Disclaimer

The information provided in Ping Identity product documentation is provided "as is" without warranty of any kind. Ping Identity disclaims all warranties, either express or implied, including the warranties of merchantability and fitness for a particular purpose. In no event shall Ping Identity or its suppliers be liable for any damages whatsoever including direct, indirect, incidental, consequential, loss of business profits or special damages, even if Ping Identity or its suppliers have been advised of the possibility of such damages. Some states do not allow the exclusion or limitation of liability for consequential or incidental damages so the foregoing limitation may not apply.

Table of Contents

PingDirectory . . . 40
Release Notes . . . 45
Installing the PingDirectory Suite of Products . . . 111
System requirements . . . 113
Installing Java . . . 115
Preparing the operating system (Linux) . . . 115
Configuring the file descriptor limits . . . 116
Tuning the file system . . . 118
Setting the maximum user processes . . . 120
Editing OS-level environment variables . . . 120
Installing sysstat and pstack (Red Hat) . . . 120
Installing dstat (SUSE Linux) . . . 121
Disabling file system swapping . . . 121
Adjusting system memory allocation . . . 122
Omitting thevm.overcommit_memoryproperty . . . 122
Managing system entropy . . . 123
Setting file system event monitoring (inotify) . . . 123
Tuning the I/O scheduler . . . 123
Running as a non-root user (Linux) . . . 124
Obtaining a Ping Identity license key . . . 125
Upgrading a PingDirectory license . . . 126
Upgrading a license using the dsconfig command . . . 126
Upgrading a license using the administrative console . . . 127
Downloading the installation packages . . . 128
Pre-installation considerations . . . 129
Installing the servers . . . 130
Installing the PingDirectory server . . . 131
Installing the PingDirectoryProxy server . . . 142
Installing Delegated Admin . . . 149
Installation requirements . . . 149
Preparing to install the application . . . 150
Installing the application . . . 151
Completing the installation . . . 153
Verifying the installation . . . 156
Installing the PingDataSync server . . . 156
Installing the PingDataMetrics server . . . 160
Uninstalling the PingDirectory and PingDirectoryProxy servers . . . 166
Upgrading the servers . . . 170
Upgrade considerations . . . 170
PingDirectory, PingDirectoryProxy, and PingDataSync . . . 170

PingDirectory and PingDirectoryProxy . . . 171
Delegated Admin . . . 175
Upgrading the PingDirectory and PingDirectoryProxy servers . . . 176
Upgrading Delegated Admin . . . 182
Upgrading PingDataSync . . . 183
Upgrading PingDataMetrics . . . 187
Starting, stopping, and restarting the server . . . 191
Starting the server . . . 191
Starting the server at boot time . . . 192
Stopping the server . . . 195
Scheduling a server shutdown . . . 195
Restarting the server . . . 196
PingDirectory Server Administration Guide . . . 196
PingDirectory product documentation . . . 198
Introduction to the PingDirectory server . . . 198
Server features . . . 198
Administration framework . . . 201
Server tools location . . . 201
Getting started with the PingDirectory server . . . 202
Directory server folder layout . . . 203
Multiple backends . . . 204
Importing data . . . 205
Running the server as a Microsoft Windows service . . . 206
Running the status tool . . . 207
Tuning the server . . . 210
About minimizing disk access . . . 210
Memory allocation and database cache . . . 211
PingDirectory server process memory . . . 211
Determining heap and database cache size . . . 212
Automatic DB cache percentages . . . 213
Automatic memory allocation . . . 214
Automatic memory allocation for the command-line tools . . . 215
Database preloading . . . 215
Configuring database preloading . . . 216
Databases on storage area networks, network-attached storage, or running in virtualized environments . . . 218
Database cleaner . . . 219
Compacting common parent DNs . . . 219
Setting the import thread count . . . 220
JVM properties for server and command-line tools . . . 220
Applying changes using dsjavaproperties . . . 221
Tuning for disk-bound deployments . . . 222
Uncached attributes and entries . . . 222
Configuring uncached attributes and entries . . . 224

JVM garbage collection using CMS . . . 225
Determining the CMSInitiatingOccupancyFraction . . . 227
JVM garbage collection using ZGC . . . 229
Configuring the PingDirectory server . . . 229
About the configuration tools. . . . 230
About the dsconfig configuration tool . . . 230
Using dsconfig in interactive command-line mode . . . 234
Configuring the PingDirectory server using dsconfig interactive mode . . . 234
Changing the dsconfig object menu . . . 236
dsconfig interactive administrative alerts . . . 237
Using dsconfig in non-interactive mode . . . 237
Configuring the Server using dsconfig non-interactive mode . . . 239
Getting the equivalent dsconfig non-interactive mode command . . . 240
Using dsconfig batch mode . . . 241
Using the PingDirectory server or the PingDirectoryProxy server with PingFederate OAuth tokens . . . 242
About recurring tasks and task chains. . . . 244
Creating a recurring task and task chain. . . . 245
LDIF export as a recurring task . . . 246
Lockdown mode as a recurring task . . . 246
File retention recurring task . . . 247
Using exec tasks . . . 247
Using custom rebranding . . . 249
Topology configuration . . . 250
Topology primary requirements and selection . . . 250
Topology components . . . 251
Monitor data for the topology . . . 252
Configure passphrase providers . . . 253
Using the Configuration API. . . . 254
Authentication and authorization with the Configuration API . . . 255
The Configuration API and the dsconfig tool relationship . . . 255
GET example . . . 257
GET list example. . . . 259
PATCH example . . . 261
Configuration API paths . . . 264
Sort and filter objects. . . . 265
Update properties . . . 266
Administrative actions . . . 268
Updating servers and server groups . . . 268
Configuration API responses . . . 269
Generating a summary of configuration components. . . . 270
Administrator account classes . . . 271
Using separate administrator accounts . . . 271
Unpredictable identifiers for server administrators . . . 274

Secure communication for server administrators . . . 274
Managing root user accounts . . . 275
Default root privileges . . . 275
Configuring administrator accounts . . . 277
Configuring a global administrator . . . 283
Configuring server groups . . . 284
Client connection policy configuration . . . 286
About the client connection policy . . . 287
When a client connection policy is assigned . . . 287
Restricting the type of search filter used by clients . . . 288
Resource limits . . . 288
Defining the operation rate . . . 292
Client connection policy deployment example . . . 293
Define the connection policies . . . 293
How the policy is evaluated . . . 294
Configuring a client connection policy using the console . . . 295
Configuring a client connection policy using dsconfig . . . 296
Restricting server access based on client IP address . . . 297
Securing the Server with lockdown mode . . . 300
Configuring maximum shutdown time . . . 301
About working with referrals . . . 301
Specifying LDAP URLs . . . 302
Creating referrals . . . 303
Modifying a referral . . . 304
Deleting a referral . . . 304
Configuring a read-only server . . . 305
Configuring HTTP access for the PingDirectory server . . . 306
Configuring HTTP Servlet Extensions . . . 306
Configuring HTTP operation loggers . . . 308
Example HTTP log publishers . . . 309
Configuring HTTP connection handlers . . . 311
Configuring the PingDirectory server to use an HTTP proxy server . . . 319
DNS caching . . . 321
IP address reverse name lookups . . . 322
Configuring traffic through a load balancer . . . 323
Working with the Referential Integrity plugin . . . 324
Working with the Unique Attribute plugin . . . 325
Working with the Purge Expired Data plugin . . . 326
Configuring uniqueness across attribute sets . . . 329
Working with the Last Access Time plugin . . . 333
Working with pass-through authentication . . . 333
Configuring pass-through authentication to LDAP servers . . . 336
The PingOne Pass-Through Authentication plugin . . . 338
Configuring pass-through authentication to custom services . . . 342

Troubleshooting server performance issues . . . 343
Configuring the PingDirectory server for Oracle compatibility . . . 347
Supporting unindexed search requests . . . 348
Syncing passwords to PingOne . . . 349
Single sign-on with the administrative console . . . 350
Setting up SSO to PingDirectory from PingOne . . . 353
Setting up SSO to PingDirectory from PingFederate . . . 354
Configuring PingFederate for SSO . . . 354
Configuring PingDirectory for SSO . . . 360
Setting up SSO to PingDirectory from a generic OpenID Connect provider . . . 363
Using the administrative console . . . 365
Signing on to and configuring the administrative console . . . 365
Working with the schema . . . 376
About the schema editor . . . 376
Using the schema editor utilities . . . 377
Modifying the schema . . . 378
Managing tasks . . . 382
Collecting support data from the administrative console . . . 382
Generating the server profile from the administrative console . . . 384
Creating a file based access log publisher . . . 385
About recurring tasks and task chains . . . 386
Scheduling LDIF export as a recurring task . . . 387
Monitoring with the administrative console . . . 389
Removing the administrative console . . . 390
Configuring Soft Deletes . . . 391
About soft deletes . . . 391
General tips on soft deletes . . . 392
Configuring soft deletes on the server . . . 394
Configuring soft deletes as a global configuration . . . 395
Searching for soft deletes . . . 397
Undeleting a soft-deleted entry using the same RDN . . . 400
Undeleting a soft-deleted entry using a new RDN . . . 401
Modifying a soft-deleted entry . . . 402
Hard deleting a soft-deleted entry . . . 403
Configuring soft deletes by connection criteria . . . 404
Configuring soft deletes by request criteria . . . 405
Configuring soft-delete automatic purging . . . 406
Soft and hard delete processes . . . 408
Soft delete controls and tool options . . . 409
Monitor soft deletes . . . 411
Disabling soft deletes as a global configuration . . . 416
Importing and exporting data . . . 416
Importing data . . . 417
Running an offline import . . . 418

Running an online LDIF import . . . 420
Adding entries to an existing PingDirectory server . . . 422
Filtering data import . . . 423
Exporting data . . . 423
Encrypting LDIF exports and signing LDIF files . . . 424
Filtering data exports . . . 426
Scrambling data files . . . 427
Backing up and restoring data . . . 429
About backing up and restoring data . . . 429
Retaining backups . . . 430
Moving or restoring a user database . . . 436
Comparing the data in two PingDirectory servers . . . 436
Reverting or replaying changes . . . 441
Working with groups . . . 443
Overview of groups . . . 443
About the isMemberOf and isDirectMemberOf virtual attribute . . . 444
Using static groups . . . 446
Creating static groups . . . 448
Searching static groups . . . 451
Using dynamic groups . . . 453
Creating dynamic groups . . . 454
Searching dynamic groups . . . 456
Using dynamic groups for internal operations . . . 459
Using virtual static groups . . . 459
Creating virtual static groups . . . 460
Searching virtual static groups . . . 462
Creating nested groups . . . 463
Maintaining referential integrity with static groups . . . 465
Monitoring the group membership cache . . . 467
Using the entry cache to improve the performance of large static groups . . . 468
Tuning the index entry limit for large groups . . . 470
Summary of commands to search for group membership . . . 471
Migrating Oracle groups . . . 472
Working with indexes . . . 475
Overview of indexes . . . 475
General tips on indexes . . . 476
Index types . . . 478
System indexes . . . 479
Managing local DB indexes . . . 480
Composite indexes . . . 484
JSON indexes . . . 486
Working with local DB VLV indexes . . . 487
Working with filtered indexes . . . 490

Tuning indexes . . . 492
About the exploded index format. . . . 492
About monitoring index entry limits . . . 493
About the dbtest Index Status table . . . 494
Configuring the index properties . . . 495
About the Index Summary Statistics table . . . 496
Managing entries . . . 497
Searching entries . . . 498
Working with the matching entry count control . . . 504
Adding entries . . . 506
Deleting entries using ldapdelete . . . 509
Deleting entries using ldapmodify . . . 510
Modifying entries using ldapmodify . . . 511
Working with the parallel-update tool . . . 518
Working with the watch-entry tool . . . 520
Working with LDAP transactions . . . 521
Working with virtual attributes. . . . 522
Viewing the list of default virtual attributes. . . . 523
Viewing the list of default virtual attributes using dsconfig non-interactive mode . . . 525
Viewing virtual attribute properties . . . 525
Enabling a virtual attribute . . . 526
Creating user-defined virtual attributes . . . 527
Creating mirror virtual attributes . . . 530
Editing a virtual attribute . . . 532
Deleting a virtual attribute . . . 532
Working with composed attributes . . . 533
Virtual attribute limitations . . . 533
Overview of composed attributes . . . 535
Composed attribute plugin configuration properties . . . 535
Populate composed attribute values task. . . . 543
Composed attribute dependency considerations . . . 544
Schema validation considerations . . . 545
Replication considerations . . . 545
Synchronization server considerations . . . 546
PingDirectoryProxy server considerations . . . 546
Troubleshooting considerations . . . 546
Security considerations . . . 546
Limitations of composed attributes relative to virtual attributes . . . 547
Encrypting sensitive data . . . 547
About encrypting and protecting sensitive data . . . 548
About the encryption settings database . . . 548
Supported encryption ciphers and transformations . . . 549
Using the encryption-settings tool . . . 551
Creating encryption settings definitions . . . 552

Changing the preferred encryption settings definition . . . 554
Deleting an encryption settings definition . . . 554
Configuring data encryption restrictions . . . 555
Freezing the encryption settings database . . . 556
Encrypting and decrypting files . . . 558
About backing up and restoring the encryption settings definitions . . . 559
Exporting encryption settings definitions . . . 560
Importing encryption settings definitions . . . 561
Enabling data encryption in the server . . . 562
Using data encryption in a replicated environment . . . 564
Handling compromised encryption settings definitions . . . 564
Configuring sensitive attributes . . . 566
Configuring global sensitive attributes . . . 569
Excluding a global sensitive attribute on a client connection policy . . . 570
Working with the LDAP changelog . . . 571
Overview of the LDAP changelog . . . 571
Viewing the LDAP changelog properties . . . 577
Enabling the LDAP changelog . . . 578
Changing the LDAP changelog database location . . . 579
Viewing the LDAP changelog parameters in the Root DSE . . . 580
Viewing the LDAP changelog, change sequence numbers, and monitoring information . . . 582
Indexing the LDAP changelog . . . 585
Tracking virtual attribute changes in the LDAP changelog . . . 586
Managing the schema . . . 587
About the schema . . . 587
About the schema editor . . . 587
Default PingDirectory server schema files . . . 589
Extending the PingDirectory server schema . . . 590
About managing attribute types . . . 592
Attribute type definitions . . . 593
Basic properties of attributes . . . 594
Viewing attributes . . . 595
Creating a new attribute over LDAP . . . 597
Managing object classes . . . 599
Managing an object class over LDAP . . . 602
Creating a new object class using the schema editor . . . 604
Extending the schema using a custom schema file . . . 605
About managing matching rules . . . 608
Matching rule definition . . . 608
Default matching rules . . . 608
Basic matching rule properties . . . 614
Viewing matching rules . . . 615

About managing attribute syntaxes . . . 615
Attribute syntax definition . . . 616
Default attribute syntaxes . . . 616
Basic attribute syntax properties . . . 620
Viewing attribute syntaxes . . . 620
Using the schema editor utilities . . . 621
Modifying a schema definition . . . 622
Deleting a schema definition . . . 622
Managing schema checking . . . 623
Managing matching rule uses . . . 624
Managing DIT content rules . . . 625
Managing name forms . . . 626
Managing DIT structure rules . . . 627
About managing JSON attribute values . . . 628
Configuring JSON attribute constraints . . . 630
Managing password policies . . . 636
Viewing password policies . . . 637
About the password policy properties . . . 639
Access log . . . 641
Replication considerations . . . 644
Get Recent Login History control . . . 644
Modifying an existing password policy . . . 645
Creating new password policies . . . 646
Deleting a password policy . . . 649
Modifying a user's password . . . 649
Enabling YubiKey authentication . . . 652
Enabling social sign-on . . . 653
Managing user accounts . . . 653
Bypassing password policy evaluation . . . 657
Managing password validators . . . 658
Password validators . . . 658
Configuring password validators . . . 660
Managing replication . . . 667
Overview of replication . . . 667
Replication versus synchronization . . . 668
Replication terminology . . . 670
Replication architecture . . . 673
Replication deployment planning . . . 674
Enabling replication . . . 677
Overview . . . 678
Command-line interface . . . 678
What happens when you enable replication . . . 679
Initialization . . . 679
Replica generation ID . . . 680

Deploying a basic replication topology . . . 681
Example deployment with non-interactive dsreplication . . . 685
Configuring assured replication . . . 690
Managing the topology . . . 698
Advanced configuration . . . 703
Modifying the replication purge delay . . . 704
Configuring a single listener-address for the replication server . . . 705
Monitoring replication . . . 705
Replication best practices . . . 707
Replication conflicts . . . 709
Troubleshooting replication . . . 716
Replication reference . . . 722
Summary of the dsreplication Subcommands . . . 722
Summary of the Direct LDAP Monitor information . . . 723
Summary of the Indirect LDAP Server Monitor information . . . 727
Summary of the Remote Replication Server Monitor information . . . 728
Summary of the Replica Monitor information . . . 733
Summary of the Replication Server Monitor information . . . 735
Summary of the Replication Server Database Monitor information . . . 735
Summary of the Replication Server Database Environment Monitor information . . . 736
Summary of the Replication Summary Monitor information . . . 742
Summary of the replicationChanges Backend Monitor information . . . 743
Summary of the Replication Protocol Buffer Monitor information . . . 744
Advanced topics reference . . . 745
About the replication protocol . . . 745
Change number . . . 747
Conflict resolution . . . 748
WAN-friendly replication . . . 750
WAN Gateway Server . . . 750
WAN message routing . . . 752
WAN Gateway Server selection . . . 753
WAN replication in mixed-version environments . . . 753
Recovering a replication changelog . . . 753
Performing disaster recovery . . . 754
Managing logging . . . 755
Default PingDirectory server logs . . . 756
Types of log publishers . . . 757
Viewing the list of log publishers . . . 761
Enabling or disabling a default log publisher . . . 762
Managing access and error log publishers . . . 762
Managing file-based access log publishers . . . 763
Access log format . . . 764
Access log example . . . 765

Modifying the access log using dsconfig interactive mode 766
Modifying the access log usingdsconfignon-interactive mode 766
Modifying the maximum length of log message strings 767
Disabling logging of inter-server periodic search requests 767
Generating access log summaries 768
About log compression 771
About log signing 771
About encrypting log files 772
Log sanitization 774
Log sanitization options 775
Customizing log field syntaxes 781
Customizing log field behaviors 782
Creating new log publishers. 784
Configuring log rotation 786
Configuring log rotation listeners 786
Configuring log retention 787
Configuring filtered logging 788
Managing Admin Alert Access Logs 789
Managing the Syslog-Based Access Log Publishers 792
Managing the File-Based Audit Log Publishers 795
Managing the JDBC Access Log Publishers 797
Managing the File-Based Error Log Publisher 802
Managing the Syslog-Based Error Log Publisher 804
Creating File-Based Debug Log Publishers 805
Monitoring PingDirectory metrics with Splunk. 806
Sending PingDirectory metrics with StatsD 806
Configuring a StatsD monitoring endpoint 806
Configuring Splunk to receive StatsD metrics 806
Sending Metrics with the Periodic Stats Logger and the Splunk Universal Forwarder. 807
Using the PingDirectory server app for Splunk 808
Monitoring server metrics with Prometheus 808
Managing notifications and alerts 812
Account status notifications 812
Account status notification types 813
Working with the Error Log Account Status Notification Handler 814
Disabling the Error Log Account Status Notification Handler . . . 814
Removing a notification type from the Error Log Handler 814
Working with the SMTP Account Status Notification Handler 814
Configuring the SMTP server 815
Configuring a StartTLS connection to the SMTP server 815
Configuring an SSL connection to the SMTP server 816
Enabling the SMTP account status notification handler 816
Viewing the account status notification handlers 817

Associating account status notification handlers with password policies . . 817
Administrative alert handlers 817
Administrative alert types 818
Configuring the JMX connection handler and alert handler. 818
Configuring the JMX connection handler. 818
Configuring the JMX alert handler 819
Configuring the SMTP alert handler 819
Configuring the SNMP subagent alert handler 820
Email account status notification handler. 821
Working with the Alerts Backend. 837
Working with alarms, alerts, and gauges 839
Testing alerts and alarms 841
Managing SCIM servlet extensions 844
Managing SCIM 1.1 and 2.0 servlet extensions 844

Introduction to the PingDirectoryProxy server . . . 940
Overview of the PingDirectoryProxy features . . . 940
Overview of the PingDirectoryProxy server components and terminology . . . 941
About locations . . . 942
About LDAP external servers . . . 942
About LDAP health checks . . . 943
About load-balancing algorithms . . . 945
Proxy transformations . . . 946
About request processors . . . 946
About server affinity providers . . . 947
About subtree views . . . 947
About the connection pools . . . 948
About client connection policies . . . 948
About entry balancing . . . 949
Server component architecture . . . 949
PingDirectoryProxy server configuration overview . . . 953
Running the server as a Microsoft Windows service . . . 954
Configuring the PingDirectoryProxy server . . . 955
About the configuration tools . . . 955
Using the create-initial-proxy-config tool . . . 956
Configuring a standard PingDirectoryProxy server deployment . . . 956
About the dsconfig configuration tool . . . 960
Using dsconfig in interactive command-line mode . . . 965
Changing the dsconfig object menu . . . 965
Using dsconfig in non-interactive mode . . . 966
Getting the equivalentdsconfignon-interactive mode command . . . 967
Using dsconfig batch mode . . . 968
Using the PingDirectory server or the PingDirectoryProxy server with PingFederate OAuth tokens . . . 969
Topology configuration . . . 971
Topology primary requirements and selection . . . 971
Topology components . . . 972
Monitor data for the topology . . . 973
Using the Configuration API . . . 974
Authentication and authorization with the Configuration API . . . 975
The Configuration API and the dsconfig tool relationship . . . 975
GET example . . . 976
GET list example . . . 979
PATCH example . . . 981
Configuration API paths . . . 984
Sort and filter objects . . . 985
Update properties . . . 986
Administrative actions . . . 988
Updating servers and server groups . . . 988

Configuration API responses . . . 989
Managing the Directory REST API . . . 990
Configuring server groups . . . 993
Generating a summary of configuration components . . . 996
DNS caching . . . 996
IP address reverse name lookups . . . 997
Configuring traffic through a load balancer usingdsconfig . . . 998
Managing root user accounts . . . 999
Default root privileges . . . 999
Configuring locations . . . 1002
Configuring batched transactions . . . 1007
Configuring server health checks . . . 1008
About the default health checks . . . 1009
About creating a custom health check . . . 1009
Configuring a health check usingdsconfig . . . 1010
Configuring LDAP external servers . . . 1013
Configuring load balancing . . . 1020
Configure failover load-balancing for load spreading . . . 1021
Configuring load balancing usingdsconfig . . . 1023
Configuring criteria-based load-balancing algorithms . . . 1024
Understanding failover and recovery . . . 1032
Configuring HTTP connection handlers . . . 1033
Configuring an HTTP connection handler . . . 1034
HTTP correlation IDs . . . 1036
Configuring HTTP correlation ID support . . . 1037
HTTP correlation ID example . . . 1038
Configuring the PingDirectoryProxy server to use an HTTP proxy server . . . 1040
Configuring proxy transformations . . . 1042
Configuring proxy transformations usingdsconfig . . . 1043
Configuring request processors . . . 1045
Configuring request processors usingdsconfig . . . 1045
Passing LDAP controls with the proxying request processor . . . 1047
Configuring server affinity . . . 1047
Configuring subtree views . . . 1049
Client connection policy configuration . . . 1050
About the client connection policy . . . 1051
When a client connection policy is assigned . . . 1051
Restricting the type of search filter used by clients . . . 1052
Defining Request Criteria . . . 1052
Setting Resource Limits . . . 1053
Defining the operation rate . . . 1053
Client connection policy deployment example . . . 1054
Define the connection policies . . . 1054
How the policy is evaluated . . . 1055

Configuring a client connection policy usingdsconfig 1055
Configuring globally unique attributes 1058
Configuring the Global Referential Integrity plugin 1059
Configuring an Active Directory Server back-end 1060
Deploying a standard PingDirectoryProxy server 1062
Introduction 1063
Automatic server discovery 1064
Joining a PingDirectoryProxy server to an existing PingDirectory server topology 1064
Creating an LDAP external server template 1072
Defining the load-balancing algorithm configuration 1073
Associating PingDirectory server instances with the appropriate load-balancing algorithms 1077
Automatic backend server discovery with entry balancing 1078
Creating a standard multi-location deployment 1078
Overview of the deployment steps 1079
Installing the first PingDirectoryProxy server 1079
Configuring the first PingDirectoryProxy server 1080
Defining locations 1081
Configuring the external servers in the east and west locations 1082
Apply the configuration to the PingDirectoryProxy server 1083
Configuring additional PingDirectoryProxy server instances 1083
Testing external server communications after initial setup 1084
Testing a simulated external server failure 1086
Expanding the deployment 1087
Overview of deployment steps 1088
Preparing two new external servers using the prepare-external-server tool 1088
Adding the new PingDirectory servers to the PingDirectoryProxy server . . 1089
Adding new locations 1090
Editing the existing locations 1090
Adding new health checks for the central servers 1091
Adding new external servers 1092
Modifying the load-balancing algorithm 1093
Testing external server communications after initial setup 1093
Testing a simulated external server failure 1095
Merging two data sets using proxy transformations 1096
Overview of the attribute and DN mapping 1096
About mapping multiple source DNs to the same target DN 1097
Example of a migrated sample customer entry 1098
Overview of deployment steps 1099
About the schema 1099
Creating proxy transformations 1100
Creating the Attribute Mapping Proxy Transformations 1101
Creating the DN mapping proxy transformations 1101

Creating a request processor to manage the proxy transformations 1102
Creating subtree views 1103
Editing the client connection policy 1104
Testing proxy transformations 1104
Deploying an entry-balancing PingDirectoryProxy server 1107
Deploying an entry-balancing proxy configuration 1107
Determining how to balance your data 1108
Entry balancing and ACIs 1109
Overview of deployment steps 1109
Installing the PingDirectoryProxy server 1109
Configuring the entry-balancing PingDirectoryProxy server 1110
Configuring the placement algorithm using a batch file 1120
Rebalancing your entries 1122
About dynamic rebalancing 1122
Configuring dynamic rebalancing 1124
About the move-subtree tool 1125
About the subtree-accessibility tool 1125
Managing the global indexes in entry-balancing configurations 1126
Creating a global attribute index 1126
Reloading the global indexes 1127
Monitoring the size of the global indexes 1129
Sizing the global indexes 1129
Priming the global indexes on startup 1130
Priming or reloading the global indexes from Sun Directory servers 1133
Working with alternate authorization identities 1133
About alternate authorization identities 1134
Configuring alternate authorization identities 1136
Managing entry-balancing replication 1137
Overview of replication in an entry-balancing environment 1137
Replication prerequisites in an entry-balancing deployment 1138
About the --restricted argument of the dsreplication command-line Tool 1139
Using the --restricted argument of the dsreplication command-line tool . . 1139
Checking the status of replication in an entry-balancing deployment 1140
Example of configuring entry-balancing replication 1141
Managing the PingDirectoryProxy server 1148
Managing logs 1148
About the default logs 1149
Error log 1149
server.out log 1150
Debug log 1150
Audit log 1151
Config audit log and the configuration archive 1151
Access and audit log 1152
Setup log 1153

Tool log . . . 1153
LDAP SDK debug log . . . 1154
Types of log publishers . . . 1154
Creating new log publishers. . . . 1155
About log compression . . . 1156
About log signing . . . 1156
About encrypting log files . . . 1157
Configuring log rotation . . . 1159
Configuring log rotation listeners . . . 1160
Configuring log retention . . . 1161
Setting resource limits . . . 1162
Monitoring the PingDirectoryProxy server . . . 1164
Working with alarms, alerts, and gauges . . . 1168
Administrative alert handlers . . . 1172
Configuring the JMX connection handler and alert handler . . . 1173
Configuring the SMTP alert handler . . . 1174
Configuring the SNMP subagent alert handler . . . 1175
Working with virtual attributes . . . 1175
DevOps and infrastructure as code . . . 1176
Server profiles . . . 1177
Variable substitution . . . 1179
Profile structure . . . 1179
setup-arguments.txt . . . 1180
dsconfig/ and pre-setup-dsconfig/ . . . 1180
server-root/ . . . 1181
server-sdk-extensions/ . . . 1181
variables-ignore.txt . . . 1181

About the manage-profile tool . . . 1182
manage-profile generate-profile. . . . 1182
manage-profile setup . . . 1183
manage-profile replace-profile. . . . 1183
Server profiles in a pets service model . . . 1184
Managing Server SDK extensions . . . 1184
About the Server SDK . . . 1184
Available types of extensions . . . 1185
Command-line tools . . . 1186
Available command-line tools . . . 1186
Saving options in a file . . . 1206
Evaluation of command-line options and file options . . . 1206
Creating a tools properties file . . . 1208
Sampledsconfigbatch files. . . . 1209
Running task-based tools . . . 1209

Consent Solution Guide . . . 1211
Introduction to the Consent Service and Consent API . . . 1213
Consent Service overview . . . 1213
Consent API overview . . . 1214
How consents are collected . . . 1214
How consents are enforced . . . 1214
How applications use the Consent API . . . 1215
Configuring the Consent Service . . . 1215
Configuration overview . . . 1216
Example configuration scenarios . . . 1216
Setting up with the configuration scripts . . . 1217
Setting up in a replicated PingDirectory server environment . . . 1218
Configuration reference . . . 1219
General Consent Service configuration . . . 1219
Creating a container entry for consent records . . . 1221
Creating an internal service account . . . 1221
Configuring an identity mapper . . . 1223
Authentication methods . . . 1225
Configuring basic authentication . . . 1226
Configuring bearer token authentication . . . 1227
Configuring Consent Service scopes . . . 1228
Authorization . . . 1229
Managing Consents . . . 1232
Overview of consent management . . . 1232
Consent definitions and localizations . . . 1232
Creating a consent definition and localization . . . 1233
Perform an audit on consents . . . 1233
Logging . . . 1238
Correlating user and consent data . . . 1239
Troubleshooting the Consent Service . . . 1241
Error cases . . . 1241
Delegated Admin Application Guide . . . 1242
Introduction to Delegated Admin . . . 1244
Configuring Delegated Admin . . . 1245
Configuration overview . . . 1245
Authentication configuration . . . 1245
Configuring delegated administrator rights on the PingDirectory server . . . 1246
Parameterized Delegated Administrator Rights . . . 1249
Configuring user self-service . . . 1250
Configuring attributes and attribute search on the PingDirectory server . . . 1253
Users and groups . . . 1257
Enable user creation . . . 1257
Enabling Account Information tab content . . . 1259
Setting up initiate password reset for REST resource types . . . 1260

