to maintain a record of both successful and failed attempts. By default, no recent login history is maintained.

> **Note**
>
> If the `maximum-recent-login-history-successful-authentication-duration` and `maximum-recent-login-history-failed-authentication-duration` properties are used to maintain records of successful and failed attempts based on their duration, then it is possible for the server to retain records older than that duration if they are the most recent record of that type in the user's entry. That is, if the server is configured to maintain a history of successful logins, then the record of the most recent successful attempt will be retained even if it is older than the maximum duration for successful login attempts. The same is true if failed authentication attempts are to be maintained and a duration is configured.

See the `config/sample-dsconfig-batch-files/enable-recent-login-history.dsconfig` batch file for more information about configuring a recent login history.

Retrieving a user's recent login history

If the server is configured to maintain a recent login history for a user, then there are several ways that this history can be retrieved. They include:

- The client can include the get recent login history request control in the bind request. If the bind succeeds, then the server includes a corresponding response control in the bind result. The UnboundID LDAP SDK for Java provides support for these controls, and the `ldapsearch` and `ldapmodify` command-line tools both offer the `--getRecentLoginHistory` argument that can be used to retrieve the history from the command line.
- If the ds-pwp-state-json virtual attribute is enabled, then it might include a `recent-login-history` field whose value is a JSON object with information about recent successful and failed attempts for that user.
- The password policy state extended operation (or the `manage-account command-line` tool) can be used to retrieve the user's recent login history.

Last login time and IP address

The server supports maintaining a record of the most recent successful attempt to sign on.

This isn't as full-featured as the recent login history, but it might still be in use in legacy environments or when the full functionality of the login history isn't needed.

The password policy configuration offers the following properties for maintaining a last login time and IP address:

`last-login-time-attribute`

The name of the attribute in which the last login time should be written. The server has reserved the `ds-pwp-last-login-time` operational attribute type for this purpose, and this value shouldn't be changed.

`last-login-time-format`

The format in which the server should record the last login time. If both this property and the `last-login-time-attribute` property are assigned values, then the server generates a last login time value after each successful authentication attempt and updates the user's entry if the generated value doesn't match the value that is currently stored in the entry. Values for this property can use any valid format string that is compatible with the java.text.SimpleDateFormat class, but we recommend using one of the following values:

- `yyyyMMdd` — Indicates that the server should maintain a last login time containing only the date. This should cause each user's last login time to be updated at most once per day.
- `yyyyMMddHHmmss'Z'` — Indicates that the server should maintain the last login time in generalized time format using precision to the nearest second. This should cause the last login time to be updated for each successful authentication, unless the user authenticates multiple times in the same second.
- `yyyyMMddHHmmss.SSS'Z'` — Indicates that the server should maintain the last login time in generalized time format using precision to the nearest millisecond. This should cause the last login time to be updated for each successful authentication, unless the user authenticates multiple times in the same millisecond

`previous-last-login-time-format`

An optional set of alternative formats in which last login time values might have previously been written. If you have changed the value of the `last-login-time-format` property, then you should update this property with any former values so that the server can decode values generated in one of those earlier formats.

`last-login-ip-address-attribute`

The name of the attribute that should be updated with the IP address of the client from which the user last authenticated. The server has reserved the `ds-pwp-last-login-ip-address` operational attribute type for this purpose, but the value isn't set by default because doing so would enable this feature and update the user's entry with the client IP address for each successful authentication attempt (unless the client IP address matches the current value for that attribute, in which case no update is needed).

Refer to the `config/sample-dsconfig-batch-files/enable-last-login-tracking-and-idle-lockout.dsconfig` batch file for more information about enabling last login time and IP address tracking.

Idle account lockout

You can configure PingDirectory server to lock a user's account if it has been too long since they last authenticated.

If the password policy has been configured to either maintain a record of recent successful authentication attempts or to maintain a last login time, then the following configuration property is used to enable idle account lockout:

`idle-lockout-interval`

Specifies the length of time that must pass after the most recent successful authentication for a user's account to be locked. A value of zero seconds (which is the default) indicates that idle account lockout should be disabled.

If an account has been locked because it has been too long since the user last authenticated, then it can be unlocked with an administrative password reset.

The `config/sample-dsconfig-batch-files/enable-last-login-tracking-and-idle-lockout.dsconfig` batch file provides more information about idle account lockout.

Self password changes

A self password change occurs whenever a user changes their own password.

This can occur when a user changes their own password on a connection authenticated as that user or when the request used to change the password includes the user's current password. This includes all of the following:

- When an authenticated client uses either a regular modify operation or a password modify extended operation to change the password for the account they used to authenticate, and when no alternate authorization identity has been requested.
- When an authenticated client uses a regular modify operation or password modify extended operation to change the password for an account, and uses the intermediate client request control, proxied authorization request control, or SASL alternate authorization to request that the operation be processed under the authority of the user that owns the account whose password is being changed.

- When a client uses the password modify extended operation to provide the current password for the account whose password is being changed. If the current password is provided, then this is considered a self-change regardless of whether the underlying connection is authenticated or the authenticated identity of that connection.
- When a client uses a regular modify operation and includes the current password for the user whose password is being changed, even if that request is received on a connection authenticated as some other user.

The password policy configuration includes the following properties pertaining to a user's ability to change their own password:

`allow-user-password-changes`

Indicates whether users are allowed to change their own passwords. If this is true (which is the default), then any user with access control permission to update their own password is permitted to do so (as long as the server considers the password acceptable). If this is set to false, then users are not allowed to change their own password regardless of the access control permissions that have been granted to them.

`password-change-requires-current-password`

Indicates whether users are required to provide their current password when choosing a new password.

`allow-expired-password-changes`

Indicates whether users are allowed to change their own password if it has already expired. If this is set to true, then they can use the password modify extended operation over an unauthenticated connection with both the current and desired new password.

Self password changes requiring current passwords

If you set the `password-change-requires-current-password` property to `true`, users must provide their current password when choosing a new password.

You can make these password changes using either a regular LDAP modify operation or a password modify extended operation.

> **Important**
>
> For either method:
>
> - If the user doesn't provide the correct current password, the server rejects the password modify request.
> - Password submissions must be in plain text, not encoded.
>
> Refer to the `config/sample-dsconfig-batch-files/require-current-password-when-changing-passwords.dsconfig` batch file for more information about requiring users to provide their current password when performing self password changes.

LDAP modify operation

For a regular LDAP modify operation, the password change request must include modifications to delete the user's current password and add their new password.

The following example uses the `ldapmodify` tool to change a user's password:

```
$ bin/ldapmodify --hostname server.example.com --port 636 --useSSL \
--bindDN "cn=admin,dc=example,dc=com" --bindPassword <bindPassword>
dn: uid=jdoe,ou=People,dc=example,dc=com
changetype: modify
delete: userPassword
userPassword: <currentPassword>
-
add: userPassword
userPassword: <newPassword>
-
```

The following example uses the `ldappasswordmodify` tool with the `--passwordChangeMethod ldap-modify` argument to change a user's password:

```
$ bin/ldappasswordmodify --hostname server.example.com --port 636 --useSSL \
  --bindDN "cn=admin,dc=example,dc=com" --bindPassword <bindPassword> \
  --userIdentity uid=jdoe,ou=People,dc=example,dc=com \
  --oldPassword <currentPassword> \
  --newPassword <newPassword> \
  --passwordChangeMethod ldap-modify
```

> **Note**
>
> In the previous example, the `ldappasswordmodify` tool creates the required modifications for an LDAP modify operation.

Password modify extended operation

Alternatively, you can use the password modify extended operation, as described in RFC 3062, to update user passwords. There are two implementation methods:

- For integration with a custom user account management application, use the UnboundID LDAP SDK for Java or another LDAP client API.
- For the server CLI implementation, use the `ldappasswordmodify` tool with the `--passwordChangeMethod password-modify-extended-operation` argument.

Advantages over LDAP modify

The password modify extended operation has several advantages over a regular LDAP modify operation, including:

- The user doesn't have to know their full DN or the name of the attribute used to store their encoded password.
- If the user's password policy is configured with `allow-expired-password-changes` set to `true`, the user can reset their expired password.

  > **Important**
  >
  > This type of request must include a value for `userIdentity`.

- The server can automatically generate a new password for the target user.

- A user can recover access to their account by providing a server-generated password reset token instead of their current password.

> **Note**
> You need to configure the server to support this operation.

Using the extended operation

The following table describes the attributes related to the password modify extended operation:

Attribute	Description
`userIdentity`	Indicates the user whose password you are changing. You can supply one of the following values: • The full DN of the user entry, with or without the `dn:` prefix • The string `u:<user_value>`, where `<user_value>` represents a value that the server can use to return a single user entry The server uses the identity mapper specified in the password modify extended operation handler to match the `u` value to the user entry. The server rejects the password modify request if a search returns more than one entry. By default, the extended operation handler's identity mapper expects an exact match of either the `uid` or `mail` attributes. For example, if you provide the argument `--userIdentity u:jdoe`, the server searches using a filter of `"(|(mail=jdoe)(uid=jdoe))"`. **Tip** If the connection making the password modify request is authenticated as the target user, you can omit `userIdentity`.
`oldPassword`	Indicates the current user password.
`newPassword`	Indicates the new user password. **Tip** To have the server generate a new password, omit `newPassword` from the request. The server uses the password generator defined in the password policy and returns the new password in the extended operation response.

The following example uses `ldappasswordmodify` to target a user by DN and set a new password:

```
$ bin/ldappasswordmodify --hostname ds.example.com --port 636 --useSSL \
  --bindDN "uid=admin,dc=example,dc=com" --bindPasswordFile admin-password.txt \
  --userIdentity uid=jdoe,ou=People,dc=example,dc=com \
  --oldPassword <currentPassword> \
  --newPasword <newPassword> \
  --passwordChangeMethod password-modify-extended-operation
```

Administrative password reset

An administrative password reset occurs when one user changes the password for another user.

This requires the password-reset privilege, and it also requires access control permission to update the password attribute.

You can configure PingDirectory server to require users to choose a new password after their password has been reset by an administrator. This can be accomplished through the following configuration properties:

`force-change-on-add`

: Indicates whether a user is required to choose a new password the first time they authenticate after their account has been created. This is false by default.

`force-change-on-reset`

: Indicates whether a user is required to choose a new password the first time they authenticate after their password has been reset by an administrator. This is false by default.

`max-password-reset-age`

: The maximum length of time that a user has to change their password after an administrative reset before their account is locked.

If a user is forced to change their password, then the server allows that user to authenticate with the new password provided by an administrator, but the bind response includes the password expired response control and a diagnostic message indicating that they must change their password. The server also rejects any operation attempted on that connection until the user has chosen a new password.

If a maximum password reset age is configured and the user does not choose a new password within that length of time after the password reset, then the account is locked and another password reset is required to restore access to it.

See the `config/sample-dsconfig-batch-files/configure-password-reset-constraints.dsconfig` batch file for more information about forcing users to change their password after an administrative reset.

Password generators

PingDirectory server provides support for password generators that are used under a variety of conditions.

These conditions include:

- If a client uses the password modify extended request to perform a self password change or an administrative password reset but does not include a new password in that request. In this case, the server can use a password generator to create a new password for the user and return it to the client in the password modify extended response.
- If a client uses an add request to create a new entry and includes the request control with that add request. The server generates a new password for that entry and returns it in a response control included with the add response.
- If the client uses the generate password extended operation, which can be used to request that the server generate one or more suggested passwords for a user. The server generates the requested number of passwords and returns them in the extended response.

- If the client uses the deliver one-time password extended operation, which can be used to generate a one-time password for use in the UNBOUNDID-DELIVERED-OTP SASL bind request.
- If the client uses the deliver password reset token extended operation, which can be used to generate a password reset token that can be used as an alternative to the user's current password the password modify extended request.
- If the client uses the deliver single-use token extended operation, which can be used to generate a token that can be used in conjunction with the consume single-use token extended operation.

You can configure the deliver one-time password, deliver password reset token, and deliver single-use token extended operation handlers to explicitly state the password generator that the server should use when creating those tokens. For the other use cases above, the server uses the password generator that is associated with the user's password policy. This can be specified with the following configuration property:

`password-generator`

Specifies the password generator that should be used for requests that require the server.

Random password generator

The random password generator constructs a password using a specified format.

It offers the following configuration properties:

`password-character-set`

Defines the character sets that can be used when generating passwords. Each character set should consist of a name followed by a colon and the set of characters that set contains (for example, `alpha:abcdefghijklmnopqrstuvwxyz` or `numeric:0123456789`). Multiple character sets can be configured.

`password-format`

Specifies the format that should be used when generating passwords. This should be a comma-delimited list in which each item is the name of a character set followed by a colon and the number of characters to include from that set (for example, `alpha:3,numeric:2,alpha:3` indicates that the generated password should consist of three alphabetic characters followed two numeric digits and three more alphabetic characters).

Passphrase password generator

The passphrase password generator attempts to construct strong, memorable passphrases by combining multiple randomly selected words from a given dictionary file.

This password generator offers the following configuration properties:

`dictionary-file`

The path to the file containing the words to use when generating passwords. By default, the server includes a `passphrase-wordlist.txt` file with a large number of non-offensive English-langauge words.

`minimum-password-characters`

The minimum number of characters that should be included in the generated passphrase. The passphrase includes enough words to ensure that the minimum character count is reached. By default, generated passphrases include a minimum of 20 characters.

`minimum-password-words`

The minimum number of words that should be included in the generated passphrase. By default, passphrases contain at least four words.

`capitalize-words`

Indicates whether the first letter of each word should be capitalized, which can help make it easier to identify the words contained in the passphrase. By default, each word is capitalized. Generated passphrases are case-sensitive.

Third-party password generator

Use the UnboundID Server SDK to create custom password generator implementations.

Password retirement

When a user changes their own password, or when an administrator resets the password for another user, that password change takes place immediately, and the new password should be used for subsequent authentication attempts.

By default, the former password is also immediately removed from the user's entry and can no longer be used to authenticate. However, PingDirectory server supports a feature called password retirement in which the user's former password can continue to be valid for a limited period of time.

Password retirement is especially useful for accounts used to authenticate applications, and particularly for applications that run on multiple systems. After the account's password is changed in the PingDirectory server, the application can continue trying to use the old password until it can be updated with the new one. Similarly, the application cannot be configured to use the new password before it is changed in the PingDirectory server because attempts to authenticate with that new password before the account has been updated will also fail. With password retirement, the password can be changed in the PingDirectory server in a way that allows either the new password or the former password to be accepted. This provides a window of time in which the application instances can be updated with the new password.

The following password policy configuration properties can be used to configure password retirement:

`password-retirement-behavior`

The password retirement behavior that the server should exhibit. By default, passwords are not retired. However, any number of the following values can be used to enable retirement functionality:

- `retire-on-self-change` — Indicates that self password changes should automatically cause the user's former password to be retired unless the request includes the purge password request control.
- `retire-on-administrative-reset` — Indicates that administrative password resets should cause the user's former password to be retired unless the request includes the purge password request control.

- `retire-on-request-with-control` — Indicates that the client can use the retire password request control to indicate that the user's current password should be retired.

`max-retired-password-age`

The maximum length of time that the retired password should be considered valid. By default, this is set to one day.

The PingDirectory server also provides support for two request controls that can be used to customize password retirement behavior. The retire password request control can be used to explicitly indicate that the user's current password should be retired, even if the server would otherwise purge it. This control is only allowed if the `password-retirement-behavior` property includes a value of `retire-on-request-with-control`. The purge password request control can be used to explicitly indicate that the user's current password should be removed from the server even if it would have otherwise retired it for example, because of the `retire-on-self-change` or `retire-on-administrative-reset` property.

See the `config/sample-dsconfig-batch-files/enable-retired-passwords.dsconfig` batch file for more information about configuring password retirement.

Password reset tokens

If a user loses access to their account for some reason, such as if they forget their password or let it expire, then they must have their password reset by an administrator to regain access to it.

This can be costly for the organization because they might have to employ additional help desk staff, and it can be frustrating for users who might have to wait on someone to become available to help them.

Many organizations have attempted to deal with this by automating the password reset process: their application can provide an "I forgot my password" link option that identifies the user and sends them a new password that can be used to authenticate. PingDirectory server provides support for password reset tokens that can be used to provide much of the heavy lifting.

Much like delivered one-time passwords, a password reset token is a single-use password that is generated by the server and delivered to the user through an out-of-band mechanism like email or SMS. However, rather than allowing the user to authenticate, a password reset token can only be used in the current password field of a password modify extended request so that they can choose a new password.

After an application has obtained whatever it considers sufficient evidence of the user's identity, such as by asking them for their username, email address, or phone number, it can use the deliver password reset token extended request to have the server generate a single-use password reset token and deliver it to the user through some out-of-band mechanism, and then it can allow the user to enter that token and their desired new password to send a password modify extended request to actually change the password.

The following password policy configuration property can be used to indicate the conditions under which a password reset token can be used:

allowed-password-reset-token-use-condition

The set of conditions under which a password reset token can be used. Allowed values include:

- `account-usable` — Indicates that a password reset token can be used if the user's account is in a usable state and would permit them to authenticate if they provided the correct credentials.
- `account-locked-due-to-failures` — Indicates that a password reset token can be used to recover access to an account that has been locked after too many failed authentication attempts.

- `account-locked-due-to-idle-time-limit` — Indicates that a password reset token can be used to recover access to an account that has been locked because it has been too long since the user last authenticated.
- `account-locked-due-to-admin-reset-timeout` — Indicates that a password reset token can be used to recover access to an account that has been locked because they failed to choose a new password in a timely manner after an administrative password reset.
- `account-locked-due-to-validation-failure` — Indicates that a password reset token can be used to recover access to an account that has been locked because their password failed to satisfy one or more bind password validators.
- `password-expired` — Indicates that a password reset token can be used to recover access to an account with an expired password.

In addition to the password policy configuration, you must configure one or more one-time password delivery mechanisms in the server and create an instance of the deliver password reset token extended operation handler. The server offers out-of-box support delivering one-time passwords as SMS (using the Twilio service) or email messages, and the Server SDK provides support for developing custom delivery mechanisms.

The deliver password reset tokens extended operation handler offers the following configuration options:

`password-generator`

The password generator that should be used to create the password reset tokens.

`default-token-delivery-mechanism`

An ordered list of one-time password delivery mechanisms that should be tried if the extended request does not indicate which methods to attempt.

`password-reset-token-validity-duration`

The length of time that password reset tokens should be valid. They are valid for five minutes by default.

See the `config/sample-dsconfig-batch-files/support-password-reset-tokens.dsconfig` batch file for more information about configuring the server to support password reset tokens.

Account status notifications

Account status notifications are used to notify users (or administrators) about events that affect their accounts or potentially to invoke custom code if such events occur.

The types of events that can generate account status notifications include:

- The account has been locked after too many failed authentication attempts.
- A bind attempt failed because it has been too long since the user last authenticated.
- A bind attempt failed because the user did not choose a new password in a timely manner after an administrative reset.
- A bind attempt failed because the password was rejected by one or more bind password validators.
- The account has been unlocked by an administrator.

- The account has been disabled or enabled by an administrator.
- A bind attempt failed because the account is not yet active or has expired.
- A bind attempt failed because the password is expired.
- The user's password is about to expire.
- The user has changed their own password.
- The user's password has been reset by an administrator.
- The user's account has been created with an add request that matches a defined set of criteria.
- The user's account has been updated with a modify or modify distinguished name (DN) request that matches a defined set of criteria.

The following password policy configuration property can be used to configure one or more account status notification handlers for use with that policy:

`account-status-notification-handler`

The set of account status notification handlers that should be invoked for users associated with the password policy.

The server offers support for a few types of account status notification handlers by default, including:

- A multi-part email account status notification handler that can generate elaborate email messages (containing plain-text and HTML-formatted body text and an optional set of attachments) from customizable templates.
- A legacy SMTP account status notification handler that can generate simple plain-text email messages.
- An error log account status notification handler that can record a message in the server's error log when such events occur.

You can also use the UnboundID Server SDK to create custom account status notification handlers if desired.

> **Tip**
>
> You can find details about configuring the multi-part email account status notification handler in the `config/sample-dsconfig-batch-files/enable-email-account-status-notifications.dsconfig` batch file and about the options for customizing the email templates in the `config/account-status-notification-email-templates/README.txt` file.

Other password policy configuration properties

The password policy configuration also provides additional configuration properties that don't fall into any of the previously discussed categories.

They include:

`password-attribute`

Specifies the attribute used to hold the password in the user's account. This is userPassword by default, but it can also be set to authPassword if you want to use the authentication password schema described in RFC 3112.

`require-secure-authentication`

Indicates whether users associated with this policy are required to authenticate in a secure manner. This is false by default, but we strongly recommend setting it to true.

`requires-secure-password-changes`

Indicates whether users associated with this policy are required to change their password in a secure manner. This is false by default, but we strongly recommend setting it to true.

`allow-multiple-password-values`

Indicates whether accounts are allowed to have multiple different passwords. Although this is technically allowed by LDAP specifications, it is strongly discouraged because it can be abused to allow a user to exempt themselves from certain password policy constraints like password expiration. If a user needs different passwords for different purposes, then we recommend creating separate accounts for that user.

`require-change-by-time`

Can be used to require that all users associated with the password policy change their password by a specified time. For example, this can be used to require all users to change their passwords after a data breach.

Managing password policy state

Because PingDirectory server offers a wide range of password policy functionality, it also has the ability to maintain a wide range of state information that corresponds to those features. It provides several ways to access and manipulate this state.

Externally modifiable user attributes

A limited set of operational attributes can be directly manipulated (for example, through LDAP add or modify operations) to manage certain aspects of a user's password policy state.

They include:

`ds-pwp-password-policy-dn`

The distinguished name (DN) of the password policy that governs the user. If this is not present in the user's entry (as either a real or virtual attribute), then the user is subject to the server's default password policy.

`ds-pwp-account-disabled`

Indicates whether a user's account should be administratively disabled. If this attribute is present with a value of true, then the account is disabled. If this attribute is present with a value of false, or if the attribute is absent, then the account is enabled.

`ds-pwp-account-activation-time`

Specifies the time at which a user's account becomes active. Attempts to authenticate as the user (or use the account as an alternate authorization identity) fails before this time.

`ds-pwp-account-expiration-time`

Specifies the time at which a user's account will expire. Attempts to authenticate as the user (or use the account as an alternate authorization identity) fails after this time.

`ds-auth-totp-shared-secret`

A shared secret that can be used to generate time-based one-time passwords in conjunction with the UNBOUNDID-TOTP SASL mechanism. Although this attribute can be manually updated, we recommend using the generate Time-based One-time Password (TOTP) shared secret extended operation for generating a shared secret and storing it in the user's entry.

`ds-auth-preferred-otp-delivery-mechanism`

The public identifier of a YubiKey device that can be used to generate one-time passwords for use in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Although this attribute can be manually updated, we recommend using the registered YubiKey OTP device extended operation.

Administrative password reset

In most cases, if a user's account is in an unusable state, an administrative password reset can restore access.

This includes:

- If a user has forgotten their password
- If the account has been locked after too many failed authentication attempts
- If the account has been locked because it has been too long since the user last authenticated
- If the account has been locked because the user failed to authenticate in a timely manner after an administrative reset
- If the account has been locked because the user attempted to bind with a password that failed validation
- If the user's password has expired

An administrative password reset does not restore access to an account under the following circumstances:

- If the account has been administratively disabled
- If the account has an activation time that is in the future

  If the account has an expiration time, not to be confused with the password expiration time, which is in the past

The password policy state extended operation and the manage-account tool

PingDirectory server supports a proprietary password policy state extended operation that can retrieve and manipulate virtually any kind of password policy state information in a user's entry.

This includes:

- Retrieving the DN of the password policy that governs the user

- Retrieving a flag that indicates whether the server considers the account usable
- Retrieving a set of error, warning, and notice conditions that can affect the account's usability
- Determining whether the account has a static password

Retrieving and updating the flag indicating whether an account is disabled

- Retrieving and updating the account's activation and expiration times
- Retrieving and updating the account's password changed time
- Determining whether the user's password is expired
- Retrieving the account's password expiration time, which is computed from the password changed time
- Retrieving and updating the account's password expiration warned time
- Retrieving and updating the set of grace login use times
- Retrieving and updating the record of failed authentication attempts
- Retrieving and overriding a failure-based account lockout
- Retrieving the time that an account was failure locked
- Retrieving and updating an account's last login time
- Retrieving and updating an account's last login IP address
- Retrieving and clearing an account's recent login history
- Retrieving the length of time until an upcoming idle lockout
- Retrieving and updating the account's "must change password" flag
- Determining whether an account is reset locked
- Retrieving the length of time until an password reset lockout
- Retrieving the number of passwords in the user's history and clearing the history
- Determining whether a user has a retired password and purging the retired password
- Retrieving the set of SASL mechanisms that are available to the user
- Retrieving the set of one-time passcode (OTP) delivery mechanisms that are available to the user
- Determining whether the user has any TOTP shared secrets
- Registering and deregistering TOTP shared secrets
- Determining whether the user has any registered YubiKey OTP devices
- Registering and deregistering YubiKey OTP devices
- Retrieving and updating the time that bind password validation was last performed for the user
- Retrieving and clearing password validation lockout

The server also includes a manage-account tool that provides command-line access to the functionality of the password policy state extended operation.

The ds-pwp-state-json and ds-pwp-modifiable-state-json operational attributes

The PingDirectory server provides a ds-pwp-state-json operational attribute whose value is a JSON object that provides read-only access to a wide variety of password policy state information and related password policy configuration.

This includes:

- The distinguished name (DN) of the password policy that governs the user
- Whether the account is usable, and information about any usability errors, warnings, and notices
- Whether the account has a static password
- The password changed time
- Whether the account is disabled
- Whether the account has an activation time or expiration time, and their relation to the current time
- Whether the user's password is expired and when it expires
- Whether the user has been warned about an upcoming password expiration
- Whether the account is locked as a result of too many failed authentication attempts
- The last login time, last login IP address, and recent login history
- Whether the account is locked because it has been too long since they last authenticated
- Whether the user must change their password
- Whether the user's account is locked because they failed to choose a new password after an administrative reset
- The number of passwords in the user's password history
- Whether the user is within the minimum password age
- Information about grace login uses
- Information about whether the user has a retired password and how long it will be valid
- Whether the server will require secure authentication or secure password changes
- A list of SASL mechanisms available to the user
- A list of onte-time passcode (OTP) delivery mechanisms available to the user
- Whether the account is locked as a result of bind validation failure

It also provides a `ds-pwp-modifiable-state-json` operational attribute that can be used to manipulate a limited set of password policy state information, including:

- The user's password changed time

- Whether the user's account is disabled
- The user's account activation time
- The user's account expiration time
- Whether the user's account is locked as a result of too many failed authentication attempts
- The time the user was warned about an upcoming password expiration
- Whether the user must change their password

The value of the `ds-pwp-modifiable-state-json` attribute is a JSON object, and it can be updated in a replace modification. Any of the fields that it contains can be included in the replace modification to manipulate the corresponding portions of the user's password policy state. Any fields omitted from the JSON object are not updated.

The password update behavior control

PingDirectory server provides support for a password update behavior request control that allows an authorized user with the `password-reset` privilege and access control permission to use the control to override the server's default behavior when updating the password.

It can be included in an add request, modify request, or password modify extended request.

The options that it provides include:

- Force the server to treat the operation as a self change or an administrative reset.
- Force the server to accept a pre-encoded password.
- Force the server to skip validation for the password.
- Force the server to ignore the user's password history.
- Force the server to ignore the user's minimum password age.
- Force the server to use a specified password storage scheme.
- Force the server to set or clear the "must change password" flag.

The retire password and purge password controls

Including the retire password and purge password controls in a modify request or a password modify extended request affect a user's current password and a user's ability to authenticate.

The retire password request control can be included in a modify request or a password modify extended request to indicate that the user's current password should be retired so that it can continue to be used to authenticate to the account, as an alternative to the new password, for a limited period of time.

The purge password request control can be used to indicate that the user's current password should be purged from the entry even if it would have otherwise been retired based on the password policy configuration.

Authentication-related controls and extended operations

The PingDirectory server also provides support for several additional controls and extended operations that can be used when authenticating or interacting with password policy-related operations.

The authorization identity request control

The authorization identity request control is described in RFC 3829 and can be included in a bind request to indicate that the server should include the resulting authorization identity in the successful bind response.

In the PingDirectory server, this authorization identity is always in the form of a distinguished name (DN), prefixed by `dn:` (for example, `dn:uid=jdoe`, `ou=People`, `dc=example`, `dc=com`).

This control is useful to determine the DN of the authenticated user entry, especially when the bind request does not identify the user by a DN, such as if the client was identified by a username, a Kerberos principal, a client certificate, or an OAuth access token.

The get authorization entry request control

While the authorization identity request control can be helpful, it only provides the distinguished name (DN) of the authenticated user and the specification does not even require that.

The PingDirectory server offers a more useful alternative in the form of the proprietary get authorization entry request control.

This control can also be included in a bind request, and if the bind is successful, then the server can return a corresponding response control with the DN and a requested set of attributes from the authenticated user's entry. If the bind request also used an alternate authorization identity, then the response control can also include information about that user.

The "Who am I?" extended request

The "Who am I?" extended request is defined in RFC 4532. It behaves much like the authorization identity request control in that it returns the authorization identity associated with the connection and it should always be in `dn:` form in the PingDirectory server, but this request can be issued at any time on a connection to retrieve the current authorization identity for that connection.

The account usable control

Include the account usable request control in a search request to indicate that matching entries should include a corresponding response control with a minimal set of information about whether the server considers the associated account to be usable.

This includes:

- Whether the account is usable
- The length of time until the user's password expires

- Whether the account is inactive
- Whether the user must change their password
- Whether the password is expired
- The number of remaining grace logins
- The length of time until the account is unlocked

This control is maintained for compatibility with a legacy system. While it is still useful, it is not updated to support new features.

The password policy control

PingDirectory server supports the password policy request control, as described in draft-behera-ldap-password-policy-10.

This control can be included in add, bind, compare, modify, and password modify extended requests to obtain information about the associated user's password policy state. This includes:

- The length of time until the user's password expires
- The number of remaining grace logins
- Whether the password is expired
- Whether the account is locked
- Whether the user must change their password
- Whether an update attempt failed because the user is not allowed to change their password
- Whether an update attempt failed because the user is required to provide their current password
- Whether an operation failed because the password is considered too weak
- Whether the proposed password is too short
- Whether the proposed password already exists in the user's password history
- Whether a user cannot change their password because there has not been enough time since the previous password change

Because this control is based on a public specification, its format is fixed and it is not updated to support additional features.

The password expiring and password expired controls

PingDirectory server supports the password expiring and password expired controls, as described in draft-vchu-ldap-pwd-policy-00.

The password expiring control can be included in the response to a successful bind attempt to indicate that the user's password is about to expire. Its value indicates the length of time until the password actually expires.

The password expired control can be included in the response to a successful or failed bind attempt to indicate that the user's password has expired and must be changed. If the bind operation was successful, then it means that the user must change their password before they are allowed to request any other operations. If the bind operation failed, then it means that the password must be reset before the user can access their account.

The get password policy state issues control

By default, PingDirectory server returns a minimal amount of information in the response to a failed bind attempt. This is intentional because revealing too much can give an attacker useful information that could allow them to improve their tactics.

Nevertheless, it is useful in some circumstances to provide an application with a way to obtain information about the reason for a failed authentication attempt. As such, PingDirectory server offers a get password policy state issues request control that can be included in a bind request to indicate that the server should include a control in the bind response with information about any error, warning, or notice conditions in the user's password policy state that might currently or soon interfere with their ability to authenticate. If the bind attempt fails, then it might also include specific information about the reason for that failure.

To prevent this control from being misused, PingDirectory server only allows it to be requested under a limited set of circumstances:

- The bind request must be issued on a connection that is currently authenticated as a user with the `permit-get-password-policy-state-issues` privilege.
- The requester must have access control permission to use the get password policy state issues request control.

The bind request must also include the retain identity request control in the bind request.

The get password quality requirements extended operation

Use the proprietary get password quality requirements extended operation to request that the PingDirectory server provide a list of the requirements that the server enforces when setting a password.

The request control allows you to indicate the context in which the password is provided (for example, whether it's an add request, a self password change, or an administrative password reset) because the requirements can vary in different circumstances.

The extended result includes a list of the requirements the server will impose, including a human readable description for each and an optional name and set of properties that can allow for some client-side validation. The result might also indicate whether the user is required to provide their current password, whether they are required to choose a new password after the add or administrative reset, and how long a new password is valid before it expires.

The password validation details control

PingDirectory server provides support for a password validation details request control that can be included in an add request, modify request, or password modify extended request.

It indicates that the server should return a corresponding response control with a list of each of the requirements that the password must satisfy and an indication as to whether the proposed password satisfied.

The generate password request control

You can include the proprietary generate password request control in an add request to indicate that the server should automatically generate a password for the user.

The add response includes a corresponding response control that contains the generated password, along with an indication as to whether the user is required to choose a new password and how long the generated password is valid.

The password is generated using the password generator defined in the password policy that governs the new entry. Although the server might attempt to re-generate the password multiple times if previous attempts do not satisfy the configured set of password validators for the user, it might end up setting a password that does not pass validation. We recommend configuring the password generator to ensure that it is capable of generating passwords of acceptable strength.

The generate password extended operation

The proprietary generate password extended operation is used to request that PingDirectory server generate one or more suggested passwords and return them to the client.

This is intended for use by applications that allow a user to change their password or allow an administrator to reset user passwords and want to allow the server to suggest several strong options that the user can choose from or use as examples when choosing their own password.

As with the generate password request control, this extended operation relies on a password generator to create the passwords. While it might optionally try multiple times to generate passwords that pass validation, it can ultimately return passwords that do not satisfy all of the configured password validators. For each generated password included in the extended response, the server indicates whether that password passed validation, and if not, it might include a list of errors that explain the reasons it was not considered acceptable.

The verify password extended operation

There is an extended operation to verify a user's password. Read carefully before enabling this operation.

For security reasons, PingDirectory provides vague responses to bind requests. If an authentication attempt is unsuccessful, the server doesn't communicate the reason for the failure. Additionally, for both security and performance reasons, the server doesn't attempt to verify the provided credentials if it can determine that the target account is not in a usable state (for example, if it has been administratively disabled, or if it has been locked as a result of too many previous authentication failures).

The `verify-password` extended operation enables you to differentiate the authentication response to the client with respect to certain kinds of failures. For example, if you can determine that a user's account has been locked as a result of too many failed authentication attempts, you can present the user with a means of resetting the password if and only if you can verify that the provided password was correct.

> **Warning**
>
> Enabling the `verify-password` extended operation circumvents server security functionality.
> An attacker could use this extended operation to get unlimited attempts to guess a user's password, circumventing the security benefit of an account lockout. We strongly discourage designing applications in a way that could provide a malicious client with information that might help them better craft an attack against user accounts.
> This extended operation is not a standalone alternative to authenticating clients. Only use it to augment the existing authentication process, if at all.

The `verify-password` extended operation determines if a provided password is correct for a specified user without performing any other password policy processing for that user. This verification is available even if the target account isn't currently allowed to authenticate, and it won't cause any updates to the user's entry as a result of the determination.

Restrictions and privileges

Because of the security risks associated with using `verify-password`, there are a number of restrictions in place to ensure that it can only be used by authorized clients, including:

- **The extended operation handler isn't defined or enabled by default.**
- **The server's access control configuration doesn't permit the use of the extended operation by default. If a client without the `bypass-acl` privilege has a legitimate need to use this extended operation, you must to create a global ACI that grants the client permission to use the extended request with OID 1.3.6.1.4.1.30221.2.6.72.**
- **Requesters must also have the `permit-verify-password-request` privilege, which isn't granted to users (even root users) by default.**
- **Clients must issue `verify-password` requests over a secure connection so that anyone able to view network messages can't access the content of that communication.**

  > **Note**
  >
  > You can disable this safeguard if necessary, but the server still requires secure communication protocol if either the target user's password policy or operational attributes in the user's entry require secure authentication.

- **The extended operation supports clients submitting password verification requests directly to PingDirectory or forwarded through a PingDirectoryProxy server (in both simple-proxy and entry-balanced configurations). When requests are forwarded from PingDirectoryProxy to PingDirectory, you must configure both server instances to enable the extended operation.**

Enabling the verify password extended operation

Before you begin

You must enable the required access privileges described in Restrictions and privileges.

About this task

To verify a password using the `verify-password` extended operation, enable the extended operation and then send a client request with the required information.

The client request must be a JavaScript Object Notation (JSON) object containing the following required fields:

dn

The distinguished name (DN) of the user account whose password the server should verify.

password

The password to verify for that user.

The server response contains a result code that explains the outcome of the `verify-password` operation. The following table describes the result codes that the server can return:

Server response code	Description
`PROTOCOL_ERROR (2)`	The extended request is malformed.
`COMPARE_FALSE (5)`	The provided password isn't correct for the target user.
`COMPARE_TRUE (6)`	The provided password is correct for the target user.
`CONFIDENTIALITY_REQUIRED (13)`	The server is required to only permit the extended operation over a secure connection, or the server is configured to require secure authentication for the target user, but the client is using an insecure connection.
`NO_SUCH_OBJECT (32)`	The target user account does not exist.
`INVALID_DN_SYNTAX (34)`	The provided DN is malformed.
`INAPPROPRIATE_AUTHENTICATION (48)`	The target user account doesn't have a password.
`INSUFFICIENT_ACCESS_RIGHTS (50)`	The client doesn't have sufficient permission to use the extended operation.
`OTHER (80)`	The server encountered an internal error while attempting to verify the password.

Steps

1. Enable the `verify-password` extended operation.

   Example:

   ```
   $ bin/dsconfig create-extended-operation-handler \
     --handler-name "Verify Password" \
     --type verify-password \
     --set enabled:true
   ```

2. Send a properly formed client request.

> **Note**
>
> Learn more about formulating a request using the extended operation.

3. Use the result code in the response to determine how the client responds to the user.

Access control

The server's access control subsystem provides a way to examine each request that a client issues to determine whether it should be allowed.

It can also examine each search result entry to determine whether the client should be permitted to retrieve it at all, and if so, which attributes or even attribute values should be permitted.

The server's access control policy is constructed from a set of access control instructions (ACIs), also called access control rules. ACIs can be defined in user data in the ACI operational attribute, and they can also be defined in the configuration in the `global-aci` property in the access control handler configuration.

The server's access control policy denies all access by default. Unless there is an ACI that allows something, then no user who is subject to access control is permitted to perform the requested operation or retrieve the specified data. It is also possible to explicitly deny access to something, which overrides any permission that would have otherwise granted access to it.

ACI syntax

The access control instruction (ACI) syntax that the PingDirectory server uses is similar to that used by other types of directory servers and is designed to make it easy to migrate data containing access control rules from other servers.

Each ACI has the following format:

1. A set of one or more targets. The targets specify the data, attributes and entries, to which the ACI applies. Each ACI target is enclosed in parentheses and has the form (`name="value"`). Defined target names include:
    - `extop` — Provides a list of extended request OIDs to which the ACI applies.
    - `requestcriteria` — Determines whether an access control rule applies to an operation based on whether that operation matches a given request criteria definition.
    - `target` — Provides an LDAP URL whose distinguished name (DN) identifies the base of the subtree to which the ACI applies.
    - `targetattr` — Provides a list of attributes to which the ACI applies.
    - `targetcontrol` — Provides a list of request control OIDs to which the ACI applies.
    - `targetfilter` — Specifies a filter used to restrict the set of entries to which the ACI applies within the scope.
    - `targattrfilters` — Provides criteria for identifying the values within an attribute to which the ACI applies.
    - `targetscope` — Specifies the scope, relative to the target base DN, to which the ACI applies.
2. An opening parenthesis.
3. The string `version 3.0` to indicate the ACI syntax version. The PingDirectory server only supports 3.0.

4. A semicolon followed by a space.
5. The keyword `acl` followed by a space and a description for the access control instruction surrounded by quotation marks, such as `acl "Allow users to update their own entries"`.
6. A semicolon followed by a space.
7. The keyword `allow` or `deny` followed by a comma-delimited list of rights enclosed in parentheses. For example, `allow (read,search,compare)`. Available rights include:
    - `read` — Indicates that the ACI grants or denies permission to retrieve attributes in search result entries.
    - `search` — Indicates that the ACI grants or denies permission to use attributes in a search filter.
    - `compare` — Indicates that the ACI grants or denies permission to request a compare assertion against target attributes.
    - `write` — Indicates that the ACI grants or denies permission to update attributes within target entries.
    - `selfwrite` — Indicates that the ACI grants or denies permission to allow the requester to update attributes to add or remove their own DN.
    - `add` — Indicates that the ACI grants or denies permission to add entries.
    - `delete` — Indicates that the ACI grants or denies permission to delete entries.
    - `export` — Indicates that the ACI grants or denies permission to move an entry out from under its current parent.
    - `import` — Indicates that the ACI grants or denies permission to move an entry beneath its proposed new parent.
    - `all` — Indicates that the ACI grants or denies permission to all of the above rights. It does not include the `proxy` right.
    - `proxy` — Indicates that the ACI grants or denies permission for one user to request that an operation be authorized as a different user, such as using a proxied authorization request control or SASL alternate authorization.
8. A semicolon followed by a space.
9. The bind rule component for the ACI, which identifies the set of requesters to which the ACI applies. Multiple bind rules can be joined with the keywords `and` and `or`, and the keyword `not` can be used to negate the result of a rule. Available bind rules include:
    - `authmethod` — Identifies the requester by the type of authentication that they used.
    - `connectioncriteria` — Allows or denies an operation based on whether the client connection matches a given connection criteria definition.
    - `dayofweek` — Identifies the requester by the current day of the week.
    - `dns` — Identifies the requester by the resolved name of the client system.
    - `groupdn` — Identifies the requester by group membership.
    - `ip` — Identifies the requester by the IP address of the client system.

- `oauthscope` — Identifies the requester by the set of OAuth scopes that they have.
- `secure` — Allows or denies an operation based on whether the client is communicating with the server over a secure connection; for example, using LDAPS or StartTLS over LDAP.
- `timeofday` — Identifies the requester by the current time of day.
- `userattr` — Identifies the requester by their relation to the value of a specified attribute.
- `userdn` — Identifies the requester by DN or by a predefined keyword that is interpreted by the server.

10. A semicolon followed by a closing parenthesis.

For example, the following ACI will allow a user to update their own password.

```
(targetattr="userPassword")(version 3.0; acl "Allow a user to update their own password"; allow (write)
userdn="ldap:///self";)
```

ACI targets

ACI targets specify the set of data to which an ACI applies.

Each ACI target should be surrounded by parentheses and should have the form `(name="<value>")`.

An access control instruction can have multiple targets by simply placing them one right after another, such as `(targetattr="userPassword")(target="ldap:///ou=People,dc=example,dc=com")(targetscope="sub")(targetfilter="(objectClass=person)")`. All of the ACI targets must appear at the beginning of the ACI.

`targetattr`

The `targetattr` ACI target is used to grant or deny access to a specified set of attributes. If multiple attributes are specified, then they should be separated by two consecutive vertical bars. For example, `(targetattr="givenName||sn||cn")` indicates that the ACI applies to the givenName, sn, and cn attributes.

The token `*` can be used as a shorthand notation to indicate all user attributes, but it does not include operational attributes. The token `+` can be used as a shorthand notation to indicate all operational attributes, but does not include user attributes. If you want an ACI to apply to all user attributes and all operational attributes, then you can use `(targetattr="*||+")`.

It is possible to use the `!=` operator to target all user attributes except a named set. For example, `(targetattr!="userPassword")` indicates that the ACI targets all userAttributes except `userPassword`. However, this is potentially dangerous because it is easy for two different ACIs using this construct to cancel each other out. For example, if one ACI includes `(targetattr!="userPassword")` and a second ACI includes `(targetattr!="socialSecurityNumber")`, then the net effect might be equivalent to `(targetattr="*")` because the first target implicitly includes the `socialSecurityNumber` attribute that you're trying to exclude with the second, while the second implicitly includes the `userPassword` attribute that you're trying to exclude with the first. When access to a specific attribute should not be allowed, it might be better to create an ACI that denies access to that attribute rather than one that grants all access to all attributes except that attribute.

target

The `target` ACI target is used to indicate that the ACI applies to entries in specified portions of the DIT. The value should be provided as an LDAP URL, but only the DN portion of that URL is used. For example, `(target="ldap:///dc=example,dc=com")` indicates that the ACI applies to entries at or below "`dc=example,dc=com`".

Each ACI can have at most one target. If an ACI defined in the user data does not contain a target element, then the effective target for that ACI would be the DN of the entry in which that ACI is defined. If a global ACI does not contain a target element, then it applies to all entries in the server, including in backends containing non-user data, like the root DSE, configuration, changelog, schema, and monitor backends. The `target` element can only use the "`=`" operator. It cannot use the `!=` operator to apply to all portions of the DIT outside of the specified distinguished name (DN).

If an ACI defined in user data includes a target element, then the DN contained in that element must be at or below the DN of the entry that contains that ACI. For example, the `ou=People,dc=example,dc=com` entry cannot have an ACI that targets entries below `ou=Groups,dc=example,dc=com`.If an ACI should not apply to all entries within the target subtree, then the `targetscope` and `targetfilter` elements can be used to narrow down the set of applicable entries.

targetscope

The `targetscope` ACI target is used to specify how much of the target subtree is covered by the ACI. These scopes exhibit the same behavior in ACIs as they do for search operations. Allowed scope values include:

`base`

Indicates that the ACI only applies to the entry specified by the target DN, and not to any of its subordinates.

`onelevel`

Indicates that the ACI only applies to entries that are immediate subordinates of the entry specified by the target DN. Neither the target entry, nor any entries that are more than one level below the target entry, are included.

`subtree`

Indicates that the ACI applies to the entry specified by the target DN, as well as all entries below it (to any depth).

`subordinate`

Indicates that the ACI applies to all entries below the entry specified by the target DN (to any depth), but does not include the target entry itself.

The `targetscope` element can only use the "`=`" operator. It cannot use the `!=` operator. If an ACI does not include a `targetscope` element, a default value of `subtree` is assumed.

targetfilter

The `targetfilter` ACI target is used to identify the set of entries in the target subtree to which the ACI applies based on their content. The value of this element is the string representation of an LDAP search filter, such as "`(targetfilter="(objectClass=person)")`".The `targetfilter` element can only use the "`=`" operator; it cannot use the "`!=`" operator although you can use the "`!`" operator in the filter itself to negate its meaning. If an ACI does not include a `targetfilter` element, then all entries within the target subtree and scope are considered applicable.

targattrfilters

The `targattrfilters` ACI target is used to identify individual attribute values to which the ACI applies. This target is used for write operations, and it can restrict which attributes can be added to or removed from an entry.

The value of this element can have either one or two components. It can specify a set of attribute values that can be added to the entry (which must start with `add=`), a set of attribute values that can be removed from the entry (which must start with "`del=`"), or both. If both clauses are present, then they should be separated by a comma.

The content of each clause should be in the form of an attribute name followed by a colon and a search filter that identifies which values will be allowed for that attribute You can target multiple attributes in the same add or delete clause by separating them with a double ampersand `&&`.

For example, `(targattrfilters="add=description:(description=allowedAddDescription) && displayName:(displayName=allowedAddDisplayName), del=description:(description=allowedDeleteDescription)")` indicates that the ACI applies to any attempt to add a value of `allowedAddDescription` to the description attribute, an attempt to add a value of `allowedAddDisplayName` to the `displayName` attribute, or an attempt to remove a value of `allowedDeleteDescription` from the description attribute.

The filters can use a variety of logic for identifying which values are allowed. For example, you can use substring filters that include wildcards to match values that start with, end with, or contain a given substring. You can use a presence filter to indicate that any value is allowed. You can use a greater-or-equal or less-or-equal to indicate a range of allowed values. You can use AND and OR filters to combine multiple filters. You can use a NOT clause to negate a filter.

When processing an add operation, the server requires that the requester have permission to add all of the attribute values. When processing a delete operation, the server requires that the requester have permission to delete all of the attribute values. When processing a modify or modify DN operation, the server requires that the requester have permission to add all values introduced in the update and to delete all values removed in the update.The `targattrfilters` element can only use the `=` operator; it cannot use the `!=` operator.

requestcriteria

The `requestcriteria` ACI target determines whether an access control rule applies to an operation based on whether that operation matches a given request criteria.

If present in an access control rule, the operator must be either "=" or "!=". The value must be enclosed in quotation marks and it must be the name or full DN of the configuration object that defines the desired request criteria.