Manage groups . . . 1261
Viewing groups . . . 1264
Create a group . . . 1264
Adding a user to a group . . . 1265
Unlocking user accounts . . . 1267
Enabling the Delegated Admin user REST resource type photo upload feature . . . 1268
Uploading a photo to a user REST resource type profile in Delegated Admin . . . 1270
Enabling the Delegated Admin user REST resource type certificate upload feature . . . 1271
Uploading a certificate to a user REST resource type profile in Delegated Admin . . . 1274
Generic resource types . . . 1275
Defining a generic resource type . . . 1276
Working with correlated REST resources . . . 1276
Setting up a DN reference attribute . . . 1279
Differentiating resource types within the same subtree . . . 1282
Configuring a resource's summary display in the Delegated Admin GUI . . . 1283
Customizing UI form fields . . . 1284
Setting up email invitations for a new user . . . 1286
Enabling the referential integrity plugin . . . 1289
Enabling log tracing . . . 1290
Specify a custom hostname and port for your PingDirectory server . . . 1290
Changing the application logo . . . 1291
Configure the session timeout . . . 1291
Reporting . . . 1292
Compatibility matrix . . . 1292
Configuring the PingFederate server . . . 1293
Configuring PingFederate as the identity provider . . . 1293
Configuring the OAuth server . . . 1296
Configuring the PingDirectory server as the token validator (create OAuth client for PingDirectory) . . . 1298
Configuring Delegated Admin as a new client (create OAuth client for Delegated Admin) . . . 1298
Setting cross-origin resource sharing (CORS) settings . . . 1300
Optional configuration tasks . . . 1300
Changing the default OIDC grant type . . . 1301
PingDataSync Server Administration Guide . . . 1301
PingDirectory product documentation . . . 1303
Introduction to the PingDataSync server . . . 1303
Data synchronization process . . . 1304
Synchronization modes . . . 1306
PingDataSync operations . . . 1306
Configuration components . . . 1308

Sync flow examples . . . 1310
Sample synchronization . . . 1315
Server folders and files . . . 1316
Changing the administrative password . . . 1318
Running the server as a Microsoft Windows service . . . 1318
Configuring the PingDataSync server . . . 1319
Configuration checklist . . . 1320
Sync user account . . . 1323
Configure PingDataSync in standard mode . . . 1324
Using the create-sync-pipe tool to configure synchronization . . . 1325
Configuring attribute mapping . . . 1327
Configuring server locations . . . 1329
Using the Configuration API . . . 1330
Authentication and authorization . . . 1330
Relationship between the Configuration API and thedsconfigtool . . . 1331
API paths . . . 1340
Sorting and filtering configuration objects . . . 1341
Update properties . . . 1342
Administrative actions . . . 1344
Update servers and server groups . . . 1344
Configuration API responses . . . 1345
Configuration with thedsconfigtool . . . 1346
Usingdsconfigin interactive mode . . . 1347
Usingdsconfigin non-interactive mode . . . 1347
Usingdsconfigbatch mode . . . 1348
Topology configuration . . . 1349
Domain Name Service (DNS) caching . . . 1351
IP address reverse name lookups . . . 1352
Configure the synchronization environment withdsconfig . . . 1352
Prepare external server communication . . . 1353
HTTP connection handlers . . . 1354
Configure an HTTP connection handler . . . 1355
HTTP correlation IDs . . . 1357
Configuring the PingDataSync server to use an HTTP proxy server . . . 1361
Theresynccommand . . . 1363
Test attribute and DN maps . . . 1363
Verify the synchronization configuration . . . 1364
Populate an empty sync destination topology . . . 1364
Set the synchronization rate . . . 1365
Synchronize a specific list of DNs . . . 1366
Therealtime-synctool . . . 1367
Start real-time synchronization globally . . . 1367
Start or Pause synchronization . . . 1368
Set startpoints . . . 1368

Restart synchronization at a specific change log event 1369
Change the synchronization state by a specific time duration 1370
Schedule a real-time sync as a task 1371
Configure the PingDirectory server backend for synchronizing deletes 1371
Configure DN maps 1372
About attribute mappings 1374
Configure synchronization with JSON attribute values 1377
SynchronizingubidEmailJSONfully 1378
Synchronizing a subset of fields from the source attribute 1378
Retaining destination-only fields 1379
Synchronizing a field of a JSON attribute into a non-JSON attribute 1380
Synchronizing a non-JSON attribute into a field of a JSON attribute 1381
Synchronizing multiple non-JSON attributes into fields of a JSON attribute . 1382
Correlating attributes based on JSON fields 1383
Configure fractional replication 1383
Configure failover behavior 1386
Conditions that trigger immediate failover 1387
Failover server preference 1387
Configuration properties that control failover behavior 1388
Themax-operation-attemptsproperty 1390
Theresponse-timeoutproperty 1390
Themax-failover-error-code-frequencyproperty 1391
Themax-backtrack-replication-latencyproperty 1391
Configure traffic through a load balancer 1392
Configure authentication with a SASL external certificate 1393
Configure an LDAPv3 Sync Source 1394
Server SDK extensions 1395
Synchronize with PingOne 1395
Prerequisites 1396
Synchronize changes to a PingOne environment 1399
Synchronize changes from a PingOne environment 1403
Testing and troubleshooting the sync 1405
PingOne synchronization limitations 1405
Synchronize with Active Directory and other directory servers 1406
Overview of configuration tasks 1407
Configuring one way synchronization from Active Directory to PingDirectory 1408
Mapping AD password policy state attributes to PingDirectory usingdsconfig 1411
Active Directory sync user account 1412
Preparing external servers 1413
Configuring sync pipes and sync classes 1413
Configuring password encryption 1415
Password sync agent 1416
Synchronize with Relational Databases 1419
Use the server SDK 1419

RDBMS synchronization process . . . 1420
DBSync example . . . 1421
Configure DBSync . . . 1422
Create the JDBC extension . . . 1423
Configure the database for synchronization . . . 1425
Considerations for synchronizing to database destination . . . 1427
Configure a directory-to-database sync pipe . . . 1428
Considerations for synchronizing from a database source . . . 1431
Synchronize a specific list of database elements . . . 1432
Synchronize with Apache Kafka . . . 1433
Restrictions . . . 1433
Configure a Kafka sync destination . . . 1433
Message format . . . 1435
Synchronize through PingDirectoryProxy servers . . . 1438
Synchronization through a PingDirectoryProxy server overview . . . 1438
Example configuration . . . 1441
Configure the source PingDirectory server . . . 1442
Configure a proxy server . . . 1443
Configure PingDataSync . . . 1446
Test the configuration . . . 1447
Index the LDAP changelog . . . 1449
Changelog synchronization considerations . . . 1450
Synchronize in notification mode . . . 1451
Notification mode overview . . . 1451
Notification mode architecture . . . 1453
Configure notification mode . . . 1456
Implementing the server extension . . . 1458
Configure the Notification sync pipe . . . 1459
Access control filtering on the sync pipe . . . 1462
Configuring Synchronization with SCIM . . . 1463
Synchronize with a SCIM sync destination overview . . . 1463
Configure synchronization with SCIM . . . 1465
Configure the external servers . . . 1466
Configure the PingDirectory server sync source . . . 1466
Configure the SCIM sync destination . . . 1467
Configure the sync pipe, sync classes, and evaluation order . . . 1468
Configure communication with the source server . . . 1469
Start the sync pipe . . . 1470
Map LDAP schema to SCIM resource schema . . . 1470
Identify a SCIM resource at the destination . . . 1476
Configuring synchronization to a SCIM 2.0 server . . . 1477
Configure the sync source . . . 1479
Configure the changelog password decryption key in the PingDataSync server (optional) . . . 1479

Configure the SCIM 2.0 external server . . . 1480
Configure SCIM 2.0 attribute mappings . . . 1482
String SCIM 2.0 attribute mappings . . . 1484
Number SCIM 2.0 attribute mappings . . . 1485
Boolean SCIM 2.0 attribute mappings . . . 1485
DateTime SCIM 2.0 attribute mappings . . . 1486
Postal address SCIM 2.0 attribute mappings . . . 1487
Dot notation support for SCIM 2.0 sub-attributes . . . 1488
Composed complex SCIM 2.0 attribute mappings . . . 1490
JSON-formatted complex SCIM 2.0 attribute mappings . . . 1491
Custom SCIM 2.0 attribute mappings for extended schemas . . . 1491
Configure SCIM 2.0 endpoint mappings . . . 1493
Configure the SCIM 2.0 sync destination . . . 1495
Configure a sync pipe . . . 1496
Configure sync classes . . . 1496
Set the changelog startpoint for the sync source (optional) . . . 1498
Perform an initial bulk synchronization with theresynccommand . . . 1499
Start real-time synchronization . . . 1499
Managing Logging, Alerts, and Alarms . . . 1500
Logs and log publishers . . . 1500
Synchronization logs and messages . . . 1503
Sync log message types . . . 1504
Creating a new log publisher . . . 1505
Configuring log signing . . . 1506
Configure log retention and log rotation policies . . . 1507
Configure log listeners . . . 1509
System alarms, alerts, and gauges . . . 1510
Testing alerts and alarms . . . 1511
Use the status tool . . . 1513
Synchronization-specific status . . . 1513
Enabling and configuring the StatsD monitoring endpoint . . . 1515
Monitor PingDataSync . . . 1517

PingDirectory

The PingDirectory suite of products includes the PingDirectory server, the PingDirectoryProxy server, the Delegated Admin application, the PingDataSync server, and the PingDataMetrics server.

Release Notes

- Current
- Previous releases

Copyright © 2025 Ping Identity Corporation

Get Started with PingDirectory

PingDirectory

A high-performance, extensible LDAP directory.

- Introduction to the PingDirectory server
- Installing the PingDirectory server
- Upgrade considerations
- Uninstalling the PingDirectory and PingDirectoryProxy servers
- Signing on to and configuring the administrative console

PingDirectoryProxy

A fast and scalable LDAPv3 gateway for the PingDirectory server.

- Introduction to the PingDirectoryProxy server
- Installing the PingDirectoryProxy server
- Upgrade considerations
- Uninstalling the PingDirectory and PingDirectoryProxy servers
- Signing on to and configuring the administrative console

Delegated Admin

An add-on to PingDirectory that enables the delegation of user and group management.

- Introduction to Delegated Admin
- Installing Delegated Admin
- Upgrade considerations

PingDataSync

An efficient, Java-based server that provides high throughput, low latency, and bidirectional real-time synchronization between two endpoint topologies.

Release Notes

Unless otherwise noted, all of the following enhancements, known issues, and resolved issues apply to the PingDirectory server, the PingDataSync server, the PingDirectoryProxy server, and the PingDataMetrics server.

PingDirectory suite of products 9.3.0.7 (November 2024)

Made it easier to upgrade replicated servers to version 9.3.0.7 or later

Improved | DS-48798, DS-49090 | PingDirectory

When upgrading a pre-9.2 PingDirectory server in a replicated topology to version 9.3.0.7 or later, the `update` tool will automatically set `replication-purge-obsolete-replicas` to `false` for that server, if not already explicitly configured.

This change helps avoid unintended consequences when upgrading a pre-9.2 replicated server because the `replication-purge-obsolete-replicas` configuration property has a value of `true` by default in version 9.2.

After upgrade, the update tool also displays a message with more information:

```
In the 9.2.0.0 release, the implicit default value for the 'replication-purge-obsolete-replicas'
global configuration property changed from 'false' to 'true'. However, it should generally only
be set to true if all servers in the topology are at version 9.2.0.0 or later. Because this server
is being updated from a pre-9.2.0.0 version, it is possible that there are still other pre-9.2.0.0
servers in the topology. As such, the 'replication-purge-obsolete-replicas' property will be explicitly
set to false for this server if it was not explicitly set. Once you have completed the upgrade across all
servers in the topology so that there are no more pre-9.2.0.0 replicas, consider manually setting this
property to 'true' on all servers.
```

Fixed a `config-diff` error

Fixed | DS-49071 | PingDirectory, PingDirectoryProxy, PingDataSync

Fixed an issue where `config-diff` would result in an `Unknown property` error when comparing configuration objects of different types.

Removed the restart prompt when changing a certificate alias

Fixed | DS-45174 | PingDirectory, PingDirectoryProxy, PingDataSync

Removed the prompt to restart the LDAP connection handler component after changing the `ssl-cert-nickname` configuration property because a restart isn't required.

Removed suppression messages for disabled alerts

Fixed | DS-49119 | PingDirectory, PingDirectoryProxy, PingDataSync

Fixed an issue where alert types that were disabled would still output suppression messages.

Copyright © 2025 Ping Identity Corporation

Fixed an issue with attribute value types in proxy transformations

Fixed DS-48958 PingDirectoryProxy

Updated the attribute mapping proxy transformation to require that both the source and target attribute types are defined in the local schema. This fix ensures that the server correctly handles those attribute values (for example, when identifying value types and formatting values for return in REST API responses).

The server now prevents you from adding a new attribute mapping proxy transformation if either of the attribute types isn't defined in the schema. If any existing transformations of this kind reference attributes whose types aren't defined in the schema, the server logs a warning message on startup.

Changed the REST API to use alternate authorization IDs

Fixed DS-49195 PingDirectoryProxy

Fixed an issue where the Directory REST API didn't use alternate authorization identities in entry-balanced proxy environments.

PingDirectory suite of products 9.3.0.6 (August 2024)

Increased replication speed

Improved DS-48826 PingDirectory

Increased throughput for replicated operations.

Fixed an issue with syncing modified PingOne attributes

Fixed DS-48669 PingDataSync

Fixed an issue where syncing from a PingOne sync source using an attribute synchronization mode of `modified-attributes-only` resulted in changed attributes not being properly synced over.

Supplied missing replication error information

Fixed DS-48785 PingDirectory, PingDirectoryProxy, PingDataSync

Fixed an issue where **`dsreplication enable`** didn't print error information if the tool failed to establish a connection to a source or target server.

Fixed an error message in the Delegated Admin report

Fixed DS-48774 PingDirectory, PingDirectoryProxy

Removed a stack trace from the error message returned when generating a Delegated Admin report with an invalid SCIM filter.

Copyright © 2025 Ping Identity Corporation

Fixed an issue with inconsistent `entryUUID` values across servers

Fixed | DS-48678, DS-48720 | PingDirectory

Fixed an issue where MODDN operations on replicated PingDirectory servers configured with Groovy-scripted or third-party type password generators or validators could result in inconsistent `entryUUID` values for the same entry on different servers.

Fixed an issue with VLV indexes and extensible match filters

Fixed | DS-48026 | PingDirectory

Fixed an issue that could prevent the server from using VLV indexes defined with certain kinds of extensible match filters, including those using the `jsonObjectFilterExtensibleMatch` or `relativeTimeExtensibleMatch` matching rules.

PingDirectory suite of products 9.3.0.5 (March 2024)

Added logging history for the `setup` tool

Improved | DS-47831 | PingDirectory

A copy of the `setup` script output is now saved to an archive file in the `/history` directory. This should help with troubleshooting installations where multiple server images have been extracted on top of each other and `setup` has been run multiple times.

Fixed a `NullPointerException` caused by an unconfigured alert handler

Fixed | DS-47455 | PingDirectory, PingDirectoryProxy, PingDataSync, PingDataMetrics

Fixed an issue where a `NullPointerException` was thrown when an alert or alarm was raised and one or more of the alert handlers weren't configured. This most commonly happened when the server was being stopped.

Now, instead of throwing a `NullPointerException`, the server logs this message: `Alert notification '<notification>' will not be processed by alert handler '<alert_handler>' since that alert handler does not have configuration.`

Fixed an encoding issue with UTF-8 in URI search filters

Fixed | DS-48300 | PingDirectory, PingDataSync

Fixed an issue where PingDataSync couldn't properly encode certain UTF-8 characters used in a URI search request filter sent to an external server. The server is now able to encode filter values that include any UTF-8 characters.

Fixed an issue with attribute duplication

Fixed | DS-48585 | PingDirectory

Fixed an issue where replace operations that target attributes with subordinate types would cause the subordinate attribute values to be duplicated.

Copyright © 2025 Ping Identity Corporation

Fixed an issue where the server could throw a `DATABASE_LOCK_CONFLICT` error

Fixed DS-45949 PingDirectory

Fixed an issue where aborting a transaction on a PingDirectory server could sometimes fail to release a write-lock, causing all subsequent transactions to fail with the error `DATABASE_LOCK_CONFLICT` until the server was restarted.

Fixed a potential `NullPointerException` during replication

Fixed DS-47289 PingDirectory

Fixed a potential `NullPointerException` that the server could throw during replication if missing changes were found for a replica, but that replica didn't exist on all servers. This scenario can happen when an obsolete replica is purged concurrent to the check for missing changes.

Fixed a replication issue where a suffix could have multiple generation IDs

Fixed DS-47695 PingDirectory

The generation ID, represented by `ds-sync-generation-id`, is a value used by replication to determine if replicas are compatible and can be replicated. To address the issue of multiple generation IDs for the same suffix, the generation ID is now calculated independent of the disk order in which the entries are stored. This new behavior is helpful when entries are imported on new servers instead of initializing them.

Fixed an issue with `dsreplication status` information

Fixed DS-47326 PingDirectory

Fixed an issue where running the `dsreplication status --displayservertable` command sometimes failed to display peer server statuses or generation IDs.

Fixed the default behavior of `check-replication-domains`

Fixed DS-47655 PingDirectory

Changed the **`check-replication-domains`** tool to default to the server's root directory and removed the `--serverRoot` argument requirement.

Fixed an incorrect suggestion in the replication terminal output

Fixed DS-47878 PingDirectory

Fixed a problem where **`dsreplication initialize`** suggested using the `--force` option if you were unable to connect to the server properly.

Copyright © 2025 Ping Identity Corporation

Fixed an issue that prevented use of the Changelog Password Encryption plugin in replicated environments

Fixed DS-48205 PingDirectory

Fixed an issue where the Changelog Password Encryption plugin would not work properly in a replicated environment if a password was changed with a Password Modify extended operation.

Fixed an issue with error logging

Fixed DS-48084 PingDirectory

Fixed an issue where a `cn=config does not exist` error message would appear in the error logs after navigating to the status page of the administrative console.

Fixed an issue with backend availability reporting

Fixed DS-48040 PingDirectoryProxy

Fixed an issue where PingDirectoryProxy wouldn't accurately report the availability of backends added through automatic backend discovery.

PingDirectory suite of products 9.3.0.4 (January 2024)

Fixed a memory issue introduced in 9.3.0.2 that could have caused the server to crash

Fixed DS-48599 PingDirectory

We fixed an uncommon issue that was causing memory usage to spike, possibly crashing the PingDirectory server.

With this issue present, when clients performed atypical `modify` operations, they might have populated entries with duplicate attribute values. If clients repeated these modifications, over time, the duplicate attribute values could have caused the server to consume a substantial amount of memory, which might have eventually caused the server to shut down with an out-of-memory error.

PingDirectory suite of products 9.3.0.3 (November 2023)

Faster server backup and recovery

Improved DS-45157 PingDirectory

We significantly improved the performance of critical disaster recovery operations, reducing both maintenance overhead and downtime, if you need to recover a server. You can now create server backups, restore from a backup, and initialize an online replica in less time.

Copyright © 2025 Ping Identity Corporation

PingDirectory suite of products 9.3.0.2 (October 2023)

Fixed an issue with replace modifications

Fixed | DS-47975 | PingDirectory

Fixed an issue that could prevent replace modifications for attribute types with subordinate types (for example, `postalAddress`) from being properly applied.

Fixed an issue that affects password policies stored outside the server configuration

Fixed | DS-43034, DS-47832 | PingDirectory

Fixed a regression that was introduced in the 9.3.0.0 release while making changes to allow additional values for the `allow-pre-encoded-passwords` property in the password policy configuration. The issue only affects password policies stored outside of the server configuration in local DB backends, and only those policies that include the `ds-cfg-allow-pre-encoded-passwords` attribute.

As part of the change to allow additional values for the `allow-pre-encoded-passwords` configuration property, we changed the syntax for the underlying attribute type from Boolean to directory string. When storing values for Boolean attributes in entries that reside in local DB backends, the server may compact the value to reduce the amount of space to store the data on disk and in memory. When the syntax for the attribute type was changed, the server no longer recognized that the value was compacted, which prevented it from properly interpreting that value.

This fix allows the server to recognize and properly interpret compacted values for the `ds-cfg-allow-pre-encoded-passwords` attribute when parsing a password policy definition contained in a local DB backend. Note that when the password policy entry is retrieved, the attribute may still appear to have a corrupt value, as the value that is actually stored in the entry would still represent the compacted token rather than the logically equivalent Boolean value. Replacing the value of the `ds-cfg-allow-pre-encoded-passwords` attribute in affected entries with the appropriate value is the best way to address that.

Made improvements to the Configuration API

Fixed | DS-47790 | PingDirectory

The Configuration API no longer treats patch operations with empty arrays as invalid. Instead, it now resets configuration attributes for replace operations with an empty array and ignores add operations with an empty array.

Fixed an issue with the `remove-defunct-server` command

Fixed | DS-47784 | PingDirectory

Fixed an issue with running `remove-defunct-server` against servers configured with an AES256 password storage scheme where encryption settings were not initialized before initializing password policy components.

Fixed an issue with processing search operations

Fixed | DS-47585 | PingDirectory

Copyright © 2025 Ping Identity Corporation

Fixed an issue that could allow the server to continue processing a search operation for longer than the allowed time limit. Previously, the server would not check the time limit in the course of index processing to identify potential matching entries, and in certain cases where the server had to iterate across a very large number of index keys (for example, when evaluating a range or substring filter component that could match a very large number of entries), the allowed time limit could be exceeded in that portion of the processing.

Fixed an issue that caused a null pointer exception to be thrown

Fixed | DS-45527 | PingDataSync

Fixed an issue where a null pointer exception would be thrown when adding a sync server to a topology of two or more existing sync servers using `manage-topology add-server`.

Improved Active Directory Sync sources

Improved | DS-46635 | PingDataSync

For Active Directory Sync sources, when setting the startpoint to the `end-of-changelog`, extraneous data is no longer sent from the Active Directory server to the Sync server. With this change, setting the startpoint to `end-of-changelog` should be faster, particularly for slow networks.

Fixed an issue when enabling or disabling a user in PingOne

Fixed | DS-47905 | PingDataSync

Resolved an issue with synchronizing the `enabled` attribute of a user in a PingOne destination. This issue only occurred when attempting to enable or disable a user in PingOne from the source server.

To create an attribute mapping that will modify the `enabled` status of a user in PingOne, use the **`dsconfig`** tool to create a constructed attribute mapping of the following form. This will ensure that `enabled` will always have a well-defined value, even if the source attribute is not present on an entry in the source server.

```
dsconfig create-attribute-mapping --type constructed --map-name mapName --mapping-name enabled --set
conditional-value-pattern:'(sourceAttribute=*) : {sourceAttribute}' --set conditional-value-pattern:'(!
(sourceAttribute=*)) : true'
```

PingDirectory suite of products 9.3.0.1 (August 2023)

Fixed a security issue

Security | DS-47632 | PingDirectory

Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported versions of the PingDirectory server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

Copyright © 2025 Ping Identity Corporation

PingDirectory suite of products 9.3.0.0 (June 2023)

What's new in the PingDirectory 9.3 suite of products?

New DS-46779

PingDirectory

- When dealing with server security, some customers require the ability to separate control of encryption settings from the typical directory administrator. In this release, several features have to added to restrict and/or revoking access to the encryption settings configuration with the ability to lock the encryption settings database with a password and by using a new monitor provider for the cipher stream provider itself. Several restrictions can be configured including the ability to prevent turning off data encryption, preventing changes to the cipher stream provider, preventing exportation of the encryption settings database and preventing access to the encrypt-file tool to decrypt files. Also, administrators can now set up a new PingDirectory instance with a pre-existing encryption settings database using the manage-profile command.
- PingDirectory has previously allowed user entries to authenticate via pass-thru authentication to other systems such as Active Directory or PingOne. There has been a limit, however, to just one pass-thru authentication plugin. A new aggregate pass-thru authentication handler has been added to version 9.3 allowing for multiple, subordinate authentication plugins each with their own criteria to identify authentication requests to be processed. The configuration order will be used to determine the priority of the plugins. Different failure types can be configured that allow a failure in one subordinate handler to continue process in another handler.
- PingDirectory provides several application interfaces (APIs) for creating efficient and powerful client applications for managing the data store. The Directory REST API has been enhanced to support specific LDAP extended operations. These include the Password Modify, Generate Password and Get Password Quality Requirements extended operations. Since JSON-format controls were recently supported in Directory REST API, all supported controls can be implemented with these extended operations as well. The Change Password extended operation allows user to modify their own password or another user's (with proper permissions, of course). The Suggest Password extended operation will generate a list of potential passwords and provides details on if they would be valid under certain policies and the Password Requirements extended operation returns a comprehensive list of password quality requirements for a given user/policy if a certain operation is performed.
- Several improvements to the `dsreplication` command will increase the performance when enabling replication and for retrieving the current status of the topology.

PingDataSync

The configuration of sync pipes continues to be a sticking point for customers as the process can be quite difficult. Currently these are created using dsconfig, the admin console or the configuration API. There are OOTB dsconfig script files provided for creating a PingOne source and/or destination server. New OOTB scripts and documentation have been created specifically for bi-directional syncs between Active Directory and PingDirectory, a reference script for syncing from Active Directory to SCIMv2 and when using Kafka as a sync destination. These scripts include the necessary steps and documentation detailing how to customize these steps for a customer's environment.

Added the `cache-duration` property

Critical DS-47166 PingDirectory

Copyright © 2025 Ping Identity Corporation

Added property `cache-duration` to allow optional caching of key managers retrieved by a PKCS11 Key Manager Provider.

Added additional values for the `allow-pre-encoded-passwords` property

New DS-43034 PingDirectory

Added support for additional values for the `allow-pre-encoded-passwords` property in the password policy configuration. Previously, the value for this property could be either "false" or "true," but it can now be any of the following:

- `false`: Do not allow pre-encoded passwords to be provided in add requests, self password changes, or administrative password resets. This remains the default setting, and the behavior with this value remains the same.
- `true`: Allow pre-encoded passwords to be provided in add requests, self password changes, or administrative password resets. The behavior with this value remains the same.
- `add-only`: Allow pre-encoded passwords to be provided in add requests, but not in self password changes or administrative password resets.
- `admin-reset-only`: Allow pre-encoded passwords to be provided in administrative password resets, but not in add requests or self password changes.
- `add-and-admin-reset-only`: Allow pre-encoded passwords to be provided in add requests or administrative password resets, but not in self password changes.

The new values can be used to allow administrators to set pre-encoded passwords without allowing end users to do so for their own accounts. Allowing pre-encoded passwords for self password changes introduces the potential for several security risks, including permitting users to password validation, password expiration, and password history constraints; permitting users to use weakly encoded passwords; or allowing users to use passwords that are encoded so strongly that it could cause excessive resource consumption in the server.

Added account status notification types

New DS-43714, DS-46355 PingDirectory

Added an `account-authenticated` account status notification type that can be used to notify users or administrators when an account has successfully authenticated with a bind request that matches a specified set of criteria.

Added an `account-deleted` account status notification type that can be used to notify users or administrators when an account has been removed with a delete request that matches a specified set of criteria.

Added support for a successful bind result criteria that can be used to classify successful bind operations based on the resulting authentication identity.

Added a UTF-8 password validator

New DS-44536 PingDirectory

Added a UTF-8 password validator that can be used to ensure that only valid UTF-8 strings can be used as passwords. Passwords can optionally be limited to only ASCII characters, and you can specify which Unicode character classes (for example, letters, numbers, punctuation, symbols, spaces, etc.) should be allowed.

Copyright © 2025 Ping Identity Corporation

Added the `--showPartialBacklog` option to `dsreplication status`

New DS-44898 PingDirectory

Added the `--showPartialBacklog` option to `dsreplication status` to display information about the `replica-partial-backlog` attribute.

Added configuration properties to the Config File Handler backend

New DS-45254, DS-47110, DS-47401

Added the configuration property `insignificant-config-archive-base-dn` to the Config File Handler backend. This property can be used to control the rate at which the configuration archive grows by removing files that record only changes under the specified base DN(s).

If an existing configuration entry is updated, but all of the changes are restricted to one or more of these base DNs, then the updated configuration will be added to the configuration archive, but that archived configuration file can be removed after the next configuration change.

By default, this property will apply to the topology registry subtree.

Added pass-through authentication handlers

New DS-45263 PingDirectory

Added an aggregate pass-through authentication handler that makes it possible to have multiple types of pass-through authentication enabled in the server at the same time.

Added a PingOne pass-through authentication handler that can be used to authenticate to the PingOne service. This handler provides the same functionality as the standalone PingOne pass-through authentication plugin, but it can be used with the aggregate pass-through authentication handler to support pass-through authentication to PingOne in conjunction with other types of services.

Added a `replication-missing-changes-risk` alert

New DS-46198 PingDirectory

A `replication-missing-changes-risk` alert is now raised during replication server connections if the backlog is within a configurable percent of the purge delay. By default, the new `missing-changes-alert-threshold-percent` replication server configuration parameter is set to 80%.

Added new properties to the Config File Handler Backend

New DS-46334 PingDirectory, PingDirectoryProxy, PingDataSync

Added two new properties to the Config File Handler Backend for managing the config archive and limiting its impact on server performance.

Copyright © 2025 Ping Identity Corporation

The first property is `maintain-config-archive`, which controls whether or not changes to the config backend are recorded in the config archive. Existing records in the archive are unaffected by changes to this property.

The second property is `max-config-archive-size`, which limits the number of config files that will be maintained by the archive. When a new file is added to the archive, if the resulting number of files exceeds the value of this property, then the oldest files will be deleted from the archive until the total is equal to the configured value.

Added a property that lets you control servlet information

New DS-46565

Added the `include-servlet-information-in-error-pages` configuration property to give you control over whether servlet information gets printed on HTTP error pages or remains hidden (by default).

Added support for encrypted PKCS #8 private key PEM files

New DS-46654 PingDirectory, PingDirectoryProxy, PingDataSync

When setting up the server with a private key read from a PEM file, or when using manage-certificates to import a certificate chain and private key from PEM files, that private key PEM file can now contain an encrypted private key, and you can specify the password needed to decrypt it. When using manage-certificates to export a private key, you can now specify a password to use to encrypt the key.

Added caching logic

New DS-46664 PingDirectory

Addressed a performance issue when adding new directory servers to large replicated topologies spanning multiple geographic locations.

Added support for syncing booean-valued attributes

New DS-46826 PingDataSync

Added support for syncing Boolean-valued attributes for PingOne destinations.

Added support for restricting administrators' access to encrypted data

New DS-46908, DS-46911, DS-46912, DS-46913, DS-46931, DS-46933, DS-46934, DS-46936, DS-46937

Updated the server to support a separation of duties between those responsible for administering the server itself and those responsible for managing the encryption settings definitions used for data encryption. This is implemented through a combination of four new capabilities that were added:

- The ability to configure data encryption restrictions that can impose limitations around the administration of data encryption and access to decrypted data, including the ability to disable encryption, to change the cipher stream provider used to protect the encryption settings database, the ability to create backups or LDIF exports that are unencrypted or encrypted with a passphrase instead of an encryption settings definition, and the ability to use the encrypt-file tool to decrypt files.

Copyright © 2025 Ping Identity Corporation

- The ability to freeze the encryption settings database with a specified password. While it is frozen, the encryption settings database will operate in read-only mode so that it is not possible to create or remove definitions, change the preferred definition, or alter the set of active data encryption restrictions. The database can only be unfrozen with the password that was initially used to freeze it.
- The ability to set up the server with a pre-existing encryption settings database. This is best done with the manage-profile setup command using a server profile that uses `--encryptDataWithPreExistingEncryptionSettingsDatabase` in the `setup-arguments.txt` file, that includes one or more batch files in the `pre-setup-dsconfig` directory with changes to configure and active the associated cipher stream provider, and that includes the encryption settings database and any metadata files needed by the cipher stream provider in the appropriate locations below the `server-root/pre-setup` directory.
- Support for a new monitor provider that can periodically ensure that the encryption settings database can be read without relying on any caching that the cipher stream provider might be using to improve performance and reliability. After a prolonged outage, it can also optionally shut down the server or force it into lockdown mode as a way of preventing or limiting access to encrypted data. This can be used as a way of revoking access to encrypted data in the event that those responsible for managing encryption settings definitions deem it necessary by removing or disabling an external element (for example, an external KMS encryption key or a secret read from a password vault) that the cipher stream provider depends on for access to the encryption settings database.

Added a disallowed characters password validator

New DS-47262 PingDirectory

The validator can be used to reject proposed passwords that contain any of a specified set of characters. It can be configured with characters that cannot appear anywhere in a password, as well as with characters that are disallowed only at the beginning or end of a password.

Added a `replication-not-purging-obsolete-replicas` alert

New DS-47366 PingDirectory

A `replication-not-purging-obsolete-replicas` alert will be raised at server startup if a replication server is not configured to purge obsolete replicas. It is recommended that replication servers always be configured to do so.

Added a `check-replication-domains` tool

New DS-47373 PingDirectory

Added a **`check-replication-domains`** tool to check the current list of known replication domains and indicate whether any obsolete domains are present. Learn more about Discovering obsolete replicas.

Improved error handling for LDAP external servers

Improved DS-43614 PingDirectoryProxy

Improved error handling for LDAP external servers that are configured with an authorization-method value of rebind. If the bind attempt fails in a way that indicates that the connection is no longer valid, the PingDirectoryProxy server might now attempt the rebind in a different server or on a newly recreated connection.

Copyright © 2025 Ping Identity Corporation

Updated the `collect-support-data` administrative task

Improved DS-44534

Updated the `collect-support-data` administrative task to allow specifying the start and end times for the range of log messages to include in the support data archive.

Updated the LDAP connection handler

Improved DS-45221

Updated the LDAP connection handler so that changes to the set of enabled TLS protocols and cipher suites take effect immediately and will be used for any new LDAPS or LDAP+StartTLS connections that are established after the change is made. This applies for changes made directly in the connection handler configuration, and if the connection handler is not configured with an explicit set of TLS protocols or cipher suites, then it also applies to changes made in the crypto manager configuration.

A restart is still required to apply TLS protocol or cipher suite changes to other types of connection handlers, as well as for replication.

Updated the modifiable password policy state plugin

Improved DS-45506 PingDirectory

Updated the modifiable password policy state plugin to allow the `ds-pwp-modifiable-state-json` attribute to be included in add requests for the purpose of specifying certain elements of the new account's password policy state.

Updated setup to encrypt the `tools.pin` file in certain situations

Improved DS-46379

Updated setup so that if it is configured to write a `tools.pin` file containing the default bind password to supply when running command-line tools, and if it is also configured to enable data encryption in the server, then it will encrypt the contents of that `tools.pin` file.

Improved how a backup of the config backend is handled

Improved DS-46467

If during a backup of the config backend, a file is deleted from the `config/archived-configs` directory, that deleted file will now be ignored instead of causing the backup to fail.

Improved password modify extended requests

Improved DS-46487 PingDirectory

Updated the server to allow password modify extended requests to include a proxied authorization request control.

Copyright © 2025 Ping Identity Corporation

Updated the pass-through authentication handler

Improved DS-46511 PingDirectory

Updated the pass-through authentication handler configuration to make it possible to configure each handler with an optional set of connection criteria, request criteria, and included local entry base DNs. When using the aggregate pass-through authentication handler, this makes it easier to indicate which handler should be used for a given bind operation.

Updated the `replace-certificate` tool

Improved DS-46653 PingDirectory

Updated the `replace-certificate` tool to support obtaining the source certificate chain and private key from PEM-formatted or DER-formatted files when replacing a listener or inter-server certificate. This is an alternative to requiring the new certificate to be provided in a key store.

Updated the Directory REST API with a new method for changing passwords

Improved DS-46816 PingDirectory

Updated the Directory REST API to add support for a means of changing passwords that is analogous to the LDAP password modify extended operation.

Updated the Directory REST API to suggest user passwords

Improved DS-46818 PingDirectory

Updated the Directory REST API to add support for a means of suggesting one or more new passwords for a user. This is analogous to the LDAP generate password extended operation.

Updated the Directory REST API for obtaining password quality requirements

Improved DS-46823 PingDirectory

Updated the Directory REST API to add support for a means of getting the requirements that a password will be required to satisfy for an add, self password modify, or administrative password reset operation. This is analogous to the LDAP get password quality requirements extended operation.

Improved the response time of `dsreplication enable` command

Improved DS-46906 PingDirectory

Improved the response time of `dsreplication enable` command on large topologies with more than 20 servers.

Improved data encryption

Improved DS-46908, DS-46911, DS-46912, DS-46913, DS-46931, DS-46933, DS-46934, DS-46936, DS-46937

Copyright © 2025 Ping Identity Corporation

The following data encryption improvements were made:

- We updated the encryption-settings create command to make it possible to specify the PBKDF2 iteration count that should be used when deriving the encryption key for the definition.
- We updated most cipher stream providers to make it possible to specify the PBKDF2 iteration count that should be used when deriving the encryption key used to protect the encryption settings database, and to use a higher default value.
- We updated the file-based cipher stream provider to support being configured with a metadata file that allows it to use stronger encryption for protecting the encryption settings database than when no metadata file is configured. A metadata file will automatically be configured when enabling data encryption during setup when not using a pre-existing encryption settings database.
- We improved encryption strength for encryption settings exports, backups, LDIF exports, log files and other file encryption, preferring 256-bit AES over 128-bit when available, and using a higher PBKDF2 iteration count to derive the key.
- We improved file encryption performance in the common case of using an encryption settings definition instead of a passphrase.
- We updated the encryption settings backend to provide additional information about each encryption settings definition, and updated the base entry for that backend to indicate if the encryption settings database is frozen or configured with any data encryption restrictions.

Improved performance of `dsreplication` command

Improved | DS-47083, DS-47084 | PingDirectory

Improved performance of **`dsreplication`** commands in topologies with a large number of PingDirectory servers and/or high network latency.

Improved `dsreplication` command response time

Improved | DS-47104 | PingDirectory

Improved response time of **`dsreplication`** command.

Improved various timeouts for replication enable and remove defunct server operations

Improved | DS-47144 | PingDirectory, PingDirectoryProxy, PingDataSync

Improved various timeouts for replication enable and remove defunct server operations to scale with the size of the topology. Smaller sized topologies should not be impacted by these changes.

Updated the server's behavior when authenticating a client connection

Improved | DS-47155 | PingDirectory, PingDirectoryProxy

Copyright © 2025 Ping Identity Corporation

Updated the server's behavior when it is configured to attempt to automatically authenticate a client connection using a certificate chain presented during TLS negotiation. Previously, if the client presented a certificate chain that could not be used to successfully authenticate the client, the server would have allowed the connection to remain established in an unauthenticated state, which could cause problems with applications that expect the connection to be authenticated. It will now terminate the client connection and log a disconnect message with details about the authentication failure.

Improved the server's support for UTF-8 password strings

Improved DS-47167 PingDirectory

Improved the server's support for passwords provided as UTF-8 strings containing non-ASCII characters with multiple Unicode representations. Previously, bind attempts with such a password would only succeed if the request included the password with exactly the same sequence of bytes used at the time the password was set. Now, the bind might also be able to succeed when the provided password contains the same logical set of characters but using a different Unicode normalization form.

Updated replace-certificate replace-inter-server-certificate

Improved DS-47345

Updated replace-certificate replace-inter-server-certificate to prevent using a certificate with an RSA key size greater than 3072 bits. It previously only required a minimum key size of 2048 bits without imposing a maximum size limit, but some of the cryptographic processing performed during inter-server authentication fails when using certificates with key sizes larger than 3072 bits.

Fixed an issue with updating password policy state information

Fixed DS-47440 PingDirectory, PingDirectoryProxy, PingDataSync

Fixed an issue that could interfere with the server's ability to update password policy state information while processing a bind operation using pass-through authentication.

> **Warning**
>
> For service accounts that use password storage schemes with high computational processing costs, such as PBKDF2, the server could process bind requests significantly slower.
> You should create a separate password policy for your service account, choose a less process-intensive password storage scheme, such as SSHA256, and set a very strong password according to NIST guidelines. Learn more in the Upgrade considerations.

Fixed an issue in the pluggable pass-through authentication plugin

Fixed DS-46544 PingDirectory

Fixed an issue in the pluggable pass-through authentication plugin that could prevent it from continuing with a local bind attempt if try-local-bind is false but the configured handler reports that the target user does not exist in the external service.

Copyright © 2025 Ping Identity Corporation

Fixed an issue when processing a modify operation

Fixed DS-45335 PingDirectory

Fixed an issue that could arise when processing a modify operation that contains a replace modification in which the attribute description has an attribute type and does not have any attribute options. If the target entry contained any attributes with the same attribute type but that also had one or more attribute options, then those attributes would have been incorrectly removed from the entry.

Fixed the server's handling for subtree searches

Fixed DS-46178 PingDirectory

Fixed an issue with the server's handling for subtree searches with an empty base DN. The server correctly returned entries from top-level backends (that is, backends whose base DNs were server naming contexts) but failed to return entries from subordinate backends.

Fixed an issue that prevented search result entry messages from being logged

Fixed DS-46656 PingDirectoryProxy

Fixed an issue that prevented search result entry messages from being logged for operations passing through the PingDirectoryProxy server.

Fixed an issue with IntraSync User operational attributes

Fixed DS-46695 PingDataSync

Fixed an issue that caused missing IntraSync User operational attributes after running the `manage-profile replace-profile` subcommand.

Fixed an issue with permit-export-reverable-passwords

Fixed DS-46810 PingDirectory

Fixed an issue that prevented including permit-export-reversible-passwords in the set of privileges that can be automatically inherited by root users and topology administrators.

Fixed an issue with passwords within minAge

Fixed DS-46882 PingDirectory

Fixed an issue where attempting to change a password that's within the `minAge` now responds with an UNABLE_TO_PERFORM code rather than INVALID_CREDENTIALS.

Copyright © 2025 Ping Identity Corporation

Fixed an issue with the `manage-profile --setup` script

Fixed | DS-46892 | PingDirectory

Fixed an issue where the `manage-profile --setup` script did not correctly find the necessary paths.

Fixed an issue with expired passwords and remaining grace logins

Fixed | DS-46945 | PingDirectory

Fixed an issue that prevented a user with an expired password but one or more remaining grace logins from being allowed to change their own password on a request that was authorized with the proxied authorization request control.

Fixed an issue with normalized search substrings

Fixed | DS-46946 | PingDirectory

Fixed an issue where normalized search substrings that were empty matched everything instead of nothing.

Fixed an issue with unindexed searches

Fixed | DS-47061 | PingDirectory

Fixed an issue that could prevent certain unindexed searches from returning all matching entries in the scope of the search. If a backend is configured with `compact-common-parent-dn` values that are at least two levels below the backend's base DN, then searches based below the backend base DN but above a `compact-common-parent-dn` value could have excluded entries from subtrees for which compaction had been configured. This issue has been fixed, but because it caused certain records to be stored in an incorrect order in the underlying database, customers affected by the issue will need to export the backend data to LDIF and re-import it to have the database rebuilt with the correct ordering.

Fixed an issue with the password modify extended operation and the no-operation control

Fixed | DS-47079 | PingDirectory

Fixed an issue in which the server could return multiple password validation details response controls in the response to a password modify extended request that included a password validation details request control and did not specify a new password, indicating that the server should generate a new password for the target user.

Also fixed an issue in which the sever would not return the generated new password in the response to a password modify extended request that included a no-operation request control and did not specify a new password.

Fixed a replication issue causing unstable master selection

Fixed | DS-47103 | PingDirectory

Fixed an internal error that could cause a replicated PingDirectory server topology to have unstable master selection.

Copyright © 2025 Ping Identity Corporation

Fixed an issue causing improper modify request processing

Fixed DS-47170 PingDirectory

Fixed an issue that could prevent the server from properly processing a modify request that contained an update to the `ds-pwp-modifiable-state-json` attribute in conjunction with one or more other attributes. If the update to `ds-pwp-modifiable-state-json` did not actually result in any changes to the user's password policy state, then the server could have short-circuited processing for the operation and returned a success result without processing the other modifications targeting other attributes.

Fixed an issue with index name length

Fixed DS-47182 PingDirectory

Fixed an issue with indexes where index names could exceed the maximum file name length of 255 characters.

Fixed an issue with the password policy state extended operation

Fixed DS-47245 PingDirectory

Fixed an issue that could cause the password policy state extended operation to return misleading results for some requesters. Previously, the server would always retrieve the target user's entry on an internal connection authorized as the user that requested the external operation, and would use that entry to construct its internal representation of the password policy state. This ensured that the operation would only be allowed if the requester had the necessary permission to retrieve the target user's entry, but if the requester didn't have permission to retrieve all of the operational attributes used to represent components of the target user's password policy state, then the perceived state used for subsequent processing in that operation might not be accurate, which could cause the server to return incorrect information about the user's account state.

To address this problem, the server first ensures that the requester has the necessary permission to issue the extended request and to access the target user's entry, but it will then retrieve the entry again on an internal connection that is not subject to access control restrictions. This ensures that it will always get a complete and accurate representation of the user's password policy state so that it can return the correct information to the requester.

> **Note**
>
> If the operation is used in an attempt to update the target user's password policy state, then the requester must still have the necessary access control permission to write to the appropriate operational attributes for that request.

Fixed an issue with the purging of obsolete replicas

Fixed DS-47369 PingDirectory

Fixed an issue where obsolete replicas were sometimes not being purged from replication servers.

Fixed an issue with case insensitivity

Fixed DS-47374 PingDirectory

Fixed an issue where case insensitivity was not correctly handled when working with static topologies.

Copyright © 2025 Ping Identity Corporation

Support for HashiCorp Vault password storage schemes

Issue | DS-49305 | PingDirectory

Currently, the PingDirectory server only supports version 1 of the HashiCorp Vault KV secrets engine for password storage schemes. Learn more about KV version 1 in the Vault KV secrets engine documentation.

PingDirectory suite of products 9.2.0.4 (November 2023)

Faster server backup and recovery

Improved | DS-45157 | PingDirectory

We significantly improved the performance of critical disaster recovery operations, reducing both maintenance overhead and downtime, if you need to recover a server. You can now create server backups, restore from a backup, and initialize an online replica in less time.

Fixed an issue with Changelog Password Encryption in replicated environments

Fixed | DS-48205 | PingDirectory

We fixed an issue where the Changelog Password Encryption plugin wouldn't work properly in a replicated environment if you changed a password using a Password Modify extended operation. The password change is now propagated to all replicas.

PingDirectory suite of products 9.2.0.3 (September 2023)

Added a new configuration property to the Config File Handler backend

New | DS-45254, DS-47110, DS-47401 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added the configuration property `insignificant-config-archive-base-dn` to the Config File Handler backend. This property can be used to control the rate at which the configuration archive grows by removing files that record only changes under the specified base DN(s).

If an existing configuration entry is updated, but all of the changes are restricted to one or more of these base DNs, then the updated configuration will be added to the configuration archive, but that archived configuration file may be removed after the next configuration change.

By default, this property will apply to the topology registry subtree.

Enhanced the `dsreplication enable` command

Improved | DS-46902 | PingDirectory

The **`dsreplication enable`** command can now add a new server to an existing topology with the same major and minor release version but a newer maintenance level.

Copyright © 2025 Ping Identity Corporation

Fixed an issue causing a null pointer exception

Fixed DS-45527 PingDataSync

Fixed an issue where a null pointer exception would be thrown when adding a sync server to a topology of two or more existing sync servers using manage-topology add-server.

Fixed an issue allowing search operations to last beyond the time limit

Fixed DS-47585 PingDirectory

Fixed an issue that could allow the server to continue processing a search operation for longer than the allowed time limit. Previously, the server would not check the time limit in the course of index processing to identify potential matching entries, and in certain cases where the server had to iterate across a very large number of index keys (for example, when evaluating a range or substring filter component that could match a very large number of entries), the allowed time limit could be exceeded in that portion of the processing.

Fixed an issue with the `remove-defunct-server` command

Fixed DS-47784 PingDirectory

Fixed an issue with running `remove-defunct-server` against servers configured with an AES256 password storage scheme where encryption settings were not initialized before initializing password policy components.

PingDirectory suite of products 9.2.0.2 (August 2023)

Fixed a security issue

Security DS-47632 PingDirectory

Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported version of the PingDirectory server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

PingDirectory suite of products 9.2.0.1 (May 2023)

Added the `cache-duration` property

New DS-47166 PingDirectory

Critical: Added the property `cache-duration` to allow optional caching of key managers retrieved by a PKCS11 Key Manager Provider.

Copyright © 2025 Ping Identity Corporation

Fixed an issue causing missing `IntraSync User` operational attributes

Fixed | DS-46695 | PingDataSync

Fixed an issue that caused missing `IntraSync User` operational attributes after running the `manage-profile replace-profile` subcommand.

Fixed an issue with changing passwords within `minAge`

Fixed | DS-46882 | PingDirectory

Fixed an issue where attempting to change a password that's within the `minAge` now responds with an `UNABLE_TO_PERFORM` code rather than `INVALID_CREDENTIALS`.

Improved the response time of `dsreplication enable`

Improved | DS-46906 | PingDirectory

Improved the response time of the `dsreplication enable` command on large topologies with more than 20 servers.

Fixed an error with replicated PingDirectory server topology

Fixed | DS-47103 | PingDirectory

Fixed an internal error that could cause a replicated PingDirectory server topology to have unstable master selection.

Fixed an issue with index name length

Fixed | DS-47182 | PingDirectory

Fixed an issue with indexes where index names could exceed the maximum file name length of 255 characters.

PingDirectory suite of products 9.2.0.0 (December 2022)

Added new access control bind rules and a new access control target

New | DS-38367, DS-38368, DS-38369 | PingDirectory

- Added a new "secure" access control bind rule that can be used to make access control decisions based on whether the client is using a secure connection (for example, LDAPS or LDAP with StartTLS) to communicate with the server. Using the bind rule secure="true" indicates that the ACI only applies to requests received over a secure connection, while secure="false" indicates that the ACI only applies to requests received over an insecure connection.
- Added a new "connectioncriteria" access control bind rule that can be used to make access control decisions based on whether the client connection matches a specified set of connection criteria. The value of the bind rule can be either the name or the full DN of the configuration object that defines the desired connection criteria.

Copyright © 2025 Ping Identity Corporation

- Added a new "requestcriteria" access control target that can be used to make access control decisions based on whether the operation request matches a specified set of request criteria. The value of the target can be either the name or the full DN of the configuration object that defines the desired request criteria.

For more information, see ACI bind rules and ACI targets.

Added an audit data security recurring task

New DS-42172 PingDirectory

Added a new "audit data security" recurring task that can be used to regularly examine server data for potential security-related issues. For more information, see Auditing data content.

Added new stats to track operations when using UnboundIDSyncDestination

New DS-44855 PingDataSync

Added new stats to track operations on account state when using an UnboundIDSyncDestination. They can be found on the monitor entry for the sync pipe associated with the destination.

Added support for Java 17

New DS-45766 PingDirectory, PingDirectoryProxy, PingDataSync

The server can now run on Java 17.

> **Important**
>
> PingDataMetrics does not support Java 17.

Updated Groovy

New DS-45970

Updated Groovy support from Groovy 2.x to Groovy 3.x for Java 17 compatibility. This change might introduce some minor incompatibilities in Groovy script support (for example, it appears that import statements split across multiple lines are no longer allowed), so deployments making use of Groovy-scripted extensions should carefully test these extensions in a temporary standalone instance to verify compatibility and make any necessary changes before updating existing instance.

Added a SCIM 2.0 sync destination

New DS-46108 PingDataSync

Added a SCIM 2.0 sync destination. For more information, see Configuring synchronization to a SCIM 2.0 server.

Added new password storage schemes

New DS-46018 PingDirectory

Copyright © 2025 Ping Identity Corporation

Added new password storage schemes that provide support for the Argon2i, Argon2d, and Argon2id variants of the Argon2 password hash and proof-of-work function. We previously offered only a single Argon2 password storage scheme (which used Argon2i behind the scenes), but the new schemes make it possible to explicitly indicate which variant should be used for encoding passwords.

For more information about password storage schemes, see Supported password storage schemes.

Added an HTTP servlet extension to support Prometheus

New DS-46593

Added an HTTP servlet extension that allows the values of numeric monitor attributes to be published as metrics in a form that can be consumed by a Prometheus monitoring server. For more information, see Monitoring server metrics with Prometheus.

Fixed issues with data security auditors

Fixed DS-12140, DS-42173, DS-46123, DS-46124, DS-46125, DS-4782, DS-4783, DS-4784, DS-5130 PingDirectory

- Fixed an issue in which the locked account data security auditor did not include the number of validator-locked entries in the summary generated when completing processing for a backend.
- Fixed an issue in which the expired password data security auditor could incorrectly report that an entry has an old password even when it has been changed more recently than the configured password evaluation age.
- Fixed an issue with the weakly encoded password data security auditor that could prevent it from detecting passwords encoded with certain schemes.
- Updated the weakly encoded password data security auditor so passwords encoded using unsalted SHA-1 digests, salted SHA-1 digests, salted MD5 digests, and the MD5 variant of the CRYPT password storage scheme are now considered weak by default.
- Updated the Server SDK to add support for creating custom data security auditors.

For more information about data security auditors, see Auditing data content.

Removed support for incremental backups

Fixed DS-44442 PingDirectory

Removed support for incremental backups, which had been deprecated since the 8.3.0.0 release. As an alternative, we recommend using LDIF exports, which are more useful, more portable, and much more compressible than full backups, and they can be taken more frequently than full backups without consuming as much disk space. Further, the extract-data-recovery-log-changes tool can be used in conjunction with either LDIF exports or backups to replay changes recorded in the data recovery log since the time the export or backup was created.

Exploded indexes are no longer created unexpectedly

Fixed DS-44966 PingDirectory

Fixed an issue where exploded indexes were unexpectedly created following an unclean shutdown.

Copyright © 2025 Ping Identity Corporation

Fixed an issue with dsreplication

Fixed DS-45044 PingDirectory

Fixed an issue with the `dsreplication` tool where baseDNs and restricted baseDNs were improperly handled as case sensitive.

The hibernate-validator library in the management console has been updated to version 6.2.1

Fixed DS-45461 PingDirectory

To close a vulnerability found in hibernate-validator 5.4.3 in the management console, we are updating the console to version 6.2.1. This newer version requires use of jakarta-validator 2.0.2 rather than the older javax-validator 1.1.0, therefore we are upgrading directory to use jakarta-validator 2.0.2 to preserve compatibility.

When moving to version 2, javax-validator was moved to jakarta, but still uses the javax namespace, and therefore no code changes need to be made other than dependencies. In the future, if we move to jakarta-validator v3 however, we will need to move to the jakarta namespace.

Fixed an issue causing the replication initialize task to fail

Fixed DS-45567 PingDirectory

Fixed an issue where a replication initialize task that ran longer than the configured connection idle-timeout-limit would cause the initialize to fail.

Resource limits are now set for the topology admin user

Fixed DS-45638 PingDirectory

Fixed an issue where resource limits for the topology admin user created during replication enable were not set.

Updated jQuery

Fixed DS-45933

Updated jQuery to 3.6.0.

Fixed an issue with replication enablement

Fixed DS-45960 PingDirectory

Fixed an issue that caused replication enablement to fail if there is at least one topology-wide administrator with no password.

Fixed an issue causing slow response time

Fixed DS-46017 PingDirectory

Copyright © 2025 Ping Identity Corporation

Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

Fixed an issue causing sync to slow down

Fixed DS-46119 PingDataSync

Fixed an issue encountered when using PingDataSync with a PingOne Sync Destination that caused sync to slow down significantly after 5 minutes and generate extraneous requests to the sync destination.

Fixed an issue preventing changes to certain password policy state attributes from being applied

Fixed DS-46121 PingDataSync

Fixed an issue where changes to certain Password Policy State attributes would not be applied to the correct entry when using a Ping Identity Sync Destination under very specific circumstances.

Exposed previously hidden properties in the PingDirectoryProxy server

Fixed DS-46129 PingDirectoryProxy

Updated the PingDirectoryProxy server to expose the `maximum-attributes-per-add-request` and `maximum-modifications-per-modify-request` properties in the global configuration. These properties were previously only visible in the PingDirectory server configuration, but they also apply to requests that pass through the PingDirectoryProxy server.

The `migrate-ldap-schema` tool now removes incorrect single quotes

Fixed DS-46169 PingDirectory

Modified the **`migrate-ldap-schema`** tool to remove incorrect single-quotes enclosing the attribute type syntax OID in schemas being imported from Microsoft Active Directory.

Users are no longer prevented from changing their own passwords

Fixed DS-46392 PingDirectory,PingDirectoryProxy

Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the Directory Proxy Server.

New servers can now be enabled into a large topology

Fixed DS-46436 PingDirectory

Fixed an issue where new servers could not be enabled into a large topology.

Copyright © 2025 Ping Identity Corporation

Enhanced the `audit-data-security` tool to use new data security auditors

Improved PingDirectory

The **`audit-data-security`** tool is used to identify potential risks or other notable security characteristics contained in directory data. This tool has been enhanced to use new data security auditors defined in the server configuration. The new data security auditors can identify:

- Accounts with password policy state issues that might currently or soon affect their usability.
- Accounts with an activation time in the future, an expiration time in the past, or an expiration time in the near future.
- Accounts with passwords encoded using deprecated password storage schemes.
- Accounts for users that have not authenticated in longer than a specified length of time.
- Accounts that are configured to use a nonexistent password policy and are therefore unable to authenticate.
- Entries that match a specified search filter.

Also, the locked account auditor is now able to identify validation-locked accounts, and the weakly encoded password auditor can now flag passwords encoded with SMD5, SHA, and SSHA, and also the MD5 variant of the CRYPT scheme.

For more information about the **`audit-data-security`** tool, see Auditing data content.

Improved logging with the addition of new features

Improved PingDirectory

Several features have been added to improve logging and the **`summarize-access-log`** tool to provide a better experience for administrators. The **`summarize-access-log`** tool already provided a list of the domain names of the target users for the most common bind failures, but the following metrics have been added to improve the detection of possible security issues:

- The IP addresses of the clients with the most failed bind attempts (in case a single client is trying to access multiple accounts, as might happen in a credential stuffing attack).
- The addresses of the users with the most consecutive authentication failures (that is, most failures between successes or most failures without a success).
- The identification of filters with parentheses, ampersands, pipes, single quotes, and double quotes, which might indicate an unsuccessful LDAP filter injection attempt.
- The identification of filters with the words "select" and "from", which might indicate an unsuccessful SQL injection attempt.
- The identification of the most common used and missing privileges.
- The tracking of the number of components used in filters as an increase in the number of filters with more components, which might suggest a successful injection attempt.

For more information about the **`summarize-access-log`** tool, see Logging Tools

Copyright © 2025 Ping Identity Corporation

Access control improvements

Improved PingDirectory

PingDirectory provides a number of features to manage control to data within the data store including Access Control Instructions and connection criteria. In this release, the access control handler now provides support for a bind rule that can make it possible to make access control decisions based on whether the client connection is secure or whether the client connection matches a given set of connection criteria or if a target that makes it possible to determine whether the rule applies to a given request based on request criteria.

Updated global configuration

Improved DS-38078 PingDirectory

Updated the global configuration to define configuration properties that can be used to set alternative size limit, time limit, idle time limit, and lookthrough limit values for unauthenticated clients. By default, the server will use the same default limits for both authenticated and unauthenticated clients, but you can now set limits for unauthenticated clients that are different from the default limits imposed for authenticated clients. It is still possible to override these limits on a per-user basis with operational attributes in the user's entry.

Added support for generating digital signatures with a key obtained from an encryption settings definition

Improved DS-38277

Added support for generating digital signatures with a key obtained from an encryption settings definition. By default, the server's preferred encryption settings definition will be used to obtain the signing key, but you can use the signing-encryption-settings property in the crypto manager configuration to choose an alternative definition.

Previously, signatures were generated using a legacy key shared among servers in the topology, which could make it difficult to validate signatures outside of the topology. The legacy key will continue to be used in environments without any encryption settings definitions.