For example, let's say that you want to allow members of the `cn=Sales Administrators,ou=Groups,dc=example,dc=com` group to be able to read from and write to the entries for the users that are members of the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. To do this, you must first create a request criteria object that will match entries for users in the `cn=Sales Employees,ou=Groups,dc=example,dc=com` group. You can do this with the following configuration change:

```
dsconfig create-request-criteria \
     --criteria-name "Requests Targeting Sales Employees" \
     --type simple \
     --set "any-included-target-entry-group-dn:cn=Sales Employees,ou=Groups,dc=example,dc=com"
```

With that request criteria defined, you can use a modification like the following to create the corresponding access control rule:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="*")(requestcriteria="Requests Targeting Sales
  Employees")(version 3.0; acl "Allow sales administrators to manage
  sales employees"; allow (read,search,compare,write)
  groupdn="ldap:///cn=Sales Administrators,ou=Groups,dc=example,dc=com";)
```

targetcontrol

The `targetcontrol` ACI target is used to indicate which request controls a requester is allowed to use. The value for this element is the OID for the desired request control, and multiple request control OIDs can be separated by a double vertical bar `||`. For example, `(targetcontrol="1.2.840.113556.1.4.473||2.16.840.1.113730.3.4.9")` is used to target requests that use either or both the server-side sort request control whose OID is "`1.2.840.113556.1.4.473`" and the virtual list view request control whose OID is `2.16.840.1.113730.3.4.9`.

Regardless of the type of control and what action the server can take for requests that contain it, the read right is used when determining whether to allow an operation containing the request control. Although it is technically allowed to include other rights in an ACI that uses the `targetcontrol` target, only the read right is used in making the determination.The `targetcontrol` element can only use the `=` operator; it cannot use the `!=` operator.

extop

The `extop` ACI target is very similar to the `targetcontrol` target, except that it is used to indicate which extended requests a requester is allowed to use. The value can be either a single OID or a list of multiple OIDs separated by double vertical bars.As with the `targetcontrol` element, only the read right is considered when determining whether to allow a client to request a given extended operation.

> **Note**
>
> The server might impose additional access control rights based on the function that the extended operation is to perform. For example, for a client to use the password modify extended operation, the server requires an ACI with an `extop` target containing the OID `1.3.6.1.4.1.4203.1.11.1`, but it also requires that the requester have permission to update the `userPassword` attribute or whatever password attribute has been configured in the user's password policy in the target user's entry.

ACI rights

The rights section of an ACI defines the permissions that are granted or denied to requesters identified by the bind rule for operations against the data specified by the target.

Every ACI must allow or deny one or more rights.

read

The `read` right covers access to attributes within search result entries. If a client does not have the `read` right for an attribute in a search result entry, then it is stripped out of the entry when it is returned to the client.

search

The `search` right covers permission to use attributes in a search filter. When performing a search (regardless of its scope), the requester must have `search` permission for all attributes in the filter.

If the requester has `search` permission for all attributes used in the filter, but only for a portion of the subtree used as the scope for the search, then only entries that reside in portions of the DIT where the search right is granted can be retrieved. For example, if a user has the search right for the `cn` attribute below `ou=People,dc=example,dc=com`, then a search based at `dc=example,dc=com` with a filter that contains the `cn` attribute only returns matching entries below `ou=People,dc=example,dc=com` even if there are other entries matching the filter below `dc=example,dc=com` but outside of `ou=People,dc=example,dc=com`.

compare

The `compare` right covers permission to perform a compare assertion for a specified set of attributes.

A compare assertion includes an entry DN, an attribute name, and an assertion value. If the specified entry has the given attribute with the provided assertion value, then the server returns a result of `compareTrue` (result code 6). If the entry does not have the indicated attribute value, then the server returns a result of `compareFalse` (result code 5). However, if the requester does not have permission to perform that compare assertion, then the server returns a result of `insufficientAccessRights` (result code 50).

write

The `write` right covers permission to update attributes in an entry. This includes modify operations, and it also includes modify DN operations that do not specify a newSuperior (that is, modify distinguished name (DN) operations that only attempt to rename an entry and do not attempt to move it beneath a new parent). This does not include adding new entries or deleting existing entries.

selfwrite

The `selfwrite` right is a limited subset of the `write` permission. It covers permission for a user to add their own DN to the set of values for specified attributes or for a user to remove their own DN from the set of values for those attributes. This is typically used to allow a user to add themselves to or remove themselves from static groups.

The `selfwrite` right should only be used for attributes that have a syntax of either distinguished name or name and optional UID. Attempts to use it for attributes with other syntaxes can fail or result in unexpected behavior.

add

The `add` right covers permission to add new entries to the server. The requester must have `add` permission for at least one attribute included in the entry to be added.

delete

The `delete` right covers permission to remove entries from the server. For the delete operation, the requester only needs to have the `delete` right for the target entry and not for individual attributes within the entry. However, the server enforces any `targattrfilters` restrictions for attribute values contained in the entry to be deleted. If a `targattrfilters` restriction is used to limit the set of values that the requester can delete, then they are only allowed to delete entries containing those values.

`export` and `import`

Although you might assume otherwise from their names, the `export` and `import` rights do not have any relation to exporting data to LDIF or importing data from LDIF. Instead, these rights cover permission to move entries within the DIT (using a modify DN operation that includes a newSuperior). The `export` right is required to move an entry out from under its current parent, and the `import` right is required to move the entry below its new parent.

These rights are not required to perform a modify DN operation that does not attempt to move the entry below a new parent. That is covered by the `write` right.

`all`

The `all` right is a shorthand notation that includes the capabilities of all of the other access control rights except the `proxy` right. Using the `all` right is equivalent to using `read`, `search`, `compare`, `write`, `selfwrite`, `add`, `delete`, `export`, and `import`.

`proxy`

The `proxy` right covers the ability to process an operation under the authority of an alternate authorization identity. This includes:

- Requests that include a proxied authorization request control
- Requests that include an intermediate client request control with a userIdentity
- SASL bind requests that request an alternate authorization identity

Because the ability to impersonate another use is a very sensitive operation, the requester must have the `proxied-auth` privilege for the operation to be allowed.

Changing the allow add ACI behavior for entries

You can require a bind user to have `allow add` permissions for all of an entry's attributes before allowing them to add the entry to PingDirectory.

About this task

By default, a bind user can add an entry to PingDirectory if they have `allow add` permissions for at least one of the attributes in the entry. To increase your control over who is allowed to add entries to your PingDirectory datastore, you can enable the `evaluate-target-attribute-rights-for-add-operations` property.

Enabling this property causes PingDirectory to require a bind user to have an `allow add` access control instruction (ACI) for each attribute of the entry in the add request. If the bind user doesn't meet this condition, or has a `deny add` ACI for any target attributes of the entry to be added, PingDirectory denies the add operation.

> **Warning**
>
> The `evaluate-target-attribute-rights-for-add-operations` property is disabled by default. Enabling this property causes PingDirectory to evaluate the `targetattr` portion of an access control rule for add operations. Before enabling this property in a production environment, you should thoroughly test your existing access control configuration. You might discover cases where you need to add or augment access control rules to ensure that your authorized bind users can continue to add entries as expected.

Steps

- Modify the `evaluate-target-attribute-rights-for-add-operations` property.

  Choose from:

  - Enable the property.

    ```
    $ bin/dsconfig set-access-control-handler-prop \
      --set evaluate-target-attribute-rights-for-add-operations:true
    ```

  - Disable the property.

    ```
    $ bin/dsconfig set-access-control-handler-prop \
      --set evaluate-target-attribute-rights-for-add-operations:false
    ```

ACI bind rules

Bind rules are used to identify the set of requesters to which an ACI applies.

ACIs can have multiple bind rules to specify multiple conditions that can be satisfied. Bind rules can be combined using either the `and` or the `or` keyword such as `userdn="ldap:///uid=admin,dc=example,dc=com` or `groupdn="ldap:///cn=administrators,ou=Groups,dc=example,dc=com`. The `not` keyword is also used to negate the result of a bind rule.

`userdn`

The `userdn` bind rule is used to target a requester based on their authenticated identity. The value of this bind rule must be in the form of an Lightweight Directory Access Protocol (LDAP) URL although in some cases it might not actually be a valid URL (for example, because the distinguished name (DN) element is not actually a valid DN). The LDAP URL can take several forms, including:

- It can have an LDAP URL that contains just a DN, without any wildcard, scope, or filter: `"ldap:///uid=admin,dc=example,dc=com"`.
- It can contain an LDAP URL that contains a DN that has a pattern with asterisks as wildcards. Wildcards can be used as follows:
  - In place of an entire attribute value: `userdn="ldap:///uid=*,ou=People,dc=example,dc=com`
  - In place of a portion of an attribute value: `userdn="ldap:///uid=admin-*,ou=People,dc=example,dc=com`
  - In place of an attribute type: `userdn="ldap:///*=jdoe,ou=People,dc=example,dc=com`
  - In place of a single entire RDN component: `userdn="ldap:///uid=admin,*,dc=example,dc=com`
  - Two consecutive asterisks in place of any number of entire RDN components: `userdn="ldap:///uid=admin,**,dc=example,dc=com`
- It can have an LDAP URL that contains a parameterized DN. See the Parameterized ACIs section for more information about this.

- It can have an LDAP URL in which the DN is the string `anyone`: `userdn="ldap:///anyone"`. This indicates that the ACI applies to any client, regardless of whether they are authenticated.
- It can have an LDAP URL in which the DN is the string `all`: `userdn="ldap:///all"`. This indicates that the ACI applies to any authenticated client (regardless of the authentication identity), but not to unauthenticated or anonymous clients.
- It can have an LDAP URL in which the DN is the string `self`: `userdn="ldap:///self"`. This indicates that the ACI applies to any operation in which the authenticated user is targeting their own entry.
- It can have an LDAP URL in which the DN is the string `parent`: `userdn="ldap:///parent"`. This indicates that the ACI applies to any operation that targets an entry whose immediate parent is the requester's own entry. That is, it allows a requester to perform operations on entries immediately below their own.
- It can be a full LDAP URL, including a base DN (without wildcards or parameterization), scope, and filter suh as `userdn="ldap:///dc=example,dc=com??sub?(objectClass=person)"`.

The `userdn` bind rule can also contain multiple LDAP URLs. In that case, each URL should be separated by two consecutive vertical bar characters `||`: `("userdn="ldap:///uid=jdoe,ou=People,dc=example, dc=com || uid=jpublic,ou=People,dc=example,dc=com"")`.

The `!=` operator can be used as an alternative to the `=` operator: `userdn!="ldap:/// uid=admin,ou=People,dc=example,dc=com"`. In that case, the bind rule matches if the provided value does not match the authenticated identity.

`groupdn`

The `groupdn` bind rule is used to target a requester based on their group membership. The value of this bind rule must be an LDAP URL, such as `groupdn="ldap:///cn=Admin Users,ou=Groups,dc=example,dc=com"`. Only the DN element of the URL is used, and that DN must not contain any wildcards or parameterization.

The `groupdn` bind rule considers both direct group membership and nested membership such as if the user is a member of a group that is itself a member of a group listed in the `groupdn` value.

As with the `userdn` bind rule, the value of the `groupdn` bind rule can include multiple LDAP URLs separated by two consecutive vertical bar characters.

The `!=` operator can be used as an alternative to the `=` operator: `groupdn!="ldap:/// cn=Administrators,ou=Groups,dc=example,dc=com"`. In that case, the bind rule matches if authenticated user is not a member of the specified group.

`connectioncriteria`

The `connectioncriteria` bind rule allows or denies an operation based on whether the client connection matches a given connection criteria definition.

If present in an access control rule, the operator must be either "`=`" or "`!=`". The value must be enclosed in quotation marks, and it must be the name or full DN of the configuration object that defines the desired connection criteria.

For example, you can use a modification like the following to allow any client matching the "Root Users and Topology Administrators" connection criteria to have full read and write access to entries below `dc=example,dc=com`:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="*")(version 3.0; acl "Full read and write access for
  administrators"; allow (read,search,compare,write)
  connectioncriteria="Root Users and Topology Administrators";)
```

secure

The `secure` bind rule allows or denies an operation based on whether the client is communicating with the server over a secure connection; for example, using LDAPS or StartTLS over LDAP.

If present in an access control rule, the operator must be either "`=`" or "`!=`", and the value must be either `"true"` or `"false"` including the quotation marks. With this in mind, the `secure` bind rule takes the following forms:

- `secure="true"` indicates that the ACI will apply only if the connection was received over a secure connection.
- `secure="false"` indicates that the ACI will only apply if the connection was received over a non-secure connection.
- `secure!="true"` indicates that the ACI will apply only if the connection was received over a non-secure connection.
- `secure!="false"` indicates that the ACI will apply only if the connection was received over a secure connection.

For example, you can use a modification like the following to allow users below `dc=example,dc=com` to update their own passwords over a secure connection:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update
  their own passwords over a secure connection"; allow (write)
  userdn="ldap:///self" and secure="true";)
```

userattr

The userattr bind rule can be used to target a requester based on their relation to the value of an attribute in the target entry. The value of the bind rule should contain the name of an attribute followed by the octothorpe character (#) and a keyword or attribute value.

There are four forms that userattr values can take:

- An attribute name followed by an octothorpe and the keyword `USERDN`, which indicates that the specified attribute should have a value that matches the DN of the authenticated user. For example, `userattr="manager#USERDN"` can be used to allow an operation if it targets an entry whose manager attribute has a value that matches the DN of the authenticated user.
- An attribute name followed by an octothorpe and the keyword `GROUPDN`, which indicates that the specified attribute should have a value that matches the DN of a group in which the authenticated user is a member. For example, `userattr="allowedEditors#GROUPDN"` can be used to allow an operation if it targets an entry whose `allowedEditors` attribute has a value that matches the DN of a group that contains the authenticated user either directly or indirectly through a nested group.

- An attribute name followed by an octothorpe and the keyword `LDAPURL`, in which case the value of the specified attribute must be an LDAP URL that is compared against the authenticated user's entry. For example, `userattr="allowedEditorCriteria#LDAPURL"` can be used to allow an operation if it targets an entry whose `allowedEditorCriteria` attribute has a value that is an LDAP URL whose base, scope, and filter matches the authenticated user's entry.
- An attribute name followed by an octothorpe and any value that is not one of `USERDN`, `GROUPDN`, or `LDAPURL`. In this case, that value is assumed to be an attribute value, and the operation can be authorized if both the authenticated user's entry and the target user's entry have that attribute value for the specified attribute. For example, `userattr="ou#Sales"` can be used to allow a user with an ou value of `Sales` to process operations against other users with an ou value of `Sales`.

When using the `USERDN` keyword, you can optionally specify a parent component to indicate that the target entry can be up to four levels below the authenticated user's entry. In this case, the word parent should be followed by an opening square bracket ([), a comma-delimited list of digits between 0 and 4 (inclusive), a closing square bracket (]), a period, and the rest of the value. A value of zero matches if the attribute value contains a DN that matches that of the authenticated user, while A value of four matches if the attribute value contains a DN that is exactly four levels below the authenticated user's entry. For example, `userattr="parent[0,1,2,3,4].manager#USERDN"` can be used to allow an operation if it targets a user whose manager attribute contains a value that matches the DN of the authenticated user or is up to four levels below that DN.

The `!=` operator can be used as an alternative to the `=` operator such as `userattr!="manager#USERDN"`. In that case, the bind rule matches if the provided value does not match for the authenticated user.

`authmethod`

The `authmethod` bind rule is used to target a requester based on the mechanism that they used to authenticate to the server. The value for this element can take one of the following forms:

`none`

This matches if the requester is not authenticated; `authmethod="none"`.

`simple`

This matches if the requester authenticated using non-anonymous LDAP simple authentication; `authmethod="simple"`.

`ssl`

This matches if the requester authenticated using a client certificate; `authmethod="ssl"`. This is equivalent to `authmethod="SASL EXTERNAL"`.

`sasl <mechanisimName>`

This matches if the requester authenticated using the specified SASL mechanism: `authmethod="SASL PLAIN"`.

> **Note**
>
> The `ssl` value does not necessarily match just because the client is communicating with the server over a secure connection. Instead, it only matches if the client authenticated to the server with a client certificate chain using the SASL EXTERNAL mechanism.

The `!=` operator can be used as an alternative to the `=` operator: `authmethod!="simple"`. In that case, the bind rule matches if the client is not authenticated using the specified mechanism.

ip

The ip bind rule can be used to target a requester based on the IP address of the client system. The value can be a comma-delimited list of any of the following IP address patterns:

- A specific IPv4 address: `ip="1.2.3.4"`.
- An IPv4 address that uses the asterisk as a wildcard character to specify a range of addresses: `ip="1.2.3.*"`.
- An IPv4 address is followed by a plus sign and a subnet mask to specify a range of addresses: `ip="1.2.3.0+255.255.255.0"`.
- An IPv4 address using CIDR notation to specify a range of addresses: `ip="1.2.3.0/24"`.
- An IPv6 address as described in RFC 2373: `ip="0:0:0:0:0:0:0:1"`. IPv6 shorthand notation is also allowed: `ip="::1"`.

The `!=` operator can be used as an alternative to the "=" operator: `ip!="1.2.3.0/24"`. In that case, the bind rule matches if the client does not match the given IP address pattern.

dns

The `dns` bind rule can be used to target a requester based on a resolvable host name. The value can be a comma-delimited list of host names in either of the following forms:

- A complete resolvable host name: `dns="client.example.com"`.
- A host name that uses the asterisk as a wildcard in the leftmost component: `dns="*.example.com"`.

The `!=` operator can be used as an alternative to the `=` operator: `dns!="*.example.com"`. In that case, the bind rule matches if the client host name does not match the provided pattern.

In general, we do not recommend using the `dns` bind rule. DNS might be vulnerable to spoofing attacks, which could help an attacker gain unauthorized access to the system. Further, if name resolution is slow (for example, as a result of a network problem or an intentional denial of service attack), then that can adversely affect the performance of the PingDirectory server.

dayofweek

The `dayofweek` bind rule is used to make access control decisions based on the current day of the week, as determined by the server's current time zone. The value should be a comma-delimited list containing one or more of the following values: `sun`, `mon`, `tue`, `wed`, `thu`, `fri`, `sat`. For example, `dayofweek="mon,tue,wed,thu,fri"`.

The `!=` operator can be used as an alternative to the `=` operator: `dayofweek!="sat,sun"`. In that case, the bind rule matches if the current day of the week is not included in the provided list.

timeofday

The `timeofday` bind rule is used to make access control decisions based on the current time of the day, as determined by the server's current time zone.

The value of this bind rule must be a four-digit number. The first two digits must represent the hour, with a value between `00` and `23`. The last two digits must represent the minute, with a value between `00` and `59`. For example, a value of `0123` represents a time of 1:23 a.m. in the server's time zone.

The operator for this bind rule can be one of the following:

=

The bind rule matches if the current time has the same hour and minute as specified in the value: `timeofday="0123"`.

!=

The bind rule matches if the current time has a different hour or minute than specified in the value: `timeofday!="0123"`.

<

The bind rule matches if the current time is between midnight (inclusive) and the time specified in the value (exclusive). That is, if the current time is earlier in the day than the specified time: `timeofday<"0123"`.

⇐

The bind rule matches if the current time is between midnight (inclusive) and the time specified in the value (inclusive). That is, if the current time is earlier in the day or the same as the specified time: `timeofday⇐"0123"`.

>

The bind rule matches if the current time is between the time specified in the value (exclusive) and 11:59 p.m. (inclusive). That is, if the current time is later in the day than the specified time: `timeofday>"0123"`.

>=

The bind rule matches if the current time is between the time specified in the value (inclusive) and 11:59 p.m. (inclusive). That is, if the current time is later in the day or the same as the specified time: `timeofday>="0123"`.

`oauthscope`

The `oauthscope` bind rule is used to make access control decisions based on the set of scopes associated with an OAuth 2.0 access token that the client used to authenticate.

The value for this bind rule might have one of the following forms:

- It can be the name of a single scope to match: `oauthscope="admin_user"`.
- It can be a substring assertion that contains one or more asterisks to use as wildcards: `oauthscope="admin_*"`.
- It can be a single asterisk to indicate that any scope is sufficient: `oauthscope="*"`.

The `!=` operator can be used as an alternative to the `=` operator: `oauthscope!="admin_user"`. In that case, the bind rule matches if the user does not have the specified scope.

Parameterized ACIs

Parameterized ACIs are useful for cases in which the data in a PingDirectory server instance has the same structure repeated many times, and when each structure needs to have a similar set of access control rules.

This is especially common in a multi-tenant environment in which users within a tenant might need access to other entries within the same tenant, but not to other entries outside their organization.

For example, consider a server that has a DIT structure like the following:

- `dc=example, dc=com`
  - `ou=tenants`
    - `ou=Company A`
      - `ou=People`
      - `ou=Groups`
        - `cn=Administrators`
    - `ou=Company B`
      - `ou=People`
      - `ou=Groups`
        - `cn=Administrators`
    - `ou=Company C`
      - `ou=People`
      - `ou=Groups`
        - `cn=Administrators`

In each case, members of the `cn=Administrators,ou=Groups,ou=<companyName>,ou=tenants,dc=example,dc=com` group might need to be able to manage entries after `ou=<companyName>,ou=tenants,dc=example,dc=com`. While it might be possible to accomplish this by creating similar ACIs throughout the DIT (one for each tenant), this can also be accomplished by creating one parameterized ACI like the following example.

```
(target="ldap:///ou=($1),ou=tenants,dc=example,dc=com")(version 3.0; acl "Allow organization administrators
to manage entries in their organization"; allow (all) groupdn="ldap:///
cn=Administrators,ou=Groups,ou=($1),ou=tenants,dc=example,dc=com";)
```

In this case, the "($1)" is a placeholder that matches between the `target` and `groupdn` elements of the access control rule. If the client is authenticated as a user who is a member of any group that matches that pattern in the `target` bind rule, then the value that matches the placeholder within that pattern is also substituted in place of the same pattern within the target element.

Parameterized ACIs can also be used in conjunction with the `userdn` bind rule. For example, the following ACI grants any user within the organization permission to access a select set of attributes from any user within the same organization.

```
(target="ldap:///ou=($1),ou=tenants,dc=example,dc=com")(targetattr="uid||cn||givenName||sn||mail")(version
3.0; acl "Allow users within an organization to access select attributes from other entries in the same
organization"; allow (read,search,compare) userdn="ldap:///
uid=($2),ou=People,ou=($1),ou=tenants,dc=example,dc=com";)
```

Parameterized DNs used in the `userdn` or `groupdn` bind rules can have multiple placeholders. Not all of those placeholders need to be used in the target.

Defining ACIs in user data

Most access control rules should be defined in the user data.

This is especially true for ACIs that apply to user data. This is accomplished by defining the rules in the ACI operational attribute in entries within the DIT.

For example, the following LDIF modify change record can be used to add an access control rule to the `ou=People,dc=example,dc=com` entry that allows users within that branch to update their own password.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update
  their own password"; allow (write) userdn="ldap:///self";)
```

Ideally, ACIs should be placed in the entry that is the base of the subtree to which it applies. For example, if an ACI applies to entries at or below `ou=People,dc=example,dc=com`, then it should be defined in the ACI attribute in the `ou=People,dc=example,dc=com` entry. While such an ACI could be defined at a higher level in the DIT, like `dc=example,dc=com`, and use the target element to indicate that it applies to a specified subtree, we generally recommend keeping ACIs as close to the data that they manage as possible.

ACIs cannot be placed in a different subtree than the data to which they apply. For example, it is not possible to define an ACI in the `ou=People,dc=example,dc=com` entry if it is intended to apply to entries in the `ou=Groups,dc=example,dc=com` branch.

Defining global ACIs

Access control rules can also be defined in the server configuration and in particular in the `global-aci` property of the access control handler configuration.

This should generally be limited to access control rules that meet one or more of the following criteria:

- They need to apply to entries in backends other than those containing user data. This includes the root DSE, the server configuration, monitor entries, the LDAP changelog, administrative tasks, and other areas of the server. If these ACIs apply to data in a specific backend, then the `target` keyword should be used to limit the scope of the rule.
- They need to apply to one or more extended operations (using the `extop` target). ACIs that grant or deny access to extended operations must be defined in the global configuration.
- They need to apply to request controls (using the `targetcontrol` target). Although it might be possible to define ACIs pertaining to request controls in user data (especially if those controls are only expected to be used when issuing requests targeting user data), ACIs pertaining to request controls are commonly placed in the global configuration.

For example, the following configuration change can be used to define a global ACI that grants members of the "Changelog Readers" group permission to read entries in the LDAP changelog.

```
dsconfig set-access-control-handler-prop --add 'global-aci:(target="ldap:///cn=changelog")(version 3.0; acl
"Allow changelog read access"; allow (read,search,compare) groupdn="ldap:///ou=Changelog
Readers,ou=Groups,dc=example,dc=com";)'
```

The get effective rights request control

After you have defined your access control policy, we recommend that you verify that it is working as expected.

While you can do this by issuing requests against the server to ensure that operations are permitted and rejected as appropriate, the PingDirectory server also provides support for a get effective rights request control that can be used to determine what access a given user has to a specified entry.

This control can be used programmatically through the UnboundID LDAP SDK for Java, but it can also be done from the command line using the `ldapsearch` tool. The tool provides the following arguments pertaining this feature:

`--getEffectiveRightsAuthzID`

Identifies the user whose access control rights should be examined. This should be an authorization ID that either identifies the user by distinguished name (DN) (prefixed by `dn:`) or username (prefixed by `u:`).

`--getEffectiveRightsAttribute`

Specifies the name of an attribute for which you wish to obtain the specified user's effective rights. This argument can be used multiple times to provide multiple attribute names.

For example:

```
$ bin/ldapsearch --hostname ds.example.com \
     --port 636 \
     --useSSL \
     --bindDN "cn=Directory Manager" \
     --baseDN dc=example,dc=com \
     --scope base \
     --getEffectiveRightsAuthzID dn:uid=test.user,ou=People,dc=example,dc=com \
     --getEffectiveRightsAttribute objectClass \
     --getEffectiveRightsAttribute dc \
     "(objectClass=*)" \
     aclRights
Enter the bind password:

dn: dc=example,dc=com
aclRights;attributeLevel;objectclass:search:1,read:1,compare:1,write:0,
 selfwrite_add:0,selfwrite_delete:0,proxy:0
aclRights;attributeLevel;dc: search:1,read:1,compare:1,write:0,
 selfwrite_add:0,selfwrite_delete:0,proxy:0
aclRights;entryLevel: add:0,delete:0,read:1,write:0,proxy:0

# Result Code:  0 (success)
# Number of Entries Returned:  1
```

Each search result entry that is returned includes an `aclRights` attribute that indicates what rights the target user has when interacting with that entry. If you do not use the `--getEffectiveRightsAttribute` argument to specify any attribute names, then only the `aclRights;entryLevel` attribute is used to show the rights the user has when interacting with the entry itself will be returned. Otherwise, there is an additional `aclRights;attributeLevel` value for each requested attribute showing the rights for that attribute.