Added support for HTTP forward proxy

Improved DS-40345

Updated the server to add HTTP forward proxy support for several server components that might need to establish HTTP and HTTPS connections to external services. Updated components include:

- The Amazon Key Manager cipher stream provider
- The Amazon Secrets Manager cipher stream provider
- The Amazon Secrets Manager passphrase provider
- The Amazon Secrets Manager password storage scheme
- The Azure Key Vault cipher stream provider

Copyright © 2025 Ping Identity Corporation

- The Azure Key Vault passphrase provider
- The Azure Key Vault password storage scheme
- The PingOne pass-through authentication plugin
- The PingOne sync source and destination
- The Pwned Passwords password validator
- The SCIMv1 sync destination
- The SCIMv2 sync destination
- The Twilio alert handler
- The Twilio OTP delivery mechanism
- The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler

The `replication-purge-obsolete-replicas` property is now set to true by default

Improved DS-41467 PingDirectory

The `replication-purge-obsolete-replicas` global configuration property is now set to true by default for new and upgraded PingDirectory servers so that obsolete replicas are purged.

The `replace-certificate` tool now re-prompts user for path to valid file containing certificates

Improved DS-45968

Updated the **`replace-certificate`** tool's behavior when running in interactive mode. Previously, when it prompted the user for the path to a file containing one or more certificates to be imported, it would exit with an error if the provided path represented a file that did not contain valid certificate information. It will now re-prompt the user for the path to a valid file after displaying the error message.

Updated replication enable synopsis

Improved DS-46127 PingDirectory

Updated replication enable synopsis to mention that schema initialization is part of the enable process and explain that the order of provided servers is significant for the initialization.

Updated the `dsconfig` tool

Improved DS-46313

Updated the **`dsconfig`** tool to ensure that it uses the correct authentication type when applying changes to all servers in a server group. Previously, it would always attempt to use simple authentication, even if the connection to the initial server was authenticated using a different mechanism.

Copyright © 2025 Ping Identity Corporation

Enhanced the replication server

Improved | DS-46332 | PingDirectory

The replication server now continues to handle incoming replication connections even when there is an unexpected exception.

Updated Amazon AWS external server configuration

Improved | DS-46615

Updated the Amazon AWS external server configuration to provide more control over the method used to authenticate to AWS. Previously, it was only possible to authenticate with an access key or an IAM role. We have added an option to use an IRSA role, and we have also added an option to use a default credentials provider chain that attempts to identify an appropriate authentication method for cases in which the server is running in the AWS environment (for example, EC2 or EKS) based on locally available information like system properties and environment variables.

`dsreplication enable` subcommand description differs based on operating system

Issue | DS-46127 | PingDirectory

There is a known issue with the description of the `dsreplication enable` subcommand differing based on the operating system. On MacOS, an updated description is shown:

"Update the configuration of the servers to replicate the data under the specified base DN(s). If one of the two servers is already part of an existing replication topology, then that server must be specified as the first server. This is because the schema of the second server will be updated to match the schema of the first. The configuration of all the servers in the existing topology will also be updated, so it is sufficient to perform this operation once for each new server that is added to the topology. The server-to-server replication communication is always secured with SSL."

But on some operating systems, including Windows and CentOS, the older description is shown that doesn't mention the schema initialization.

Support for HashiCorp Vault password storage schemes

Issue | DS-49305 | PingDirectory

Currently, the PingDirectory server only supports version 1 of the HashiCorp Vault KV secrets engine for password storage schemes. Learn more about KV version 1 in the Vault KV secrets engine documentation.

PingDirectory suite of products 9.1.0.4 (November 2023)

Added a configuration property to the Config File Handler backend

New | DS-45254, DS-47110, DS-47401 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Copyright © 2025 Ping Identity Corporation

Added the configuration property `insignificant-config-archive-base-dn` to the Config File Handler backend. This property can be used to control the rate at which the configuration archive grows by removing files that record only changes under specified base DNs.

If an existing configuration entry is updated, but all of the changes are restricted to one or more of these base DNs, then the updated configuration gets added to the configuration archive, but that archived configuration file can be removed after the next configuration change.

By default, this property applies to the topology registry subtree.

Faster server backup and recovery

Improved DS-45157 PingDirectory

We significantly improved the performance of critical disaster recovery operations, reducing both maintenance overhead and downtime, if you need to recover a server. You can now create server backups, restore from a backup, and initialize an online replica in less time.

Enhanced the `dsreplication enable` command

Improved DS-46902 PingDirectory

The `dsreplication enable` command can now add a new server to an existing topology with the same major and minor release version but a newer maintenance level.

Improved the response time of `dsreplication enable`

Improved DS-46906 PingDirectory

Improved the response time of the `dsreplication enable` command on large topologies with more than 20 servers.

Fixed an issue with the purging of obsolete replicas

Fixed DS-47369 PingDirectory

Fixed an issue where obsolete replicas were sometimes not being purged from replication servers.

Fixed a potential NPE for missing changes in replication

Fixed DS-47289 PingDirectory

Fixed a possible null pointer exception in replication where missing changes were found for a replica, but that replica didn't exist on all servers. This could have occurred in scenarios where the replica was obsolete and purged concurrent to the check for missing changes.

Fixed an issue with the `remove-defunct-server` command

Fixed DS-47784 PingDirectory

Copyright © 2025 Ping Identity Corporation

Fixed an issue with running `remove-defunct-server` against servers configured with an AES256 password storage scheme. In these cases, the encryption settings were not initialized before initializing the password policy components.

Fixed an error with replicated PingDirectory server topologies

Fixed | DS-47103 | PingDirectory

Fixed an internal error that could cause a replicated PingDirectory server topology to have unstable master selection.

Fixed an issue with index name length

Fixed | DS-47182 | PingDirectory

Fixed an issue with indexes where index names could exceed the maximum file name length of 255 characters.

Fixed an issue where adding a hotfix server to a topology failed

Fixed | DS-46807 | PingDirectory

Fixed an issue where `dsreplication enable` failed to add a server with a hotfix build to an existing topology with a previous build. The hotfix server would attempt to become topology master immediately, interrupting proper initialization.

Fixed an issue with nondescript logging for `manage-profile replace-profile` errors

Fixed | DS-46983 | PingDirectory

Fixed an issue where errors that occurred during a `manage-profile replace-profile` operation would only log `Batch command failed` entries.

Batched `dsconfig` commands that are executed during `manage-profile replace-profile` will now report a detailed cause for the failing command.

Fixed an issue that caused an NPE when using `realtime-sync`

Fixed | DS-47609 | PingDataSync

Fixed an issue where the server would throw a null pointer exception and fail to synchronize during a `realtime-sync` operation.

Fixed an issue that caused an NPE when adding a server

Fixed | DS-45527 | PingDataSync

Fixed an issue where a null pointer exception would be thrown when adding a sync server to a topology of two or more existing sync servers using `manage-topology add-server`.

Copyright © 2025 Ping Identity Corporation

PingDirectory suite of products 9.1.0.3 (August 2023)

Fixed a security issue

Security DS-47632 PingDirectory

Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported version of the PingDirectory Server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

PingDirectory suite of products 9.1.0.2 (March 2023)

Fixed an issue with resource limits for the topology admin user

Fixed DS-45638 PingDirectory

Fixed an issue where resource limits for the topology admin user created during replication enable were not set.

Fixed an issue with password policy state attributes

Fixed DS-46121 PingDataSync

Fixed an issue where changes to certain Password Policy State attributes would not be applied to the correct entry when using a Ping Identity Sync Destination under very specific circumstances.

Fixed an issue causing missing IntraSync User operational attributes

Fixed DS-46695 PingDataSync

Fixed an issue that caused missing IntraSync User operational attributes after running the `manage-profile replace-profile` subcommand.

Fixed an issue with changing passwords within minAge

Fixed DS-46882 PingDirectory

Fixed an issue where attempting to change a password that's within the minAge now responds with an `UNABLE_TO_PERFORM` code rather than `INVALID_CREDENTIALS`.

PingDirectory suite of products 9.1.0.1 (November 2022)

Fixed an issue with the `dsreplication` tool

Fixed DS-45044 PingDirectory

Copyright © 2025 Ping Identity Corporation

Fixed an issue with the `dsreplication` tool where baseDNs and restricted baseDNs were improperly handled as case sensitive.

Fixed an issue with replication enablement

Fixed | DS-45960 | PingDirectory

Fixed an issue that caused replication enablement to fail if there is at least one topology-wide administrator with no password.

Fixed an issue with slow response times on PingDirectory servers

Fixed | DS-46017 | PingDirectory

Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

Fixed an issue preventing users from changing their passwords

Fixed | DS-46392 | PingDirectory, PingDirectoryProxy

Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the Directory Proxy Server.

Updated the PingDirectoryProxy server to expose properties in global configuration

Improved | DS-46129 | PingDirectoryProxy

Updated the PingDirectoryProxy server to expose the `maximum-attributes-per-add-request` and `maximum-modifications-per-modify-request` properties in the global configuration. These properties were previously only visible in the PingDirectory server configuration, but they also apply to requests that pass through the PingDirectoryProxy server.

Improved the replication server's handling of incoming replication connections

Improved | DS-46332 | PingDirectory

The replication server now continues to handle incoming replication connections even when there is an unexpected exception.

PingDirectory suite of products 9.1.0.0 (June 2022)

Added support to sanitize access logs to protect sensitive information

New

Log files can contain potentially contain sensitive or identifiable information that you might not necessarily want recorded in the clear. The server can now be configured to support sanitizing access logs as they are being written. It is available for any writer-based or JSON-formatted access log, and elements in the log message can either be sanitized, redacted, or omitted altogether. This includes the ability to genericize diagnostic messages written to the access or error log. For more information, see Log sanitization.

Copyright © 2025 Ping Identity Corporation

Added support for processing JSON-formatted access logs

New

PingDirectory provides a robust logging system allowing for detailed analysis of the server's functioning. Included is support for creating log files written using JSON format. The `summarize-access-log` command, which is used to display several metrics about operations processed within the server, now supports processing JSON formatted access logs.

Updated Directory REST API

New

The Directory REST API allows developers to create customized application for managing the entries in a directory instance. The Directory REST API now supports controls previously only available through LDAP calls. This includes the ability to do joins allowing for advanced data modeling of relationships.

Added conflict error messages for replicated PingDirectory deployments

New

In deployments with replicating PingDirectory instances, conflicts can occur if the same entry is added to different servers at the same time. Many conflicts can be handled automatically and, in such cases, the server whose add attempt creates a conflict, now returns a `CONFLICT` result in the replication response control and LDAP result code.

JSON-formatted access logger updated

Improved DS-44507, DS-45243, DS-45530

Updated the JSON-formatted access logger to include the requester IP address in disconnect, security negotiation, and client certificate log messages when appropriate.

PingDataSync Server supports PingOne as a sync destination

Improved PingDataSync

PingOne recently added support for multi-valued attributes. Now, using PingOne as a sync destination, multi-valued attributes can be synchronized as either a one-time data migration or as part of a continual real-time synchronization strategy.

Synchronize data to custom attributes defined in the PingOne environment

Improved PingDataSync

When using PingOne as a sync destination, PingDataSync Server provides support for synchronizing data to custom attributes that are defined in the PingOne environment. This includes attributes defined as multi-valued or JSON in PingOne.

Copyright © 2025 Ping Identity Corporation

Repeating cycle when resetting a password

Issue PingDirectory

> **Important**
>
> If your password policy for an admin user (such as a topology administrator or rootDN) is set with `--set force-change-on-reset:true` or `--set force-change-on-add:true`, you cannot update that administrator's password without it being considered an administrator reset.

An administrator reset results in the prompt of another required password reset, so using these password policy attributes sends an administrator in a repeating cycle when resetting the password.

One recommendation to work around this issue is to not set these password policy attributes on administrator accounts that are stored in `cn=config`. If you do need `--set force-change-on-reset:true` or `--set force-change-on-add:true`, you must clear the `mustChangePassword` flag by running the following command each time you change the password:

```
$ bin/manage-account set-must-change-password \
    --mustChangePassword false \
    --targetDN cn=<admin cn>
```

`setup` tool failure because of Bouncy Castle JAR files

Issue

The `setup` command might fail on Windows operating systems because of the presence of Bouncy Castle JAR files in the `lib` directory that begin with `bc`. The JAR files are mentioned in an error message similar to the following: `An unexpected error occurred while attempting to copy the non-FIPS Bouncy Castle jar file into the server's classpath: FileSystemException: lib\bcprov-jdk15to18-1.71.jar: The process cannot access the file because it is being used by another process`. A temporary workaround is to delete the JAR files that begin with `bc` from the `lib` directory before attempting to run `setup` again.

Bouncy Castle libraries are not removed from the `lib` directory.

Issue DS-46007

If you update an existing installation to the 9.1 release of the server and then subsequently want to revert that update, Bouncy Castle libraries from the 9.1 release might not be properly removed from the `lib` directory, resulting in both the older and newer versions of the library being in the `lib` directory. This should not cause any problems with the server, but it might result in warning messages in the server's error log about different versions of the same JAR file in the classpath (for example, `The following classpath entries appear to be multiple versions of the same jar, which may cause server issues: bc-fips-1.0.2.1.jar, bc-fips-1.0.2.3.jar` and `The following classpath entries appear to be multiple versions of the same jar, which may cause server issues: bctls-fips-1.0.11.4.jar, bctls-fips-1.0.13.jar`). This message can be safely ignored. You can eliminate this warning by stopping the server and manually removing the newer versions of the jar files referenced in the warning message.

Copyright © 2025 Ping Identity Corporation

JSON-formatted controls rejected

Issue DS-46016 PingDirectory, PingDirectoryProxy

JSON-formatted join request controls with their criticality set to `false` are rejected as if their criticality were `true` by non-search requests.

Fixed an issue that prevented the server from refreshing monitor data

Fixed DS-41468

Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced. For information on log sanitization, see Log sanitization.

Fixed the `status` tool

Fixed DS-44481

The **`status`** tool now shows the current **`collect-support-data`** version.

Fixed key and trust store PIN issues

Fixed DS-45336

Fixed issues that prevented obtaining key and trust store PINs with the Amazon Secrets Manager, CyberArk Conjur, or HashiCorp Vault passphrase providers.

Updated the server to create the `esTokenizer.ping` file if it does not exist

Fixed DS-45449 PingDirectory

Updated the server to create the `esTokenizer.ping` file if it does not exist for a backend containing encrypted data. This file might be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.

Password policies using virtual attributes are now correctly applied

Fixed DS-45466 PingDirectory

Fixed an issue where password policies specified using a virtual attribute were sometimes not correctly applied to users.

Improved string representations of active operations and persistent searches

Fixed DS-45485 PingDirectory, PingDirectoryProxy

Copyright © 2025 Ping Identity Corporation

Updated the active operations monitor provider to improve the string representations of active operations and persistent searches. The timestamps now have a precision of milliseconds rather than seconds, and the strings can now be parsed using the access log API in the UnboundID LDAP SDK for Java.

The `encode-password` tool now works with AES256 password storage

Fixed | DS-45546 | PingDirectory

Fixed an issue that caused the `encode-password` tool to fail when the AES256 password storage scheme is enabled.

Support added for synchronizing custom attributes defined in PingOne destinations

Fixed | DS-36184, DS-45125 | PingDataSync

Added support for synchronizing data to custom attributes defined in PingOne destinations. This includes multi-valued attributes and JSON attributes in the PingOne environment.

Set a consistent priority index when adding two PingDataSync servers into a new failover topology

Fixed | DS-45123 | PingDataSync

Updated the `manage-topology add-server` command to set a consistent priority index when adding two PingDataSync servers into a new failover topology. The server listed as the remote server in the command-line arguments is given the higher priority index, which results in an overall lower priority compared to the other server.

Updated the `sanitize-log` tool

Fixed | DS-16236 | PingDirectory

Updated the `sanitize-log` tool to better align with the server's support for sanitizing log messages as they are logged. Changes include:

- It is preconfigured with default behaviors for an expanded set of log fields.
- It can be configured to suppress the default log field behavior configuration and only explicitly specified configuration.
- It offers support for additional sanitization options, including omitting fields and differentiating between values should be redacted or tokenized in their entirety or by components.
- It now uses syntax-aware redaction and tokenization.
- It offers support for specifying a default behavior to use on a per-syntax basis.
- It can obtain its settings from a log field behavior definition in the server configuration.

Improved assured replication result codes for conflicts

Improved | DS-42302 | PingDirectory

Copyright © 2025 Ping Identity Corporation

Added support for improved assured replication result codes when replication conflicts occur. For `processed` assured levels, for each replica that has a replication conflict resulting in an alternate distinguished name (DN) being updated, a `CONFLICT` result will be returned. If any such conflicts are detected, a result code of 68 (ENTRY_ALREADY_EXISTS) will be returned.

Fixed password policy state extended operation

Fixed | DS-44667 | PingDirectory

Fixed an issue in which the password policy state extended operation could be used to create duplicate authentication failure time or grace login use time values.

Added a new Docker command-line tool

Improved | DS-45147 | PingDirectory, PingDataSync, PingDirectoryProxy

Added a **`docker-pre-start-config`** command-line tool for PingData Docker containers. Use the tool before the server is started to make configuration changes to the server that depend on the running container's environment.

Added a new argument for `manage-profile generate-profile`

Improved | DS-45163

Added a `--excludeSetupArguments` argument for the `manage-profile generate-profile` command. Added a `--skipValidation` argument for the `manage-profile replace-profile` command. This argument allows skipping the final server validation step when running on an offline server and allows generating a server profile that does not include a setup-arguments.txt file. Updated the setup and `replace-profile` subcommands to fail when a server profile includes an `encryption-settings-db` file in the profile's *<server-root>*`/pre-setup/` directory.

Fixed an issue with server privileges

Fixed | DS-45250

Directory Server privileges that are assigned through virtual attributes now apply consistently when accessing topology-related features through the administrative console.

Improved protections around the `dw-pwp-modifiable-state-json` operational attribute

Improved | DS-45255, DS-45504, DS-45505 | PingDirectory

Updated the server to protect against attempts to modify the `ds-pwp-modifiable-state-json` operational attribute without the Modifiable Password Policy State plugin enabled. The plugin is disabled by default, and the server would previously allow writes to that attribute with the plugin disabled, but those writes would just pollute the entry and have no effect on its password policy state. The server now only allows updates to `ds-pwp-modifiable-state-json` if the Modifiable Password Policy State plugin is enabled. Similarly, the server also rejects attempts to add entries that contain the `ds-pwp-modifiable-state-json` operational attribute, even with the Modifiable Password Policy State plugin disabled. Writes to this attribute are only supported for **`modify`** operations, and the server would properly reject **`add`** attempts targeting that attribute if the plugin had been enabled but would not reject those attempts if the plugin were disabled.

Copyright © 2025 Ping Identity Corporation

The server now also prohibits administrators from using the `ds-pwp-modifiable-state-json` operational attribute to update their own password policy state, and it prohibits attempts to update `ds-pwp-modifiable-state-json` operational attribute in an another user's entry in the same **`modify`** request that also resets that user's password. The former restriction prevents certain kinds of changes that could allow an administrator to exempt themselves from certain password policy restrictions while the latter protects against potential conflicts that could arise from two modifications in the same request that attempt to alter a user's password policy state.

Fixed a backwards compatibility issue with the `migrate-ldap-schema` tool

Fixed | DS-45322 | PingDirectory

A former version of the tool allowed the `--useSSL` argument to indicate that SSL should be used to secure communication with both servers, whereas a newer version did not allow that argument but instead required both `--sourceUseSSL` and `--targetUseSSL`. Similarly, support for the `--useStartTLS` argument was inadvertently dropped, requiring both `--sourceUseStartTLS` and `--targetUseStartTLS`. The legacy arguments have been restored.

Removed two password policies for non-password users

Fixed | DS-45439, SF:00741269 | PingDirectory

Minimum and maximum age password policies are no longer applied for users without a password.

Updated Kafka version

Security | DS-45462

Updated PingDirectory products to use Kafka 2.8.1, which resolves.

Fixed incorrect index skipping

Fixed | DS-45470 | PingDirectory

Fixed an issue in which the server could incorrectly skip certain indexes when evaluating search criteria. In cases where the server can determine where the results from one index should already be encompassed by results from another index that is already in use for the search, it ignores the redundant index. However, there were cases in which an index would be ignored even if the already-in-use index was not actually suitable for that search (for example, because its index entry limit had been exceeded).

Updated the topology registry and the `replace-certificate` tool

Improved | DS-45480, DS-45636

Updated the topology registry to allow using issuer certificates when determining whether to trust the certificate chain presented by another server in the topology. Previously, a server's certificate chain would only be trusted if the server certificate itself was found in the topology registry. Now, a certificate chain can be trusted if either the peer certificate or any of its issuers is found in the topology registry.

Copyright © 2025 Ping Identity Corporation

Made the following updates to the `replace-certificate` tool:

- Added new `list-topology-registry-listener-certificates` and `list-topology-registry-inter-server-certificates` subcommands that can be used to display a list of the listener or inter-server certificates for a specified server instance in the topology registry.
- Added a new `add-topology-registry-listener-certificate` subcommand that can be used to add one or more certificates to the set of listener certificates for an instance in the topology registry. This subcommand does not alter the contents of any key store, and it can be used to add an issuer certificate to the topology registry or to add a new peer listener certificate in advance of actually activating that certificate on the server.
- Updated the `replace-certificate replace-listener-certificate` subcommand to add `--topology-registry-update-type` and `--trust-store-update-type` arguments that allow indicating which types of certificates to include in the topology registry and trust store, respectively. Available options suppressing the update, only adding the listener certificate itself, only adding the listener certificate's issuers, or adding both the listener certificate and its issuers.
- Updated the `replace-certificate replace-listener-certificate` subcommand to add an `--ignore-current-listener-certificate-validity-window` argument that allows the tool to establish a connection to the server even if its certificate has expired or is not yet valid so that a non-valid certificate can be replaced.

Fixed an access log reporting issue

Fixed | DS-45487 | PingDirectory

Fixed an issue where access logs incorrectly reported negative processing times for certain operations.

Added support for JSON-formatted request and response controls

Improved | DS-45494 | PingDirectory, PingDirectoryProxy

Most existing controls have been updated to support an alternative JSON encoding, which might make it easier to use certain controls in clients written with APIs that do not provide direct support for those controls.

Updated the server Bouncy Castle cryptographic library versions

Security | DS-45503

Updated the server to use the latest versions of the FIPS 140-2-compliant and non-FIPS-compliant Bouncy Castle cryptographic libraries.

Added support for generic strings in access and error log messages

Improved | DS-45541, DS-45542

Updated the text-formatted and JSON-formatted access and error loggers to provide an option to use generic versions of strings in log messages. If enabled, error messages, additional log info messages, disconnect reasons, and authentication failure reasons will use a string with placeholders instead of context-specific values that could potentially include identifiable or sensitive information.

Copyright © 2025 Ping Identity Corporation

Updated the local DB backend to disable the index cursor entry limit by default

Improved | DS-45564 | PingDirectory

This limit (which is not exposed in the configuration) reflects the maximum number of index keys that the server cursors through when evaluating a single substring or range filter component. If the limit is reached, then that component is considered unindexed, and the server will rely on other filter components or the search scope for the filter to be indexed. This limit was originally intended to help prevent the server from spending too much time evaluating an expensive filter component when other components might be better, but we have since dramatically improved the logic the server uses to determine the order in which the server should evaluate filter components and when to skip potentially expensive components, so it is unlikely that this option will ever be needed. Further, the former limit of 100,000 could have unnecessarily caused the server to consider a search unindexed when it could actually be efficiently processed using indexes.

In the unlikely event that this limit is actually needed in a directory environment, it can still be activated by setting the `com.unboundid.directory.server.backends.jeb.AttributeIndex.cursorEntryLimit` system property to the desired value.

Fixed gauge alarm issues

Fixed | DS-45578 | PingDirectory, PingDirectoryProxy, PingDataSync

Fixed issues where gauges could raise an alarm and create an alert, but not create an alert when that same alarm was later cleared, making it unclear when the reported condition had abated.

Fixed server lockdown issue in newly initialized databases

Fixed | DS-45582 | PingDirectory

Fixed an issue where a server with a newly initialized database (through `dsreplication initialize`) could go into lockdown mode and report that the server `…may have missed one or more update(s).` if the source server is in the pre-external-initialize state. This generally occurred only if the initialized server was restarted right after initialization completed.

Updated the `export-reversible-passwords` tool

Fixed | DS-45600 | PingDirectory

Updated the **`export-reversible-passwords`** tool to fix a potential issue in which the tool could encounter a timeout while waiting for the response from the server. Updated the export reversible passwords extended operation handler to provide support for canceling an export that is in progress. If the export-reversible-passwords tool is terminated, or if the associated extended operation is abandoned or canceled, then the export process now stops processing. Previously, it ignored the cancel request and continued processing the export until all entries in the backend had been examined.

Fixed a server operation rejection issue

Fixed | DS-45767 | PingDirectory

Fixed an issue in which the server would always reject an operation with a request control that the client did not have permission to use, regardless of the control's criticality. It continues to reject the operation if the disallowed control has a criticality of `true`, but if the criticality is `false`, the server continues processing the operation as if that control had not been requested.

Copyright © 2025 Ping Identity Corporation

Fixed a replication protocol message issue

Fixed | DS-45714, SF:00753519 | PingDirectory

Fixed an issue that allowed replication protocol messages to be dropped.

Updated to LDAP SDK version 6.0.5

Fixed | DS-45746 | PingDirectory

Updated to LDAP SDK for Java version 6.0.5 for bug fixes and new functionality.

Fixed a server issue causing internal errors during monitoring

Fixed | DS-45786 | PingDirectory

Fixed a PingDirectory server issue that could cause an internal error to be logged while monitoring database statistics for read-only backends.

Fixed a Directory REST API error with mismatched time syntax attribute values

Fixed | DS-45788 | PingDirectory

Fixed an issue where the Directory REST API returns an HTTP 500 error response when trying to retrieve a System for Cross-domain Identity Management (SCIM) entry whose corresponding LDAP entry contains a valid Generalized Time Syntax attribute value not matching the specific format `YYYYMMDDhhmmssZ`.

Fixed Proxy server `manage-profile replace-profile` errors

Fixed | DS-45798 | PingDirectoryProxy

In PingDirectoryProxy Server, `manage-profile replace-profile` sometimes failed with an error similar to the following:

```
The tool was unable to merge configuration from the existing server into the new server:
LDAPException(resultCode=80 (other)
...
```

This fix ensures that the configuration is loaded before the merge that the error message refers to.

Updated Jackson Databind version

Security | DS-45806

Updated Jackson Databind to 2.13.3.

Copyright © 2025 Ping Identity Corporation

Updated the commons-codec library

Security DS-45898

Updated the commons-codec library to version 1.13.

Updated the Google Guava dependency in common libraries

Security DS-45903

Updated the Google Guava dependency in common libraries.

Updated Directory REST API to exclude RDN values in modify requests

Improved DS-45948 PingDirectory

The Directory REST API no longer includes RDN values in `modify` requests to update the DN of an entry, because RDN values are updated by default in modify DN requests.

Delegated Admin 4.10 (June 2022)

Accounts can be directly unlocked

New Delegated Admin

Managing accounts includes the ability to unlock accounts. Previously, the only way to unlock an account was for an administrator to reset the password. Now, Delegated Admin users can directly unlock an account without resetting the password.

> **Note**
>
> The initiate password reset option does not unlock accounts.

Assign custom names for Members and Nonmembers columns

New Delegated Admin

Managing group membership is a common administrative user task. Resource types can now have custom names assigned for Members and Nonmembers columns. This option is available for the Groups, Users and Generic REST resource types.

`Implicit` grant type is no longer recommended

New Delegated Admin

Currently, we are using the `Implicit` grant type. However, the `Implicit` grant type is no longer recommended for use because it can leak the access tokens. For more information, see https://oauth.net/2/grant-types/implicit/. For new installations of Delegated Admin, the grant type is set to Authorization Code with PKCE.

Copyright © 2025 Ping Identity Corporation

Upload and display image files and certificates

New Delegated Admin

Customers using Delegated Admin can now upload and display image files and upload certificates for properly configured resource types. Certificates are encoded before being stored.

Name of uploaded file is not displayed

Issue DS-45739 Delegated Admin

When uploading certificates or photos to REST resource types in Delegated Admin, the name of the uploaded file is not displayed. If multiple certificates are uploaded for a user, a number will be assigned based on the order the certificates were uploaded in.

Fixed input validation issue

Fixed DS-45760 Delegated Admin

Fixed a form input validation issue for required integer attributes on a resource type that was preventing users from saving new resources.

Non-members are no longer displayed initially for group's resource types

Fixed DS-45483 Delegated Admin

Non-members of a group are no longer displayed initially on the edit group membership view for the group resource types.

Non-members are no longer displayed initially for users and generic resource types

Fixed DS-45611 Delegated Admin

Non-member groups are no longer displayed initially on the edit group membership view for the users and generic resource types.

Non-members are no longer loaded in group resource type search results

Fixed DS-45591 Delegated Admin

Non-members of a group are no longer loaded in the group resource type search results on the group membership tab.

PingDirectory suite of products 9.0.0.6 (August 2023)

Fixed an issue where the server rejected certain operations

Fixed DS-45767 PingDirectory

Copyright © 2025 Ping Identity Corporation

Fixed an issue in which the server would always reject an operation with a request control that the client did not have permission to use, regardless of the control's criticality. It will continue to reject the operation if the disallowed control has a criticality of true, but if the criticality is false, the server will continue processing the operation as if that control had not been requested.

Fixed a security issue

Security DS-47632 PingDirectory

Fixed a security issue that could potentially affect customers using Delegated Admin. Customers are advised to apply a maintenance patch or upgrade to the latest supported versions of the PingDirectory Server. The Delegated Admin application is unaffected and does not require updating. Additional details are provided in SECADV039.

PingDirectory suite of products 9.0.0.5 (April 2023)

Fixed an issue causing missing operational attributes

Fixed DS-46695 PingDataSync

Fixed an issue that caused missing `IntraSync User` operational attributes after running the `manage-profile replace-profile` subcommand.

Fixed an issue with changing passwords

Fixed DS-46882 PingDirectory

Fixed an issue where attempting to change a password that's within the `minAge` now responds with an `UNABLE_TO_PERFORM` code rather than `INVALID_CREDENTIALS`.

PingDirectory suite of products 9.0.0.4 (January 2023)

Fixed an issue preventing the server from refreshing monitor data

Fixed DS-41468

Fixed an issue that prevented the server from refreshing the monitor data used to detect and warn about an upcoming certificate expiration. This could cause the server to continue to warn about an expiring certificate even after that certificate had been replaced.

Fixed an issue with the `dsreplication` tool

Fixed DS-45044 PingDirectory

Fixed an issue with the dsreplication tool where baseDNs and restricted baseDNs were improperly handled as case sensitive.

Copyright © 2025 Ping Identity Corporation

Fixed an issue with the `encode-password` tool

Fixed DS-45546 PingDirectory

Fixed an issue that caused the encode-password tool to fail when the AES256 password storage scheme is enabled.

Fixed an issue with resource limits

Fixed DS-45638 PingDirectory

Fixed an issue where resource limits for the topology admin user created during replication enable were not set.

Fixed an issue causing configurations not to load correctly

Fixed DS-45798 PingDirectoryProxy

In the PingDirectoryProxy server, `manage-profile replace-profile` sometimes failed with an error similar to the following: `The tool was unable to merge configuration from the existing server into the new server: LDAPException(resultCode=80 (other)` . This fix ensures that the configuration is loaded before the merge that the error message refers to.

Fixed an issue causing replication enablement to fail

Fixed DS-45960 PingDirectory

Fixed an issue that caused replication enablement to fail if there is at least one topology-wide administrator with no password.

Fixed an issue with changes to Password Policy State attributes

Fixed DS-46121 PingDataSync

Fixed an issue where changes to certain Password Policy State attributes would not be applied to the correct entry when using a Ping Identity Sync Destination under very specific circumstances.

Fixed an issue preventing users from changing their passwords

Fixed DS-46392 PingDirectory, PingDirectoryProxy

Fixed an issue in which the server could prevent users from changing their own passwords with the password modify extended operation if their account was in a "must change password" state and the request passed through the PingDirectoryProxy server.

The `maximum-attributes-per-add-request` and `maximum-modifications-per-modify-request` properties are now exposed in the global configuration

Improved DS-46129 PingDirectoryProxy

Copyright © 2025 Ping Identity Corporation

Updated the PingDirectoryProxy server to expose the `maximum-attributes-per-add-request` and `maximum-modifications-per-modify-request` properties in the global configuration. These properties were previously only visible in the PingDirectory server configuration, but they also apply to requests that pass through the PingDirectoryProxy server.

The replication server now continues to handle incoming replication connections

Improved DS-46332 PingDirectory

The replication server now continues to handle incoming replication connections even when there is an unexpected exception.

PingDirectory suite of products 9.0.0.2 (July 2022)

Updated Kafka version

Security DS-45462

Updated PingDirectory products to use Kafka v2.8.1.

Updated the server to create the `esTokenizer.ping` file if it does not exist

Fixed DS-45449 PingDirectory

Updated the server to create the `esTokenizer.ping` file if it does not exist for a backend containing encrypted data. This file might be needed to open the database environment for a backend containing encrypted indexes, but it would not have been automatically created when upgrading from a pre-7.0 server to a later version with support for encrypted indexes.

Updated the active operations monitor provider

Improved DS-45485 PingDirectory, PingDirectoryProxy

Updated the active operations monitor provider to improve the string representations of active operations and persistent searches. The timestamps now have a precision of milliseconds rather than seconds, and the strings can now be parsed using the access log API in the LDAP SDK for Java.

Fixed a Directory REST API error with mismatched time syntax attribute values

Fixed DS-45788 PingDirectory

Fixed an issue where the Directory Rest API returns an HTTP 500 error response when trying to retrieve a SCIM entry whose corresponding LDAP entry contains a valid Generalized Time Syntax attribute value not matching the specific format `YYYYMMDDhhmmssZ`.

Fixed a SCIM POST request error response issue

Fixed DS-45863 PingDirectory

Copyright © 2025 Ping Identity Corporation

Resolved an issue where SCIM POST requests that violated a unique attribute constraint received an error response with status 400 (Bad Request) instead of 409 (Conflict).

Fixed a performance issue with large numbers of virtual static groups

Fixed DS-46017 PingDirectory

Resolved an issue with slow response time on PingDirectory servers configured with a large number (10,000 or more) of virtual static groups.

Fixed a SCIM POST request error response issue

Fixed DS-45647 PingDirectory

Resolved an issue where SCIM POST requests that violated a unique attribute constraint got an internal error instead of the expected SCIM error response.

Fixed a PingDataSync to PingOne sync performance issue

Fixed DS-46119 PingDataSync

Fixed an issue encountered when using PingDataSync with a PingOne Sync Destination that caused sync to slow down significantly after 5 minutes and generate extraneous requests to the sync destination.

PingDirectory suite of products 9.0.0.1 (March 2022)

Issue with syncing multi-valued JSON attributes to a PingOne destination

Issue PingDataSync

For multi-valued JSON attributes, you should not use JSON attribute mappings when synchronizing data to a PingOne destination. When synchronizing JSON data, you can use a direct attribute mapping if the data at the source server is JSON. If the data at the source server should be assembled into JSON form, you can define a constructed attribute mapping.

Added support for synchronizing data to custom attributes defined in PingOne destinations

Improved DS-36184, DS-45125 PingDataSync

Added support for synchronizing data to custom attributes defined in PingOne destinations. This includes multi-valued attributes and JSON attributes in the PingOne environment.

When defining attribute mappings for a PingOne destination, you can use direct attribute mappings for string to string or JSON to JSON synchronizations. If a string attribute at the source server should be stored as JSON in the PingOne environment, you should define a constructed attribute mapping in PingDataSync.

Copyright © 2025 Ping Identity Corporation

PingDirectory suite of products 9.0.0.0 (December 2021)

New entry-balancing options

Improved PingDirectory

Entry-balancing is a PingDirectoryProxy Server configuration that allows the entries within a portion of the directory information tree (DIT) to reside on multiple external servers. The entry counter, hash distinguished name (DN) and round-robin placement algorithms can now be configured to exclude backend sets for `add` operations allowing for greater control over the use of multiple servers for entry balancing.

You can interact with entries within the data store including LDAP and several REST APIs

Improved PingDirectory

PingDirectory provides several interfaces for interacting with entries within the data store including LDAP and several REST APIs. In this release, the Directory REST API can now return any tagging options that are defined for an attribute. These tagging options are treated as subtypes of the same attribute while not explicitly declared in the schema.

CyberArk Conjur and Azure Key Vaults support added

Improved PingDirectory

In an earlier release, PingDirectory added support for a passphrase provider API to secure administrative passphrases, pins or passwords. This release adds both CyberArk Conjur and Azure Key Vaults to the list of available passphrase and cipher stream providers. Cipher stream providers are used to protect the keys stored in the encryption settings database

OAuth tokens ca be used with the File Servlet

Improved PingDirectory

Because administrators now have the ability to single sign-on (SSO) to the PingDirectory administrative console, the File Servlet used to download files from a server instance can now also use OAuth tokens for authentication along with the basic HTTP authentication method, such as username and password.

Apply your own branding to console elements.

Fixed PingDirectory, PingDirectoryProxy, PingDataSync

The administrative console is one tool you can use to configure and manage PingDirectory servers. In this release, you can now apply your own branding to console elements such as background colors, images and logos, and certain text elements. Sign on, sign out, and configuration pages are included in possible configuration areas. For more information, see the `README.txt` file in the console `.war` file shipped with PingDirectory.

Copyright © 2025 Ping Identity Corporation

New `--performLocalCleanup` option added to the `remove-defunct-server` command

Improved PingDirectory

To improve the defunct server topology cleanup process when your topology is unhealthy, such as during a network outage or disaster recovery, a new option to the **`remove-defunct-server`** command cleans up stale replication metadata before the server is added back into the topology. This new argument, `--performLocalCleanup`, allows administrators to easily take a server out of a topology for maintenance or troubleshooting and return the server back to the topology later. For more information on **`remove-defunct-server`** and its options, run `bin/remove-defunct-server --help`.

Added support for a pluggable pass-through authentication plugin

Improved PingDirectory

Earlier PingDirectory Server versions support pass-through authentication to remote LDAP servers or to PingOne, which can be useful when migrating data into the Directory Server from another service, or when the Directory Server needs to coexist with another service that is an authoritative source for user passwords. This release adds support for a pluggable pass-through authentication plugin, which makes it possible to pass through simple bind requests to an arbitrary external service using a pass-through authentication handler to manage interaction with that service, and the Server SDK has been updated to allow creating custom pass-through authentication handlers. As with existing pass-through authentication support, this functionality is only available for LDAP simple binds, and it does not support SASL authentication. For more information on this plugin, see Working with pass-through authentication

Added new options to the `dsreplication` command to make replication faster

Improved PingDirectory

In multi-server deployments, replication is used to maintain consistency of data and schema between the servers. With larger deployments, attempting to initialize replication for multiple servers can take longer. New options to the **`dsreplication`** command can now speed up this process by initializing replication on multiple servers in parallel. The number of servers can either be the entire set of servers in the deployment, or a subset of servers based on location, or instance name or a specific number. For more information on **`dsreplication`** subcommands, see Summary of the dsreplication Subcommands.

Added a new password storage scheme to provide enhanced security

Improved PingDirectory

Typically, the passwords for administrative users have been stored directly in PingDirectory based on the configured password storage scheme. To provide enhanced security for those administrative accounts that need it, a new password storage scheme has been added that allows for the password to be stored in an external vault. Currently, Amazon AWS Secrets Manager, Azure Key Vault, CyberArk Conjur, and HashiCorp Vault are supported.

The `config-audit` logs now tracks the originating account information when individual changes are made

Improved PingDirectory

Copyright © 2025 Ping Identity Corporation

To better manage the configuration of multiple servers in large topologies, PingDirectory uses the `config-audit` log file to allow administrators to easily determine, replay or undo configuration changes made to servers. Previously, when modifying topology or cluster configuration, the original requesting account information was not logged. Now, to assist administrators and improve server auditing, the `config-audit` logs will track the originating account information that made individual changes. For circumstances where more protection is required, there is a new property that will redact any sensitive attributes that might be written to the log file (instead of the default obfuscation behavior). This includes instances where administrative users change their passwords and affects any other condition where the sensitive attribute might be displayed for informational purposes such as alerts.

PingDataSync can now include Active Directory account state information

Improved PingDataSync

Many customers use PingDataSync Server to either migrate from Active Directory or use Active Directory in conjunction with PingDirectory to manage user accounts. Administrators can now configure PingDataSync to include account state information set in Active Directory specifically lockout time, the last time the password was set and whether or not the account is disabled. This information can now be properly set within PingDirectory based on the information set in the account in Active Directory.

Entry balancing and global index

Issue PingDirectoryProxy

If the DirectoryProxy Server is configured to use entry balancing and cannot use the global index to determine which backend sets should be used to process an operation, it broadcasts the request to all backend sets, and it will examine the results obtained from each of the backend sets to determine which is the best one to return to the client.

In previous releases, the server always preferred a success result over a non-success result, but if the operation failed in all backend sets, then the DirectoryProxy Server could have selected a result from a backend server in which the target entry didn't exist (for example, with a `noSuchObject` result code) rather than from one in which the entry did exist but the operation failed for some other reason. The 9.0.0.0-EA release addresses this by examining the result codes for all broadcast operations and prioritizing failure results indicating that the target entry exists in the associated backend set over those that do not.

There are still known cases, however, in which the DirectoryProxy Server might select a less appropriate result to return to the client. For example, if a **`bind`** operation fails, the backend server is likely to return an `invalidCredentials` result regardless of whether the target user entry exists in that backend set. If the **`bind`** attempt fails in one backend set because the target user exists but their account is in a state that doesn't allow it to authenticate (for example, if their password is expired or their account is locked), then the **`bind`** response from that server might include response controls that would be useful to return to the client, but the 9.0.0.0-EA release might not choose that response as the one to return to the client. This will be addressed in the 9.0.0.0 GA release later this year.

Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology

Fixed PingDirectory, PingDataSync

When a server is removed with the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys will now be distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

Copyright © 2025 Ping Identity Corporation

Fixed lost access to keys used for reversible password encryption when removing servers from the topology

Fixed DS-44591 PingDirectory

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, before this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

> **Note**
>
> Because this change only applies to the most recent version of **`remove-defunct-server`** and **`dsreplication disable`**, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it will not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

Fixed Directory REST API

Fixed DS-37117 PingDirectory

Fixed an issue where the Directory REST API encountered internal server errors while processing entries whose attributes have LDAP tagging options.

Added LDAP pass-through authentication handler

Fixed DS-38498, DS-38621 PingDirectory

An LDAP pass-through authentication handler has also been provided, which allows the new plugin to be used as an alternative to the existing LDAP-specific pass-through authentication plugin. The new implementation provides additional functionality not available in the previous plugin, including the ability to indicate whether pass-through authentication should be allowed for accounts that are locked or have expired passwords and the ability to set timeouts that will be used when interacting with external LDAP servers. It also has improved default settings and offers better diagnostic information about its processing.

Added authentication support for passwords stored in several services

Fixed DS-40671 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added support for password storage schemes that allow users to authenticate with passwords stored in the Amazon AWS Secrets Manager service, the Microsoft Azure Key Vault service, a CyberArk Conjur instance, or a HashiCorp Vault instance.

The `dsreplication initialize-all` command now initializes multiple target servers in parallel when the `--parallel` option is used

Fixed DS-40796 PingDirectory

Copyright © 2025 Ping Identity Corporation

To enhance initialization performance, the `dsreplication initialize-all` command now initializes multiple target servers in parallel when the `--parallel` option is used (subject to the `--parallelLimit` option). The `--sameLocationOnly` and `--destinationInstanceName` options can be used to limit the destinations that are initialized.

Added a global configuration property to indicate that the values of sensitive configuration properties should be redacted when constructing the `dsconfig` representation for a configuration change

Fixed | DS-40926 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added a global configuration property to indicate that the values of sensitive configuration properties should be redacted when constructing the **`dsconfig`** representation for a configuration change, which could be included in the server's configuration audit log or administrative alerts whenever a configuration change is applied. By default, the values of configuration properties that are defined as sensitive will be obscured rather than redacted, which allows the change to be replayed without revealing the actual value of the property. However, it is now possible to redact such values rather than obscuring them, which provides stronger protection against exposing those values, but could interfere with the ability to replay the configuration audit log if it contains changes involving sensitive properties.

Added sorting to the Name and Category columns of the monitor table

Fixed | DS-42752 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added sorting functionality to the **Name** and **Category** columns of the monitor table in the administrative console.

Added `replica-partial-backlog` attribute to replication summary monitor

Fixed | DS-42961 | PingDirectory

To help with replication backlog analysis, the replication summary monitor now includes a `replica-partial-backlog` attribute that shows how each origin replica contributes partial backlog with the `per-origin-replication-backlog` property. The `replica-partial-backlog` attribute also shows the change numbers used for the calculation.

Updated the server to record the original requester distinguished name (DN) and IP address

Fixed | DS-43056 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Updated the server to record the original requester distinguished name (DN) and IP address in access log and config audit log messages for mirrored configuration changes.

Fixed issues related to server handing of controls in search requests

Fixed | DS-43582 | PingDirectory, PingDirectoryProxy

Fixed a couple of issues in which the server might not properly handle other controls included in a search request containing a join request control. For search operations passing through the Directory Proxy Server, other response controls could have been inadvertently stripped from search result entries when adding the join result control. Further, if a search request included a join request control in conjunction with one or more other controls, the request control immediately following the join request control might not have been properly handled.

Copyright © 2025 Ping Identity Corporation

Added support for obtaining secrets from CyberArk Conjur

Fixed | DS-43917 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

The Conjur cipher stream provider can use a retrieved secret to generate the encryption key used to protect the contents of the encryption settings database. The Conjur passphrase provider can be used in other cases in which the server might need a clear-text secret, including as a PIN needed to access a certificate key store or as credentials for authenticating to an external service. The server can authenticate to Conjur using a username and a password or an API key.

Added support for obtaining secrets from Azure Key Vault

Fixed | DS-43918 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSYnc

The Azure Key Vault cipher stream provider can use a retrieved secret to generate the encryption key used to protect the contents of the encryption settings database. The Azure Key Vault passphrase provider can be used in other cases in which the server might need a clear-text secret, including as a PIN needed to access a certificate key store or as credentials for authenticating to an external service.

New global configuration properties to impose limits on the maximum number of attributes that can be present in an add request and the maximum number of modifications in a modify request

Fixed | DS-43959, DS-44924 | PingDirectory

These can be used to avoid potential denial of service attacks. Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that can be provided for an attribute.

Fixed proxied authorization issue

Fixed | DS-44081 | PingDirectory

Addressed an issue where proxied authorization would fail in rare cases for usernames with 57 or 58 characters and DNs with 108 or 109 characters.

Fixed `manage-profile replace-profile` keystore files issue

Fixed | DS-44280, DS-45027, DS-45037 | PingDirectory, PingDirectoryProxy, PingDataSync

Fixed an issue where `manage-profile replace-profile` did not correctly handle keystore files with a `.bcfks` extension while in FIPS-140-2-compliant mode.

Fixed View API Commands issue

Fixed | DS-44329 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Resolved an issue where the **View API Commands** link appeared to be disabled in the administrative console.

Copyright © 2025 Ping Identity Corporation

Fixed silent replication failure

Fixed DS-44454 PingDirectory

Fixed an issue where non-DN modifications associated with a `moddn` change would silently fail to replicate.

Added new `--performLocalCleanup` argument to `remove-defunct-server`

Fixed DS-44495 PingDirectory

Added a new argument, `--performLocalCleanup`, to **`remove-defunct-server`** that simplifies the replication artifact cleanup process. To clean up replication artifacts on earlier releases of the Directory Server, run **`remove-defunct-server`** with no bind arguments while the server is offline.

Added a PKCS #11 cipher stream provider

Fixed DS-44519 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added a PKCS #11 cipher stream provider that can require access to a certificate in a PKCS #11 token to unlock the server's encryption settings database. Only certificates with RSA key pairs can be used because Java virtual machines (JVMs) do not currently provide adequate key wrapping support for elliptic curve key pairs.

Server instances can now be safely mirrored to older servers in mixed-version topologies

Fixed DS-44577 PingDirectory

Server instances, which are within a mirrored subtree, can now be safely mirrored to older servers in mixed version topologies. This is done by adding the following to server instances: objectclass: extensibleObject.

Fixed an issue where secret keys under `cn=Topology,cn=config` could be lost when removing a server from the topology

Fixed DS-44591 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

When a server is removed with the `dsreplication disable` or **`remove-defunct-server`** tools, its secret keys are now distributed among the remaining members of the topology. The keys from the rest of the topology will also be copied to the server being removed.

The cipher secret keys in the topology that are affected by this change are used by reversible password storage schemes (except for AES256, which uses the encryption settings database). If you are using a reversible password storage scheme other than AES256, before this fix, you could lose access to keys that had been used for reversible password encryption when removing servers from the topology.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Because this change only applies to the most recent version of **`remove-defunct-server`** and **`dsreplication disable`**, if you are removing a server from a multi-version topology, you should run that tool from the most recent version. In the past **`dsreplication`** and **`remove-defunct-server`** could only be run from an older version, but now in the case of removing a server from the topology, they should be run from the most recent version in the topology. If you run the tool from an older server, it does not include this fix, and you might lose access to secret keys from servers that are removed from the topology.

Added PingData Administrative Console configuration capability

Fixed | DS-44595 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

The PingData Administrative Console can now be configured to supply PINs to its trust stores through the `oidc-trust-store-pin-passphrase-provider` and `trust-store-pin-passphrase-provider` settings. This means trust store types that require passphrases (ex: PKCS12 or BCFKS) are now properly supported.

The PingData Administrative Console can now retrieve files created from `collect-support-data` or `server-profile` tasks

Fixed | DS-44601 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

The PingData Administrative Console can now retrieve files created from `collect-support-data` or `server-profile` tasks when using single sign-on (SSO) to authenticate with the managed server.

Updated the file servlet

Fixed | DS-44602 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Updated the file servlet to add support for token-based authentication using an OAuth 2.0 access token or an OpenID Connect ID token. The servlet previously only supported basic authentication.

Improved `includePath` argument validation performed by the `manage-profile generate-profile` tool

Fixed | DS-44604 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

The tool will only use relative paths that exist below the server root, and it previously silently ignored absolute paths or relative paths that referenced files outside of the server root. It will now exit with an error if the `includePath` argument is used to provide an absolute path or a path outside the server root. It will accept but warn about paths that reference files that do not exist.

Fixed an issue that caused an internal root account to be subject to the server's default password policy

Fixed | DS-44623 | PingDirectory, PingDirectoryProxy

Copyright © 2025 Ping Identity Corporation

Fixed an issue that caused an internal root account (used for processing certain types of internal operations) to be subject to the server's default password policy. With some password policy configurations, if a DirectoryProxy Server attempted to perform an internal operation that targeted data in a backend Directory Server, that operation could have been incorrectly rejected.

Fixed symmetric keys issue

Fixed | DS-44648 | PingDirectory

Addressed an issue where symmetric keys were not being sanitized in the `config-audit.log`.

Updated the `export-ldif` tool

Fixed | DS-44669 | PingDirectory

Updated the **`export-ldif`** tool to always base64 encode values with any ASCII control characters. The LDIF specification in RFC 2849 only requires base64 encoding for the NUL, LF, and CR control characters, and those are the only control characters that were previously base64 encoded. However, the specification also permits base64 encoding for any type of character, and always base64 encoding all control characters is safer and reduces the chance for errors when working with values containing such characters.

Made several improvements to the `ldap-diff` tool

Fixed | DS-44757 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

- Added the ability to perform a byte-for-byte comparison of attribute values rather than using schema-based logical equivalence.
- Added the ability to use a properties file to obtain default values for command-line arguments.
- Improved the ability to use different TLS-related settings for the source and target servers.
- Improved support for SASL authentication.

Updated the `migrate-ldap-schema` tool

Fixed | DS-44758 | PingDirectory

Updated the **`migrate-ldap-schema`** tool to provide more flexibility for TLS negotiation, support for SASL authentication, support for using a properties file, and better validation for migrated attribute type and object class definitions.

Fixed a `remove-defunct-server` issue

Fixed | DS-44793 | PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Fixed an issue in which **`remove-defunct-server`** would remove attributes from `config.ldif` if they were identical apart from case.

Copyright © 2025 Ping Identity Corporation

Improved performance for modify operations

Fixed DS-44884 PingDirectory

Improved performance for modify operations that need to insert an entry ID into the middle of a very large composite index ID set.

Addressed a connection error in `remove-defunct-server`

Fixed DS-44892 PingDirectory

Addressed a connection error in **`remove-defunct-server`** when the tool tried to migrate secret keys on a single-instance topology (in other words, a server that is not part of a replication topology). The tool now only moves secret keys if the server is part of a topology.

Fixed an error when backing up an encrypted backend

Fixed DS-44904 PingDirectory

Fixed a race condition that could sporadically cause an error when backing up an encrypted backend.

Addressed an issue where simple binds on entries

Fixed DS-44931 PingDirectory

Addressed an issue where simple binds on entries without passwords would not update the relevant password policy attributes, such as `ds-pwp-auth-failure`.

Updated the crypto manager configuration to add properties for controlling the set of TLS protocols and cipher suites

Fixed DS-44940 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Updated the crypto manager configuration to add properties for controlling the set of TLS protocols and cipher suites that will be used for outbound connections, as well as properties for controlling whether to enable TLS cipher suites that rely on the SHA-1 digest algorithm or the RSA key exchange algorithm.

Fixed an issue in which the server might not use appropriate resource limit values

Fixed DS-44942 PingDirectory, PingDirectoryProxy

Fixed an issue in which the server might not use appropriate resource limit values for accounts that bind with pass-through authentication. In such cases, the server might apply size limit, time limit, idle time limit, and other constraints from the global configuration instead of alternative values for those limits set in the user entry.

Copyright © 2025 Ping Identity Corporation

Fixed server hang issues

Fixed DS-45032 PingDirectory

- Addressed an issue that caused `remove-defunct-server` to hang.
- Addressed an issue that caused `remove-defunct-server` to hang when performing replication artifact cleanup in non-interactive mode.

For the `initilaze-all` `dsreplication` subcommand avoid closing connections to remote servers multiple times

Fixed DS-45038 PingDirectory

For the `initilaze-all` `dsreplication` subcommand avoid closing connections to remote servers multiple times in order to apply the new generation ID.

Added support for Eclipse Foundation JDKs

Fixed DS-45039 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added support for the use of Java Development Kits (JDKs) obtained through Eclipse Foundation.

Fixed an issue where explicit `createTimestamp` values are replicated to peer servers

Fixed DS-45056 PingDirectory

Fixed an issue where explicit `createTimestamp` values are replicated to peer servers using a default timestamp format rather than the non-default format value stored on the first server.

Updated the mirror virtual attribute provider to include an option to bypass access control evaluation for the internal searches that it performs

Fixed DS-45060 PingDirectory

This might allow the virtual attribute to provide values from another entry even if the requester would not otherwise have permission to access those values.

Fixed a Ping Directory Server performance issue involving high CPU usage

Fixed DS-45115 PingDirectory

Fixed a Ping Directory Server performance issue involving high CPU usage when writing LDAP data to certain clients using TLSv1.3 connection security.

Copyright © 2025 Ping Identity Corporation

Removed `-XX:RefDiscoveryPolicy=1` from the default `start-server` Java arguments

Fixed DS-45124 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

In rare cases, this argument was related to segmentation faults in the JVM, especially when used with the G1 garbage collector.

Fixed a composed attribute plugin issue

Fixed DS-45153 PingDirectory

Fixed an issue that prevented the composed attribute plugin from working for operations that are part of a multi-update request.

Fixed an issue where a server with a newly initialized database could go into lockdown mode

Fixed DS-45154 PingDirectory

Fixed an issue where a server with a newly initialized database (through `dsreplication initialize`) could go into lockdown mode and report that the server might have missed one or more updates. This generally occurred only if the initialized server was restarted right after initialization completed.

Changed default tab in the administrative console

Fixed DS-45160 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Changed the default tab in the administrative console to **Modify** when updating an existing server resource with new changes

Added support for new extended operations

Fixed DS-45162 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added support for new extended operations to help manage the server's listener and inter-server certificates. Updated the `replace-certificate` tool to add support for replacing and purging certificates in a remote instance, and to allow skipping validation for the new certificate chain.

Added support for BellSoft JDKS

Fixed DS-45190 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added support for the use of JDKs obtained through BellSoft.

Improved performance of server encryption

Fixed DS-45203 PingDirectory

Resolved a performance issue that could cause servers installed using a server encryption option to spend several minutes waiting in the `Initializing Crypto Manager` phase during server startup.

Copyright © 2025 Ping Identity Corporation

Added a scroll bar to the administrative console's Server list

Fixed DS-45284 PingDirectory, PingDirectoryProxy, PingDataMetrics, PingDataSync

Added a scroll bar to the administrative console's **Server** list to ensure all servers are accessible regardless of screen size.

Updated the entry counter, hash DN, and round robin placement algorithms

Fixed DS-44678 PingDirectoryProxy

Updated the entry counter, hash DN, and round robin placement algorithms to make it possible to exclude specified backend sets from consideration when adding new entries to an entry-balanced topology.

Improved server logic

Fixed DS-44798 PingDirectoryProxy

Improved the logic the server uses to select the best result to return to the client when an operation fails in an entry-balanced topology after the request was broadcast to all backend sets. In some cases, the server could have incorrectly returned a result from a backend set in which the target entry did not exist instead of a more appropriate result from the backend set that did contain the entry.

Fixed dashboard icon issue

Fixed DS-44224 PingDataMetrics

Addressed an issue where icons on the dashboards were not properly displayed.

Synchronize from Active Directory attribute `lockoutTime` source systems to PingDirectory attribute `pwdAccountLockedTime`

Fixed DS-44513 PingDataSync

Because `pwdAccountLockedTime` cannot be written to directly, an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `pwdAccountLockedTimeFromAD` to `pwdAccountLockedTime`.

Added direct attribute mapping that maps from `ds-pwp-account-disabled-from-ad` to `ds-pwp-account-disabled`

Fixed DS-44636 PingDataSync

Synchronize from Active Directory `userAccountControl` bit indicating that the account is disabled (bit #2) (or `msDS-UserAccountDisabled` on AD-LDS) to PingDirectory attribute `ds-pwp-account-disable`. Because `ds-pwp-account-disabled` cannot be written to directly, an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `ds-pwp-account-disabled-from-ad` to `ds-pwp-account-disabled`.

Copyright © 2025 Ping Identity Corporation

Added direct attribute mapping that maps from `pwdChangedTimeFromAD` to `pwdChangedTime`

Fixed DS-44660 PingDataSync

Synchronize from Active Directory attribute `pwdLastSet` with the password changed time to PingDirectory attribute `pwdChangedTime`. Because `pwdChangedTime` can not be written to directly an extended operation is used. This synchronization depends on a direct attribute mapping that maps from `pwdChangedTimeFromAD` to `pwdChangedTime`.

Fixed an issue where the PingDataSync server failed to synchronize certain modifications involving multiple attributes

Fixed DS-44922 PingDataSync

Fixed an issue where the PingDataSync server failed to synchronize certain modifications involving multiple attributes with the same base name but with different option tags, and any of these attributes having more values in the source entry than the `replace-all-attr-values-limit` for the `Sync` class.

Fixed an issue where PingDataSync was not syncing entries to PingOne environments

Fixed DS-45134 PingDataSync

Addressed an issue where PingDataSync was not syncing entries to PingOne environments because of rate-limiting responses from PingOne.

Fixed a `max-rate-per-second` configuration setting

Fixed DS-45138 PingDataSync

Addressed an issue where the `max-rate-per-second` configuration setting was not being applied to the `resync` tool.

Delegated Admin 4.9 (March 2022)

Managing accounts now includes the ability to unlock accounts

Improved Delegated Admin

Previously, the only way to unlock an account was for an administrator to reset the password. Now, delegated administrative users can directly unlock an account without resetting the password. For more information, see Unlocking user accounts.

> **Note**
>
> The initiate password reset option does not unlock accounts.

Resource types can now have custom names assigned for Members and Nonmembers columns

Improved Delegated Admin

Copyright © 2025 Ping Identity Corporation

This option is available for the Groups, Users, and Generic rest resource types.

For more information, see Manage groups.

The grant type is now set to Authorization Code with PKCE

Improved Delegated Admin

Earlier versions of Delegated Admin have used the Implicit grant type as the default OpenID Connect (OIDC) grant type. Because the Implicit grant type can leak access tokens, it is no longer recommended for use. In new installations of Delegated Admin, the grant type is set to Authorization Code with PKCE. To change your default OIDC grant type to Authorization Code with PKCE in existing installations of Delegated Admin, see Changing the default OIDC grant type.

For more information on the Implicit grant type, see OAuth 2.0 Implicit Grant.