Debugging ACI issues

If you encounter a scenario in which the server seems to exhibit a behavior that is not in-line with the expected access control configuration, you can use the Debug ACI Logger to obtain detailed information about the access control decisions the server is making.

You can do this with the following configuration change.

```
dsconfig set-log-publisher-prop \
     --publisher-name "Debug ACI Logger" \
     --set enabled:true
```

After you enable it, this logger records information about its access control decisions to the `logs/debug-aci` file. Because the server can write huge amounts of data to this file on a busy production server, you might want to try this on a separate instance that has been populated with the same set of access control rules. Alternatively, you can configure the logger with criteria that only matches the operations you are trying to investigate.

Other ways of restricting requests and data access

To preserve security and privacy, applications should only be permitted to perform the bare minimum set of operations that they need, and they should only be permitted to access a minimal set of information in the entries that they are allowed to access.

It is also critical to severely restrict what unauthorized users are allowed to do. The PingDirectory server provides several mechanisms to help with this:

- It has a fine-grained access control subsystem that are used to indicate which requests are allowed and which data can be retrieved from the server.
- It has a privilege subsystem that can be used to require additional authorization when processing certain types of operations or to grant additional capabilities to some users.
- Client connection policies can be used to impose limits on the types of operations that clients are allowed to request, even restricting what is possible for root users and topology administrators.
- Sensitive attributes can also impose strong restrictions on access to certain attribute types and can also impose restrictions on root users and topology administrators.

Rejecting unauthenticated requests

One of the best ways to prevent unauthorized access to the server is to require authentication for all operations processed in the server.

If the server is configured to reject unauthenticated requests, then attackers would either need to legitimate access to an account in the server, or they would need to somehow obtain credentials for a valid account.

The global configuration makes it easy to reject requests from unauthenticated clients through the following properties:

`reject-unauthenticated-requests`

Indicates whether the server rejects requests from unauthenticated clients, including clients that have not yet authenticated, clients whose most recent authentication attempt failed, or clients whose most recent authentication attempt was an anonymous bind.

`allowed-unauthenticated-requests-criteria`

Specifies an optional set of criteria used to indicate that certain operations are allowed over an unauthenticated connection.

Even if `reject-unauthenticated-requests` is true, then the server allows a small number of requests from unauthenticated connections. These include:

- Bind requests, which are used to authenticate connections.
- StartTLS extended requests, which are used to add TLS encryption to initially insecure connections.
- The start administrative session extended request, which is used to indicate that subsequent operations are part of an administrative session. When it is used, this should be the first operation on the connection, even before bind and StartTLS operations. There is no inherent security risk in allowing this for unauthenticated clients.

If any other types of requests should be allowed for unauthenticated clients, then the `allowed-unauthenticated-requests-criteria` property should be used to define criteria that matches only those operations.

Privileges

The PingDirectory server defines several privileges that it can use to give a user additional functionality or restrict access to some functionality.

Available privileges

Some of the defined privileges include in the following.

Privilege	Description
`audit-data-security`	Required for a user to invoke the audit data security task to generate a report on security-related aspects of the data contained in the server.
`backend-backup`	Required to initiate an online backup through an administrative task.
`backend-restore`	Required to initiate an online restore through an administrative task.
`bypass-acl`	Exempts the user from access control evaluation for all operations. This grants the user full access to all data in the server, although they might still be limited by things like client connection policies or sensitive attributes.

Privilege	Description
`bypass-pw-policy`	Exempts the user from certain password policy restrictions when changing another user's password. This includes: • The user is allowed to set a pre-encoded password for another user even if the password policy forbids it. • The user is allowed to set a password for another user even if it fails validation. • The user is allowed to set a password for another user even if it is in the user's password history.
`bypass-read-acl`	Exempts the user from access control evaluation for read operations, including search and compare. Write operations are still subject to access control evaluation, and the user might still be limited by constraints in the client connection policy and sensitive attribute definitions.
`collect-support-data`	Required to invoke the `collect-support-data` tool through an administrative task or an extended operation.
`config-read`	Required for a user to to read any information from the server configuration.
`config-write`	Required (in addition to the `config-read` privilege) to update the server configuration.
`disconnect-client`	Required to forcefully disconnect another client.
`exec-task`	Required to invoke an exec task.
`file-servlet-access`	Might be required to access the content of certain file servlet instances, including the instance root file servlet.
`jmx-notify`	Required to subscribe to receive JMX notifications.
`jmx-read`	Required to read monitor data from JMX.
`ldif-export`	Required to initiate an online LDIF export through an administrative task.
`ldif-import`	Required to initiate an online LDIF import through an administrative task.
`lockdown-mode`	Required to cause the server to enter and leave lockdown mode, and also to submit requests while the server is in lockdown mode.
`manage-topology`	Required to process topology-related operations, like adding servers to and removing servers from the topology.
`modify-acl`	Required to add and remove ACIs.

Privilege	Description
`password-reset`	Required to change the password for another user. This privilege is also required to use the password policy state extended operation and might be required for other password-policy-related operations. Either this privilege or the `permit-externally-processed-authentication` privilege is required to use the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASLmechanism.
`permit-externally-processed-authentication`	Either this privilege or the password-reset privilege is required to be able to use the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL mechanism.
`permit-get-password-policy-state-issues`	Required to use the get password policy state issues request control.
`privilege-change`	Required to alter the set of privileges assigned to a user.
`proxied-auth`	Required to request an alternate authorization identity (that is, to impersonate another user). This includes the ability to use the proxied authorization request control, the intermediate client request control with a userIdentity value, and requesting an alternate authorization identity in applicable SASL mechanisms.
`server-restart`	Required to initiate an online restart through an administrative task.
`server-shutdown`	Required to initiate a server shutdown through an administrative task.
`soft-delete-read`	Required to access soft-deleted entries.
`stream-values`	Required to use the stream directory values or stream proxy values extended operation.
`third-party-task`	Required to invoke a custom task implemented using the Server SDK.
`unindexed-search`	Required to request an unindexed search.
`unindexed-search-with-control`	Required to request an unindexed search in conjunction with the permit unindexed search request control.
`update-schema`	Required to update the server schema.
`use-admin-session`	Required to create an administrative session that allows operations to be processed in a dedicated thread pool.

Assigning privileges

Privileges can be assigned to users by adding the `ds-privilege-name` operational attribute to a user's entry with a value set to the desired privilege. This is a multivalued attribute, so multiple privileges can be assigned.

For example, the following modification demonstrates the process for granting the password-reset privilege to a user. The `privilege-change` privilege is required to alter the set of privileges assigned to a user, so this modification is only allowed if the requester has that privilege.

```
dn: uid=pwadmin,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

This process also works for root users and topology administrators although you can also use `dsconfig` or the admin console to alter the set of privileges for those users through the `privilege` property in the user configuration.

Root users and topology administrators can also automatically inherit a default set of privileges from the configuration. This default set of privileges is defined in the `default-root-privilege-name` property of the Root DN configuration object. If a root user or topology administrator is to automatically inherit this default set of privileges, then their configuration object has the `inherit-default-root-privileges` property set to true.

Client connection policy restrictions

Client connection policies can be used to set hard limits on what types of requests clients are allowed to issue.

This applies to all clients associated with the policy, regardless of what privileges they have and what access control rights they have been granted. If a client connection policy prohibits something, then not even root users or topology administrators are permitted to do it if they are using a connection associated with that policy.

The following client connection properties can be used to restrict the set of requests that clients can issue.

Property	Description
`allowed-operation`	The types of operations that clients associated with the policy are allowed to request. Allowed values include any non-empty combination of the following: `abandon`, `add`, `bind`, `compare`, `delete`, `extended`, `modify`, `modify-dn`, and `search`. By default, all operation types are allowed.
`required-operation-request-criteria`	A set of criteria that requests must match in order to be processed by the server. If required operation request criteria is defined and a client associated with the policy issues a request that does not match that criteria, then the operation is rejected. By default, no required operation request criteria are defined.
`prohibited-operation-request-criteria`	A set of criteria that requests must not match in order to be processed by the server. If a prohibited operation request criteria is defined and a client associated with the policy issues a request matching that criteria, then the operation is rejected. By default, no prohibited operation request criteria are defined.

Property	Description
`prohibited-operation-request-criteria`	A set of criteria that requests must not match in order to be processed by the server. If a prohibited operation request criteria is defined and a client associated with the policy issues a request matching that criteria, then the operation is rejected. By default, no prohibited operation request criteria are defined.
`allowed-request-control`	The OIDs of the controls that clients associated with the policy will be allowed to include in requests. If any allowed request control OIDs are defined, then any request that contains a control other than one of those listed is rejected. By default, no allowed request control OIDs are defined, which indicates that any control not included in the set of denied request controls is permitted.
`denied-request-control`	The OIDs of the controls that clients associated with the policy are not allowed to include in requests. If any denied request control OIDs are defined, then any request that contains a control whose OID is contained in this set IS rejected. By default, no denied request control OIDs are defined.
`allowed-extended-operation`	The OIDs of the extended operations that clients are allowed to request. If any allowed extended operation OIDs are defined, then any extended request that uses an OID other than one of those listed is rejected. By default, no allowed extended operation OIDs are defined, which indicates that any request not included in the set of denied extended operations is permitted.
`denied-extended-operation`	The OIDs of the extended operations that clients are not allowed to request. If any denied extended operation OIDs are defined, then any request that contains a control whose OID is included in this set is rejected. By default, no denied extended operation OIDs are defined.
`allowed-auth-type`	The types of authentication that clients are allowed to request. Allowed values include `simple` and `sasl`, and both are allowed by default.
`allowed-sasl-mechanism`	The names of the SASL mechanisms that clients are allowed to use to authenticate. If any allowed SASL mechanism names are defined, then any SASL bind attempt that uses a mechanism not included in this list is rejected. By default, no allowed SASL mechanism names are defined, which indicates that any SASL mechanism not included in the set of denied mechanisms is permitted.

Property	Description
`denied-sasl-mechanism`	The names of the SASL mechanisms that clients are not allowed to use to authenticate. If any denied SASL mechanism names are defined, then any SASL bind attempt that uses one of those mechanisms is rejected. By default, no denied SASL mechanism names are defined.
`allowed-filter-type`	The types of search filters that clients are allowed to use for searches with a scope other than baseObject (searches with a baseObject scope are allowed to use any kind of filter, as those searches are always be efficient to process). Allowed values include any non-empty combination of the following: `and`, `or`, `not`, `compare`, `equality`, `sub-initial`, `sub-any`, `sub-final`, `greater-or-equal`, `less-or-equal`, `present`, `approximate-match`, and `extensible-match`. By default, all filter types are allowed.
`minimum-substring-length`	The minimum number of consecutive non-wildcard bytes that must be present in each subInitial, subAny, and subFinal element of a substring filter component. Any attempt to use a substring filter with an element containing fewer than this number of non-wildcard bytes is rejected. By default, no minimum substring length is enforced.
`allow-unindexed-searches`	Indicates whether clients associated with the policy are allowed to request unindexed searches. If this is set to true (which is the default), then unindexed search operations are permitted in cases in which at least one of the following is true: • The requester has the `unindexed-search` privilege. • The `unindexed-search` privilege is disabled in the global configuration. • The requester has the `unindexed-search-with-control` privilege and the request includes the permit unindexed search request control. • The `unindexed-search-with-control` privilege is disabled in the global configuration and the request includes the permit unindexed search request control.

Property	Description
`allow-unindexed-searches-with-control`	**Indicates whether clients associated with the policy are allowed to request unindexed searches as long as the request also includes the permit unindexed search request control. If this is set to true (which is the default), then unindexed search operations are permitted in cases in which the requester has either the `unindexed-search` privilege or the `unindexed-search-with-control` privilege (or at least one of those privileges is disabled in the global configuration) and the request includes the permit unindexed search request control.** **Note** If this property is set to true, then unindexed searches can be allowed for authorized requests that include the permit unindexed search request control even if the `allow-unindexed-searches` property is set to false.

Sensitive attributes

PingDirectory servers allow you to create sensitive attribute definitions, which provide enhanced protection for interactions with a specified set of attributes.

You can prevent the values of sensitive attributes from being retrieved at all, or you can ensure that they are only retrieved over secure connections, and similar protections are available for other kinds of read and write operations. Sensitive attribute definitions can be imposed for all clients, even for root users and topology administrators.

Sensitive attribute definitions include the following configuration properties.

Property	Description
`attribute-type`	**The names or OIDs of the attribute types that are to be governed by this sensitive attribute definition. If the same attribute type is included in multiple sensitive attribute definitions, it is subject to the most strict intersection of those definitions.**
`include-default-sensitive-operational-attributes`	**Indicates whether the server should automatically declare a predefined set of special operational attributes as sensitive under the conditions of this sensitive attribute definition. At present, this includes the ds-sync-hist attribute, which is used to hold historical information for replication conflict resolution, and it can include former values for some attributes in the entry. This is true by default.**

Property	Description
`allow-in-returned-entries`	Indicates whether to allow the specified attributes to be included in search result entries that are returned to clients (or other forms of entries that can be returned, like the "before" and "after" versions of an entry when used with the pre-read and post-read request controls). Allowed values include: • `secure-only` — Only allow the attributes to be returned to clients over a secure connection (for example, one encrypted with TLS). The attributes are stripped from search result entries over an insecure connection. • `suppress` — Do not allow the attributes to be returned to clients, even over a secure connection. The attributes are always stripped from search result entries. • `allow` — Allow the attributes to be returned to clients over a secure or insecure connection.
`allow-in-filter`	Indicates whether to allow the specified attributes to be included in search filters. If an attribute can be used in a filter, then clients with the ability to read the entry might be able to determine its values through brute force, by simply trying different values until a match is found. They can also be used to find all entries with a given value. Allowed values include: • `secure-only` — Only allow the attributes to be used in filters for requests sent over a secure connection. Search requests that use a sensitive attribute in the filter are rejected if they are received over an insecure connection. • `reject` — Reject any search request that includes the sensitive attribute in a filter, even over a secure connection. • `allow` — Allow the attributes to be used in filters over a secure or insecure connection.
`allow-in-add`	Indicates whether to allow the specified attributes to be included in add requests. Allowed values include `secure-only`, `reject`, and `allow`.
`allow-in-compare`	Indicates whether to allow the specified attributes to be used in compare assertions. As with search filters, compare assertions can be used to try to discover attribute values through brute force. Allowed values include `secure-only`, `reject`, and `allow`.
`allow-in-modify`	Indicates whether to allow the specified attributes to be updated in modify requests. Allowed values include `secure-only`, `reject`, and `allow`.

By default, the server includes sensitive attribute definitions that prevent clients from accessing passwords and other sensitive authentication information like generated one-time passwords and TOTP shared secrets. They prevent clients from retrieving attribute values or using them in search filters or compare assertions, even over a secure connection, and they only allow the values to be included in add and modify requests that are received over a secure connection. However, these sensitive attribute definitions are not enforced by default.

To ensure that the server enforces the restrictions imposed by sensitive attribute definitions, they must be associated with one or more client connection policies. The following property in the global configuration can enable specified sensitive attribute definitions across all client connection policies:

`sensitive-attribute`

The set of sensitive attribute definitions that should be enabled by default across all client connection policies.

You can also customize the set of client connection policies in which sensitive attribute definitions should be enforced. This is done through the following properties in the client connection policy configuration:

`sensitive-attribute`

The set of sensitive attribute definitions that should be enabled for connections using that client connection policy.

`exclude-global-sensitive-attribute`

The set of sensitive attribute definitions that are enabled in the global configuration that should not be enforced for clients using that client connection policy.

We recommend preventing clients (even root users or topology administrators) from being able to retrieve passwords or other kinds of authentication secrets, and to only allow them to be updated over secure connections. This can be done by updating the global configuration to enable those sensitive attribute definitions across all client connection policies using a change, as in the following example.

```
dsconfig set-global-configuration-prop \
     --add "sensitive-attribute:Sensitive Password Attributes" \
     --add "sensitive-attribute:Delivered One-Time Password" \
     --add "sensitive-attribute:TOTP Shared Secret"
```

However, you might have an application that has a legitimate need to access encoded passwords. For example, you might want to use the PingDataSync server to synchronize passwords from PingDirectory to other data stores. In such cases, the best solution might be to create a custom client connection policy with connection criteria that only matches that application, and then configure it to exclude the appropriate sensitive attribute from the global configuration, as in the following example.

```
dsconfig set-client-connection-policy-prop \
     --policy-name "Synchronization Application" \
     --add "exclude-global-sensitive-attribute:Sensitive Password Attributes"
```

See the `config/use-sensitive-attributes-to-prevent-password-access.dsconfig` sample batch file for more information.

Writability mode

Use writability mode to indicate whether the server allows clients to update the data in the server.

This can be configured through the `writability-mode` property in the global configuration, or through the `writability-mode` property for each backend. In either case, the property offers the following values:

`enabled`

Indicates that writes are enabled.

`disabled`

Indicates that all write attempts are rejected, regardless of their origin.

`internal-only`

Indicates that write attempts from external clients are rejected, but writes received from replication or initiated internally within the server (for example, as a result of password policy state processing).

> **Note**
>
> The writability mode defined in the global configuration applies only to user data backends. It will not apply to private backends, like the server configuration or schema.
> If the `writability-mode` values differ between the global configuration and the backend configuration, then the server uses whichever property is more restrictive. That is, if either one is set to disabled, then all write attempts in that backend are rejected. If one is enabled and the other is set to `internal-only`, then the `internal-only` mode is used for that backend.
> If you want to configure a PingDirectory server instance to be a read-only replica, then you should use the `internal-only` writability mode so that replication changes are still accepted but writes from external clients are rejected. If you would prefer that the server generate a referral for external each write attempt rather than rejecting it outright, then you should create an instance of the "Referral on Update" plugin and specify the base referral URLs that the server should use.

User resource limits

The PingDirectory server can impose limits on client connections to restrict the amount of data they can retrieve or limit their ability to request expensive operations.

This includes:

- The maximum number of entries they can retrieve in any search operation
- The maximum number of entries the server considers when processing any search operation
- The maximum length of time the server is allowed to spend while processing a search operation
- The maximum length of time that a client connection can remain idle between requests
- The maximum number of entries that can be joined with any single search result entry when performing a search using the LDAP join request control

Default values for each of these limits can be defined in the global configuration, but they can be overridden on a per-user basis with operational attributes in the user's entry. Hard upper bounds for these limits for these properties can also be imposed by client connection policies, and the client can set upper bounds for the size limit and time limit when submitting a search request.

Defining resource limits in the global configuration

Use the following global configuration properties to enforce resource limits and provide protection against denial-of-service attacks.

Property	Description
`size-limit`	The default maximum number of entries that a client can retrieve in any single search operation. If the client attempts to process a search that matches more than 1000 entries, then the operation fails with a `sizeLimitExceeded` result (after returning all matching entries identified before the size limit was reached). This is set to 1000 by default. A value of zero indicates that no limit should be enforced.
`time-limit`	The default maximum length of time in seconds that the server is allowed to spend processing any single search operation. If the client requests a search operation that takes longer than this length of time to complete, then the operation fails with a `timeLimitExceeded` result (after returning any matching entries identified before the time limit was reached). This is set to one minute by default. A value of zero seconds indicates that no limit should be enforced.
`idle-time-limit`	The default maximum length of time that a client connection should be allowed to remain established after the server has completed processing on the most recent request issued on that connection. If the client remains idle for longer than this duration, the connection is terminated. A value of zero seconds (which is the default value) indicates that no idle time limit should be enforced.
`lookthrough-limit`	The default maximum number of entries that the server can examine in the course of processing a search request, regardless of whether those entries actually match the search criteria. This is primarily useful for limiting resource consumption when processing unindexed searches, and if the client attempts to process a search operation in which the server needs to examine more than this number of entries, then the operation fails with an `adminLimitExceeded` result (after returning any matching entries identified before the lookthrough limit was reached). This is set to 5000 by default. A value of zero indicates that no limit should be enforced.
`ldap-join-size-limit`	The default maximum number of entries that can be joined with each search result entry when processing a search using the LDAP join request control. If an entry is joined with more than this number of entries, then the join result control for that entry has a sizeLimitExceeded result code (and might or might not include any matching entries). This is set to 10,000 by default. A value of zero indicates that no limit should be enforced.

Property	Description
`maximum-concurrent-connections`	The maximum number of connections that can be established to the server at any one time. After this limit has been reached, then any subsequent connection attempts are rejected until an existing client connection has been closed. A value of zero (which is the default) indicates that no limit is imposed by the server, although the operating system can impose a limit (for example, based on the number of available file descriptors).
`maximum-concurrent-connections-per-ip-address`	The maximum number of connections that can be established to the server at any one time from the same client IP address. After this limit has been reached, then any subsequent attempts to establish a connection from that client are rejected until an existing connection from that client has been closed. A value of zero (which is the default) indicates that no limit is enforced.
`maximum-concurrent-connections-per-bind-dn`	The maximum number of connections that can be established to the server at any one time while authenticated as the same user. After this limit has been reached, then any subsequent attempts to bind as that user cause the connection to be terminated until an existing connection authenticated as that user is closed or binds as a different user. A value of zero (which is the default) indicates that no limit is enforced.
`maximum-concurrent-unindexed-searches`	The maximum number of unindexed searches that can be in progress within the server at any one time. If an unindexed search is requested while the maximum number of searches are already in progress, then that search is rejected with an `unwillingToPerform` result. This is set to ten by default. A value of zero indicates that no limit is enforced.

You can also configure the server to suppress duplicate error log messages and administrative alerts. This can help prevent flooding the log with repeated messages if the same condition keeps occurring. The global configuration properties used to control this are:

Property	Description
`duplicate-error-log-limit` and `duplicate-error-log-time-limit`	The maximum number of error log messages of the same type that can be written within a given length of time. If that error log message rate is exceeded, then any additional error log messages of that type within that time period are suppressed, and the server writes a message at the end of that time indicating the number of messages that were suppressed. By default, the server starts suppressing error log messages after 200 messages of the same type in a five-minute period.

Property	Description
`duplicate-alert-limit` and `duplicate-alert-time-limit`	The maximum number of administrative alerts of the same type that can be generated within a given length of time. If that alert rate is exceeded, then any additional alerts of that type within that time period are suppressed, and the server generates an additional alert at the end of that time period indicating the number of alerts that were suppressed. By default, the server starts suppressing alerts after 10 alerts of the same type are generated in a ten-minute period.

Defining resource limits in operational attributes

Although the global configuration defines default values for several resource limits, it is possible to override those default values on a per-user basis by adding an appropriate set of operational attributes to the user's entry.

Resource limits set through operational attributes can grant a user a higher limit than is available by default in the global configuration, or it can impose a lower limit than would otherwise be permitted by default.

These operational attributes include:

Attribute	Description
`ds-rlim-size-limit`	The maximum number of entries that the user is allowed to retrieve in any single search operation. A value of zero indicates that no size limit is enforced for the user. If this attribute is present in a user's entry, then it overrides the default `size-limit` value from the global configuration.
`ds-rlim-time-limit`	The maximum length of time in seconds that the server is allowed to spend processing any single search operation for the user. A value of zero indicates that no time limit is enforced for the user. If this attribute is present in a user's entry, then it overrides the default `time-limit` value from the global configuration.
`ds-rlim-lookthrough-limit`	The maximum number of entries that the server is allowed to examine while processing any single search operation for the user. A value of zero indicates that no lookthrough limit is enforced for the user. If this attribute is present in a user's entry, then it overrides the default `lookthrough-limit` value from the global configuration.
`ds-rlim-idle-time-limit`	The maximum length of time in seconds that the user is allowed to have an idle connection (one in which no operations in progress) established. A value of zero indicates that no idle time limit is enforced for the user. If this attribute is present in a user's entry, then it overrides the default idle-time-limit value from the global configuration.

Attribute	Description
`ds-rlim-ldap-join-size-limit`	The maximum number of entries that are joined with any single search result entry when processing a search request that includes the LDAP join request control. A value of zero indicates that no LDAP join size limit is enforced for the user. If this attribute is present in the user's entry, then it overrides the default `ldap-join-size-limit` from the global configuration.

Each of these attributes can be explicitly set in the entries for users that should have a value that is different from the corresponding property in the global configuration. You can also use virtual attributes to dynamically assign values for these attributes using criteria like the location or content of the user's entry or the groups in which that user is a member or the client connection policy to which they are assigned.

Defining resource limits in client connection policies

Use client connection policies to impose hard upper bounds on the values of some resource limit properties.

If the client connection policy is configured with a resource limit that is lower than the limit that would otherwise be imposed for the associated client, then the client connection policy's lower limit is enforced (even for root accounts and other types of administrative accounts). However, the client connection policy never grants a client a higher limit than it would otherwise have.

The client connection policy properties that are used to define resource limits include the following.

Property	Description
`maximum-concurrent-connections`	The maximum number of client connections that can be associated with the client connection policy at any one time. If the maximum number of connections are already associated with the policy, any attempt to assign another connection to the policy causes that connection to be terminated. A value of zero (which is the default) indicates that no limit is enforced.
`maximum-connection-duration`	The maximum length of time that connections associated with the policy can be established, regardless of how active those connections are. Any connection that is established for longer than this period of time will be terminated. A value of zero seconds (which is the default) indicates that no maximum connection duration is enforced.
`maximum-idle-connection-duration`	The maximum length of time that connections associated with the policy are allowed to remain idle (without issuing any new requests). Any client connection that is idle for longer than this period of time is terminated. A value of zero seconds (which is the default) indicates that no maximum idle connection duration is enforced.

Property	Description
`maximum-operation-count-per-connection`	The maximum number of requests that connections associated with the policy are allowed to request over the life of that connection. After a connection has already requested the maximum number of operations, if it attempts to request any other operations, then that connection is terminated. A value of zero (which is the default) indicates that no maximum operation count is enforced.
`maximum-concurrent-operations-per-connection`	The maximum number of operations that a client associated with the policy can request at any one time. After the maximum number of concurrent operations are already active for a connection, then any new requests can optionally block for a period of time (specified by the `maximum-concurrent-operation-wait-time-before-rejecting` property) to see if any of the outstanding operations complete. At that point, the request can be rejected or the connection can be terminated based on the value of the `maximum-concurrent-operations-per-connection-exceeded-behavior` property. By default, no maximum concurrent operation limit is imposed.
`maximum-connection-operation-rate`	The maximum rate at which a client can issue requests. If provided, then the value should be provided as a count followed by a slash and a time duration (for example, 100/s indicates a maximum rate of one hundred requests per second, while 10K/6h indicates a maximum rate of 10,000 requests over a six-hour period). If any connection exceeds this rate, subsequent requests within that time period can be rejected or the connection can be terminated, as controlled by the `connection-operation-rate-exceeded-behavior` property. By default, no maximum connection operation rate is enforced.
`maximum-policy-operation-rate`	The maximum rate at which all clients associated with the client connection policy can issue requests. If provided, then the value should be provided as a count followed by a slash and a time duration. If the maximum policy operation rate is exceeded, then subsequent requests within that time period can be rejected or the connection can be terminated, as controlled by the `policy-operation-rate-exceeded-behavior` property. By default, no maximum connection operation rate is enforced.
`maximum-search-size-limit`	The maximum number of entries that can be returned in response to any single search operation for clients associated with the client connection policy. A value of zero (which is the default) indicates that the policy does not impose a maximum size limit for client connections, and they are subject to whatever limit is in place through the global configuration or operational attributes in the authenticated user's entry.
`maximum-search-time-limit`	The maximum length of time that the server can spend processing any single search operation for clients associated with the client connection policy. A value of zero seconds (which is the default) indicates that the policy does not impose a maximum time limit for client connections, and they are subject to whatever limit is in place through the global configuration or operational attributes in the authenticated user's entry.

Property	Description
`maximum-search-lookthrough-limit`	The maximum number of entries that the server can examine when processing any single search operation for clients associated with the client connection policy. A value of zero (which is the default) indicates that the policy does not impose a maximum lookthrough limit for client connections, and they aer subject to whatever limit is in place through the global configuration or operational attributes in the authenticated user's entry.
`maximum-ldap-join-size-limit`	The maximum LDAP join size limit that is enforced for clients associated with the client connection policy. A value of zero (which is the default) indicates that the policy does not impose a maximum join size limit for client connections, and they are subject to whatever limit is in place through the global configuration or operational attributes in the authenticated user's entry.
`maximum-sort-size-limit-without-vlv-index`	The maximum number of entries that the server attempts to sort without the benefit of a VLV index. If the client issues a search request that includes the server-side sort control and matches more than this number of entries, then the server either returns the results in unsorted form (if the sort request control is not marked critical), or it rejects the search (if the control is critical). A value of zero (which is the default) indicates that no limit should be enforced.

Defining resource limits in search requests

Each search request allows the client to specify the size limit and time limit that should be used for that operation.

If the client requests a size limit of zero, then that indicates that the client does not want to impose any limit and the search request is processed using whatever size limit imposes for that client. If the client requests a nonzero size limit and that requested size limit is lower than what the server would otherwise impose, then the client-requested size limit is used. If the client requests a size limit that is higher than what the server would otherwise impose, then the server-imposed limit is used.

The same logic applies to the requested time limit. That is, the time limit from the search request is used if it is lower than what the server would have otherwise imposed. Otherwise, the server's limit is used.

Controls for interacting with resource limits

The PingDirectory server offers a few controls pertaining to resource limits.

The get user resource limits control

The get user resource limits request control can be included in a bind request to indicate that the server should return information about resource limits that aree enforced for the user in the response to the successful bind. The information returned can include:

- The maximum size limit that the server imposes for the user
- The maximum time limit that the server imposes for the user
- The maximum idle time limit that the server imposes for the user

- The maximum lookthrough limit that the server imposes for the user
- The name of the client connection policy that has been selected for the connection
- The DNs of the groups in which the user is a member
- The names of the privileges that have been assigned to the user
- The DN of a user with roughly equivalent authorization characteristics that can be used for operations as the user in entry-balancing backend sets that do not contain that user

The permit and reject unindexed search controls

The permit unindexed search request control can be included in a search request to indicate that the server should process the requested search operation even if it is unindexed. This control is only honored if the requester has the `unindexed-search-with-control` privilege. For applications that have a legitimate need to issue unindexed search requests, this control and privilege combination can provide a better alternative than granting the requester the `unindexed-search` privilege because that privilege can allow the client to inadvertently issue unindexed search requests.

On the other hand, the reject unindexed search request control can be included in a search request to indicate that the server should reject the operation if the search is not at least partially indexed and therefore cannot be processed efficiently. This might help clients with the `unindexed-search` privilege avoid unintentionally requesting expensive searches.

Considerations for account security

There are several things to keep in mind when creating and managing user accounts.

Require secure communication

Whenever feasible, all communication with the server should be secure, and connections that are initially secure should be preferred over those that use StartTLS.

This can be accomplished by setting up the server with only LDAPS and HTTPS connection handlers, while leaving the LDAP and HTTP connection handlers disabled.

It is unlikely that you have clients that support StartTLS but do not support creating connections that are initially created as secure. However, if that is the case, then you should consider using the reject-insecure-requests global configuration property to ensure that clients are only allowed to establish insecure connections for the purpose of using the StartTLS extended operation.

If you do need to accept from clients that only support insecure communication, then you should try to keep those clients to a minimum, and you should take steps to limit what those clients can do when possible. Recommendations include:

- Create a client connection policy that are used for insecure connections, and use it to restrict what types of requests those clients can issue and to impose resource limits on those connections.
- Use a virtual attribute to set the `ds-auth-require-secure-communication` operational attribute to true for all users, and override that with a real attribute set to false for accounts that have a legitimate need to use insecure communication.

At a bare minimum, you should require secure communication for administrative accounts.

Prevent unauthenticated requests

Preventing requests from unauthenticated clients creates an initial hurdle that attackers must overcome for online attacks against the server. Whenever feasible, clients should be required to authenticate before they are allowed to issue requests.

If possible, use the `reject-unauthenticated-requests` global configuration property to prevent all clients from issuing unauthenticated requests. If a small, well-defined set of requests should be allowed to unauthenticated clients, then you can use the `allowed-unauthenticated-request-criteria` property to permit them while rejecting all other types of requests.

If it is not feasible to use the `reject-unauthenticated-requests` property, then consider creating a client connection policy that matches unauthenticated connections. Use it to restrict what types of requests are allowed for unauthenticated clients and to impose significant resource limits for those clients.

Delay bind responses after too many authentication failures

You should have some mechanism in place to protect against online password guessing attacks.

Traditionally, this is done by locking accounts (at least temporarily) after too many failed authentication attempts. However, this is undesirable because an attacker could use it to intentionally lock those accounts and deny access to its legitimate owner. While you might be willing to accept this possibility for regular user accounts, you don't want to risk the chance that administrative accounts can become locked and unusable.

A compelling alternative to actually locking user accounts is to delay bind responses after too many failed attempts. This can help limit the rate at which attackers might make guesses without significantly impeding the legitimate account owner. To do this, use the `failure-lockout-action` property in the password policy configuration to select a policy that delays bind responses rather than locking the account.

If you do need to actually lock accounts to prevent them from being used after too many failed attempts, then you should choose a high enough `lockout-failure-count` value to ensure that accounts are not inadvertently locked by legitimate users who know their passwords but just mistype it several times in a row.

Require strong authentication

There are several actions that you can and should take to help ensure that passwords are not compromised.

These include:

- Use secure communication to prevent passwords (even encoded passwords) from being exposed to network observers.
- Use password validators to help prevent users from choosing weak passwords.
- Use delayed bind responses or account lockout to prevent online password guessing attacks.
- Use strong password storage schemes to resist offline password guessing attacks.
- Use data encryption, encrypted backups, and encrypted LDIF exports to ensure that encoded passwords are not accessible in the clear to anyone with access to server files.

However, using passwords as the only authentication factor might still constitute a security risk. No matter what password validation restrictions you impose, some users will still try to choose the simplest password they can get away with. There is also the risk that they will reuse passwords across multiple services, making their accounts vulnerable to credential stuffing attacks in the event of a data breach across any of those services. Phishing attacks can also trick users into revealing their passwords attackers.

To help further protect accounts in the event that their password becomes compromised, you should consider requiring strong authentication. The PingDirectory server provides three primary options for this:

- Use a SASL mechanism that supports two-factor authentication. The UNBOUNDID-TOTP mechanism is a great one that doesn't rely on interaction with any third-party service, and there are several free options to allow users to generate time-based one-time passwords. However, the UNBOUNDID-DELIVERED-OTP and UNBOUNDID-YUBIKEY-OTP mechanisms also provide much better security than just a password on its own.

  > **Note**
  >
  > While two-factor authentication might not completely protect against phishing attacks, because the fake site can also ask the user to provide the one-time password in addition to the static password, it does at least prevent the password from being reused.

- Consider certificate-based authentication, as with the EXTERNAL or UNBOUNDID-CERTIFICATE-PLUS-PASSWORD SASL mechanism. Certificates are much stronger than passwords when used as the only authentication factor, and requiring a certificate and password together provides the best of both worlds. Certificates are also not vulnerable to replay attacks in the way that passwords (and one-time passwords) are, and as long as clients take the proper steps to validate the authenticity of the certificate and perform hostname validation, they are much more resistant to phishing attacks.

- If users are not directly communicating with the PingDirectory server itself, but are interacting with applications that use the server behind the scenes, then the application could obtain an OAuth token for that user, and then authenticate to the server using the OAUTHBEARER SASL mechanism. This enables support for additional authentication mechanisms that are typically not available to LDAP clients, like FIDO security keys.

Even if you cannot require strong authentication for all user accounts, you should at least require it for administrators.

Use non-identifiable user DNs

It is a common practice to include identifiable information in user distinguished names (DNs).

Attributes like uid, mail, and cn are often used as RDN attributes. However, this can lead to a few undesirable issues:

- This leads to personally identifiable information in the DNs for their accounts, and DNs are susceptible to being exposed in more ways than other content in user entries. For example, DNs commonly appear in log files. Further, if a client has access control permission to see any attributes in an entry, then they can also see its DN.

- Personal information might need to change. For example, a person can change their name, username, or email address. If this information is included in an entry's DN, then it requires a modify DN rather than a modify operation to change it. This is more onerous for applications, and it can often mean that two operations are required when making such a change (a modify DN to change the values of attributes used in the entry's RDN, and a separate modify operation to change other affected attributes that are not used in the RDN). It also means that an entry's DN might not be a stable identifier over the life of that entry.

- If DNs contain identifiable information, then they also likely contain predictable information. If it is possible to make reasonable guesses about what a user's DN might be, then their account is more susceptible to targeted attacks.

A better alternative is to choose an RDN attribute that is both unpredictable and unrelated to the user. UUIDs (universally unique identifiers, as described in RFC 4122) are a good way to accomplish this, and the PingDirectory server already generates a UUID value for every entry stored in the server, as the value of the `entryUUID` attribute, as described in RFC 4530.

The `entryUUID` operational attribute type is declared with the NO-USER-MODIFICATION constraint, which means that clients are not allowed to specify its value, nor should they attempt to do so, because it is vital that it be unique across all entries in the server. This means that clients can't use it as the RDN attribute when adding new entries to the server. However, the PingDirectory server provides support for automatically using the `entryUUID` value that it generates as the entry's RDN attribute, using it in place of whatever RDN the client initially provided. There are two ways to accomplish this:

- Clients can use the name with entryUUID request control in add requests to explicitly request that the server replace the RDN that it provides with one based on the `entryUUID` attribute.
- The server can be configured with criteria to automatically identify which entries should be automatically created with `entryUUID` as the naming attribute. This can be done with the following properties in the global configuration:
  - `auto-name-with-entry-uuid-connection-criteria` — Connection criteria that can be used to identify clients whose add requests should automatically be updated to use `entryUUID` as the naming attribute.
  - `auto-name-with-entry-uuid-request-criteria` — Request criteria that can be used to identify which add requests should automatically be updated to use `entryUUID` as the naming attribute.

If you cannot or do not wish to use `entryUUID` itself as the naming attribute for accounts, then you might still be able to define a custom attribute for this purpose. In that case, clients would generate the value and use it as the naming attribute in add requests.

> **Note**
>
> It is not possible to use `entryUUID` as the naming attribute in the accounts for root users and topology administrators. These accounts reside in the configuration, and the server's configuration framework requires that `cn` be used as the naming attribute for those entries. However, we strongly recommend creating those accounts with a `cn` value that is not predictable and does not contain any identifiable information. This also applies to alternate bind DNs for those users.

Use separate accounts for each administrator

The PingDirectory server's setup process automatically creates an initial root user that can be used to manage content in the server, and it suggests a DN of `cn=Directory Manager` for this account.

Many directory servers only support creating a single root account that is shared by server administrators. However, this comes with a lot of disadvantages, including:

- If there is only a single root account, then it is difficult to audit the actions of individual administrators.
- If there is only a single root account, then its credentials have to be shared across multiple administrators. This increases the risk that those credentials will be compromised because the more people who have access to them, the greater the chance that they will be leaked.

- If there is only a single root account whose credentials have to be shared across multiple administrators, then it can be disruptive to change those credentials if required (for example, if the credentials are compromised, or if one of the administrators leaves the organization or takes on a different role).
- If there is only a single root account, then it becomes more difficult to use strong authentication for that account in a secure manner.
- If there is only a single root account, then that account must have full access to perform any operation that any administrator might need to do. If this account is shared by multiple administrators, then that can give some of them more access than necessary.

PingDirectory server allows you to create any number of root user and topology administrator accounts. Each administrator should have their own account with separate credentials, support for strong authentication, and rights and privileges tailored to their role.

Prefer topology administrator accounts over root users

In PingDirectory server, administrative accounts can be placed in any of three places.

- They can be created as root users. These accounts exist in the configuration (after `cn=Root DNs,cn=config`) and are not synchronized across server instances. If you want to use root accounts across multiple servers, then you must create the account in each server and keep it up to date across all of them. Root user accounts can optionally automatically inherit a default set of privileges, and you can also explicitly grant and revoke privileges as needed.
- They can be created as topology administrators. These accounts also exist in the configuration (after `cn=Topology Admin Users,cn=topology,cn=config`), and these accounts are automatically synchronized between server instances within the same topology. Topology administrators can also automatically inherit a default set of privileges, and you can also explicitly grant or revoke privileges.
- They can be created in the user data. These accounts will be replicated across all directory servers and they can be used to authenticate to PingDirectory and PingDirectoryProxy servers, but they cannot be used to authenticate to PingDataSync servers. They cannot automatically inherit a default set of privileges, but you can explicitly grant privileges to them as needed. Accounts created in the user data can also be unavailable if the backend containing that data is offline, such as when performing an online restore, replica initialization, or LDIF import.

We recommend using topology administrator accounts over root users or accounts created in the user data. Topology administrators have all of the same capabilities as root users, and their accounts are also automatically synchronized across all servers in the topology so there is no need to apply the same change across multiple servers.

See the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file for more information about creating topology administrator accounts. The contents of the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file are shown below:

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts.  If you create a root user account, then it is only created
# in that one instance.  If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise.  They should be required to have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features).  You may also want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service.  For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you disable
# or remove the initial root user created during setup.  See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE:  Do not edit this file directly.  Changing this file could prevent it
# from being updated during a server upgrade.  If you want to alter the
# dsconfig commands below before applying the configuration changes, copy this
# file to another directory and edit that copy.
#

# Create a new topology administrator account.  In this example, the user will
# be able to read the configuration but will not be allowed to update it, and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration.  They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
     --user-name "[USER_NAME]" \
     --set "password:[PASSWORD]" \
     --set "first-name:[FIRST_NAME]" \
     --set "last-name:[LAST_NAME]" \
     --set "user-id:[USER_NAME]" \
     --set inherit-default-root-privileges:true \
```

```
    --set privilege:bypass-read-acl \
    --set privilege:-bypass-acl \
    --set privilege:-config-write \
    --set search-result-entry-limit:0 \
    --set time-limit-seconds:0 \
    --set look-through-entry-limit:0 \
    --set idle-time-limit-seconds:0 \
    --set require-secure-authentication:true \
    --set require-secure-connections:true \
    --set "allowed-authentication-type:SASL EXTERNAL" \
    --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

Disable or delete the initial root account

The initial root user account that `setup` creates should only be used to apply an initial set of configuration changes and create individual accounts for all of the other administrators.

From that point on, each administrator should use their own account for managing the server, and the initial root account is no longer needed.

To ensure that the initial root user account cannot be compromised or otherwise used inappropriately, it should be disabled by setting its `disabled` property to true or by setting the `ds-pwp-account-disabled` operational attribute to true in the configuration entry or completely removed from the server.

See the `config/sample-dsconfig-batch-files/disable-or-remove-the-initial-root-user.dsconfig` batch file for more information about disabling or removing this account.

Logging

Logging is the best mechanism for understanding what is happening in the server.

Log messages can be invaluable when troubleshooting problems, and log analysis can reveal performance characteristics and usage patterns.

Types of loggers

The PingDirectory server offers several types of loggers. It allows you to have any number of loggers of each type.

Error loggers

Despite their name, error loggers are not only used to report about errors. They can also provide information about significant events that occur within the server as well as warning conditions that might become a problem in the future.

Error loggers usually do not report information about operation processing unless an internal error is encountered during the course of processing an operation. Operation processing is covered by access loggers.

Each error log message has a severity that can be used to indicate how important the message is. Defined severities include:

- Fatal Error — Critical problems that might affect the server's ability to continue running

- Severe Error — Significant problems that might affect the server's functionality
- Mild Error — Less significant and more isolated problems that might not require immediate attention
- Severe Warning — Warnings about significant issues that might not represent errors can still require administrative action
- Mild Warning — Warnings about less significant issues
- Notice — Informational messages about significant events that occur within the server
- Information — Informational messages about less significant events
- Debug — Information that can generally only be useful when debugging low-level problems

Each logger can be configured to indicate which message severities should actually be recorded. The text-based error logger that is enabled in the out-of-the-box configuration logs messages at the following severities by default: fatal error, severe error, severe warning, and notice.

Each error log message also includes a category that is related to the server subsystem that generated it. Loggers can optionally be configured to record messages with different severities on a per-category basis.

The PingDirectory server offers several types of error loggers:

- The text error log publisher writes messages in a structured plain-text format to files on the server filesystem. The default error logger that the server maintains is a text error log publisher. The UnboundID LDAP SDK for Java provides an API for parsing error log messages written by this log publisher.
- The JSON error log publisher writes messages as JSON objects to files on the server filesystem. These messages are more likely to be parsable by third-party software than the format used by the text error log publisher.
- The console JSON error log publisher writes messages as JSON objects to the server's standard output or standard error stream. This is primarily useful for cases in which the server is running in Docker or some other type of container, and when using a framework that consumes standard output and standard error content for ingestion into a log management system.
- The syslog error log publisher writes messages to a syslog server. This can allow log messages to be sent to a centralized system through a commonly used logging protocol.
- The Java Database Connectivity (JDBC) error log publisher writes messages to a relational database using a specified column layout. This can also allow for centralized logging.

You can also use the UnboundID Server SDK to create custom error loggers. These can be used to customize the format of the log messages or to send log messages to other types of systems.

Access loggers

Access loggers are used to record information about interaction with clients. This includes:

- New connections that are established
- Connection closure and termination
- TLS negotiation used to secure connections, including certificate chains presented by clients
- Requests issued by clients

- Results returned by the server, including entries and references returned for searches as well as intermediate responses returned for any operation
- Requests that are forwarded to other servers
- The result of any replication assurance processing that was performed
- Entry rebalancing processing performed by PingDirectoryProxy server to move data between backends sets

Access log messages should always include a connection ID that identifies the associated client connection. Messages that are associated with operations (those other related to connects, disconnects, and TLS negotiation) should also include an operation ID that can be used to identify all log messages associated with that operation.

Access loggers might not actually record all of these types of messages. For example, the server's default access logger is configured to only record one message per operation when processing has completed for that operation. That message includes details about the request and result. Search result messages include the number of entries and references for that operation, but it does not record a separate message for each entry and reference that is returned.

The PingDirectory server also provides support for filtered logging. You can define fine-grained criteria to indicate which types of messages should be included in the log. This can be used to create log files that only include certain types of messages or to exclude messages that you consider unimportant.

The types of access loggers that The PingDirectory server offers include:

- The text access log publisher writes messages in a structured plain-text format to files on the server filesystem. The default access logger that the server maintains is a text access log publisher. The UnboundID LDAP SDK for Java provides an API for parsing access log messages written by this log publisher.
- The JSON access log publisher writes messages as JSON objects to files on the server filesystem. These messages are more likely to be parsable by third-party software than the format used by the text access log publisher.
- The console JSON access log publisher writes messages as JSON objects to the server's standard output or standard error stream. This is primarily useful for cases in which the server is running in Docker or some other type of container and when using a framework that consumes standard output and standard error content for ingestion into a log management system.
- Text audit log publishers write information about changes processed by the server to files using the standard LDIF format. Audit logs can be helpful in understanding exactly what changes have been made to data in the server, and they can also be useful if you need to replay or revert changes.
- The operation timing access log publisher is similar to the text access log publisher, but it can also include detailed information about the length of time required to process various phases of an operation. This can help identify which portions of operation processing are most expensive and might be able to help identify potential ways to improve performance.
- The debug access log publisher is a file-based logger that writes multi-line messages with detailed information about the contents of each request received from a client and response returned by the server. It can optionally be configured to also include detailed information about access control evaluation performed in the course of processing the operation.
- The syslog access log publisher writes messages to a syslog server. This can allow log messages to be sent to a centralized system through a commonly used logging protocol.
- The JDBC access log publisher writes messages to a relational database using a specified column layout. This can also allow for centralized logging.

- The admin alert access log publisher can be used to generate an administrative alert whenever the server processes an operation that matches the associated logging criteria.

The UnboundID Server SDK also provides support for creating custom access loggers if you want to use a particular log format or write log messages to other targets.

The PingDirectory server also offers the following JSON-formatted loggers:

JSON-formatted audit loggers

These complement the existing file-based audit logger in that they provide a record of changes to data in the server. Whereas the existing file-based audit logger writes information about changes as LDIF records, these loggers record information about the changes as JSON objects. There are three flavors of these JSON-formatted audit loggers:

- One that writes to files
- One that writes to the console (standard output or standard error)
- One that writes to syslog

JSON-formatted HTTP operation loggers

These complement the existing HTTP operation logger in that they provide a record of all HTTP requests received by and responses sent by the server. These messages are also formatted as JSON objects, and there are file-based, console-based, and syslog-based versions.

JSON-formatted Sync loggers

These complement the existing file-based Sync logger and Sync failed operations loggers in that they provide information about the processing performed by the PingDataSync server, formatted as JSON objects. Again, these log messages can be written to files, to the console, or to syslog.

HTTP operation and trace loggers

HTTP operation loggers record information about requests and responses to HTTP-based clients. The PingDirectory server provides two types of HTTP operation loggers:

- A file-based logger that uses the W3C common log format, which includes a timestamp, client address, the username of the requester, the HTTP request method, the request URI and optional query string, the protocol, and the status code.
- A file-based logger that provides more detailed information about each request, which can include elements like request headers, the authorization type, cookie names, request parameters, the request content type, and the response content length.

You can also use the UnboundID Server SDK to customize HTTP operation loggers. Trace loggers are also used for recording information about processing associated with HTTP clients, but they can include content that is more specific to the type of request being processed, including OAuth token validation, SCIM, the Directory REST API, and the consent API.

PingDirectory server provides the following types of trace loggers:

- A file-based logger that writes information in plain text format.

Sync loggers

Sync loggers provide a way to record information specific to processing performed by the PingDataSync server. Events that can trigger a sync log message include:

- Whenever a change is detected from a source
- Whenever a change is applied at the destination
- Whenever an attempt to apply a change fails for some reason
- Whenever a change is dropped or ignored (for example, because it was not needed or was outside the scope of all configured sync classes)
- Whenever a source entry is mapped to a destination entry
- Whenever a change is aborted during plugin processing
- Whenever a plugin generates a custom log message

The following types of sync loggers are available:

- A text sync log publisher that uses a multi-line plain text format to record information about the PingDataSync server processing
- A text sync failed ops log publisher that uses a mutli-line plain text format to record more detailed information about failed synchronization processing

> **Note**
>
> Both of these log publishers generate output that is intended to be read by a person. It is not optimized for automated parsing.

Debug loggers

Debug loggers provide a way to obtain detailed information about internal processing performed by the server. This can include specific informational content specifically added for low-level debugging, but at a minimum it likely includes things like any exceptions caught and handled internally during processing.

The PingDirectory server offers the following types of debug loggers:

- A file-based debug log publisher that records messages about debug content generated within the server. These messages can span multiple lines, and they are primarily intended to be read by people rather than parsed by automated mechanisms.

Debug logging has the potential to be extremely verbose, and it might have a notable impact on performance. It should only be enabled when it is needed, and it should be limited to as small an area of the server as possible. Because optimal configuration can require detailed knowledge of server internals, debug logging should generally only be used under the direction of support personnel.

However, there is one area of debugging that can be useful without assistance from support: debugging issues with custom extensions. The UnboundID Server SDK provides support for generating debug messages within custom extensions, and the PingDirectory server includes a "Server SDK Extension Debug Logger" instance that is pre-configured to record debug messages generated by extensions created using the Server SDK.

Standard output logger

The server should only write data to standard output or standard error under very limited circumstances, like when it is specifically configured to write JSON-formatted access or error log messages to the console. However, there might be limited cases in which it could write to standard output or standard error for other purposes, or in which the underlying JVM generates messages written to those streams (for example, if you enable certain low-level JVM debugging features). In such cases, the output that would have been written to standard output or standard error should be redirected into the `logs/server.out` file.

Log file rotation and retention

The PingDirectory server provides support for rotating log files to limit how large they can become. It also provides support for deleting old log files to limit how much total disk space can be consumed by log content.

Rotation policies

Each file-based logger can be configured with one or more rotation policies that can be used to determine when the server should rotate the active log file. When this occurs, it closes the active log file, renames it to include a timestamp indicating when it was rotated and creates a new, empty file to use for subsequent log messages.

The PingDirectory server provide support for the following log rotation policies:

- Size-Based — Rotate log files after they reach a specified size.
- Time Limit — Rotate log files after the active file has been in use for at least a specified length of time.
- Filed Time — Rotate log files at fixed times of the day.
- Never Rotate — Do not rotate the file. This should only be used in limited circumstances because it can allow log files to grow large and potentially consume all available disk space.

If a logger is configured with multiple rotation policies, then a log file can be rotated as soon as it satisfies the criteria for any of those policies. For example, if a logger is configured to rotate files after they reach 100 megabytes or after they have been active for 24 hours, then a log file can be rotated in less than 24 hours if it grows larger than 100 megabytes within that time frame. Conversely, it can be rotated before it reaches 100 megabytes in size if it does not hit that size limit within 24 hours.

Log file rotation listeners

Whenever a logger rotates its active log file, it can optionally perform additional processing on that file. This can be accomplished through a log file rotation listener. The PingDirectory server provides the following log file rotation listener implementations:

- Copy Log File — Copies the log file to a specified alternative location.
- Summarize — Invokes the summarize-access-log tool on the rotated log file.

You can also use the UnboundID Server SDK to create custom log file rotation listeners.

Retention policies

Retention policies are used to determine when the server should delete a log file that had previously been rotated.

The PingDirectory server supports the following retention policies:

- File Count — Only retain a specified number of rotated log files.
- Time Limit — Only retain rotated log files that are younger than a specified age.
- Size Based — Only retain a specified maximum aggregate size of rotated log files.
- Free Disk Space — Delete rotated log files if needed to maintain a specified minimum amount of free disk space.
- Never Delete — Never delete rotated log files. This should only be used in limited circumstances because it can allow rotated log files to accumulate and potentially consume all available disk space.

If a logger is configured with multiple retention policies, then rotated log files can be deleted if the criteria associated with any of the policies is reached. For example, if a logger is configured to maintain up to twenty rotated files or up to one gigabyte of disk space, then it can retain fewer than twenty files if the aggregate space consumed by rotated log files exceeds one gigabyte. Alternatively, it can retain less than a gigabyte of rotated log files if the most recent twenty files consume less than one gigabyte of space.

When the logger needs to delete one or more files because of the retention policy, it deletes the files in chronological order based on the timestamp in the rotated file name, starting with the oldest timestamp first.

Filtered logging

The PingDirectory server allows you to access loggers with criteria that are used to identify which messages should actually be recorded.

This allows you to:

- Maintain a log containing only non-successful operations.
- Maintain a log containing operations that took longer than a specified duration to complete.
- Maintain a log of requests by root users or topology administrators.
- Maintain a log of search operations in which encoded passwords were returned to clients.

Enable filtered logging using the following access logger configuration properties:

`connection-criteria`

An optional connection criteria object that is required to match the associated client connection. If connection criteria is provided, then the logger does not attempt to generate any connect, disconnect, request, search entry, search reference, or result log messages from clients that do not match that criteria.

`request-criteria`

An optional request criteria object that is required to match the associated operation request. If request criteria is provided, then the logger does not attempt to generate any request, search entry, search reference, or result log messages for requests that do not match that criteria.

`result-criteria`

An optional result criteria object that is required to match the associated operation result. If result criteria is provided, then the logger does not attempt to generate any result log messages for results that do not match that criteria.

`search-entry-criteria`

An optional search entry criteria object that i required to match the associated search result entry. If search entry criteria is provided, then the logger does not attempt to generate any search result entry log messages for entries that do not match that criteria.

`search-reference-criteria`

An optional search reference criteria object that is required to match the associated search result reference. If search reference criteria is provided, then the logger does not attempt to generate any search result reference log messages for references that do not match that criteria.

See the `log-operations-by-administrators.dsconfig` and `log-encoded-password-access.dsconfig` batch files in the `config/sample-dsconfig-batch-files` directory for examples of creating loggers that use criteria to filter log messages.

Log file compression

The PingDirectory server supports compressing log files, which can help significantly reduce the amount of disk space required to store log files on disk.

Because the server does not support maintaining a mix of compressed and uncompressed content for the same log, it can only be enabled when creating a new logger. When creating a new logger in which you want to compress the content, use the following configuration property:

`compression-mechanism`

Indicates the type of compression that should be used when writing log files. Available values include:

- `none` — Do not use compression for the log files.
- `gzip` — Compress the log files using the gzip compression algorithm.

Because the PingDirectory server allows you to create any number of loggers of the same type, you might want to maintain both compressed and uncompressed versions of the same content. The compressed version of the logger can have rotation and retention policies allowing for keeping a larger amount of log data for a longer period of time. The uncompressed version of the logger can keep a smaller amount of log content so that it is easier to find information about recent client interaction or other content without needing to decompress any files. However, both the `search-logs` and `summarize-access-log` tools transparently support operating on compressed log files.

Log file encryption

The PingDirectory server also supports encrypting log files, which can help prevent unauthorized access to sensitive information that they might contain.

As with compressed logging, the server cannot maintain a mix of encrypted and unencrypted content for the same log, so you can only enable encryption when the logger is created. This can be done using the `encrypt-log` configuration property. See the `config/sample-dsconfig-batch-files/create-encrypted-loggers.dsconfig` batch file for an example that demonstrates the process for creating encrypted access and error loggers. These examples also enable compression for the log files.

Log parsing APIs

The UnboundID LDAP SDK for Java provides support for programmatically parsing log file content.

This includes:

- Use the AccessLogReader class to read and parse access log messages using the server's default text-based access log format.
- Use the ErrorLogReader class to read and parse error log messages using the server's default text-based error log format.
- Use the AuditLogReader class to read and parse change records written by the server's audit logger. While the audit logger writes changes in LDIF form (and can therefore also be read by the LDIFReader), the AuditLogReader provides additional support for extracting information from comments that are associated with log messages, including:
  - The message timestamp
  - The connection ID
  - The operation ID
  - The requester distinguished name (DN) and IP address
  - The entry DN for any alternate authorization identity that was used
  - The replication change ID
  - For add operations, whether the operation was an undeleted
  - For delete operations, the attributes from the deleted entry, whether it was a soft delete, or whether it was a subtree delete
  - For modify operations, whether the operation targeted a soft-deleted entry
- Use the JSONObjectReader class to files comprised of JSON objects. Use this to read the contents of JSON-formatted access and error log files.

Logging Tools

The PingDirectory server provides tools that can be used to access content in access and error log files.

search-logs

Use the `search-logs` tool to search for content in log files. This tool provides grep-like support for searching log files, but it offers several additional benefits, including:

- It can automatically trace backward through rotated log files to find matching records in older log files.
- It supports searching log files that are compressed and encrypted.
- It can handle multi-line messages.
- It allows you to specify start and end times for the messages to match.

summarize-access-log

Use the `summarize-access-log` tool to examine one or more access log files and produce a plain-text report of the log data that they contain. The output can include:

- The length of time covered by the log files that were examined
- The number of connections that were established and disconnected
- The addresses of the clients that most frequently connected to the server
- The average rate of connects and disconnects per second
- The most common TLS protocols and cipher suites
- The number of operations processed, both overall and by operation type
- The average rate of operations processed per second, both overall and by operation type
- The average duration of operations processed, both overall and by operation type
- The breakdown of operation processing times into sets of predefined buckets, ranging from less than one millisecond to over one minute
- A breakdown of the most common result codes for each type of operation and their relative frequencies
- The most common authentication mechanisms
- The most common bind distinguished names (DNs) for successful and failed bind attempts
- The most common types of extended operations processed and their relative frequencies
- The number of unindexed search operations processed and the most common types of filters used when processing unindexed searches
- The most common base DNs for searches with non-baseObject scopes
- The relative frequencies for each search scope
- The most common types of search filters used and their relative frequencies
- The most common types of filters for searches returning zero, one, and multiple entries
- Filters used for searches that took the longest to complete

The `summarize-access-log` tool supports operating on log files that are compressed and encrypted. It also attempts to anonymize sensitive information in the output by replacing attribute values with placeholders.

Change logging

The PingDirectory server can be configured to maintain an LDAP-accessible changelog with a record of changes that have been processed in the server.

It is based on the specification in draft-good-ldap-changelog, but includes several proprietary enhancements that provide access to additional useful information. This can include:

- The values of updated attributes as they appeared before and after the change
- The values of a configured set of key attributes from the entry, even if they weren't altered by the change
- The content of an entry that was deleted
- The values of virtual attributes from the entry

The changelog can be useful for auditing changes that have been processed in the server, as well as for synchronizing changes to other systems. It is disabled by default, but it can be enabled with the following configuration change:

```
dsconfig set-backend-prop \
     --backend-name changelog \
     --set enabled:true
```

Additional properties that you might want to use to customize the changelog configuration include the following.

Property	Description
`changelog-include-attribute`	Specifies which attributes are included in changelog entries for add and modify operations. If this is specified, then only those attributes are included, even if the operation added or updated other attributes.
`changelog-exclude-attribute`	Specifies which attributes should be excluded from changelog entries for add and modify operations. By default, the changelog excludes several attributes that might contain sensitive information that is unlikely to be required externally. However, encoded passwords are not excluded by default because it might be necessary to synchronize them to other systems.
`changelog-deleted-entry-include-attribute`	Specifies which attributes should be included in changelog entries for delete operations. By default, all user attributes are included, but operational attributes are not.
`changelog-deleted-entry-exclude-attribute`	Specifies which attributes should be excluded from changelog entries for delete operations.

Property	Description
`changelog-include-key-attribute`	An optional set of attributes that should be included in changelog entries, even if they were not changed in the course of processing the operation.
`changelog-max-before-after-values`	Indicates that the changelog entry should include up to the specified number of before and after values for the updated attributes. This is zero by default to indicate that before and after values should not be included, but if it is changed to a nonzero value, then before and after values are included for any changed attributes whose value count is below this limit.
`use-reversible-form`	Indicates whether to log modifications in reversible form, which contains enough information to allow the change to be reverted. By default, changes are logged using the set of modifications as the client requested them.
`include-virtual-attributes`	Indicates which types of virtual attributes should be included in changelog entries. This might include zero or more of the following: • `add-attributes` — Indicates that the changelog entry for an add operation should include any virtual attributes that would be generated for the entry at the time it was added. • `deleted-entry-attributes` — Indicates that the changelog entry for a delete operation should include any virtual attributes present in the entry at the time it was deleted. • `before-and-after-values` — Indicates that the changelog entry should include any virtually values for attributes updated in the operation. • `key-attribute-values` — Indicates that the changelog should include virtual values for any key attributes to be included.
`apply-access-controls-to-changelog-entry-contents`	Indicates whether the server should pare down the contents of each changelog entry based on the requester's access control rights for the updated entry.

Property	Description
`report-excluded-changelog-attributes`	Indicates whether to report information about any attributes that were excluded from the changelog entry on the basis of the `apply-access-controls-to-changelog-entry-contents` property. Allowed values include: • `none` — Do not report on any attributes that were excluded. • `attribute-counts` — Report the number of attributes that were excluded. • `attribute-names` — Report the names of the attributes that were excluded.
`soft-delete-entry-included-operation`	Indicates whether to include operations that target soft-deleted entries. By default, operations that target soft-deleted entries, but they can be included with one or more of the following values: • `delete` — Indicates that the changelog should include records of soft-deleted entries that are removed from the server. • `modify` — Indicates that the changelog should include records of modify operations that update soft-deleted entries.

By default, the server does not include any access control rules that grant users access to retrieve changelog entries. As such, only users with the `bypass-acl` or `bypass-read-acl` can see them. If you want to grant access to other users who are subject to access control evaluation, you must do so using global ACIs.

The data recovery log

The PingDirectory server is preconfigured with an audit log instance that can be used to help replay or revert changes if the need arises. This is the data recovery log, and the log files are written into the `logs/data-recovery` directory.

The log files are compressed, and they are also encrypted if data encryption is enabled in the server. The logger is configured to use reversible form to make it usable to revert changes as well as to replay them. The server is configured to keep the data recovery log files for up to one week or up to ten gigabytes of disk space.

The server also provides an `extract-data-recovery-log-changes` tool to use in conjunction with this log. It offers a wide variety of arguments that can be used to identify which changes to extract, and it generates an LDIF file with the extracted changes. The changes can be exported in a form that allows them to be replayed, or they can be exported in a form that allows them to be reverted.

Some of the things that can be used to identify the changes to extract from the data recovery log are:

- The time that the changes were processed
- The operation types (add, delete, modify and modify distinguished name (DN)) for the changes to extract

- The connection ID for the connection on which the changes were requested
- The identity of the user that requested the changes
- The location of the changes in the DIT
- The content of the change

Monitoring

Monitoring is a vital part of a deployment because it allows you to ensure that the service remains available and functioning properly and because it can help alert you to problems as soon as they arise. PingDirectory server provides a broad range of monitoring support.

Monitor entries

The PingDirectory server provides a monitor backend, based at `cn=monitor`, with a wealth of information about the current state of the server.

Some of the available monitor entries include:

- Information about the version of the server and key libraries that it uses
- A list of all client connections currently established to the server
- A list of all active operations currently being processed in the server
- Information about each connection handler that is enabled in the server
- Information about each backend that is enabled in the server
- Information about each database used by local DB backends
- Information about the overall database environment for each local DB backend
- Information about the server's replication state
- Information about external servers accessed by PingDirectoryProxyProxy server
- Information about load balancing state in PingDirectoryProxy server
- Information about entry balancing state in PingDirectoryProxy server
- Information about the PingDataSync server's sync engine and pipes
- A timeline of server state changes
- Information about the host system on which the Java Virtual Machine (JVM) is running
- Information about the work queue and worker thread utilization
- Information about JVM memory utilization

- Information about file system disk space utilizationInformation about HTTP servlets configured within the serverInformation about cache utilization
- Information about each certificate that is in use within the server
- Information about the name resolution performance
- Information about server file descriptor usage and availability
- Stack traces for all active threads in the server
- Information about result codes returned by different types of operations
- Information about processing times, both overall and on a per-operation basis, including a histogram of processing times
- Information about supported and enabled TLS protocols and cipher suites
- A summary of various metrics that can be used for determining the availability status of the server
- Detailed information about the JVM and environment in which the server is running

You can also use the UnboundID Server SDK to create custom monitor entries. While this is typically done for the purpose of exposing monitor information about other custom extensions, it could also be used for other purposes, like providing information about external systems or services.

Each monitor entry is a read-only entry that can be searched and retrieved like data in user backends. However, the server does not maintain indexes for arbitrary monitor attributes. For best performance when searching for and retrieving monitor entries, you should do one of the following:

- If you know the DN of the desired monitor entry, issue a search with that DN as the search base DN and a scope of baseObject. In this case, any filter can be used.
- If you do not know the DN of the monitor entry, or if you want to retrieve multiple entries of a given type, then issue a search with a base DN of `cn=monitor`, a whole Subtree scope, and a filter that is based on the specific structural object class for that type of monitor entry (for example, `(objectClass=ds-backend-monitor-entry)` if you want to retrieve entries providing general information about each backend enabled in the server). The filter can optionally be ANDed with other components to further narrow down the search results.

Any LDAP client can be used to retrieve these monitor entries, but the UnboundID LDAP SDK for Java provides specific support for many types of monitor entries.

The availability state servlet

There are cases in which you want to obtain basic information about the state of the server over HTTP, or ideally, HTTPS.

These might include:

- When server HTTP endpoints are fronted by a load balancer capable of issuing and interpreting the results of HTTP requests for health-checking purposes.
- When using an orchestration framework such as Kubernetes, you can assess the current state of the server to determine if the instance is in a state that is ready to be used or if it has encountered an issue that has caused it to become degraded or unavailable. In this case,you can call the availability servlet in a liveness or readiness probe.

To assist with this, the PingDirectory server includes an availability state HTTP servlet that can be used to determine whether the server considers itself to be available, degraded, or unavailable. It is accessed using the GET, POST, or HEAD methods, and it returns a configurable status code and optional JSON-encoded response body that can be used to determine the server's self-assessed health state.

There are two instances of this servlet configured by default:

- One that uses a path of `/available-state` that returns an HTTP status code of 200 (OK) if the server considers itself available or an HTTP status code of 503 (Service Unavailable) if the server considers itself degraded or unavailable
- One that uses a path of `/available-or-degraded-state` that returns an HTTP status code of 200 if the server considers itself available or degraded or an HTTP status code of 503 if the server considers itself unavailable

The server's assessment of its health state is based on the presence of any unavailable or degraded alert types that are active in the server. If the server currently has one or more unavailable alert types, then it considers itself unavailable. If the server does not have any unavailable alert types but has one or more degraded alert types, then it considers itself degraded. If the server does not have any unavailable or degraded alert types, then it considers itself available.

Administrative alerts

The PingDirectory server can generate administrative alerts to notify administrators of errors, warnings, and significant events that occur in the server. Each alert has a name, severity, and message.

The `docs/admin-alerts-list.csv` and `docs/admin-alerts-list.html` files provide a listing of all alert types that are defined in the PingDirectory server. Some of these alert types include:

- Whenever the server begins or completes the startup process
- Whenever the server begins the shutdown process
- Whenever a change is made to the server configuration
- If the server detects that a configuration change was made with the server offline
- Whenever a change is made to the server's access control policy
- If a backend is disabled with the server online
- If an error occurs while attempting to enable a connection handler
- If an error occurs while attempting to enable a backend
- If an error occurs while trying to create or restore a backup
- If an error occurs while trying to retrieve or decode an entry from a backend database
- If the server detects that a backend was not cleanly shut down and it can take additional time to bring it back up while it performs recovery processing
- If a backend index needs to be built or is in the process of being built
- If replication has become backlogged, is missing changes, fails to replay a change, encounters a conflict that cannot be automatically resolved, or encounters some other problem
- If the server work queue has become backlogged or full

- If an attempt is made to assign a user an invalid privilege
- If available disk space becomes too low
- If debug logging is enabled
- Whenever the server executes a command on the underlying system
- Whenever the server enters or leaves lockdown mode
- Whenever an alarm is raised or cleared
- If the server detects an invalid or non-recommended Java Virtual Machine (JVM) configuration
- If the PingDirectoryProxy server changes the assessed health check state for any of its backend servers
- If the PingDirectoryProxy server encounters a problem while performing entry rebalancing processing
- If the PingDataSync server detects a backlog or encounters a problem during processing

Whenever an administrative alert is raised within the server, the server provides it to all alert handlers that are defined and enabled in the configuration. Alert handlers that are available in the PingDirectory server include:

- Error Log — Write a message about the alert to server error log.
- Exec — Execute a specified command on the underlying system.
- JMX — Emit a Java Management Extensions (JMX) notification with information about the alert.
- Output — Write a message about the alert to standard output or standard error.
- SMTP — Send an email message with information about the alert to a specified set of recipients.
- SNMP — Emit an SNMP trap with information about the alert.
- Twilio — Send an SMS text message with information about the alert using the Twilio service.

The UnboundID Server SDK can also be used to create custom alert handler implementations.

Information about recent alerts generated by the server is also available in the `cn=alerts` backend. It is also included in the output of the `status` tool.

Alarms and gauges

Each PingDirectory server includes a set of gauges for tracking various metrics over time.

Each gauge is associated with a monitor attribute and can be configured with warning, minor, major, and critical thresholds. If the monitor value crosses one of those threshold values, then the server raises an alarm condition that might indicate a problem such as low disk space or unavailability of an external server, and can optionally trigger administrative alerts.

Like alerts, alarms have a name, severity, and message. They also have a condition that is indicated by the alarm, like "Disk Usage," and they can be associated with a specific resource, such as which filesystem is running low on disk space. If alarm conditions are published using SNMP, then they can also include probable cause and alarm type properties.

Alarms are exposed in the `cn=alarms` backend. Their values can change over time, and they can be cleared whenever the monitored value returns to normal. Active alarms can be viewed using the `status` tool.

Account status notifications

PingDirectory server can generate account status notifications whenever certain events occur in the server regarding an account's state.

These notifications are used to notify end users or administrators about that event, or potentially to invoke custom code in response to them. For more information, see the Account status notifications section in the discussion on password policies.

Stats logging

The PingDirectory server provides a stats logger plugin that can be used to write a log file with a variety of performance metrics and other information collected within the server.

The information can be written in either CSV or JSON formats. Although CSV was originally the only format supported for this log file, use JSON for new deployments because it is easier to parse in automated form, especially given that the set of fields included in the output can change over time.

A configuration change like the following can be used to enable a stats logger instance using the JSON format.