`dadmin-account-locked` is not available for filtering

Issue Delegated Admin

Because the account locked state, `dadmin-account-locked`, is not a true attribute, it is not available for filtering in reporting.

No resources displayed for a correlated resource type

Issue Delegated Admin

If a resource is linked to more correlated resources than the correlated resource type's search limit, then no resources will be displayed for that correlated resource type. To view the resources for that correlated resource type, increase the correlated resource type's search limit.

Fixed error message issue

Fixed DS-40723 Delegated Admin

Fixed an issue where an error message was not displayed when password generation was unsuccessful.

Fixed multi-valued attribute deletion error

Fixed DS-45075 Delegated Admin

Fixed an issue that prevented the first value in a multi-valued attribute from being deleted.

Updated the warning banner for configuration errors

Fixed DS-45079 Delegated Admin

Updated the warning banner for configuration errors to only display for the first 10 seconds after signing in to Delegated Admin.

Copyright © 2025 Ping Identity Corporation

Added the `ds-pwp-modifiable-state-json` attribute

Fixed DS-45448 Delegated Admin

Added the `ds-pwp-modifiable-state-json` attribute to user resource types automatically.

Fixed a user password policy issue

Fixed DS-45502 Delegated Admin

Fixed an issue in which a user's password policy was not being used to generate new passwords for the user.

Previous Releases

For information about enhancements and issues resolved in previous major and minor releases of PingData products, follow the links below to their release notes:

- 8.3
- 8.2
- 8.1
- 7.3

Copyright © 2025 Ping Identity Corporation

Installing the PingDirectory Suite of Products

PingDirectory offers a highly portable and scalable architecture that runs on multiple platforms and operating systems. The server is specifically optimized for operating systems used in environments that process a large number of entries.

This guide describes how to install the PingDirectory server and its add-ons, PingDirectoryProxy, Delegated Admin, PingDataSync, and PingDataMetrics.

It contains instructions for preparing your environment for installation, obtaining or upgrading a Ping Identity license key, downloading the installation packages, and installing the servers. It also describes how to uninstall and upgrade the servers, and how to start, stop, and restart the servers.

System requirements

The PingDirectory server requires certain software packages to operate properly.

For optimal performance, the server requires Java for 64-bit architectures. To view the minimum required Java version, contact your authorized support provider for the latest supported software versions.

> **Tip**
>
> Implement a Network Time Protocol (NTP) system so that multi-server environments are synchronized and timestamps are accurate.

The following system requirements are qualified and certified to be compatible with the PingDirectory server.

Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software are suspected of causing issues.

CPU and memory

When sizing an instance of the PingDirectory server, provide at least the following minimum specs:

- 2 processor cores
- 4 GB of RAM

You can find more information about memory allocation in Memory allocation and database cache or Finding the optimal heap size (requires authentication).

Running PingDirectory on Amazon Web Services (AWS)

To take advantage of snapshots for backing up any important files, install the PingDirectory server on an Elastic Block Store (EBS) file system. You should also move any databases, logs, and other files to a high-performance file system that's separate from the rest of the server image and create an S3 bucket for storing backups, schema, and other artifacts.

The following guidelines and considerations apply to AWS environments:

- PingDirectory does not support the Elastic File System (EFS) for database persistence. For the best performance, use the local SSD.
- Using network load balancers (NLBs) can lead to severed connections, which could cause issues that are difficult to diagnose.

Copyright © 2025 Ping Identity Corporation

Platforms

The PingDirectory, PingDirectoryProxy, PingDataSync, and PingDataMetrics servers support the following operating systems for installation and deployment:

- Amazon Linux 2 and 2022
- Canonical Ubuntu 18.04 LTS and 20.04 LTS
- CentOS 7.7 and 8.1
- Microsoft Windows Server 2016, 2019, and 2022
- Oracle Linux
  - Release 7 up to 7.9
  - Release 8 up to 8.6
- Red Hat Enterprise Linux ES
  - Release 7 up to 7.9
  - Release 8 up to 8.7
  - Release 9 up to 9.1
- SUSE Enterprise Linux 12 SP5, 15 SP3, and 15 SP4

Docker

To deploy the PingDirectory server using Docker, you must have a supported version of Docker. The following versions of Docker are supported:

- Docker 20.10.9

Learn more in the pingidentity/pingdirectory Docker image and the Ping Identity DevOps documentation.

> **Note**
>
> Only the PingDirectory server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source or third-party license.
> Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment

You must have one of the following versions of the Java Development Kit installed prior to installing the server:

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- Oracle JDK 17
- OpenJDK 8 64-bit

Copyright © 2025 Ping Identity Corporation

- OpenJDK 11 and 17
- Corretto 8, 11, and 17

> **Important**
>
> Refer to the following with regard to Java support:
> - Due to the number of supported JDK variants, we do not explicitly list all of them here. The criteria for supported JDKs are:
>   - They must be built from the OpenJDK codebase.
>   - They must use the HotSpot JIT compiler. They cannot use OpenJ9 or other JIT implementations.
> - PingDataMetrics doesn't support Java 17.
> - The Java Support Policy applies to your Java Runtime Environment (JRE).

Browsers

The following browsers are supported by the PingDirectory server administrative console:

- Chrome
- Firefox
- Edge

Installing Java

The PingDirectory server requires Java. For optimized performance, use Java for 64-bit architectures. See System requirements for the list of supported Java versions.

About this task

Even if your system already has Java installed, you might want to create a separate Java installation for use by the PingDirectory server so that updates to the system-wide Java installation do not impact the server.

> **Note**
>
> A separate Java installation requires that you download the Java Development Kit (JDK) instead of the Java Runtime Environment (JRE) for the 64-bit version.

To install Java, go to the website for the type of Java you want to install, locate the preferred version, and follow the instructions.

Preparing the operating system (Linux)

Several operating system customizations can improve server performance on Linux systems.

These customizations include:

- Configuring the file descriptor limits
- Tuning the file system

Copyright © 2025 Ping Identity Corporation

- Setting the maximum user processes
- Editing OS-level environment variables
- Installing sysstat and pstack (Red Hat)
- Installing dstat (SUSE Linux)
- Disabling file system swapping
- Adjusting system memory allocation
- Omitting the `vm.overcommit_memory` property
- Managing system entropy
- Setting file system event monitoring (**`inotify`**)
- Tuning the I/O scheduler

Configuring the file descriptor limits

The operating system default file descriptor limits restrict the number of PingDirectory server connections. You can change the descriptor limits to allow more connections.

About this task

The PingDirectory server allows for an unlimited number of connections by default, but the file descriptor limit on the operating system restricts the number of connections. Many Linux distributions have a default file descriptor limit of 1024 per process, which might be too low for the server if it needs to handle a large number of concurrent connections.

If the operating system relies on `systemd`, see the Linux operating system documentation for instructions on setting the file descriptor limit.

After you set the operating system limit, you can configure the number of file descriptors that the server will use either by using a **`NUM_FILE_DESCRIPTORS`** environment variable, or by creating a **`config/num-file-descriptors`** file with a single line such as **`NUM_FILE_DESCRIPTORS=12345`**. If these are not set, the operating system uses the default of 65535 descriptors. This is an optional change that you can make if you want to make sure the server shuts down safely before reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

   ```
   sysctl fs.file-max
   ```

   The `fs.file-max` limit is the maximum server-wide file limit that you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file.

   If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit.

   If there is no line that sets a value for this property, add the following to the end of the file:

Copyright © 2025 Ping Identity Corporation

```
fs.file-max = 100000
```

> **Note**
>
> 100000 is just an example here. Specify a value of at least 1.5 times the per-process limit.

3. Display the current hard limit of the system.

```
ulimit -aH
```

The `open files (-n)` value is the maximum number of open files per process limit.

The value should be set to at least 65535.

4. Edit the `/etc/security/limits.conf` file.

If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines before `#End of file`, making certain to insert a tab between the columns.

```
*   soft   nofile   65535
*   hard   nofile   65535
```

> **Note**
>
> The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.
>
> ```
> cat /proc/sys/fs/file-max
> ```
>
> If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the **`ulimit`** command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

Result

Copyright © 2025 Ping Identity Corporation

Note

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits.

```
/etc/security/limits.d/20-nproc.conf

 Add or edit the following lines if they do not already exist:

*          soft    nproc     65536
*          soft    nofile    65536
*          hard    nproc     65536
*          hard    nofile    65536
root       soft    nproc     unlimited
```

Tuning the file system

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and `noatime` to improve server performance.

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation.

This feature might increase the risk of data loss in cases where a system loses power before all of the data has been written to disk. This can occur if a program is replacing the contents of a file without forcing a write to the disk with **`fsync`**. To reduce this risk, make sure the default **`auto_da_alloc`** option is enabled on ext4 file systems.

The following changes can be made in the `/etc/fstab` file.

Click the following tabs to see instructions for the type of tuning you want to perform.

Copyright © 2025 Ping Identity Corporation

Set file system flushes

Setting the file system flushes

Reduce the span between file system flushes to improve PingDirectory server performance.

About this task

By default, Linux servers running the ext3 file system flush the data to disk every five seconds.

Steps

1. If the PingDirectory server is running on a Linux server using the ext3 file system, consider editing the mount options for that file system to include the following command.

   ```
   commit=1
   ```

   This variable changes the flush frequency from five seconds to one second.

2. You should also set the flush frequency in the `/etc/fstab` file.

   Changing the mount command alone does not survive across reboots.

Set noatime

Setting noatime on ext3 and ext4 Systems

If your Linux server uses an ext3 or ext4 file system, set `noatime` to improve performance by turning off any *atime* updates during read access.

About this task

Additionally, set the flush frequency in the `/etc/fstab` file. Performing the change through the **`mount`** command alone does not survive across reboots.

Steps

- Run the **`mount`** command for the relevant system.

  Choose from:

  - ext3 system:

    ```
    # mount -t ext3 -o noatime /dev/fs1
    ```

  - ext4 system:

    ```
    # mount -t ext4 -o noatime /dev/fs1
    ```

Copyright © 2025 Ping Identity Corporation

Setting the maximum user processes

To address memory problems when running multiple servers, increase the default maximum user process limit.

About this task

Some Linux distributions, such as Redhat Enterprise Linux Server and CentOS 6.0 or later, set the default maximum number of user processes to 1024. This is considerably lower than the same parameter on older distributions. The default value of 1024 leads to some Java virtual machine memory errors when running multiple servers on a machine, because each Linux thread counts as a user process.

At startup, the PingDirectory server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by **`ulimit`** is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, it displays an error message.

There are several ways to set the maximum user process limit.

Steps

- Set the limit in `/etc/security/limits.conf`.

  Replace the (`*`) with the name of the user under which the software will run.

  Example:

  ```
  * soft nproc 65535
  * hard nproc 65535
  ```

- Set the *NUM_USER_PROCESSES* environment variable to `16383`.
- In the `config/num-user-processes` file, set *NUM_USER_PROCESSES* to `16383`.

Editing OS-level environment variables

Certain environment variables might affect the PingDirectory server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the PingDirectory server explicitly overrides the values of key environment variables like *<PATH>*, *<LD_LIBRARY_PATH>*, and *<LD_PRELOAD>* to ensure that environment settings used to start the server do not inadvertently impact its behavior.

If you need to edit any of these environment variables, set the values of those variables by manually editing the *<set_environment_vars>* function of the `lib/_script-util.sh` script.

You must stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

Installing sysstat and pstack (Red Hat)

If you plan to run PingDirectory on a Red Hat Linux system, install the **`sysstat`** and **`pstack`** packages. These packages are disabled by default, but are useful for troubleshooting.

Copyright © 2025 Ping Identity Corporation

About this task

The troubleshooting tool **collect-support-data** uses the **iostat**, **mpstat**, and **pstack** utilities to collect monitoring, performance, and stack trace information on the server's processes.

Steps

- To install **systat** on your Red Hat system, run the following command:

```
$ sudo yum install sysstat gdb dstat -y
```

Installing dstat (SUSE Linux)

The system monitoring tool **dstat** can help you troubleshoot PingDirectory servers on SUSE distributions.

About this task

The **collect-support-data** tool uses the **dstat** utility for system monitoring. You can obtain **dstat** from the OpenSUSE project website. The following process shows how to install the **dstat** utility.

Steps

1. Sign on as the root user.
2. Add the appropriate repository using the **zypper** tool.
3. Install the **dstat** utility.

```
$ zypper install dstat
```

Disabling file system swapping

Because file system swapping can interfere with PingDirectory, disable performance tuning tools like **tuned**.

Steps

1. Sign on as the root user.
2. Add the line `vm.swappiness = 0` to the file `/etc/sysctl.conf`.
3. Restart the system to apply the change.
4. (Optional) If you need to tune performance after disabling file system swapping, do the following:
    1. Clone the existing performance profile.
    2. Run **tuned**.
    3. Add the line `vm.swappiness = 0` to the file `/usr/lib/tuned/profile-name/tuned.conf`.

Copyright © 2025 Ping Identity Corporation

4. To select the updated profile, run `tuned-adm profile customized_profile`.
5. Restart the system to apply the changes.

Adjusting system memory allocation

You can adjust system memory allocation to improve overall performance by setting the `/proc/sys/vm/max_map_count` kernel tuning parameter. Doing this can prevent problems such as the slowing down of batch execution and a continuous increase of memory used by the JVM.

About this task

A good setting to use is four times the number of megabytes of system memory. For example, if you're running on a system with 128 gigabytes of memory, then calculate (128*1024=131072 megabytes) times 4, which is 524288.

Steps

1. Sign on as root user.
2. Add the line `vm.max_map_count = <megabytes>` to the file `/etc/sysctl.conf`. For example:

```
vm.max_map_count = 524288
```

3. Restart the system to apply the change.
4. (Optional) If you need to tune performance further after setting the `max_map_count` parameter, do the following:
    1. Clone the existing performance profile.
    2. Run the `tuned` command.
    3. Add the line `vm.max_map_count = <megabytes>` to the file `/usr/lib/tuned/profile-name/tuned.conf`.
    4. To select the updated profile, run `tuned-adm profile customized_profile`.
    5. Restart the system to apply the changes.

vm.overcommit_memory property">

Omitting the `vm.overcommit_memory` property

An improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file might cause the `setup` or `start-server` tool to fail.

About this task

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, the operating system might grab too much memory, reducing the amount of available memory for the `setup` or `start-server` tools.

Copyright © 2025 Ping Identity Corporation

Steps

- Omit the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing system entropy

Linux uses entropy to calculate random data that is used by the system in cryptographic operations.

About this task

Some environments with low entropy might have intermittent performance issues with SSL-based communication. This is more typical on virtual machines but can occur in physical instances as well.

Steps

- For best results, monitor the **`kernel.random.entropy_avail`** in **`sysctl`** value.

inotify)">

Setting file system event monitoring (`inotify`)

You can configure an event monitoring tool such as **`inotify`** for notifying processes about file system events, including file creation, deletion, and updates.

About this task

Linux limits the number of **`inotify`** watches a user can receive.

Steps

- To increase the limit, edit **`etc/sysctl.conf`** to add the following line.

```
fs.inotify.max_user_watches = 524288
```

- Run the following command.

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tuning the I/O scheduler

Using the correct I/O scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load.

About this task

Copyright © 2025 Ping Identity Corporation

Important

- For file systems running on an SSD or in a virtualized environment, use the recommended `noop` scheduler.
- For additional considerations related to network attached storage, see Databases on storage area networks, network-attached storage, or running in virtualized environments.
- For all other systems, use the `deadline` scheduler.

The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Steps

1. To determine which scheduler is configured on your system, run the following command.

```
$ cat /sys/block/<block-device>/queue/scheduler
```

2. To change the scheduler on a running system, run the following command.

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

3. Restart the system to apply the change.

Running as a non-root user (Linux)

You have two options to run as a non-root user but still allow connections on a privileged port.

Use a load balancer or directory proxy server

Many environments can run the server on a non-privileged port but be hidden by a hardware load balancer or LDAP directory proxy server.

Use `netfilter`

Use the `netfilter` mechanism, exposed through the `iptables` command, to automatically redirect any requests from a privileged port to the non-privileged port on which the server is listening.

Enabling the server to listen on privileged ports (Linux)

For your convenience, enable the server to listen on privileged ports while running as a non-root user.

About this task

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account:

- The `setcap` command assigns capabilities to an application.

Copyright © 2025 Ping Identity Corporation

- The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024).

Steps

1. If Java is installed in `/ds/java` and the Java command to run the server is `/ds/java/bin/java`, you can grant the `cap_net_bind_service` capability to the Java binary with the following command:

   ```
   $ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
   ```

2. Create the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file.

   The Java binary needs an additional shared library (`libjli.so`) as part of the Java installation. Because this process imposes stricter limits on where the operating system looks for shared libraries to load for commands that have capabilities assigned, it is also necessary to tell the operating system where to look for this library.

   Example:

   For example, if the Java installation is in `/ds/java`, the contents of that file should be:

   ```
   /ds/java/lib/amd64/jli
   ```

3. To apply the changes, run the following command:

   ```
   $ sudo ldconfig -v
   ```

Obtaining a Ping Identity license key

License keys are required to install, update, and renew all Ping Identity products.

How to obtain a license

To obtain a license key, contact your account representative or use the Ping Identity licensing portal.

When you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 8.3 to 9.0. When cloning a server instance with a valid license, you do not need a new license.

> **Note**
>
> The upgrade process displays a prompt for a new license.

Copyright © 2025 Ping Identity Corporation

How to specify a license

- Specify a license at setup.

  You have these options:

  - Use the `--licenseKeyFile` *<path-to-license>* option with `setup`.
  - Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.

- Specify a license after setup

  Use the administrative console or `dsconfig` (in the Topology section, select License).

  > **Note**
  >
  > Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- Use the server's `status` tool.
- In the administrative console, go to the **Status** page and search for **License** on the **Monitors** tab.

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the administrative console. For more information, see Upgrading a PingDirectory license.

> **Note**
>
> An expiring license causes alerts and alarms but does not affect the functionality of the product.

Upgrading a PingDirectory license

You can upgrade the license used by the PingDirectory server and any of its plugins with the `dsconfig` command-line tool and the administrative console.

This topic assumes you already have a valid, new license file that you want your server to use.

Upgrading a license using the dsconfig command

Follow these instructions to upgrade your license using the `dsconfig` command in interactive or non-interactive mode. The `dsconfig` command is located in `<server-root>/bin`.

Copyright © 2025 Ping Identity Corporation

In interactive mode

In interactive mode
Steps

1. Run the **`dsconfig`** command-line tool.
2. Select **License** from the **Topology** section of the menu.
3. Select **View and edit the license** from the menu.
4. Enter `1` to edit the `directory-platform-license-key` property.

   You should see a message like the following:

   ```
   The value of 'directory-platform-license-key' has been written to the file below.  You can
   edit and save the file,
   return here, and choose 'finish' to import the changes:

   /Users/<your_id>/PingDirectory/tmp/dsconfig-5614232350526437974-license-directory-platform-
   license-key.lic
   ```

5. Open the new license file in a text editor.
6. Overwrite the contents of the temporary file specified by the **`dsconfig`** tool with the contents of the new license.
7. Save your changes.

In non-interactive mode

In non-interactive mode
Steps

1. Enter the following command, providing the path to the new license and making sure to preserve the double quotes:

   ```
   dsconfig set-license-prop \
     --set "directory-platform-license-key:<path_to_new_file.lic>"
   ```

2. Confirm that the command completed successfully.

Upgrading a license using the administrative console

Steps

1. Sign on to the administrative console.

Copyright © 2025 Ping Identity Corporation

2. In the **Topology** area, click **License**.
3. Click **Load From File...**.
4. Select the new license file, and click **Open**.
5. Save your changes.

Downloading the installation packages

Download the latest PingDirectory installation packages from the downloads page on the Ping Identity website.

About this task

To download PingDirectory and its add-ons, you must have an active license and be signed on to the Ping Identity website with the email address used to obtain the license. The add-ons require you to have an installation of the PingDirectory server. Add-ons include PingDirectoryProxy, PingDataSync, PingDataMetrics, the PingData Server SDK, and Delegated Admin.

Steps

1. Sign in to the Ping Identity website.
2. Go to the relevant PingDirectory page.

   Choose from:

   - For the latest version, go to the downloads page.
   - For previous versions, go to the previous releases page.
3. Click **PingDirectory** to download the server's `.zip` distribution file.
4. If you want to install one or more add-ons:

   Choose from:

   - For the latest versions, click the **Add-ons** tab on the downloads page.
   - For previous versions, locate the add-ons grouped with the version of PingDirectory on the previous releases page.
5. Click the add-ons that you want to download.
6. Extract the compressed PingDirectory `.zip` file to a directory of your choice. For example:

   ```
   $ unzip  {pingdir}-<version>.zip
   ```
7. Extract the compressed `.zip` files for any add-ons that you downloaded.
8. For Delegated Admin, copy the folder named `/delegator` and its contents to the appropriate directory as shown in the following table.

Copyright © 2025 Ping Identity Corporation

Server	Directory
PingDirectory server	`/webapps`
Replicated instance of PingDirectory server	`/webapps`
PingDirectoryProxy server	`/webapps`
External web server	Directory for web-based apps

Pre-installation considerations

After you have unzipped the PingDirectory server distribution file, you might want to carry out the following functions depending on your deployment requirements:

Custom schema elements

If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you can do one of the following:

- Copy your custom schema file to the `config/schema` directory before running setup.
- Copy your custom schema file to the `config/schema` directory after setup and restart the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
- Use the **Schema Editor** after setup. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.

Certificates

If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory before running setup. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.

Encryption passphrase

You can enable encryption for directory data, backups, LDIF exports, and log files during setup by providing or generating an encryption key with a passphrase.

Locations

Location names are used to define a grouping of PingDirectory server products based on physical proximity. For example, a location is most often associated with a single data center location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.

Copyright © 2025 Ping Identity Corporation

Validate ACIs

Many directory servers accept invalid access control instructions (ACIs) because of a less restrictive application of ACIs. For example, if a Sun/Oracle server encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server might not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory server. If you are migrating from a Sun/Oracle deployment to a PingDirectory server, the PingDirectory server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see Validating ACIs before migrating data.

Important

Each server deployment requires an execution of `setup`. Duplicating a server-root is not supported. The installation of the server doesn't write or require any data outside of the server-root directory.
After you run the `setup` tool, do not copy the server-root to another location or system to duplicate the installation, because this isn't a supported method of deployment. If a host or file system change is needed, you can move the server-root to another host or disk location.

Installing the servers

The `setup` tool allows you to quickly install and configure a stand-alone server instance.

Server installation modes

You can run the tool in either of the following modes:

- **Interactive command-line mode**. This mode prompts for information during the installation process. To start the installation in this mode, run the `setup` command without any options.
- **Non-interactive command-line mode**. This mode is designed for setup scripts to automate installations or for command-line usage. To start the installation in this mode, run the `setup` command with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

Note

Make sure you perform all installation steps while logged on to the system as the user or role under which the server will run.

Installation instructions

See the instructions in the following topics to install the PingDirectory suite of products:

- Installing the PingDirectory server
- Installing the PingDirectoryProxy server
- Installing Delegated Admin
- Installing the PingDataSync server

Copyright © 2025 Ping Identity Corporation

- Installing the PingDataMetrics server

Installing the PingDirectory server

After you prepare your hardware and software systems, you can set up the PingDirectory server.

Click the following tabs to see instructions for the type of installation you want to perform.

Copyright © 2025 Ping Identity Corporation

In interactive mode

Installing the PingDirectory server in interactive mode

The `setup` command provides an interactive text-based command-line interface to set up a PingDirectory server instance.

Before you begin

Review Pre-installation considerations.

Steps

1. Extract the distribution `.zip` archive, then go to the server root directory.
2. Run the `setup` command.

   Example:

   ```
   $ ./setup
   ```

   If the *<JAVA_HOME>* environment variable is set to an older version of Java, explicitly specify the path to the Java Development Kit (JDK) installation during the setup process. Either set the *<JAVA_HOME>* environment variable with the JDK path or execute the `setup` command in a modified Java environment using the `env` command.

   Example:

   ```
   $ env JAVA_HOME=/ds/java ./setup
   ```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
4. Enter the fully qualified host name or IP address of the local host, or press Enter to accept the default.
5. Enter the distinguished name (DN) for the initial root user, or press Enter to accept the default (`cn=Directory Manager`).
6. Enter and confirm the root user password.
7. Press Enter to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS.

   After setup, you can enable or disable individual services and applications by configuring the HTTPS Connection Handler.
8. Enter the port on which the PingDirectory server will accept connections from HTTPS clients, or press Enter to accept the default.
9. Select the unencrypted LDAP connection setting option for this server or press Enter to accept the default (option 3).

   Choose from:

   - Do not accept unencrypted LDAP connections

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you select this option, skip to step 12.

- Accept unencrypted LDAP connections, but require StartTLS to secure all communication on those connections
- Accept unencrypted LDAP connections, but optionally allow StartTLS to secure communication on those connections
- Accept unencrypted LDAP connections and do not enable support for StartTLS

10. Enter the port on which the PingDirectory server will accept connections from LDAP clients, or press Enter to accept the default.
11. Select the desired setting for enabling LDAPS, or press Enter to accept the default.

> **Note**
>
> If you do not enable LDAPS, skip to step 12.

12. Enter the port on which the PingDirectory server will accept connections from LDAPS clients, or press Enter to accept the default.
13. Select the certificate option for this server:

    Choose from:

    - Generate self-signed certificate (recommended for testing purposes only).
    - Use an existing certificate located on a Java Keystore (JKS). Enter the keystore path and keystore PIN to use an existing certificate using a Java Keystore.
    - Use an existing certificate located on a PKCS12 keystore. Enter the keystore path and the keystore PIN to use an existing certificate using use a PKCS#12 keystore.
    - Use an existing certificate on a PKCS11 token. Enter only the keystore PIN to use the PKCS#11 token.

14. Choose the desired encryption for the directory data, backups, and log files from the choices provided:

    Choose from:

    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments. Use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
    - Do not encrypt server data.

Copyright © 2025 Ping Identity Corporation

15. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.
16. To choose an option to generate and import sample data, type the desired number of entries, or press Enter to accept the default number (10000).

    This option is used for quick evaluation of the PingDirectory server. See Importing data if you want to use other options to initialize the server.
17. Choose the option to tune the amount of memory that will be consumed by the PingDirectory server and its tools.
18. Press Enter to prime or preload the database cache at startup before accepting client connections.

    Priming the cache can increase the startup time for the PingDirectory server but provides optimum performance after startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this PingDirectory server instance is starting. Priming the cache can also allow the server to collect information at startup that can be helpful in tuning garbage collection in the Java virtual machine (JVM). See JVM garbage collection using CMS.
19. Enter a location name for this server.
20. Enter a unique instance name for this server.

    You cannot change the name after you set it.
21. Press Enter to accept the default (yes) to start the PingDirectory server after the configuration has completed.

    Enter `no` if you want to configure additional settings or import data. Doing this keeps the server in shutdown mode.
22. Select the desired option for populating the `config/tools.properties` file during setup, or press Enter to select the default (option 1).

    Choose from:

    - Do not populate the `tools.properties` file
    - Populate the `tools.properties` file with properties needed to connect to the server
    - Populate the `tools.properties` file with properties needed to connect to the server, and also include the initial root user DN as the default bind DN
    - Populate the `tools.properties` file with properties needed to connect to the server, and also include the DN and password for the initial root user DN as the default bind DN and password

    > **Caution**
    >
    > This fourth option, which is not recommended for production environments, populates the `tools.properties` file with properties needed to connect to the server, includes the DN for the initial root user as the default bind DN, and writes the password for that user to a `tools.pin` file for use as the default bind password.
23. In the **Setup Summary** window, review your configuration details, and then select your setup option, or press Enter to select the default (option 1):

Copyright © 2025 Ping Identity Corporation

Choose from:

- Set up the server with the parameters you have given
- Provide the setup parameters again
- Cancel the setup

Result

If you select option 1, your PingDirectory server is configured and initialized.

Copyright © 2025 Ping Identity Corporation

In non-interactive mode

Installing the PingDirectory server in non-interactive mode

Run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements. There are two ways to set up a server in non-interactive mode:

- Use the `setup` command with the required arguments.
- Use the `manage-profile setup` command to set up the server with a configured server profile. For more information, see *Setting up the server with an existing encryption settings database* and Server profiles.

Using the `setup` command in non-interactive mode requires that all mandatory arguments be present for each command call. If there are missing or incorrect arguments, the `setup` command fails and aborts the process. You must use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. You must also specify the port on which the server listens for connections:

- `--ldapPort` for connections from unencrypted LDAP clients
- `--ldapsPort` for connections from TLS-encrypted LDAPs clients

Lastly, you must use the `--acceptLicense` option. To view the license, run the `bin/review-license` command.

To automatically tune the Java Virtual Machine (JVM) to use maximum memory, use the `--maxHeapSize` option. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see *Installing the PingDirectory server with a truststore*.

To see a description of the available command-line options for the `setup` command, use `setup --help`.

Instructions for additional tasks you can perform while installing the server in non-interactive mode are provided in the following sections.

Enabling data encryption during non-interactive setup

Enabling data encryption during setup provides the strongest protection for your PingDirectory server.

About this task

Enabling encryption during setup ensures that all data written to the local DB backends, the changelog, and the replication database will be encrypted. Enabling encryption during setup also ensures that directory backups and LDIF exports are encrypted by default.

If you enable encryption after setup, then only entries created or updated after enablement will be encrypted, along with their corresponding records in the LDAP changelog and replication database. Any data and indexes that existed before enabling encryption remain unencrypted. To encrypt pre-existing local DB backends, export the data to LDIF and then re-import the LDIF file. To ensure future encryption of backups and LDIF exports, set the `encrypt-backups-by-default` and `encrypt-ldif-exports-by-default` system configuration properties to `true`.

You can enable encryption in either interactive or non-interactive setup. For information on enabling encryption in interactive setup, see *Installing the PingDirectory server in interactive mode*.

To enable encryption non-interactively:

Copyright © 2025 Ping Identity Corporation

Steps

- Run the `setup` command with one of the following arguments:

Arguments	Description
`--encryptDataWithRandomPassphrase`	Creates an encryption settings definition for you with a strong, randomly generated key. **Note** Because all instances in a topology should have the same encryption settings definitions, you should only use this argument for standalone instances or the first instance in a topology that will export its definitions to other instances.
`--encryptDataWithPassphraseFromFile`	Creates an encryption settings definition from a passphrase you specify. When using this argument, you must specify the path for the file containing the desired passphrase. If you are setting up multiple server instances, you should supply the same passphrase to ensure that definitions are consistent.
`--encryptDataWithSettingsImportedFromFile`	Imports one or more definitions from a file generated by the `encryption-settings export` command. When using this argument, you must specify the path for the file containing the passphrase that protects the encryption settings export.
`--encryptDataWithPreExistingEncryptionSettingsDatabase`	Uses the encryption settings definitions from an encryption settings database that was created by another server instance. For more information, see *Setting up the server with an existing encryption settings database*.