```
dsconfig create-plugin \
        --plugin-name "JSON-Formatted Stats Logger" \
        --type periodic-stats-logger \
        --set enabled:true \
        --set log-file:logs/stats-log.json \
        --set log-file-format:json \
        --set "rotation-policy:Fixed Time Rotation Policy" \
        --set "rotation-policy:Size Limit Rotation Policy" \
        --set "retention-policy:File Count Retention Policy" \
        --set "log-interval:1 s" \
        --set "collection-interval:200 ms" \
        --set suppress-if-idle:true \
        --set local-db-backend-info:basic \
        --set replication-info:basic \
        --set included-ldap-stat:active-operations \
        --set included-ldap-stat:num-connections \
        --set included-ldap-stat:op-count-and-latency \
        --set included-ldap-stat:work-queue \
        --set included-resource-stat:memory-utilization \
        --set histogram-op-type:all
```

External monitoring

While the PingDirectory server provides extensive access to monitoring information to clients or in files on the server filesystem, there is a lot of benefit to using an external mechanism for monitoring individual servers and especially for aggregating information across multiple servers.

> **Important**
>
> SNMP is deprecated.

StatsD endpoints

The PingDirectory server offers support for StatsD endpoints that can send metrics to third-party monitoring software using a simple, well-defined protocol. Many popular monitoring products (like Splunk and DataDog) provide support for ingesting metrics using the StatsD protocol.

The PingDirectory server supports communicating with StatsD servers over TCP or UDP. It optionally supports TLS encryption when using TCP-based communication.

JMX

Java Management Extensions (JMX) is a core java framework that provides support for publishing metrics and notifications. JMX is supported by a wide range of monitoring software, and the `jconsole` tool that is provided as part of Java installations can also be used to interact with JMX-enabled services.

The PingDirectory server provides support for publishing all monitor information as JMX MBeans. It also provides support for a JMX alert handler that can generate a JMX notification in response to administrative alerts that are raised within the server. The `jmx-read` privilege is required for access to monitoring data, and the `jmx-notify` privilege is required to be able to subscribe to JMX notifications.

SNMP

SNMP is another standard protocol that is widely supported by monitoring software. The PingDirectory server can act as an SNMP subagent to make selected monitoring information available for consumption by SNMP clients and monitoring software. The server can also generate SNMP traps in response to administrative alerts that are raised within the server.

Auditing

It is important to regularly audit the PingDirectory server and its content to ensure that the data remains secure.

Auditing configuration changes

Proper server configuration is critical to maintaining security. Be aware of all changes to the server configuration and understand whether the configuration in its current state matches what you intend and expect it to be.

Administrative alerts

The PingDirectory server generates an administrative alert whenever a configuration change is made with the server online. It also generates an alert during startup if it detects unauthorized changes to the `dsconfig` tool in offline mode or the `manage-profile` tool.

You should make sure that an appropriate set of alert handlers are in place so that administrators are notified of configuration changes as soon as they occur.

The configuration audit log

The PingDirectory server maintains a `logs/config-audit.log` file that contains a record of all authorized configuration changes made within the server. This includes:

- Changes made through the `dsconfig` command-line tool with the server online

- Changes made through the `dsconfig` command-line tool running in offline mode
- Changes made through the web administration console
- Changes made through the `manage-profile` tool
- Changes made through the configuration API
- Changes made by clients updating configuration entries over LDAP

The configuration audit log will not include a record of any changes made by directly editing the `config.ldif` file with the server offline, but the server should detect any such changes at startup and generate an administrative alert in response to them.

Each record in the configuration audit log should include the following information:

- A timestamp indicating when the change occurred
- The connection ID and operation ID for the request that was used to make the change
- The DN of the user who made the change and the type of authentication they used
- The address of the client system used to request the change
- A command that is used to undo the change
- The change that was applied

The configuration archive

The PingDirectory server also maintains a configuration archive, in the `config/archived-configs` directory. This directory should contain a compressed and timestamped copy of every version of the configuration that the server has used. It also includes a version of the configuration as it existed when setup completed and a "clean" baseline configuration for the current version of the server without any customization applied.

The `config-diff` tool

The PingDirectory server provides a `config-diff` tool to compare different versions of the server configuration and identify differences between them. This tool can compare different versions of the configuration from the same server, or it can be used to compare configurations between different servers. Any differences will be written in the form of a `dsconfig` batch file that can update the source server so that its configuration matches that of the target.

Auditing data access

It's also important to understand the kinds of requests that clients make. This can help you identify requests that are out of the ordinary, which might be evidence of a potential attack.

Log analysis

The primary way to accomplish this is through log analysis. It is important to regularly examine (or at least summarize) the log files to classify the types and frequency of operations being performed. A sudden increase in any one kind of traffic can be a red flag, but situations like the following might be of particular interest:

- Connections from unusual client addresses, or a spike in requests from certain clients.

- Operations that fail with invalidCredentials (49) or insufficientAccessRights (50) results.
- Search operations that fail with a timeLimitExceeded (3), sizeLimitExceeded (4), or adminLimitExceeded (11) results.
- Search operations that do not return any entries.
- Search operations that return large numbers of entries.
- Search or compare operations that explicitly attempt to retrieve or target the userPassword attribute (or another password attribute).
- Search operations that might represent attempts to exfiltrate data from the server through trawling. This can include things like repeated substring filters with subInitial filters in sequential order, such as searches with filters like `(cn=aa*)`, `(cn=ab*)`, `(cn=aa*)`, and so on. It can also include greater-or-equal and less-or-equal filters with similar patterns.
- Unindexed search attempts.

If you regularly characterize the types of operations that clients request, then you might be able to more easily identify anomalous requests.

There might be other specific events that you always want to know about. For example, you might want to know whenever clients retrieve search result entries that contain encoded passwords, or whenever a client alters the server's access control definitions or the set of privileges granted to an account. In such cases, you can create criteria to specifically identify those types of operations, and then you can use that criteria to create a logger that only records those types of events.

If you want to know about these kinds of events right away, then you could create an admin alert access logger using that criteria. This causes the server to generate an administrative alert (with an alert type of `access-log-criteria-matched`) whenever it processes an operation matching that criteria.

Account status notification handlers

You might want to audit certain events related to password policy processing. For example, if the server is configured to lock accounts after too many failed attempts, then you might want to have a record of any time that happens. You might also want to have a record of all administrative password resets and self password changes.

This can be accomplished with account status notification handlers, and the server provides implementations that can either record messages about these kinds of events in the server error log or that can send email messages about them. If you would like to handle them in other ways, then you can use the UnboundID Server SDK to create a custom account status notification handler that implements the desired behavior.

Auditing data content

It's also a good idea to keep track of the data itself and identify any potential security-related issues that affect user entries or other data.

Data security auditors

One way to do this would be to regularly export the data to LDIF (ideally in encrypted form so that it is not exposed in the clear) and examine its content for unusual or undesirable conditions. You could also do this with search operations. However, in large data sets, such searches can be expensive and time consuming.

The server also provides an "audit data security" administrative task and an associated audit-data-security command-line tool that can help with this. When invoked, the task causes the server to efficiently iterate through all entries in the configured set of backends, comparing each one against a configured set of data security auditors.

The report is written into a directory structure on the server filesystem. There is a `summary.ldif` file that provides a summary of all of the processing that was performed. There is also a subdirectory for each of the backends that were examined with a set of LDIF files containing more detailed output from each of those auditors.

Data security auditors included with the PingDirectory server do the following:

- Identify all entries that contain ACIs.
- Identify administratively disabled users.
- Identify users with passwords that are expired or are about to expire.
- Identify users whose accounts are locked because of too many failed authentication attempts because it's been too long since the user authenticated or because the user did not change their password in a timely manner after an administrative reset.
- Identify users who have multiple passwords.
- Identify users who have explicitly configured privileges or root users or topology administrators who inherit the default set of root privileges.
- Identify users who have passwords encoded with password storage schemes that are considered weak.
- Identify all accounts with password policy state issues that can currently or soon affect their usability.
- Identify all accounts with activation times in the future, expiration times in the past, or expiration times in the near future.
- Identify accounts with passwords encoded using a deprecated password storage scheme.
- Identify accounts for users that have not authenticated in longer than a specified length of time.
- Identify accounts that are configured to use a nonexistent password policy (and are therefore unable to authenticate).
- Identify accounts that match a specified search filter.

> **Note**
>
> You can also use the PingDirectory server SDK to develop custom data security auditors for identifying other kinds of issues.

The `audit-data-security` tool offers the provided set of command-line arguments in addition to the usual options for connecting and authenticating to the server and scheduling tasks:

`--outputDirectory`

The directory (on the server filesystem) where the report files are created. If this is not specified, then it defaults to a directory whose name reflects the current time in the reports/audit-data-security subdirectory.

`--reportFilter`

An optional filter that can be used to indicate which entries should be examined. If this is provided, then only entries matching that filter are audited. Otherwise, all entries are examined. This can be provided multiple times if multiple filters should be specified, and only entries matching at least one of those filters are examined.

`--backendID`

An optional set of backend IDs for the backends to examine. If this is not provided, then all supported backends, including local DB backends and the server configuration, are examined.

`--includeAuditor`

An optional set of the names for the data security auditors that are invoked. By default, all data security auditors defined in the configuration are included, except for those excluded by the `--excludeAuditor` argument.

`--excludeAuditor`

An optional set of the names for the data security auditors that are not invoked.

Soft deletes

Normally, when an authorized client deletes an entry, it is completely removed from the server. However, the PingDirectory server provides support for soft deletes, in which the server preserves the entry instead of removing it. When an entry is soft-deleted, the server makes the following changes to it:

- The server adds the ds-soft-delete-entry auxiliary object class to the entry, which causes it to be hidden from normal search results.
- The server renames the entry to add the entry's entryUUID attribute to the set of RDN attributes. This allows a new entry to be created with the same distinguished name (DN) as the former entry without conflicting with the soft-deleted form of the entry.
- The server adds the following additional operational attributes to the entry:
  - `ds-soft-delete-from-dn` — The original DN for the entry.
  - `ds-soft-delete-timestamp` — The time that the entry was soft-deleted.
  - `ds-soft-delete-requester-dn` — The DN of the user that requested the delete.
  - `ds-soft-delete-requester-ip-address` — The IP address of the client that requested the delete.

There are two ways that regular deletes can be turned into soft deletes. The first is to include the soft delete request control in the delete request, such as using the `--softDelete` argument to `ldapmodify`.

However, it is also possible to have the server automatically convert regular deletes into soft deletes. This can be done by creating a soft-delete policy, which can include the following properties:

`auto-soft-delete-connection-criteria`

Connection criteria that can identify client connections whose deletes should be converted to soft deletes.

`auto-soft-delete-request-criteria`

Request criteria that can identify delete requests that should be converted to soft deletes.

`soft-delete-retention-time`

The maximum length of time that soft-deleted entries should be retained in the server.

`soft-delete-retain-number-of-entries`

The maximum number of soft-deleted entries that should be retained in the server.

After a soft delete policy has been created, the global configuration can be updated to use it with the following property:

`soft-delete-policy`

The soft-delete policy that should be used by the server. If this is not configured, then soft deletes are disabled in the server, even for delete requests that use the soft delete request control.

Only soft-delete policies that contain values for at least one of the `auto-soft-delete-connection-criteria` and `auto-soft-delete-request-criteria` properties can automatically convert regular deletes to soft deletes. If the server has a soft delete policy without criteria, then soft deletes are only allowed with the soft delete request control.

Turning deletes into soft deletes provides a way to verify the content of deleted entries. Even though soft-deleted entries are excluded from search results by default, users with the soft-delete-read privilege can retrieve them by including the soft-deleted entry access request control in the search request, such as by providing the `--includeSoftDeletedEntries` argument to `ldapsearch`.

If necessary, `soft-deleted` entries can be resurrected with the undelete request control in an add request, such as using the `--allowUndelete` argument to `ldapmodify`. The attributes of the add request can be used to provide the details of the undelete. In particular, the DN from the add request specifies the DN to use for the resurrected entry, and the `ds-undelete-from-dn` attribute specifies the DN of the soft-deleted entry to undelete.

Consent Solution Guide

This guide provides information for configuring and managing the PingDirectory server's Consent Service, which supports end-user control of personal data by collecting authorization from users and customers.

Introduction to the Consent Service and Consent API

Companies gain loyalty and trust when they offer transparency and control to their users and customers regarding the personal data that is collected, processed, or shared.

For example, in Europe, the General Data Protection Regulation (GDPR) was designed specifically for allowing companies to collect and use valuable data about its users, while protecting the rights of citizens to control what is collected and used.

To support the collection and end-user control of personal data, the PingDirectory server includes schema and REST APIs that provide the ability to collect fine-grained data authorizations (consents) from users and customers.

Consent Service overview

The Consent Service is an HTTP-based REST API hosted by the PingDirectory server or by the PingDirectoryProxy server.

Enterprises can integrate the following Consent Service features into their applications to give users transparency and control of their data privacy:

- The collection of consent from application users
- The enforcement of consent
- A user's management of his or her consent
- Auditing of consent actions

The following terms are used throughout this guide:

Collaborators

A list of individuals for whom access to this consent record is shared.

Consent definition

The terms of the fine-grained contract, which describes the data that can be processed or shared, and a purpose for processing or sharing the data. The consent definition is stored in the server configuration.

Consent localization

A child object of a definition that contains versioned, localized text for the consent definition, to be used when prompting an individual. This is stored in the server configuration.

Consent record

A record of a consent interaction with a user. Consent records are stored in the directory tree.

Subject

The individual whose data can be collected, processed, or shared.

Actor

The individual who granted, denied, or revoked consent. This is usually the same as the subject.

Audience

The entity, application, or service that is granted or denied access to a subject's data for a specific purpose.

Consent API overview

PingDirectory and PingDirectoryProxy provide a REST application programming interface (API) for managing an individual's consent to handle their data.

The PingDirectory Consent API enables the following authorization services for managing an individual's consent and data:

- Captures a user's consent for sharing or processing data
- Confirms a user's consent to share or process data has been granted
- The user can manage the consent that they have granted

The Consent REST API can be used as a component of a larger solution, such as a General Data Protection Regulation (GDPR) compliance system.

For more information on the Consent API, see the PingDirectory Consent API Reference and How applications use the Consent API.

How consents are collected

The Consent API allows the user to make the decision about sharing their data with other applications through a consent record.

User consent is collected by creating a consent record through the Consent API. In most cases, the Consent API client uses the consent localization data to construct an approval prompt that displays to the user. This prompt should include text describing what data is collected and for what purpose, allowing the user to make an informed decision about the value of sharing his or her data.

For example, a web application needing to collect consent for a user's browsing behavior uses the Consent API to look up the localizations for the `browsing-behavior` consent definition. It selects the localization appropriate for the user and use data from the localization resource to construct a consent prompt for display to the user. After the user is prompted and makes a decision, the client stores the decision by creating a new consent record through the Consent API.

How consents are enforced

The Consent API can be used as a data source for making access control decisions and enforcing the user's consent.

If a data usage scenario requires consent, then the application or service can't process or access the data unless the user has provided consent. The entity that performs this consent check can be the application itself or some other service.

To perform a consent check, the Consent API client tries to correlate a data access request type with a consent definition. For example, if a web application needs to collect a user's browsing behavior, it can use the `browsing-behavior` consent definition. In this data collection scenario, the application searches the Consent API and checks the an existing consent grant for a consent record that matches the user and the `browsing-behavior` consent definition. If a match is found, then the application proceeds. If a match is not found, the application must collect consent from the user.

How applications use the Consent API

The following example illustrates both consent capture and consent enforcement using the Consent API.

This example follows a user's journey on a website during which the company must gather consent to track the user's browsing behavior.

1. A user launches the company's application and authenticates.
2. The application wants to record the page visit but first checks if the user has granted consent to do so.
3. The application makes a call to the Consent API to determine if the `browsing-behavior` consent record exists for this user and whether consent been granted.
4. The API returns a result indicating that no consent record exists.
5. The application prompts the user for his or her consent.
6. The application calls the Consent API to retrieve the localization for the `browsing-behavior` consent, which includes the language that the application uses to produce a prompt for the user.
7. After the user makes a decision, the application stores the user's decision by creating a new consent record through a call to the Consent API.
8. Later, the user visits another page in the company's site, and the application wants to record the page visit, so it checks whether the user has granted consent to do so.
9. The application makes a call to the Consent API to get the `browsing-behavior` consent record for this user.
10. If the user's consent record agrees to have the company track his or her browsing behavior, the application can then make the appropriate calls to track browsing behavior.

Configuring the Consent Service

This section provides information for installing and configuring the components to support the Consent Service.

Installing and configuring the Consent Service includes the following topics:

- Configuration overview
- Example configuration scenarios
- Setting up with the configuration scripts
- Setting up in a replicated PingDirectory server environment
- Configuration reference

- Authorization

For more configuration information, see PingDataSync Server Administration Guide.

Configuration overview

Your Consent Service configuration can vary depending on client application capabilities, authentication methods used, and other factors.

By default, the Consent Service is not enabled. The setup and configuration process varies depending on the following factors:

- Whether client applications allow an individual to self-manage consents
- Whether some or all client applications can be privileged with the ability to manage all consents
- The HTTP authentication method used by client applications
- Whether consent records exist in the same directory as user entries

Example configuration scenarios

Review the following client application scenarios to determine how to configure the Consent Service to meet your business needs.

Directly managed consents

In this scenario, one or more client applications provide an interface for individuals to directly manage their own consent records. These applications can only manage consents for the currently authenticated user. In addition, there's a client application for consent administrators.

An OAuth 2 authorization server grants access tokens that the applications use to access the Consent API.

Configuration for this scenario includes:

1. Configure an OAuth 2 authorization server to issue a `urn:pingdirectory:consent` scope to individuals and a `urn:pingdirectory:consent_admin` scope to consent administrators.
2. Create an identity mapper to map subject identifiers used by the authorization server to Lightweight Directory Access Protocol (LDAP) distinguished names (DNs) used by the PingDirectory server.
3. Configure an access token validator to validate tokens issued by the OAuth 2 authorization server.
4. Configure the Consent HTTP Servlet Extension to disable HTTP basic authentication and restart the HTTPS Connection Handler.
5. Configure the Consent Service to use the OAuth scopes and token validator.

Indirectly managed consents (basic authentication)

In this scenario, an application uses a privileged service account to manage its users' consents. The application's privileged account can access any consent record, which gives the application the ability to perform operations that an individual user can't.

The following configuration steps describe the setup needed for the PingDirectory server's Open Banking Account Requests service to use the Consent Service as its backend.

Configuration for this scenario includes:

1. Create a service account for the application.
2. Configure the Consent HTTP Servlet Extension to enable HTTP basic authentication and restart the HTTPS Connection Handler.
3. Create an identity mapper to map the consent record subject and actor attribute values to LDAP DNs.
4. Configure the Consent Service to use the application's service account.
5. Configure the Consent Service to use the identity mapper.

Setting up with the configuration scripts

The PingDirectory server includes two configuration scripts that can serve as the starting point for setting up the Consent Service.

About this task

You can use one of the following two configuration scripts to start setting up the Consent Service:

- `consent-service-base-entries.ldif` - Import this LDIF script to create the base distinguished name (DN) where consent records are stored.
- `consent-service-cfg.dsconfig` - Import this script to configure and enable the Consent Service.

Both scripts are located in the `/resource/consent/` directory of the PingDirectory server root.

> **Tip**
>
> Carefully review and update both scripts to support your client application scenarios and business needs.

Steps

1. Choose a configuration script to set up the Consent Service.

   Choose from:

   - Basic configuration with the `consent-service-base-entries.ldif` file.
     1. Edit the LDIF script and change the location of where you want to store the consent records.
     2. Import the LDIF script using the `ldapmodify` command. See the following example.

        ```
        $ bin/ldapmodify --defaultAdd \
          --filename consent-service-base-entries.ldif
        ```

   - Basic configuration with the `consent-service-cfg.dsconfig` file.
     1. Search for `CHANGE-ME` and replace values.

2. Review configuration commands and make additional changes to match existing Ping environment parameters, application scenarios, and business needs.
3. Impost the script with the `dsconfig` command. See the following example.

```
$ bin/dsconfig --no-prompt \
  --batch-file consent-service-cfg.dsconfig
```

Setting up in a replicated PingDirectory server environment

Running the Consent Service setup script differs depending on if your environment includes replicated PingDirectory servers.

About this task

Setting up the Consent Service requires different steps depending on if replication is enabled in your environment or not.

> **Tip**
>
> If possible, you should set up the Consent Service after replication is enabled for the PingDirectory servers.

You can find more information about server replication in the PingDirectory Server Administration Guide.

Steps

1. Choose a Consent Service setup:

   Choose from:

   - If you are setting up the Consent Service after replication is enabled for PingDirectory servers:
     1. Configure the PingDirectory servers to use a configuration group called `all-servers`.

        > **Note**
        >
        > This ensures that configuration changes are applied to all servers in a topology.

        ```
        $ bin/dsconfig set-global-configuration-prop \
          --set configuration-server-group:all-servers
        ```

     2. Run the Consent Service setup script.

        ```
        $ bin/dsconfig --no-prompt \
          --batch-file resource/consent/consent-service-cfg.dsconfig
          --applyChangeTo server-group
        ```

   - If you have set up the Consent Service on a standalone PingDirectory server before enabling replication:

> **Note**
>
> In this example, DS1 is the original PingDirectory server, and DS2 is the second server to be added as a replica.

1. Run the `config-diff` command without arguments on DS1 to produce a batch file that contains configuration changes that will be applied to DS2.

```
$ bin/config-diff > config-changes.dsconfig
```

2. Apply the `config-changes.dsconfig` file to DS2.

```
$ bin/dsconfig --no-prompt \
  --batch-file config-changes.dsconfig \
  --applyChangeTo single-server
```

3. Restart DS2.

4. Enable replication between the two servers.

Configuration reference

Use this section as a reference for information about the Consent Service properties and configuration.

There are many configuration options for the Consent Service and application integration. The configuration scripts included with PingDirectory server provide a starting point. Additional information about the Consent Service properties and configuration is provided as reference.

General Consent Service configuration

The Consent Service configuration is used to control authorization behavior and determines where consent records are stored in the PingDirectory server.

You configure the Consent Service properties using the `dsconfig set-consent-service-prop` command. You can use the Consent Service configuration script to configure the Consent Service properties, as show in the following example.

```
$ bin/dsconfig set-consent-service-prop \
  --set enabled:true \
  --set base-dn:ou=consents,dc=example,dc=com \
  --set "bind-dn:cn=consent service account" \
  --set unprivileged-consent-scope:urn:pingdirectory:consent \
  --set privileged-consent-scope:urn:pingdirectory:consent_admin \
  --set "consent-record-identity-mapper:User ID Identity Mapper"
```

Consent Service properties

Property	Description	Required to enable service
`enabled`	If set to `true`, the property enables the Consent Service for handling client requests.	Yes
`base-dn`	Specifies a container distinguished name (DN) for consent record entries.	Yes
`bind-dn`	Specifies an internal service account used by the Consent Service to perform LDAP operations.	Yes
`service-account-dn`	Specifies one or more DNs of requesters that are considered privileged when using basic authentication. If not defined, a requester is only considered privileged if it's mapped to a DN with the `bypass-acl` privilege.	No
`unprivileged-consent-scope`	Specifies the name of the scope required for bearer tokens representing unprivileged requesters.	Yes
`privileged-consent-scope`	Specifies the name of the scope required for bearer tokens representing privileged requesters.	Yes
`consent-record-identity-mapper`	Specifies one or more identity mappers used to map consent record `subject` and `actor` values to DNs. By default, these values are inferred from the authentication context, such as the bearer token subject.	No
`audience`	Specifies an `audience` claim value that the Consent Service requires to be present in bearer tokens that it accepts.	No

For the Consent Service to report itself as available to clients:

- The Consent Service must be enabled.
- The Consent Service base DN must be configured and must exist.
- The internal service account must be configured and exist.
- The internal service account must have the right to read, add, modify, and delete entries under the Consent Service base DN.

Creating a container entry for consent records

Each consent record is a distinct entry in the PingDirectory server. The Consent Service requires that these entries are stored under a common base distinguished name (DN).

About this task

The `base-dn` property of the Consent Service configuration defines the base DN. The Consent Service LDIF file sets the base DN.

To choose a different location to store consent records:

Steps

1. To create the Consent Service base DN, open a text editor and save the following to the `consent-service-base-dn.ldif` file.

   Example:

   ```
   dn: ou=consents,dc=example,dc=com
   objectClass: top
   objectClass: organizationalUnit
   ou: consents
   ```

2. Use `ldapmodify` to add the entry.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename consent-service-base-dn.ldif
   ```

Creating an internal service account

Create an internal LDAP connection to operate against consent records that are stored as LDAP entries.

About this task

The Consent Service uses an internal LDAP connection to operate against consent records that are stored as LDAP entries. The Consent Service authenticates the LDAP connection using a service account that must be created and dedicated solely to the Consent Service.

The Consent Service configuration script configures the internal service account using a topology administrator user. If needed, this can be changed to a root distinguished name (DN) user or a user DN whose entry is in the user backend. In all cases, the service account should exist in every LDAP server in the topology.

This service account must have:

- Full read and write access to the Consent Service base DN.
- The ability to read users' `isMemberOf` attribute.
- The right to use the following LDAP controls:
  - IntermediateClientRequestControl (1.3.6.1.4.1.30221.2.5.2)
  - NameWithEntryUUIDRequestControl (1.3.6.1.4.1.30221.2.5.44)
  - RejectUnindexedSearchRequestControl (1.3.6.1.4.1.30221.2.5.54)
  - PermissiveModifyRequestControl (1.2.840.113556.1.4.1413)

- PostReadRequestControl (1.3.6.1.1.13.2)

For more information about configuring access, see Managing access control.

Steps

1. To ensure the correct access, create a user with the `bypass-acl` privilege.

   Example:

   The following `dsconfig` command creates a topology admin user with the `bypass-acl` privilege.

   ```
   $ dsconfig create-topology-admin-user \
     --user-name "Consent Service Account" \
     --set "description:Consent API service account" \
     --set "alternate-bind-dn:cn=consent service account" \
     --set first-name:Consent \
     --set inherit-default-root-privileges:false \
     --set last-name:Service \
     --set password:CHANGE-ME \
     --set privilege:bypass-acl
   ```

   Tip

   The `bypass-acl` privilege grants a broad level of access, so you might not want to grant this privilege to the Consent Service account.

2. Set this user as the `bind-dn` for the Consent Service.

3. To enable a targeted set of functionality for the Consent Service, add the following access control instruction (ACI).

   Example:

   The following example grants the access to the `cn=consent service account` DN using global ACIs.

   ```
   # Grant access to the consent record base DN ou=consents,dc=example,dc=com
   dsconfig set-access-control-handler-prop --add 'global-aci:(target="ldap:///
   ou=consents,dc=example,dc=com")(targetattr="*||+")(version 3.0; acl "Consent Service account access
   to consent record data"; allow(all) userdn="ldap:///cn=consent service account";)'

   # Grant access to the LDAP request controls used by the Consent Service.
   dsconfig set-access-control-handler-prop --add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.2||
   1.3.6.1.4.1.30221.2.5.44||1.3.6.1.4.1.30221.2.5.54||1.2.840.113556.1.4.1413||1.3.6.1.1.13.2")
   (version 3.0; acl "Consent Service account access to selected controls"; allow (read)
   userdn="ldap:///cn=consent service account";)'
   ```

Configuring an identity mapper

The Consent Service uses identity mappers to map requester identities, subject values, and actor values to distinguished names (DNs).