Setting up the server with an existing encryption settings database

For added convenience, you can use an existing encryption settings database when setting up the server.

About this task

Setting up the server with an existing encryption settings database offers several advantages. You can:

- Use an encryption settings database protected by an alternative cipher stream provider. Other methods for enabling data encryption during setup will create an encryption settings database that is protected by an unencrypted password stored in a local file, and anyone with access to the system during setup can decrypt that database's contents. Alternative cipher stream providers offer stronger protection.
- Enable data encryption restrictions during setup without the need to configure them later.
- Use an encryption settings database that is frozen at the time of setup without needing to freeze it later.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you provide a frozen encryption settings database with data encryption restrictions enabled, the definitions it contains are not exposed, even to server administrators.

To set up the server with an existing encryption settings database:

Steps

- Run the `manage-profile setup` command on a server profile with the following properties:
  - A `setup-arguments.txt` file including the `--encryptDataWithPreExistingEncryptionSettingsDatabase` argument
  - A `<server-root>/pre-setup/config/encryption-settings/encryption-settings-db` file representing the desired encryption settings database
  - The `pre-setup-dsconfig` directory including one or more `dsconfig` batch files containing changes needed to enable the cipher stream provider
  - Any metadata files contained in the `<server-root>/pre-setup` directory that the cipher stream provider needs to access the encryption settings database.

  The metadata files needed depend on the enabled cipher stream provider:
  - For the file-based cipher stream provider, use the file specified by the cipher stream provider's `password-file` configuration property. If `encryption-metadata-file` has a value, you must also include the file specified by that property.
  - For the Amazon Key Management Service cipher stream provider, use the file specified by the cipher stream provider's `encrypted-metadata-file` configuration property.
  - For the Amazon Secrets Manager cipher stream provider, use the file specified by the cipher stream provider's `encryption-metadata-file` configuration property.
  - For the Azure Key Vault cipher stream provider, use the file specified by the cipher stream provider's `encryption-metadata-file` configuration property.
  - For the Conjur cipher stream provider, use the file specified by the cipher stream provider's `encryption-metadata-file` configuration property.
  - For the PKCS #11 cipher stream provider, use the file specified by the cipher stream provider's `encryption-metadata-file` configuration property.
  - For the Vault cipher stream provider, use the file specified by the cipher stream provider's `vault-encrpytion-metadata-file` configuration property.

Installing the PingDirectory server with no security enabled

You can install a PingDirectory server in non-interactive mode in a production or QA environment with no security enabled.

Steps

- Extract the distribution `.zip` file and, from the server root directory, run the `setup` command with the `--no-prompt` option for non-interactive mode.

Copyright © 2025 Ping Identity Corporation

The following example command uses the default root user distinguished name (`cn=Directory Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the setup generates an error message. The `--instancename` option specifies the name for the server instance and should be unique across all instances in the topology. The `--location` option specifies the name of the location in which the instance will be installed. You should generally configure your topology with a separate location for each data center to allow inter-server communication to prioritize servers in the same location over those in remote locations.

Example:

```
$ ./setup --no-prompt --rootUserPassword "password" \
  --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389 \
  --instancename Instance1 --location Location1
```

Installing the PingDirectory server with a truststore

You can set up the PingDirectory server in non-interactive mode using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

About this task

Steps

- Unzip the distribution `.zip` file and, from the server root directory, run the **`setup`** command with the `--no-prompt` option for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

  Example:

  ```
  $ ./setup --no-prompt --rootUserPassword "password" \
    --baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
    --ldapsPort 636 --useJavaKeystore config/keystore.jks \
    --keyStorePasswordFile config/keystore.pin \
    --certNickName server-cert --useJavaTrustStore config/truststore.jks \
    --acceptLicense --instancename Instance1 --location Location1
  ```

  The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the administrative console or the **`dsconfig`** command by editing the Trust Manager Provider standard configuration object.

Copyright © 2025 Ping Identity Corporation

As a lightweight server

Installing a lightweight server

Users who want to demo or test a lightweight version of the PingDirectory server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects.

All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that are notified of changes to those objects.

The configuration framework does not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you must first remove the reference to it. If you try to remove a configuration object that is referenced, both `dsconfig` and the administrative console should prevent you from removing it and tell you what still references it.

Depending on your test configuration, some example configuration changes that you can make are as follows:

Reduce the number of worker threads

Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
  --set num-worker-threads:8 \
  --set num-administrative-session-worker-threads:4 \
  --set max-work-queue-capacity:100
```

Reduce the percentage of JVM memory used for the JE database cache

When you have a memory-constrained environment, you want to ensure that as much memory as possible is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:5
```

Disable the Dictionary Password Validator

The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it frees up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.By default, the Dictionary Password Validator is referenced by the Secure Password Policy and the Root Password Policy. Therefore, you must first enter the following commands to update the password policies so that they no longer reference the validator.

```
$ bin/dsconfig set-password-policy-prop --policy-name "Secure Password Policy" --remove password-
validator:Dictionary
$ bin/dsconfig set-password-policy-prop --policy-name "Root Password Policy" --remove password-
validator:Dictionary
```

Copyright © 2025 Ping Identity Corporation

Then, you can disable the Dictionary Password Validator by using the following command:

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

Disable the Commonly-Used Passwords Validator

The Commonly-Used Passwords Validator loads a relatively large dictionary of banned passwords into memory. By default, this validator is referenced by the Secure Password Policy and the Root Password Policy. Therefore, you must first enter the following commands to update the password policies so that they no longer reference the validator.

```
$ bin/dsconfig set-password-policy-prop --policy-name "Secure Password Policy" --remove password-
validator:Commonly-Used Passwords
$ bin/dsconfig set-password-policy-prop --policy-name "Root Password Policy" --remove password-
validator:Commonly-Used Passwords
```

Then, you can disable the Commonly-Used Passwords Validator by using the following command.

```
$ bin/dsconfig delete-password-validator --validator-name Commonly-Used Passwords
```

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

Copyright © 2025 Ping Identity Corporation

On Windows

Installing the server on Windows

Use the `setup.bat` script to install the server on Windows.

Before you begin

- Make sure that you have set the `JAVA_HOME` environment variable to the location of your Java installation directory. For more information, see the "Java Runtime Environment" section in System requirements and Installing Java.
- Review Pre-installation considerations.

About this task

Complete the following steps to install the PingDirectory server.

Steps

1. Extract the distribution `.zip` file.
2. In the Windows Command Prompt or PowerShell, go to the server's root directory, and enter **setup.bat**.
3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
4. Respond to the prompts. You can enter your own values or press Enter to accept the defaults.

   If you want to see a detailed step-by-step description of the installation, see *Installing the PingDirectory server in interactive mode*, starting with step 3.
5. In the setup summary, review your configuration details, and then select your setup option, or press Enter to select the default (option 1):

   Set up the server with the parameters you have given.

   Result:

   If you select option 1, your PingDirectory server is configured and initialized.
6. If you want to run the server as a Windows service, follow the instructions in Running the server as a Microsoft Windows service.

Installing the PingDirectoryProxy server

After you install the PingDirectory server, you can install and set up the PingDirectoryProxy server.

Click the following tabs to see instructions for the type of installation you want to perform.

Copyright © 2025 Ping Identity Corporation

In interactive mode

Installing the server in interactive mode

The `setup` command provides an interactive text-based interface to install a PingDirectoryProxy server instance.

Installing the first server
Steps

1. Change to the server root directory.

   Example:

   ```
   cd PingDirectoryProxy
   ```

2. Run the `setup` command.

   ```
   $ ./setup
   ```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.

4. Press **Enter** to accept the default of `no` in response to adding this new server to an existing topology.

   ```
   Would you like to add this server to an existing Directory Proxy Server topology? (yes / no)
   [no]:
   ```

5. Enter the fully qualified host name for this server, or press **Enter** to accept the default.

6. Create the initial root user DN for this server, or press **Enter** to accept the default.

7. Enter and confirm a password for this account.

8. To enable the PingDirectoryProxy server services (Configuration, Documentation, and Directory REST API) and Administrative Console over HTTPS, press **Enter** to accept the default. After setup, individual services can be enabled or disabled by configuring the HTTPS Connection Handler.

9. Enter the port on which the PingDirectoryProxy server should accept connections from HTTPS clients, or press **Enter** to accept the default.

10. Enter the port on which the PingDirectoryProxy server should accept connections from LDAP clients, or press **Enter** to accept the default.

11. The next two options enable LDAPS and StartTLS. Press **Enter** to accept the default (yes), or type **no**. If either are enabled, certificate options are required. To use the Java Keystore or the PKCS#12 keystore, the keystore path and the key PIN are required. To use the PKCS#11 token, only the key PIN is required.

12. Choose a certificate server option:

    Choose from:

    - 1) Generate self-signed certificate (recommended for testing purposes only)
    - 2) Use an existing certificate located on a Java Keystore (JKS)

Copyright © 2025 Ping Identity Corporation

- 3) Use an existing certificate located on a PKCS#12 keystore
- 4) Use an existing certificate on a PKCS#11 token

13. Choose the desired encryption for backups and log files from the choices provided:

    Choose from:

    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
    - Do not encrypt server data.

14. To configure your PingDirectoryProxy server to use entry balancing, type `yes`, or accept the default `no`. In an entry balancing environment, entries immediately beneath the balancing base DN are divided into disjoint subsets. Each subset of data is handled by a separate set of one or more directory server instances, which replicate this subset of data between themselves. Choosing `yes` will enable more memory be allocated to the server and tools.
15. Choose the option for the amount of memory to assign to this server.
16. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.
17. After setup is complete, choose the next configuration option.

```
This server is now ready for configuration What would you like to do?

   1) Start 'create-initial-proxy-config' to create a basic
      initial configuration (recommended for new users)
   2) Start 'dsconfig' to create a configuration from scratch
   3) Quit

Enter choice [1]:
```

Installing additional servers
About this task

The **`setup`** command provides an interactive text-based interface to install a PingDirectoryProxy server instance that clones a previously installed PingDirectoryProxy server instance.

Steps

1. Change to the server root directory.

Copyright © 2025 Ping Identity Corporation

Example:

```
cd PingDirectoryProxy
```

2. Use the **`setup`** command.

```
 $ ./setup
```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
4. Enter `yes` in response to add this new server to an existing topology.

```
Would you like to add this server to an existing Directory Proxy Server topology? (yes / no)
[no]: yes
```

5. Enter the host name of the PingDirectoryProxy server from which configuration settings are copied during setup.

```
Enter the host name of the peer Directory Proxy Server from which you would like
to copy configuration settings. [proxy.example.com]:
```

6. Type the port number of the peer PingDirectoryProxy server from which configuration settings are copied during setup. You can press **Enter** to accept the default port, which is 389.

```
Enter the port of the peer Directory Proxy Server [389]:
```

7. Enter the option corresponding to the type of connection you want to use to connect to the peer PingDirectoryProxy server.

```
How would you like to connect to the peer Directory Proxy Server?
  1) None
  2) SSL
  3) StartTLS

Enter choice [1]:
```

8. Type the root user DN of the peer PingDirectoryProxy server, or press **Enter** to accept the default (`cn=Directory Manager`), and then type and confirm the root user password.

```
Enter the manager account DN for the peer Directory Proxy Server [cn=Directory Manager]:
Enter the password for cn=Directory Manager:
```

Copyright © 2025 Ping Identity Corporation

9. Enter the host name of the new local PingDirectoryProxy server.

```
Enter the fully qualified host name or IP address of the local host [proxy.example.com]:
```

10. Choose the location of your new PingDirectoryProxy server instance or enter a new one.
11. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.
12. After setup is complete, choose the next configuration option.

Copyright © 2025 Ping Identity Corporation

In non-interactive mode

Installing the server in non-interactive mode

You can run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line.

The following sections describe how to install the first PingDirectoryProxy server, how to install additional servers, and how to install the server with a truststore.

Installing the first server
About this task

The `setup` command automatically chooses the maximum heap size. You can manually tune the maximum amount of memory devoted to the server's process heap using the `--maxHeapSize` option. The `--maxHeapSize` option is only valid if the `--entryBalancing` option is also present.

If you are using entry balancing, tune the amount of memory devoted to the PingDirectoryProxy server using the `--entryBalancing` option as follows.

```
--entryBalancing --maxHeapSize 1g
```

The amount of memory allowed when using the `--entryBalancing` option is calculated and depends on the amount of system memory available.

If you already configured a truststore, you can run the `setup` command to enable security. The following example enables both SSL and StartTLS security. It also specifies a Java Keystore (JKS) and Truststore that define the server certificate and trusted CA. The passwords for the keystore files are defined in the corresponding `.pin` files, where the password is written on the first line of the file. The values in the `.pin` files are copied to the `<server-root>/config` directory in the `keystore.pin` file.

```
$ env JAVA_HOME=/ds/java ./setup \
   --no-prompt --rootUserDN "cn=Directory Manager" \
   --rootUserPassword "password" --ldapPort 389 \
   --enableStartTLS --ldapsPort 636 \
   --useJavaKeystore /path/to/devkeystore.jks \
   --keyStorePasswordFile /path/to/devkeystore.pin \
   --certNickName server-cert \
   --useJavaTrustStore /path/to/devtruststore.jks \
   --trustStorePasswordFile /path/to/devtruststore.pin \
   --acceptLicense
```

> **Note**
>
> The password to the private key within the keystore is expected to be the same as the password to the keystore. If this is not the case, you can define the private key password within the administrative console or using the `dsconfig` command by editing the Trust Manager Provider standard configuration object.

Steps

- Run the `setup` command with the `--no-prompt` option.

Copyright © 2025 Ping Identity Corporation

The command uses the default root user distinguished name (DN) (`cn=Director Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` , `--instanceName` , and `--location` options or the **`setup`** command will generate an error message.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 389 \
--acceptLicense \
--instanceName ds1 --location Denver
```

Installing additional servers
Steps

- Run the **`setup`** tool with the `--no-prompt` option.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 1389 \
--localHostName proxy2.example.com \
--peerHostName proxy1.example.com --peerPort 389 \
--peerUseNoSecurity --acceptLicense --instanceName ds1 \
--location austin1
```

Installing the server with a truststore
About this task

If you've already configured a trust store, you can use the **`setup`** command to enable security. The following example enables SSL security and specifies a Java KeyStore (JKS) and truststore that define the server certificate and trusted certificate authority (CA). The passwords for the keystore files are defined in the corresponding `.pin` files, where the password displays on the first line of the file. The values in the `.pin` files are copied to the `server-root/config` directory in the `keystore.pin` and `truststore.pin` files.

Copyright © 2025 Ping Identity Corporation

Steps

- To install a PingDirectoryProxy server with a truststore, run the **`setup`** command.

```
$ env JAVA_HOME=/ds/java ./setup \
  --no-prompt --rootUserDN "cn=Directory Manager" \
  --rootUserPassword "password" \
  --ldapPort 389 --ldapsPort 636 \
  --useJavaKeystore /path/to/devkeystore.jks \
  --keyStorePasswordFile /path/to/devkeystore.pin \
  --certNickName server-cert \
  --useJavaTrustStore /path/to/devtruststore.jks \
  --acceptLicense \
  --instanceName ds1 --location Denver

In order to update the trust store, the password must be provided

See 'prepare-external-server --help' for general overview

Installing Delegated Admin

Different options and procedures are available when you install Delegated Admin depending on your environment and the location of your installation.

To install Delegated Admin, read the following sections:

- Installation requirements
- Preparing to install the application
- Installing the application
- Completing the installation

Installation requirements

Before you install Delegated Admin, make sure you meet the requirements for the installation.

Copyright © 2025 Ping Identity Corporation

Before you begin

Regardless of the location of your Delegated Admin installation, ensure the following Ping Identity products are installed and configured before attempting to install Delegated Admin.

Product	Description	Version
PingDirectory server	Stores user-identity data. The HTTPS port that was configured during PingDirectory server setup is required to install Delegated Admin. For information about upgrading a PingDirectory server, see Upgrading the PingDirectory and PingDirectoryProxy servers. For information about installing and configuring a PingDirectory server, see Installing the PingDirectory server and PingDirectory Server Administration Guide.	See Compatibility matrix.
PingFederate Server	Provides identities for authentication and authorization. Learn more about installing and configuring the PingFederate server in Configuring the PingFederate server or the PingFederate documentation.	PingFederate 9.0.0 or later

Installation locations

The location that you choose determines the steps that you must perform to install Delegated Admin.

You can install Delegated Admin in any of the following locations:

- A PingDirectory server, including replicated instances
- A PingDirectoryProxy server
- An external web server

Preparing to install the application

To install Delegated Admin on a PingDirectory server or on a replicated instance of a PingDirectory server, complete the relevant tasks in this section before installing the application.

Click the following tabs to see instructions for the type of install you want to prepare for.

Copyright © 2025 Ping Identity Corporation

On a PingDirectory server

Preparing to install Delegated Admin on a PingDirectory server
About this task

You can install Delegated Admin on a PingDirectory server with or without `Install with sample data` chosen as the installation option.

To install without `Install with sample data`, see step 8 in Downloading the installation packages.

To install with `Install with sample data`:

Steps

- Remove the relevant access control instruction (ACI) from the PingDirectory server base entry.

  For more information, see the `delegator/remove-sample-directory-data-aci.ldif` file.

On a replicated instance of a PingDiretory server

Preparing to install Delegated Admin on a replicated instance of the PingDirectory server
About this task

To install Delegated Admin on a replicated instance of the PingDirectory server:

Steps

1. Make sure that replication is enabled for the PingDirectory servers.

   For information about enabling server replication, see Managing replication.

2. To ensure that configuration changes are applied to all the servers in your topology, configure the PingDirectory servers to use a configuration group called `all-servers`.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set configuration-server-group:all-servers
   ```

3. If you are installing Delegated Admin on a replicated PingDirectory server that had `Install with sample data` chosen as the installation option, remove the relevant ACI from the PingDirectory server base entry.

   > **Note**
   >
   > Because replicated instances share the same data, perform this step against only one of the servers. For more information, see the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

4. If you're installing Delegated Admin on a PingDirectory server installation that didn't have `Install with sample data` chosen as the installation option, proceed to Downloading the installation packages.

Copyright © 2025 Ping Identity Corporation

Installing the application

The steps for installing Delegated Admin depend on whether you are setting up the application in a Unix or Linux environment or in a Windows environment.

> **Important**
>
> In all environments, if port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT` .

Click the following tabs to see instructions for the type of install you want to perform.

On Unix or Linux

Unix or Linux
Steps

- Run the following script in the `/delegator` directory.

```
$ ./set-up-delegator.sh
```

Result:

The system generates:

- A configuration file, `config.js` , located in the `/webapps/delegator/app` directory.
- A batch file, `delegated-admin.dsconfig` , in the `/webapps/delegator` directory.
- If you answer `y` to the **`setup`** script question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?` , the system generates a batch file, `delegated-admin-for-proxy.dsconfig` in the `/webapps/delegator` directory.

The `setup` tool also generates several command-line prompts for completing the Delegated Admin installation. After you provide the distinguished name (DN) of the root user for your PingDirectory instance, you're prompted to enter information regarding your PingFederate server and the hosting location of the Delegated Admin web app. Enter your own values or press Enter to accept the default values.

Copyright © 2025 Ping Identity Corporation

On Windows

Windows
Steps

1. In the Delegated Admin application directory, copy or rename the file `example.config.js` to `config.js`.

   The `config.js` file contains comments and placeholders for necessary information. For example, the Client ID that is required in this file must be one of the Client IDs that has been defined for the PingFederate configuration. This value represents the client intended for token issuance, such as `dadmin`.

2. Open `config.js` in a text editor.

3. Change the variable values to match your setup configuration.

config.jsVariable	Value
`window.PF_HOST`	Public address of the PingFederate server to which the application redirects the user's browser when signing on.
`window.PF_PORT`	PingFederate port number. **Note** If port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT`.
`window.DADMIN_CLIENT_ID`	PingFederate Client ID for the application.

4. Save your changes to `config.js`.

5. Concatenate the following files into a single file named `delegated-admin.dsconfig`:

   - `delegated-admin-template-common.dsconfig`
   - `delegated-admin-template-ds.dsconfig`
   - `delegated-admin-template-ds-or-proxy.dsconfig`
   - `delegated-admin-template-webapp.dsconfig`

6. Open `delegated-admin.dsconfig` in a text editor and replace the variables, `${variable}`, with actual values.

7. Save your changes to `delegated-admin.dsconfig`.

Completing the installation

Regardless of whether you are installing Delegated Admin in a Unix or Linux or Windows environment, perform the relevant steps in this section after you complete the previous OS-specific tasks.

Click the following tabs to see instructions for the type of installation you want to complete.

Copyright © 2025 Ping Identity Corporation

PingDirectoryProxy

The PingDirectoryProxy server
Before you begin

> **Note**
>
> The following task assumes that when you ran the **`setup`** command, you answered `y` to the question `Is Delegated Admin being installed in a topology containing PingDirectoryProxy?`

About this task

If you are installing Delegated Admin on the PingDirectoryProxy server, you must configure the proxy instance using the **`delegated-admin-for-proxy.dsconfig`** script as described in the "Locations other than PingDirectoryProxy" tab.

To configure all instances of the PingDirectory server:

Steps

1. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of the PingDirectory server.

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
  --applyChangeTo server-group
```

2. Apply the commands from the `delegated-admin.dsconfig` batch file to all instances of the PingDirectory server as explained in the "Replicated instances of PingDirectory" tab.

Replicated instances of PingDirectory

Replicated instances of the PingDirectory server
About this task

If you are installing Delegated Admin on one or more replicated instances of the PingDirectory server:

Steps

- Apply the following commands in `delegated-admin.dsconfig` to each instance:

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig \
  --applyChangeTo server-group
```

Copyright © 2025 Ping Identity Corporation

External web server

External web server
Before you begin

> **Note**
>
> The following steps assume that when you ran the **`setup`** command, you answered `n` to the question `Will the web app be hosted in PingDirectory?`

Steps

1. Open `config.js` in a text editor.
2. Change the variable values to specify the location of the PingDirectory server.

config.jsVariable	Value
`window.DS_HOST`	Host name of the PingDirectory server
`window.DS_PORT`	HTTPS port of the PingDirectory server

   To view an example outline that features these settings, see `example.config.js`.
3. Save your changes to `config.js`.
4. Create a CORS policy for the Delegated Admin HTTP servlet extension, where *<origin>* represents the public name of the host, proxy, or load balancer that presents the Delegated Admin web application.

   Example:

```
dsconfig create-http-servlet-cross-origin-policy
  --policy-name "Delegated Admin Cross-Origin Policy"
  --set "cors-allowed-methods: GET"
  --set "cors-allowed-methods: OPTIONS"
  --set "cors-allowed-methods: POST"
  --set "cors-allowed-methods: DELETE"
  --set "cors-allowed-methods: PATCH"
  --set "cors-allowed-origins: <origin>"

dsconfig set-http-servlet-extension-prop
  --extension-name "Delegated Admin"
  --set "cross-origin-policy:Delegated Admin Cross-Origin Policy"
```

5. (Optional) If you will be enabling administrators to run Delegated Admin reports in your configuration, run **`dsconfig`** with the `set-http-servlet-cross-origin-policy-prop` option.

   Example:

```
dsconfig set-http-servlet-cross-origin-policy-prop \
  --policy-name "Delegated Admin Cross-Origin Policy" \
  --set cors-exposed-headers:Content-Disposition
```

Copyright © 2025 Ping Identity Corporation

Locations other than PingDirectoryProxy

All locations except the PingDirectoryProxy server
About this task

To continue installing Delegated Admin on a PingDirectory server or on an external web server:

Steps

- Run the following command with `delegated-admin.dsconfig` on the appropriate server:

```
$ ./bin/dsconfig \
  --bindDN "cn=Directory Manager" \
  --bindPassword <password> \
  --no-prompt \
  --batch-file webapps/delegator/delegated-admin.dsconfig
```

Next steps

Important

You cannot sign on to Delegated Admin until you configure the rights of the delegated administrators. For more information about configuring administrative rights, the REST resource type, session timeout values, and other properties, see Configuring Delegated Admin.

After you configure Delegated Admin, verify that the application is installed and working successfully.

Verifying the installation

Steps

- To verify that Delegated Admin is installed successfully, go to `https://<webserverHost>:<httpPort>/delegator` and sign on to the application.

Troubleshooting

If your sign on attempt is unsuccessful, see Enabling log tracing and use your browser's debug feature to gain insight into the token-validation process.

Installing the PingDataSync server

This section describes how to install and run PingDataSync.

Click the following tabs to see instructions for the type of installation you want to perform.

Copyright © 2025 Ping Identity Corporation

Install the main server

Installing the main server
About this task

Use the `setup` tool to install the server. The server needs to be started and stopped by the user who installed it.

Steps

1. Sign on as a user other than root.
2. Obtain the latest zip release bundle, as described in Downloading the installation packages, and unpack it in a directory owned by this user.

   ```
   $ unzip  PingDataSync-<version>.zip
   ```

3. Change to the server root directory.

   ```
   $ cd  PingDataSync
   ```

4. Run the `setup` command.

   ```
   $ ./setup
   ```

5. Type `yes` to accept the End-User License Agreement and press Enter to continue.
6. If adding this server to an existing PingDataSync topology, type `yes`, or press Enter to accept the default (no).
7. Enter the fully qualified host name or IP address of the local host.
8. Create the initial root user DN for PingDataSync, or press Enter to accept the default (cn=Directory Manager).
9. Enter and confirm a password for this account.
10. Press Enter to enable server services and the administrative console.
11. Enter the port on which PingDataSync will accept connections from HTTPS clients, or press Enter to accept the default.
12. Enter the port on which PingDataSync will accept connections from LDAP clients, or press Enter to accept the default.
13. Press Enter to enable LDAPS, or enter no.
14. Press Enter to enable StartTLS, or enter no.
15. Select the certificate option for this server.

Copyright © 2025 Ping Identity Corporation

16. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
    - Do not encrypt server data.
17. Choose the option for the amount of memory that should be allocated to the server.
18. To start the server when the configuration is complete, press Enter for (yes).
19. A Setup Summary is displayed. Choose the option to set up the server with the listed parameters, change the parameters, or cancel the setup.

Next steps

After the server configuration is complete, you can run the `create-sync-pipe-config` tool configure the synchronization environment.

The administrative console enables browser-based server management, the `dsconfig` tool enables command-line management, and the Configuration API enables management by third-party interfaces.

Copyright © 2025 Ping Identity Corporation

Install a failover server

Installing a failover server
About this task

PingDataSync supports redundant failover servers that automatically become active when the primary server is not available. Multiple servers can be present in the topology in a configurable prioritized order.

Before installing a failover server, have a primary server already installed and configured. When installing the redundant server, the installer will copy the first server's configuration.

The primary and secondary server configuration remain identical. Both servers should be registered to the `allservers` group and all `dsconfig` changes need to be applied to the server group `allservers`.

> **Note**
>
> If the primary server has extensions defined, they should also be installed on any cloned or redundant servers. If extensions are missing from a secondary server, the following message is displayed during the installation:
>
> ```
> Extension class <com.server.directory.sync.MissingSyncExtension> was not
> found. Run manage-extension --install to install your extensions. Re-run setup to
> continue.
> ```

To remove a failover server, use the `uninstall` command.

Steps

1. Unpack the PingDataSync zip build. Name the unpacked directory something other than the first server instance directory.

   ```
   $ unzip PingData<server_version>.zip -d  <server2>
   ```

2. Go to the server root directory.

3. Run the `setup` command without any options to install the failover server in interactive mode, or run the following command to install it in non-interactive mode:

   ```
   $ ./setup --localHostName <server2>.example.com --ldapPort 7389 \
     --masterHostName <server1>.example.com --masterPort 8389 \
     --masterUseNoSecurity \
     --acceptLicense \
     --rootUserPassword password \
     --no-prompt
   ```

   The secondary server is now ready to take over as a primary server in the event of a failover. No `realtime-sync` invocations are needed for this server.

Copyright © 2025 Ping Identity Corporation

4. Verify the configuration by using the `bin/status` command. Each server instance is given a priority index. The server with the lowest priority index number has the highest priority.

```
$ bin/status --bindPassword secret

...(status output)...
                              --- Sync Topology ---
Host:Port                              :Status   :Priority
---------------------------------------:-------------:---------------
<server>.example.com:389 (this server) : Active      : 1
<server>.example.com:389        : Unavailable : 2
```

5. To obtain the name of a particular server, run the `dsconfig` command with the `list-external-servers` option.

```
$ bin/dsconfig list-external-servers
```

6. To change the priority index of the server, run the `bin/dsconfig` command as follows:

```
$ bin/dsconfig set-external-server-prop \
  --server-name  <server2>.example.com:389 \
--set  <server>-priority-index:1
```

Installing the PingDataMetrics server

This section describes how to install the PingDataMetrics server.

> **Important**
>
> PingDataMetrics will be deprecated in the PingDirectory 10.0 release. For more information about support for versions of PingDirectory containing PingDataMetrics, see Ping Identity's End-of-Life Policy (sign on required). To monitor and provide statistics for your PingDirectory suite of products, see Monitoring PingDirectory metrics with Splunk.

Click the following tabs to see instructions for the task you want to perform.

Copyright © 2025 Ping Identity Corporation

Configure a non-root user

Configuring a non-root user

The PingDataMetrics server installer cannot be run as the root user, and generally, the server (and PostgreSQL) should not be run as root.

As a non-root user, network port numbers below 1024 cannot be used.

In general, the account must do the following:

- Listen on privileged network ports.
- Bypass restrictions on resource limits.

For security, the account should be restricted from the following:

- The ability to see processes owned by other users on the system.
- The ability to create hard links to files owned by other users on the system.

Copyright © 2025 Ping Identity Corporation

Configure servers to be monitored

Configuring servers to be monitored

Before installing the PingDataMetrics server, configure the servers to be monitored:

- PingDirectory server
- PingDirectoryProxy server
- PingDataSync server
- PingAuthorize

The monitored servers require sufficient disk space to store the monitoring data and can be configured with Tracked Applications if there are specific application bind distinguished names (DNs) that should be monitored.