An identity mapper takes a user identifier string and correlates the identifier with the DN of a user entry. The PingDirectory server provides four different types of identity mappers.

Identity mapper types and descriptions

Identity mapper type	Description
Exact match identity mapper	Maps a user identifier to a DN by searching for an entry with an attribute that exactly matches the identifier.
Regular expression identity mapper	Similar to an exact match identity mapper, but allows a regular expression to be specified for more flexible matching.
Third-party identity mapper	A custom Java identity mapper implementation written using the Server SDK.
Groovy scripted identity mapper	A custom Groovy identity mapper implementation written using the Server SDK.

The Consent Service can be configured to use identity mappers for each of the following scenarios:

Requesters authenticating using basic authentication

Use the Consent HTTP Servlet Extension `identity-mapper` property to configure an identity mapper that takes the HTTP Basic authorization user name string to find the corresponding user's identity in the PingDirectory server.

Requesters authenticating using bearer token authentication

Use the Access Token Validator `identity-mapper` property to configure an identity mapper that takes the subject or other claim value from the OAuth token to find the corresponding user's identity in the PingDirectory server.

Consent record actor and subject values

Use the Consent Service `consent-record-identity-mapper` property to configure an identity mapper that takes these consent record attribute values and uses them to find the corresponding users' identities in the PingDirectory server.

The consent record identity mapper

By default, the Consent Service sets the `subject`, `subjectDN`, `actor`, and `actorDN` values to the identity of the authenticated requester. If the requester uses basic authentication, then all values are set to the auth DN determined by the basic authentication identity mapper. If the requester uses bearer token authentication, then the `subject` and `actor` values are set to the bearer token's subject claim value, while the `subjectDN` and `actorDN` values are set to the auth DN determined by the access token validator identity mapper.

Privileged clients can manually set a consent record's `subject` and `actor` values. In those cases, the Consent Service's `consent-record-identity-mapper` property is used to map a consent record's `subject` and `actor` values to `subjectDN` and `actorDN` values, respectively.

Identity mapper configuration options

The Consent Service configuration script configures a single identity mapper to be used for all three scenarios. The provided identity mapper searches by `uid`, `cn`, or `entryUUID` attributes under the base DNs `cn=config` and `ou=people,dc=example,dc=com`.

The following configuration provides an example of an identity mapper that matches a user identifier to an Lightweight Directory Access Protocol (LDAP) entry with the same value in its `uid` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "User ID Exact Match" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid
```

This configuration shows another typical example: an identity mapper that matches a user identifier to an LDAP entry with the same value in its `entryUUID` attribute.

```
$ bin/dsconfig create-identity-mapper --mapper-name "EntryUUID Exact Match" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:entryUUID
```

This final example creates an identity mapper that matches a user identifier to an LDAP entry with the same value in either its `uid`, `cn`, or `entryUUID` attribute. This identity mapper also constrains its search to the `cn=config` and `ou=people,dc=example,dc=com` and **`cn=config`** base DNs. By default, the `cn=config` base DN is not searched and must be explicitly listed to be searched.

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "User ID Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:uid \
  --set match-attribute:cn \
  --set match-attribute:entryUUID \
  --set match-base-dn:cn=config \
  --set match-base-dn:ou=people,dc=example,dc=com
```

Authentication methods

The Consent Service supports the following HTTP authentication methods and the use of token validators for authorization.

Supported HTTP authentication methods

The Consent Service supports the following HTTP authentication methods that are enabled by default:

Basic authentication

With basic authentication, the client provides an encoded user name-password pair in the HTTP Authorization request header. When the Consent Service receives a request using basic authentication, it maps the user name credential to a distinguished name (DN) using an identity mapper. This DN is designated the `auth DN` and is used to make subsequent authorization decisions. The Consent Service then performs an Lightweight Directory Access Protocol (LDAP) bind using the DN and password to determine if the request can be processed.

Bearer token authentication

With bearer token authentication, the client provides an access token in the HTTP Authorization request header. The access token is always obtained by the client from an external OAuth 2 authorization server and encapsulates information "claims" about a user identity, the client identity, and the requests that the client is authorized to make.

The Consent servlet looks at the request's Authorization header to determine which authentication type is being used by the client.

Configuring token validators

The PingDirectory server must be configured to accept access tokens using one or both of the following access token validators:

PingFederate access token validator

Supports access tokens issued by a PingFederate authorization server. This validator verifies an access token and discovers its claims by making a request to the PingFederate server's token introspection endpoint.

> **Note**
>
> If you are using PingFederate 10.0 or earlier, ensure that PingFederate is configured to respond to OAuth and OpenID Connect (OIDC) requests by selecting the check boxes mentioned in steps 2 and 3 in Enabling the OAuth AS role in the PingFederate documentation.
> Starting with PingFederate 10.1, these items are always enabled.

JWT access token validator

Supports signed or encrypted JSON Web Token (JWT) access tokens issued by an arbitrary authorization server. This validator checks an access token by cryptographically verifying the token's signature using a trusted public certificate. The token's claims are encoded in the token itself, so discovering the token's claims does not require an outgoing token introspection request.

The token validator uses its identity mapper to map the subject claim to a DN. This DN is designated the `auth DN` and is used along with the token's claims to make subsequent authorization decisions.

If the PingDirectory server is configured with at least one access token validator, the Consent Service uses this access token validator. If the PingDirectory server is configured with more than one access token validator, the validators are consulted in order until one is able to successfully authenticate the request. If the PingDirectory server is configured with multiple access token validators, but only one should be used by the Consent Service, the access token validator can be configured by setting the `access-token-validator` property of the Consent HTTP Servlet Extension.

> **Note**
>
> Configuring an access token validator for the Consent Service requires the following from the authorization server configuration:
>
> - The values that the authorization server sets for `subject` claims must be mappable to a DN in the PingDirectory server.
> - The authorization server must be configured to authorize clients and grant scopes appropriately for privileged or unprivileged Consent API access.
> - The authorization server must be configured to issue tokens with scopes corresponding to the Consent Service's `unprivileged-scope-name` and `privileged-scope-name` configuration.
>
> See the authorization server's documentation for guidance.

Configuring basic authentication

Disable or enable basic authentication and configure an identity mapper for basic authentication.

About this task

By default, basic authentication is enabled. The settings are configured in the Consent HTTP Servlet Extension configuration.

> **Note**
>
> All of these configuration changes require the Consent servlet to be reloaded before they can take effect. To do this, see the last step.

Steps

- **To disable basic authentication, use the following command.**

  Example:

  ```
  $ bin/dsconfig set-http-servlet-extension-prop \
    --extension-name Consent \
    --set basic-auth-enabled:false
  ```

- **To enable basic authentication, use the following command.**

  Example:

  ```
  $ bin/dsconfig set-http-servlet-extension-prop \
    --extension-name Consent \
    --set basic-auth-enabled:true
  ```

- **To configure an identity mapper for basic authentication, use the following command.**

  Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Consent \
  --set "identity-mapper:User ID Exact Match"
```

- To restart the connection handler that hosts the Consent servlet, use the following commands.

  Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:false
```

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

Configuring bearer token authentication

Configure an access token validator.

About this task

> **Note**
>
> You can configure the Consent Service to use a single validator.

Steps

- Configure an access token validator using `dsconfig`.

  Example:

  This example shows an access token validator configured on a PingDirectory server for a PingFederate server.

```
$ bin/dsconfig create-external-server \
  --server-name PingFederate \
  --type http \
  --set base-url:https://my-ping-federate-server:1443/
```

```
$ bin/dsconfig create-access-token-validator \
  --validator-name "PingFederate Token Validator" \
  --type ping-federate \
  --set enabled:true \
  --set "identity-mapper:User ID Exact Match" \
  --set authorization-server:PingFederate \
  --set client-id:id \
  --set client-secret:secret
```

- (Optional) If more than one access token validator is configured on a PingDirectory server, you can configure the Consent Service to use a single validator with the following command.

  Example:

  ```
  $ bin/dsconfig set-http-servlet-extension-prop \
    --extension-name Consent \
    --set "access-token-validator:PingFederate Token Validator"
  ```

Configuring Consent Service scopes

Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

About this task

The Consent Service checks access tokens for a `subject` claim and uses an identity mapper to map the value to a distinguished name (DN), called the request DN or auth DN. If no request DN can be mapped, the request is rejected.

The Consent Service only accepts an access token with a scope that it is configured to recognize.

`unprivileged-consent-scope`

An unprivileged consent scope designates the requester as unprivileged. The scope's name is configured with the Consent Service's `unprivileged-consent-scope` property.

`privileged-consent-scope`

A privileged consent scope designates the requester as privileged. This is configured using the Consent Service's `privileged-consent-scope` property.

> **Note**
>
> The authorization server must also be configured to issue tokens with these scopes.

Steps

- Configure the `privileged-consent-scope` and `unprivileged-consent-scope` for the Consent Service.

  Example:

  ```
  $ bin/dsconfig set-consent-service-prop \
    --set unprivileged-consent-scope:consent \
    --set privileged-consent-scope:consent_admin
  ```

Authorization

The Consent Service's distinction between `privileged` and `unprivileged` requesters determines the type of operations that can be performed by requesters.

During the authorization phase, the Consent servlet performs checks on both the bearer token claims, if present, and the `auth DN` to determine if the requester is privileged or unprivileged. These are summarized in the following table.

Available operations per requester type

Requester type	Description	Access determined by	Can create consent records	Can update consent records	Can delete consent records
`Unprivileged`	Requesters with no authority to operate on consent records other than their own.	A requester is considered `unprivileged` if it does not meet any of the criteria for a `privileged` requester. If using bearer token authentication, the access token must include a scope named by the `unprivileged-consent-scope` property of the Consent Service configuration. Also, an unprivileged requester can only perform actions on consent records where the subject distinguished name (DN) matches the requester DN.	Yes. The subject/subjectDN and actor/actorDN values will be set based on the requester.	Yes, if the requester DN matches the subject DN.	No
`Privileged`	A requester with the authority to perform any operation on any consent record.	When using basic authentication, a requester is considered `privileged` if the requester DN either has the `bypass-acl` privilege or is listed in the `service-account-dn` property of the Consent Service configuration. If using bearer token authentication, the access token must include a scope named by the `privileged-consent-scope` property of the Consent Service configuration.	Yes	Yes	Yes

Bearer token check

If a bearer token was used, the following checks are performed:

- If the Consent Service's `audience` property is configured, the bearer token's audience claim must match the configured value.
- If the bearer token contains a scope matching the Consent Service's `privileged-scope-name` property, then the requester is considered privileged.
- If the bearer token doesn't contain a scope matching the Consent Service's `privileged-scope-name` property, the bearer token must have a scope matching the Consent Service's `unprivileged-scope-name` property, and the requester is considered unprivileged.

Basic authentication check

If basic authentication is used, the following checks are performed:

- If the `auth DN` has the Lightweight Directory Access Protocol (LDAP) privilege `bypass-acl`, the requester is `privileged`.
- If the `auth DN` is listed in the Consent Service's `service-account-dn` property, the requester is `privileged`.
- If the `auth DN` isn't listed in the Consent Service's `service-account-dn` property, the requester is considered `unprivileged`.

Managing Consents

This section provides information about the collection and end-user control of personal data as well as managing users' consents.

Managing users' consents includes the following topics:

- Overview of consent management
- Consent definitions and localizations
- Perform an audit on consents
- Logging
- Correlating user and consent data
- Troubleshooting the Consent Service

Overview of consent management

Consent management involves more than collecting the user's consent.

In the consent management life cycle:

1. The terms of each consent contract are centrally managed.
2. The user reviews previously granted consents and potentially revokes some of them.
3. Companies trace the history of updates to any consent in order to resolve a dispute or respond to audit.

Consent definitions and localizations

The Consent Service requires consent definitions and localizations, which collect and share a use's data and define the purpose for collecting and sharing this data.

Companies can centrally manage the language used when prompting a user to give consent to ensure a consistent user experience across multiple applications, such as mobile and web.

The Consent Service requires one or more consent definitions to be defined in the PingDirectory server configuration. Each consent definition represents the combination of:

- The data to be collected or shared
- The purpose for collecting or sharing the data

For example, a consent definition could represent users' email addresses that are used to deliver a third party's email newsletter. A consent definition could also represent access to a user's network-connected IoT device that could be used for a home automation task controlled by a third party.

Each consent definition must have one or more localizations. A localization is a versioned object consisting of the data that a Consent API client needs to prompt a user for consent. When a consent record is accepted or denied by a Consent Service client, it must include a reference to a consent definition, locale, and version.

Creating a consent definition and localization

Create and update a consent definition and localization.

Steps

- Create a consent definition using `dsconfig create-consent-definition`.

  Example:

  ```
  $ bin/dsconfig create-consent-definition \
    --definition-name email_newsletter \
    --set "display-name:Email newsletter"
  ```

- Create a localization for the consent definition using `dsconfig create-consent-definition-localization`.

  Example:

  ```
  $ bin/dsconfig create-consent-definition-localization \
    --definition-name email_newsletter \
    --localization-name en-US \
    --set version:1.0 \
    --set "data-text:Your email address" \
    --set "purpose-text:To receive newsletter updates"
  ```

- Update a localization and the version using `dsconfig set-consent-definition-localization-prop` and `set version`.

  Example:

  The following example updates a localization and its version.

```
$ bin/dsconfig set-consent-definition-localization-prop \
  --definition-name email_newsletter \
  --localization-name en-US \
  --set version:1.1 \
  --set "data-text:Your preferred email address"
```

Perform an audit on consents

The Consent Service offers two types of audit logs to track changes and to perform audits on Consent Service resources.

For examples of configuring either type of log, see the `<server-root>/resource/consent-service-cfg.dsconfig` script bundled with the server or Logging.

This example uses the Consent Trace Logger, which represents Consent Service change events using the same field names used by the Consent API.

Log Publishers

Log publisher	Log publisher type	Description
collaborators	Trace logger key	The collaborators value, available only when the resource type is `consent`.
Consent Trace Logger	file-based-trace	Records Consent Service events at the Consent API level. Change events are recorded using messages of type `audit`.
Consent LDAP Audit Logger	file-based-audit	Records data changes at the LDAP level. In combination with a Request Criteria configuration object, an LDAP audit logger can be configured to record changes to Consent Service resources only.

Trace logger keys for auditing

Trace logger audit messages consist of a timestamp, the `CONSENT AUDIT` message type, and a set of key/value pairs.

> **Note**
>
> The keys used in trace log audit messages vary depending on the type of resource.

The following table describes a subset of important keys.

Trace logger key	Description
`requestID`	A server-specific HTTP request ID. This value can be correlated with messages produced by other loggers.

Trace logger key	Description
`resourceType`	The type of Consent Service resource that was changed. Possible values are `definition`, `localization`, or `consent`.
`changeType`	The type of change recorded by this message. Possible values are `create`, `update`, or `delete`.
`attrsAdded`	A comma-delimited list of the attributes that were added to the resource.
`attrsUpdated`	A comma-delimited list of the attributes that were modified on the resource.
`attrsDeleted`	A comma-delimited list of the attributes that were removed from the resource.
`requestDN`	The distinguished name (DN) of the requester, which is available only when the resource type is `consent`.
`definitionID`	The consent definition ID. The following list identifies the possible resource types and their definitions: **`definition`** Identifies the definition that was changed. **`localization`** Identifies the parent definition. **`consent`** Identifies the consent record's related definition.
`locale`	The locale. The following list identifies the possible resource types and their definitions: **`localization`** Identifies the localization in combination with the definition ID. **`consent`** Identifies the related localization combined with the definition ID.
`consentID`	The consent record ID, available only when the resource type is `consent`.
`subject`	The subject value, available only when the resource type is `consent`.
`subjectDN`	The subject's mapped LDAP DN. This is available only when the resource type is `consent`.
`actor`	The actor value. This is available only when the resource type is `consent`.
`actorDN`	The actor's mapped LDAP DN. This is available only when the resource type is `consent`.

Trace logger key	Description
`audience`	The audience value. This is available only when the resource type is `consent`.
`status`	The consent status. This is only available when the resource type is `consent`. Possible values are `pending`, `accepted`, `denied`, `revoked`, and `restricted`.
`previousStatus`	The previous consent status, if applicable. This is only available when the resource type is `consent`.
`msg`	A multiline value that includes the complete body of the changed resource. If the action is an `update` or a `delete`, the resource's body before the change is included.

Perform an audit

Consent resource changes for particular entities, such as a specific user or a specific consent definition, can be audited by searching the trace log using a combination of one of the message keys and the desired value.

For example, if an individual's LDAP distinguished name (DN) is known, the `subjectDN` key can be used to construct a text search for any audit log messages containing that DN. Any matching log messages constitute a history of that individual's consent activity.

New consent record example

This example shows an audit log message that provides important values in a parseable key/value format and includes a complete new consent record.

```
[22/May/2018:18:02:42.584 -0500] CONSENT AUDIT requestID=57 requestDN="uid=user.0,ou=people,
  dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24" subject="user.0" subjectDN="uid=user.
0,
  ou=People,dc=example,dc=com" actor="user.0" actorDN="uid=user.0,ou=People,dc=example,dc=com"
audience="client1"
  definitionID="cats" locale="en-US" status="accepted"
attrsAdded="actor,audience,createdDate,dataText,subject,
  purposeText,definition,id,updatedDate,actorDN,status,subjectDN" changeType="create"
resourceType="consent" msg="
New Consent Record:
    {'id':'6cff325b-e092-4094-b7f9-5a30864b0d24','status':'accepted','subject':'user.
0','subjectDN':'uid=user.0,
  ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.

    {'id':'6cff325b-e092-4094-b7f9-5a30864b0d24','status':'revoked','subject':'user.0','subjectDN':
   'uid=user.0,ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,
   dc=example,dc=com','audience':'client1','definition':{'id':'cats','version':'1.0','currentVersion':
   '1.0','locale':'en-US'},'dataText':'Collect data about your cats','purposeText':'To recommend cat food
   flavors that will satisfy and delight your feline companion','createdDate':'2018-05-22T23:02:42.553Z',
   'updatedDate':'2018-05-22T23:05:08.655Z'}"
```

Logging

Use the PingDirectory server trace log publisher for logging events generated by HTTP service operations.

About this task

You can use the trace logger to observe, debug, and audit consent requests.

Steps

- Create a trace logger for all consent events using `dsconfig create-log-publisher`.

> **Tip**
>
> To create a log of consent audit events only, remove all message types except for **`consent-message-type:audit`**.

Example:

The following example creates a trace logger for all consent events and summaries of HTTP requests and responses.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "Consent Trace Logger" \
  --type file-based-trace \
  --set "description:Records Consent API operations" \
  --set enabled:true \
  --set consent-message-type:audit \
  --set consent-message-type:consent-created \
  --set consent-message-type:consent-deleted \
  --set consent-message-type:consent-retrieved \
  --set consent-message-type:consent-search \
  --set consent-message-type:consent-updated \
  --set consent-message-type:definition-created \
  --set consent-message-type:definition-deleted \
  --set consent-message-type:definition-retrieved \
  --set consent-message-type:definition-search \
  --set consent-message-type:definition-updated \
  --set consent-message-type:error \
  --set consent-message-type:localization-created \
  --set consent-message-type:localization-deleted \
  --set consent-message-type:localization-retrieved \
  --set consent-message-type:localization-search \
  --set consent-message-type:localization-updated \
  --set http-message-type:request \
  --set http-message-type:response \
  --set 'exclude-path-pattern://.css' \
  --set 'exclude-path-pattern://.eot' \
  --set 'exclude-path-pattern://.gif' \
  --set 'exclude-path-pattern://.ico' \
  --set 'exclude-path-pattern://.jpg' \
  --set 'exclude-path-pattern://.js' \
  --set 'exclude-path-pattern://.png' \
  --set 'exclude-path-pattern://.svg' \
  --set 'exclude-path-pattern://.ttf' \
  --set 'exclude-path-pattern://.woff' \
  --set 'exclude-path-pattern://*.woff2' \
  --set 'exclude-path-pattern:/console/' \
  --set 'exclude-path-pattern:/console/template/' \
  --set log-file:logs/consent-trace \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy"
```

Correlating user and consent data

An organization that has been granted consent by a group of users can perform an LDAP search so that they can use the consent data in the aggregate.

About this task

For this task, consider the example scenario where a marketing group has collected consent to send a newsletter by email. To find all the users that have granted consent to receive emails, the marketing group performs a search that lists all of the consent records where the consent definition is `email` and the status is `accepted`. Then, the marketing group must correlate these consent records to user entries and retrieve each user's email address.

Every consent record contains a `subject` field, the user whose data is collected and stored. You can configure the Consent Service so that it stores the subject's distinguished name (DN) in the `subjectDN` field.

Steps

- Perform a search using the `ldapsearch` command.

  Example:

  > **Note**
  >
  > The example includes the following modifications in the `ldapsearch` command:
  > - To correlate the consent record entries to user entries and retrieve each user entry's `mail` attribute value, `ping-consent-subject-dn` is used.
  > - To find all of the relevant consent record entries, the LDAP search specifies values where `ping-consent-definition.id` is `email` and the `ping-consent-status` is `accepted`.

  ```
  $ bin/ldapsearch \
     --baseDN "ou=consents,dc=example,dc=com" \
     --searchScope sub \
     --joinRule "dn:ping-consent-subject-dn" \
     --joinBaseDN "ou=people,dc=example,dc=com" \
     --joinScope sub \
     --joinRequestedAttribute mail
     '&(ping-consent-definition:jsonObjectFilterExtensibleMatch:={ "filterType" : "equals", "field" : "id",
  "value" : "email" })(ping-consent-state=accepted)' \
     1.1
  ```

  - A consent record's `subjectDN` field is the `ping-consent-subject-dn` attribute.
  - A consent record's status is in the `ping-consent-state` JSON attribute field.
  - A consent record's definition ID is in the `ping-consent-definition.id` JSON attribute field.
  - A user entry's email address is in the `mail` attribute.

    Result:

    The example LDAP search returns the following results.

```
# Join Result Control:
   #      OID:  1.3.6.1.4.1.30221.2.5.9
   #      Join Result Code:  0 (success)
   #      Joined With Entry:
   #           dn: uid=user.0,ou=People,dc=example,dc=com
   #           mail: user.0@example.com
   dn: entryUUID=9e481010-8330-425a-bbf1-6637de053d48,ou=Consents,dc=example,dc=com

   # Result Code:  0 (success)
   # Number of Entries Returned:  1
```

> **Note**
>
> The `Join Result Control:` output specifies the `mail` value.

Troubleshooting the Consent Service

This section provides general guidelines for troubleshooting the Consent Service and any connection issues.

When evaluating the configuration:

- Make sure that the Consent Service is enabled.
- Make sure that the Consent Service base distinguished name (DN) exists.
- Make sure that the Consent Service's service account has the correct permissions.
- If the Consent Service should accept bearer tokens, make sure that:
  - One or more access token validators are configured correctly.
  - The identity mappers for the access token validators are configured correctly.
  - The authorization servers are configured correctly to issue tokens that the Consent Service can accept. Check the `audience`, `privileged-consent-scope`, and `unprivileged-consent-scope` properties of the Consent Service configuration.
- If privileged users are defined, make sure that the members of the Lightweight Directory Access Protocol (LDAP) group are specified by the Consent Service configuration's `privileged-users-group-dn` property.
- If there are applications that allow individuals to manage their own consents, make sure that the system is properly configured to map `actor` and `subject` DNs. Check the Consent Service configuration's `consent-record-identity-mapper` property.

Error cases

The following topic discusses troubleshooting possible error cases and solutions.

Consent Service is unavailable

If the Consent Service is unavailable, check the following:

- Ensure that the service is enabled and that communication with the service is available.
- Confirm that the service account for the Consent Service has been properly provisioned.
- If the Consent Service resides on a PingDirectoryProxy server, make sure that the service account exists on the PingDirectoryProxy server and all PingDirectory servers behind the PingDirectoryProxy server.

Requester lacks sufficient rights to perform operation

A request might be rejected with a 403 for the following reasons:

- The bearer token does not contain a required scope. Check the `privileged-consent-scope` and `unprivileged-consent-scope` properties of the Consent Service configuration.
- The bearer token does not contain a required `audience` claim. Check the `audience` property of the Consent Service configuration.
- Authentication was successful, but the requester is `unprivileged` and attempted to perform an operation that only a `privileged` requester can perform. For example, the requester attempted to act upon a consent record that it does not own, or it attempted to delete a consent record.

When using basic authentication, the requester must be listed in the Consent Service configuration `service-account-dn` property to be considered `privileged`.

Subject and actor do not match

Only a `privileged` requester can `create` or `modify` a consent record whose `subject` and `actor` values do not match.

Unindexed search

The Consent Service doesn't allow a client to make an unindexed search. In most cases, a client should be able to fix this by refining the search. For example, if a search by `subject` is unindexed, perform a search by `subject` and `definition` ID.

Search size limit exceeded

The Consent Service caps the maximum number of records that can be returned in a search result using its `search-size-limit` configuration property. This limit can be increased, or the client might be able to refine the search to produce fewer results.