Disk space requirements and monitoring intervals

The metrics backend on the monitored servers is responsible for the temporary storage of metric data and is configured to keep a maximum amount of metric history based on log retention policies, which are configured with the `dsconfig` command.

The default retention policies define a cap on disk space usage, which in turn determines the amount of metric history retained. If the PingDataMetrics server is stopped for a period of time, the monitored servers should be configured to retain enough metrics history to prevent gaps in data when the PingDataMetrics server restarts. The amount of disk space required for metrics history might also depend on the monitored server's Stats Collector Plugin settings. In general, 500MB is enough to retain an eight-hour span of metrics history.

The value of the `sample-flush-interval property` of the monitored server's metrics backend determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics server. The flush interval can be set between 15 and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in a chart or dashboard. Changing the `sample-flush-interval` attribute to 60 seconds has the PingDataMetrics server keep 2000 minutes of history.

The number of metrics produced per unit of time varies based on the configuration. No formula can compute exact storage required for each hour of history. However, 60MB per hour is a standard estimate.

Tracked applications

If the PingDataMetrics server monitors client applications associated with the monitored servers, configure the Tracked Applications feature for monitored servers as well.

Activity performed by a particular LDAP bind DN can be associated with a PingDataMetrics server application-name, which in turn can be included in PingDataMetrics server service level agreement (SLA) definitions.

The Processing Time Histogram plugin is configured on each PingDirectory server and PingDirectoryProxy server as a set of histogram ranges. These ranges should be defined identically across all monitored servers. For each monitored server, set the `separate-monitor-entry-per-tracked-application` property of the processing time histogram plugin to `true`. Per-application monitoring information appears under `cn=monitor`. The `per-application-ldap-stats` property must also be set to `per-application-only` in the Stats Collector Plugin. For Tracked Application configuration details, see the PingDirectory Server Administration Guide.

Copyright © 2025 Ping Identity Corporation

The following example sets the required property of the Processing Time Histogram plugin:

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following example sets the required property of the Stats Collector plugin:

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set per-application-ldap-stats:per-application-only
```

Copyright © 2025 Ping Identity Corporation

Install the server

Installing the server

Use the `setup` command to install the server.

About this task

The server must be started and stopped by the user who installed it.

> **Note**
>
> A Windows installation requires that the Visual Studio 2010 runtime patch be installed before running the setup command.

Steps

1. Sign on as a user other than root.
2. Obtain the latest `.zip` release bundle, as described in Downloading the installation packages, and extract it in a directory owned by this user.

   ```
   $ unzip PingData<server-version>.zip
   ```

3. Change to the server root directory.

   ```
   $ cd PingData<server>
   ```

4. Run the `setup` command.

   ```
   $ ./setup
   ```

5. To accept the End-User License Agreement, enter `yes` or press Enter to accept the default.
6. Read the installation process and prerequisites. Press Enter.
7. Enter the port number of the PostgreSQL database instance to use to store monitoring or press Enter to accept the default port.
8. Enter the directory to be used for PostgreSQL data files or press Enter to accept the default.

   The default is `pgsql_data`.

   > **Note**
   >
   > If the name entered is a relative path name, it is created in the current working directory.

9. Enter a name for the database administrative account or press Enter to accept the default.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `setup` command creates a user (role) and database to be used by the PingDataMetrics server. These credentials are strictly for use by this command during this session and are not retained.

10. Enter and save a password.
11. Choose the name of the PostgreSQL account to be associated with the PingDataMetrics server historical monitoring data, or press Enter to accept the default.

    The default is `metrics`.

    > **Note**
    >
    > The `setup` command creates this user account using the administrative account specified in step 9.

12. To enter and confirm a new password, type `yes` and provide a new password or press Enter to accept the default.
13. Enter the fully-qualified host name for the server or press Enter to accept the default.
14. Create the initial root user DN for the server or press Enter to accept the default.
15. Enter and confirm a password for this account.
16. Enter the port for HTTPS connection to the Platform APIs or press Enter to accept the default.

    The Platform APIs are the System for Cross-domain Identity Management (SCIM) and the Configuration.

17. Enter the port on which the PingDataMetrics server accepts LDAP client connections or press Enter to accept the default.
18. To enable LDAPS, enter `yes` or press Enter to accept the default of `no`.
19. If LDAPS is enabled, enter the port on which the server accepts LDAPS client connections or press Enter to accept the default of `2636`.
20. To enable StartTLS, enter `yes` or press Enter to accept the default of `no`.
21. Select a certificate option for the server.

    Choose from:

    - Generate self-signed certificate. This is recommended for testing purposes only.
    - Use an existing certificate located on a Java KeyStore (JKS).
    - Use an existing certificate located on a PKCS12 KeyStore.
    - Use an existing certificate on a PKCS11 token.

    > **Note**
    >
    > Depending on the option you choose, you might need additional information. If you choose the Java or the PKCS#12 KeyStore, you need the KeyStore path and PIN. If you choose the PKCS#11 token, you need the key PIN.

Copyright © 2025 Ping Identity Corporation

22. Select the desired encryption for the directory data, backups, and log files.

    Choose from:

    - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
    - Encrypt data with a key generated from a passphrase read from a file.
    - Encrypt data with a randomly generated key. This is intended for testing, or if you intend to import the resulting encryption settings definition into other instances in the topology.
    - Do not encrypt server data.

23. Choose an option to assign the amount of memory that the server should allocate to the PingDataMetrics server, or press Enter to accept the default.
24. When the configuration is complete, press Enter (yes) to start the server.
25. To install the PingDataMetrics server with the defined parameters, press Enter.

Next steps

After you install the PingDataMetrics server, access the Metrics landing page at https://<host>:<HTTPS-port>/view/index for access to the default dashboards, chart builder tool, and online documentation.

Uninstalling the PingDirectory and PingDirectoryProxy servers

The server provides an **`uninstall`** command-line utility for quick removal of the code base.

To uninstall a server instance, run the **`setup`** command in interactive command-line, or non-interactive command-line mode.

Interactive command-line mode

Interactive command-line mode is a text-based interface that prompts the user for input. To use this mode, run the **`bin/uninstall`** command without any options.

Non-interactive command-line mode

Non-interactive command-line mode suppresses progress information from being written to standard output during processing, except for fatal errors. To run this mode, use the **`bin/uninstall`** command with the `--no-prompt` option.

Note

For standalone installations with a single server instance, you can also manually remove the server by stopping it and recursively deleting the directory and subdirectories as shown in the following example:

```
$ rm -rf /ds/PingDirectory
```

Copyright © 2025 Ping Identity Corporation

Click the following tabs to see instructions for the type of uninstall you want to perform.

Copyright © 2025 Ping Identity Corporation

In interactive mode

Uninstalling the server in interactive mode

Interactive mode uses the **`uninstall`** command, a text-based, command-line interface to help you remove your server instance.

About this task

If the **`uninstall`** command cannot remove all of the server files, it generates a message with a list of the files and directories that must be deleted manually. The **`uninstall`** command must be run as either the root user or the same user (or role) that installed the server.

Steps

1. From the server root directory, run the **`uninstall`** command.

   Example:

   ```
   $ ./uninstall
   ```

2. Select the components to be removed.

   Choose from:

   - Remove all components - If you want to remove all components, press Enter to accept the default (remove all).
   - Select the components to be removed - If you do not want to remove all components, enter the option to specify the removal of only specific components.

     For each type of server component, press Enter to remove it or enter `no` to keep it.

3. If the server is part of a replication topology, enter `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a standalone server, continue to step 6.
4. Enter the Global Administrator ID and password to remove the references to this server in other replicated servers, and then enter or verify the host name or IP address for the server that you are uninstalling.
5. Select how you want to trust the server certificate if you have set up SSL or StartTLS. Press Enter to accept the default.

   Example:

   ```
   How do you want to trust the server certificate for the PingDirectory Server
   on server.example.com:389?

   1) Automatically trust
   2) Use a trust store
   3) Manually validate

   Enter choice [3]:
   ```

6. View the logs for any remaining files and manually remove any remaining files or directories.

Copyright © 2025 Ping Identity Corporation

If your server is running, it shuts down before continuing the uninstall process. The uninstall action processes the removal requests before completing.

In non-interactive mode

Uninstalling the server in non-interactive mode

The `uninstall` command provides a non-interactive method to run with the `--no-prompt` option.

About this task

Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command fails and aborts.

Steps

1. From the server root directory, run `uninstall` with the `--remove-all` option to remove all of the server's libraries.

   The optional `--quiet` option suppresses output information.

   Example:

   The following command assumes that the server is standalone and not part of a replication topology:

   ```
   $ ./uninstall --remove-all --no-prompt --quiet --forceOnError
   ```

2. View the logs for any remaining files and manually remove any remaining files or directories.

Individual components in non-interactive mode

Uninstalling selected components in non-interactive mode

Use the `--backup-files` with the `uninstall` command to remove the server's backup files.

Steps

1. From the server root directory, run the `uninstall` command with the `--backup-files` option.

   Example:

   ```
   $ ./uninstall --backup-files --no-prompt --quiet --forceOnError
   ```

2. To view the other options available to remove specific components, use the `--help` or `-H` option.

Upgrading the servers

Software builds of the servers are periodically released with new features, enhancements, and fixes for improved server performance. This section describes how to upgrade the servers in the PingDirectory suite of products.

See the following topics:

- Upgrading the PingDirectory and PingDirectoryProxy servers
- Upgrading Delegated Admin
- Upgrading PingDataSync
- Upgrading PingDataMetrics

Upgrade considerations

When upgrading your server, there are multiple upgrade scenarios with different implications that you need to consider.

PingDirectory, PingDirectoryProxy, and PingDataSync

Consider the following when upgrading the PingDirectory suite of products.

> **Important**
>
> After reviewing the following considerations, for upgrades of PingDirectory or PingDirectoryProxy, review these additional upgrade considerations.

Considerations when upgrading to 9.3.0.0 or later

For service accounts that use password storage schemes with high computational processing costs (for example, PBKDF2, bcrypt, scrypt, or Argon2), the server could process bind requests much slower than in previous versions.

> **Important**
>
> The default root password policy for the PingDirectory suite of products uses the PBKDF2 password storage scheme.

Storing a password encoded with the PBKDF2 scheme can make it many times more expensive for an adversary to crack, but you can get even better protection by creating a very strong password stored with SSHA256.

You should create a separate password policy for your service account. Choose a fast but cryptographically strong password storage scheme, such as SSHA256, and set a very strong password according to NIST guidelines.

Considerations when upgrading to 9.0.0.0 or later

Because of major updates to Spring dependencies, Spring configuration properties in the administrative console configuration files for the PingDirectory suite of products earlier than version 9.0.0.0 are not compatible with the administrative console bundled with 9.0.0.0 and later versions. Attempting to use these older configuration files will result in the console failing to start.

Copyright © 2025 Ping Identity Corporation

If you are using older admin console configuration files, you must update them. Replace the following excerpt in the old `application.yml` file:

```
spring:
  profiles.active: default
  main.show-banner: false
  thymeleaf.cache: true
  thymeleaf.prefix: classpath:/public/app/
```

with the following:

```
spring:
  profiles.active: default
  web.resources:
    # 1 year. Update the corresponding value in MvcConfig if this changes.
    cache.period: 31536000
    add-mappings: false # use our custom mappings instead of the defaults
  main:
    banner-mode: "OFF"
  thymeleaf:
    prefix: classpath:/public/app/
```

Considerations when upgrading to 8.2.0.0

This upgrade moves to Jetty 9.4. As a result, the HTTPS connection handler will no longer support TLS_RSA ciphers by default. If you use any legacy HTTPS clients that still require TLS_RSA ciphers, modify the `ssl-cipher-suite` property of the HTTPS Connection Handler to include them.

PingDirectory and PingDirectoryProxy

The following content provides a brief description of the upgrade process and considerations that might affect your upgrade decisions.

> **Important**
>
> If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

Overview

For the upgrade process, you must download and extract a new version of the PingDirectory server `.zip` file on the server that will be updated. In addition, you must run the **`update`** command with the `--serverRoot` or `-R` option value from the new root server pointing to the installation that will be upgraded.

Copyright © 2025 Ping Identity Corporation

Considerations

Consider the following when planning for and upgrading replicating servers:

- The upgrading process affects only the server being upgraded. The process does not alter the configuration of other servers.
- The `update` command verifies that the Java version installed meets the new server requirements. Before running the command, install the Java version that is supported by the new server.
- For precautionary measures, back up the user data `userRoot` before an upgrade. Restoring from a backup might be necessary if all other servers in the replication topology have been upgraded, and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` commands issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This results in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology.
- After all replicating servers are upgraded, enable new features.

Tip

Learn more in Planning your upgrade in the Best Practices Guides.

Upgrade considerations introduced in PingDirectory 9.x

Keep in mind the following upgrade considerations introduced in PingDirectory 9.x versions.

Important

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

Disabling restart scripts before starting the upgrade process is recommended

Important

The use of any such script is discouraged under most circumstances, as they could lead to data corruption, data loss, or result in failed upgrades. In addition, troubleshooting any issues that arise during or after the upgrade becomes considerably more challenging in the presence of these scripts.

Copyright © 2025 Ping Identity Corporation

Permissive Modify no longer enabled by default in Directory REST API

> **Important**
>
> In previous versions, Permissive Modify behavior was enabled by default for all API modify (PATCH) requests. In version 9.3, this behavior is controlled by an `always-use-permissive-modify` configuration parameter, which now has a default value of `false`. If you see a change in your application's behavior as a result of this default configuration, you can re-enable Permissive Modify by changing the value of the configuration parameter to `true` with `bin/dsconfig`.

Enabling Permissive Modify behavior affects operations like removing an attribute that does not exist, or adding a duplicate value to a single-value attribute, by returning a "success" response without actually modifying the underlying data. Having the `always-use-permissive-modify` configuration parameter set to `false` by default will return "failure" responses for such permissive operations.

Enabling replication-purge-obsolete-replicas

> **Warning**
>
> The following requirement applies when upgrading from a version earlier than 9.2 to version 9.2 or higher:
> You must set the `replication-purge-obsolete-replicas` global configuration property to `true` on each server in the topology before beginning the upgrade process. Failure to do so could result in a server entering lockdown mode over missing changes from an obsolete replica.
> Learn more about Discovering obsolete replicas or Purging obsolete replicas.

Cleaning replication history

When cleaning replication history from a PingDirectory server, you must now use the new `remove-defunct-server` argument `--performLocalCleanup`. If you have existing automation around disaster recovery, the previous method of running `remove-defunct-server` without bind credentials no longer performs this replication cleanup step. For PingDirectory versions 9.0.0.0 and later, update any existing automation to use the `--performLocalCleanup` flag.

Upgrade considerations introduced in PingDirectory 8.x

Keep in mind the following upgrade considerations introduced in PingDirectory 8.x versions.

Copyright © 2025 Ping Identity Corporation

Important

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

Upgrade considerations introduced in 8.3.0.0

- RFC 8996 was released, officially deprecating the TLSv1 and TLSv.1.1 protocols and explicitly stating that these must not be used. Per this specification, only TLSv1.2 and TLSv1.3 are considered acceptable for use. Therefore, for this release, TLSv1 and TLSv.1.1 are disabled by default. Disabling support for TLSv1 and TLSv1.1 does not prevent these protocols from being used, it only disables them by default. Support for these legacy protocols can be re-enabled in the configuration if necessary. Also, support for TLS cipher suites that use the SHA-1 message digest is being deprecated, as SHA-1 is no longer considered secure. We are also deprecating support for TLS cipher suites that use RSA key exchange because these do not provide forward secrecy.
- Changes to entries made by the clients using the SCIMv2 API will now have the actual user ID, making the request stored in the access and audit logs. By default, the server will continue to use the "SCIM2 Servlet" user as the authorization identity for all SCIM2 requests, and the DN of this user will be recorded in the access log and in the `creatorsName` and `modifiersName` attributes. If you want to change this behavior, change the value of the `map-access-tokens-to-local-users` property from `disabled` to either `optional` or `required`. This will cause the server to map the token to a local user, and if the mapping is successful, the mapped user's DN will be used as the authorization identity for the operations.

Upgrade considerations introduced in 8.1.0.0

- If you have upgraded a server that is in a cluster (that has a cluster name set in the server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you can create temporary clusters based on server versions and modify the cluster name appropriately on each of the servers to minimize the impact while you are upgrading.
- The `bypass-pw-policy privilege` was intended to provide a way for administrators to bypass certain password restrictions that would normally be imposed when managing passwords for other users. A user with this privilege could use it to bypass password validation for their own entry. The `bypass-pw-policy` privilege now only applies when changing another user's password (that is, an administrative password reset), and only in the following scenarios:
    - A user with this privilege will be permitted to set pre-encoded passwords.
    - A user with this privilege will be permitted to set passwords that would otherwise be rejected by one or more password validators.
    - A user with this privilege will be permitted to set passwords that match the current password or that are in the password history.

Copyright © 2025 Ping Identity Corporation

The privilege will only apply when changing the password for another user, and it will have no effect for a self-password change. Further, a user with this privilege will no longer be exempted from any other restrictions in their own password policy. Before upgrading, you should search for users that have the `bypass-pw-policy`

- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing-changes state the local replica will not accept changes from the local replication server. You can use the existing password validators and a custom password policy to enforce passwords for administrative users.
- Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients might require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition might become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the `encryption-settings export` and `encryption-settings import` commands) and then making it the preferred definition (with `encryption-settings set-preferred`) in all instances.
- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

Delegated Admin

Consider the following points when upgrading your version of Delegated Admin.

Considerations

> **Note**
>
> If you're running Delegated Admin 3.5 or earlier, upgrade it to the latest version to use PingDirectory 8.0 or later. For information about the compatibility between Delegated Admin and PingDirectory server versions, see the Compatibility matrix.

Upgrade considerations introduced in Delegated Admin 4.9

The default OpenID Connect (OIDC) grant type used by the `dadmin` client has been updated to Authorization Code with PKCE. The Delegated Admin application will continue to function normally with the Implicit grant type.

If you want to switch to Authorization Code with PKCE, see Changing the default OIDC grant type.

Copyright © 2025 Ping Identity Corporation

Upgrade considerations introduced in Delegated Admin 4.8

Two new permissions that affect user resource types have been added in Delegated Admin 4.8:

- `Update-profile` grants the ability to update user profiles without allowing password-related privileges.
- `Reset-password` grants the permission to reset passwords without the ability to change other user attributes.

To preserve current admin rights, no action is required after you upgrade.

For more information, see Configuring delegated administrator rights on the PingDirectory server.

Upgrade considerations introduced in Delegated Admin 4.6

To use the functionality that allows a help desk agent to trigger a password reset for a user, you must enable the Modifiable Password Policy State plugin on the PingDirectory server that serves as a resource backend.

To enable the **Initiate Password Reset** menu option on user entries, perform the following steps:

1. Run the following command to enable the plugin needed for triggering **Initiate Password Reset**:

```
dsconfig set-plugin-prop \
--plugin-name "Modifiable Password Policy State Plugin" \
--set enabled:true --set "base-dn:${searchbasedn}" \
--set "filter:(|(objectClass=person)(objectClass=ds-cfg-user))"
```

2. Run the following command to add a Delegated Admin attribute to the users rest type for `ds-pwp-modifiable-state-json`:

```
dsconfig create-delegated-admin-attribute \
--type-name users  \
--attribute-type ds-pwp-modifiable-state-json  \
--set "display-name:Modifiable Password Policy State"  \
--set display-order-index:9999
```

> **Note**
>
> When you install Delegated Admin 4.6 using the `delegated-admin.dsconfig` script, the Modifiable Password Policy State plugin is enabled. If you're upgrading from a previous version of Delegated Admin, you must manually enable the plugin and add the `ds-pwp-modifiable-state-json` attribute as a Delegated Admin attribute.

Upgrading the PingDirectory and PingDirectoryProxy servers

When upgrading your server, there are multiple upgrade scenarios with different implications that you need to consider. Use the server's `update` utility to upgrade the current server code version.

Click the following tabs to see instructions for the tasks you want to perform.

Copyright © 2025 Ping Identity Corporation

Upgrade servers in a topology

Upgrading servers in a topology

An update to the current server release includes the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts.

Before you begin

Before you can update and migrate the admin backend, the following conditions must be satisfied:

- Run the **`update`** command and provide LDAP authentication options to the peer servers of the server being updated. The **`update`** command connects to the peer servers of the server being updated to obtain the necessary information to populate the topology registry.
- On every server in the topology, configure the encryption protocol requested, either plain, TLS, StartTLS, or SASL, for an LDAP connection.
- Ensure the LDAP credentials are present on every server in the topology.
- Ensure the users related to the LDAP credentials have permissions to read from the admin backend and the config backend of every server in the topology. For example, you can use a root DN user that has `inherit-default-privileges` set to true, such as the `cn=Directory Manager` user, that exists on every server.
- The instance name is set on every server and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server is uniquely identified by its instance name. After the name is set, it cannot be changed.

> **Tip**
>
> If needed, use the following command to set the instance name of a server before the update.
>
> ```
> $ bin/dsconfig set-global-configuration-prop \
>   --set instance-name:uniqueName
> ```

> **Important**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than a 7.x to a 7.x version and is not applicable to any updates to a server version of 8.x or later.

About this task

Upgrade to a server that uses a topology registry to store network configuration, administrator user accounts, and keys information, as well as migrate the information from the previous server version. The following requirements must be met:

- When the first server is being updated, all other servers in the topology are online.
- When updating additional servers, all topology information was obtained from one of the servers that has already been updated.

Copyright © 2025 Ping Identity Corporation

- The users related to the provided LDAP credentials have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server and is unique across all servers in the topology.

Steps

1. To make clustered configuration changes in a mixed-version cluster:

   Choose from:

   - Update each server to the same version.
   - Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.

     > **Note**
     >
     > Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names.

2. Make clustered configuration changes again to mirror these changes across the topology.

   Result:

   When all of these conditions are met, the cluster-wide configuration is synchronized on all servers in the topology.

   > **Note**
   >
   > Older versions have some topology configuration under the **`cn=cluster,cn=config`** JSON attribute and field constraints. These items do not support mirrored cluster-wide configuration data. In an update, avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary.

3. To synchronize the cluster-wide configuration data across all servers in the topology, run the **`config-diff`** command on each pair of servers to determine the differences, and use **`dsconfig`** to update each instance using the **`config-diff`** output.

   Example:

   ```
   $ bin/config-diff --sourceHost hostName \
     --sourcePort port \
     --sourceBindDN bindDN \
     --sourceBindPassword password \
     --targetHost hostName \
     --targetPort port \
     --targetBindDN bindDN \
     --targetBindPassword password
   ```

Restoring a mixed topology to a clean state

Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally.

Copyright © 2025 Ping Identity Corporation

About this task

> **Note**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version and is not applicable to any updates to server version 8.x or later.

If you are upgrading a PingDirectory server version earlier than 7.3 to 7.3 or later and at least one server was previously removed from the topology, you might receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \
                                 threadID=438 category=REPLICATION severity=NOTICE msgID=118947975
msg="The \
                                 replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \
                         severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997 \
                         o=mycompany, the following error happened: (JE 7.5.12) Attempted to remove \
                         non-existent database 997 o=mycompany DatabaseNotFoundException: (JE 7.5.12)
\
                         Attempted to remove non-existent database 997 o=pingone (DbTree.java:922 \
                         DbTree.java:1183 DbTree.java:1235 Environment.java:1001 Environment.java:
1221 \
                         Environment.java:1204 Environment.java:1009 ReplicationDbEnv.java:1186 \
                         DomainDbEnv.java:995 ReplicationDB.java:1002 DbHandler.java:1324
DbHandler.java:1064 \
                         DbHandler.java:1042 DbHandler.java:798 DbHandler.java:723
DirectoryThread.java:352 \
                         (7.3.0.4-20191127203417.000Z-83a75e2a))"
```

Steps

1. To export a safe copy of the data, run `bin/export-ldif` on the primary server.
2. Start the down-level primary server and stop the upgraded replica server.
3. Run `bin/remove-defunct-server` on the upgraded replica server and do the following when prompted:
    1. Select the replica server itself.
    2. Supply the credentials for the primary server when prompted.
    3. Select **[c]** to continue.
    4. Enter the path to the local `changelogDB` when prompted.
4. Leave the upgraded replica server stopped and stop the down-level primary server.
5. Run `bin/dsreplication` on the primary server and do the following:
    1. Select **2) Manage the topology (add and remove servers)**.

Copyright © 2025 Ping Identity Corporation

2. Select **4) Cleanup Server**.
3. Select **[c]** to continue.
4. Enter the path to the local `changelogDB` when prompted.

6. Start the down-level primary server and the upgraded replica server.
7. Run `bin/status` on both servers and verify that status of **Replication: disabled** in **Data Sources**.
8. Upgrade the replica server to version 7.3.0.5 or later, which contains fixes for issues 00668265 and DS-40955.
9. Upgrade the primary server to the same level as the replica server.
10. To re-enable replication between the primary and replica server, run the `bin/dsreplication` tool.
11. Re-initialize the replica server data from the primary server.
12. Run `bin/status` on both servers to verify that replication is enabled in **Data Sources** and that both servers show the same number of entries.

Upgrade the server

Upgrading the server

Use the following steps to upgrade the PingDirectory and PingDirectoryProxy servers.

Before you begin

This task shows the upgrade process for the PingDirectory server as an example.

Steps

1. Download and extract the new version of the PingDirectory server in a location outside the existing server's installation.

   For these steps, assume the existing server installation is located in `/prod/PingDirectory` and the new server version is extracted in the `/home/stage/PingDirectory` location.

2. Run the `update` command provided with the new server package to update the existing PingDirectory server.

   > **Note**
   >
   > The update tool might prompt for confirmation of the server configuration changes if it detects customization and display the following code.
   >
   > ```
   > $ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
   > ```

Copyright © 2025 Ping Identity Corporation

Reverting an update

After the server has been updated, you can revert to the last version or one level back using the **`revert-update`** command.

About this task

The **`revert-update`** command accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the **`revert-update`** command multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the server, you can run the **`revert-update`** command to revert to its previous state, then run the **`revert-update`** command again to return to its original state. The following steps detail reverting from 7.x to a version earlier than 7.0.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server displays warnings about "offline configuration changes," but they are not critical and do not appear on subsequent start ups.

To revert to the most recent server version:

Steps

- Run the **`revert-update`** command in the server root directory to revert back to the most recent version of the server.

  Example:

  ```
  $ PingDirectory-old/revert-update
  ```

Next steps

Reverting from the 7.0 version or later to a version earlier than 7.0 using the **`revert-update`** command might require extra steps. This is also the case when updating or reverting from a version earlier than 6.2.0.2 to a 6.2.0.2 version or later. These steps are listed when the **`update`** and **`revert-update`** command are run as well. Depending on your installation and configuration, you might need to perform one or more of the following tasks:

- When updating or reverting from 6.2.0.2 or later to a version earlier than 6.2.0.2, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and rebuild the indexes using the **`rebuild-index`** command. The command for recreating an index is in the `Undo` portion of the `logs/config-audit.log` file. To later revert to an older version, delete and recreate those composite indexes again after the revert process completes.
- When updating to 7.x for the first time, instance names must be set for each server in the topology if they were not previously set. This is done with the following **`dsconfig`** command.

  ```
  $ bin/dsconfig --bindDN "cn=Directory Manager" \
    --bindPassword secret \
    --no-prompt set-global-configuration-prop \
    --set instance-name:<name>
  ```

Copyright © 2025 Ping Identity Corporation

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, you can use the `revert-update` command to return to the previous version. However, if new servers are added, then the restored `admin` backend of this server does not contain information about the new servers, and the local server cannot communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a version earlier than 7.x, any servers in the topology using the topology portion of the configuration rather than the `admin` backend must know that the reverted server was downgraded to the `admin` backend. To do this, run the following `dsconfig` command on one of the servers that has not been reverted.

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a primary server when this command is run, the `revert-update` will not succeed. In this case, you must make one of the remaining updated servers in the topology the primary with the following command. This enables the chosen instance to run the `revert-update` command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions, such as 6.x or earlier. To later revert to an older version, you must export the data to LDIF before performing the reversion. Then, re-import the data after the revert process completes. In addition, you must delete the `changelogDb/` and `db/changelog/` directories in the reverted server root after the revert process completes.

Upgrading Delegated Admin

If you are running Delegated Admin 4.3 or earlier, upgrade it to the latest version to use PingDirectory 8.2 or later.

Before you begin

For information about the compatibility between Delegated Admin and PingDirectory server versions, see the Compatibility matrix.

Steps

1. Extract the contents of the Delegated Admin upgrade `.zip` archive.
2. Rename the original `delegator` folder to retain a backup copy of the earlier version.
3. Copy the extracted folder named `delegator` to the PingDirectory server folder named `webapps`.
4. Copy the `{OriginalDelegatorFolder}/app/config.js` configuration file to the new `delegator` folder.
5. Restart the PingDirectory server by running `$ bin/stop-server --restart`

Upgrade servers in a topology

Upgrading servers in a topology

> **Note**
>
> This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version, and is not applicable to any updates to server version 8.x or later.

> **Tip**
>
> Learn more in Planning your upgrade in the Best Practices Guides.

An update to the current release includes significant changes, and the introduction of a topology registry, which will store information previously stored in the admin backend (server instances, instance and secret keys, server groups, and administrator user accounts). For the admin backend to be migrated, the `update` command must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security options requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to `true` (such as the `cn=Directory Manager` user) that exists on every server can be used.

- Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the `cn=Cluster,cn=config` subtree and only applies to servers with matching cluster names. Consider this when updating multiple servers in a cluster.
- To make clustered configuration changes in a mixed-version cluster, choose one of the following options:
  - Update each server to the same version.
  - Temporarily split up the cluster by changing the `cluster-name` property on the server instance configuration objects.
- After you have updated all the servers to the same version, you can again make clustered configuration changes and those changes will mirror across the topology.

The `update` command will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The `update` command will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the configuration and admin backends of the peer servers.

Copyright © 2025 Ping Identity Corporation

- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. After it has been set, the name cannot be changed. If needed, you can use the following command to set the instance name of a server before the update:

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under `cn=cluster,cn=config` (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` command on each pair of servers to determine the differences, and use the `dsconfig` command to update each instance using the `config-diff` command's output. For example:

```
$ bin/config-diff --sourceHost hostName \
  --sourcePort port \
  --sourceBindDN bindDN \
  --sourceBindPassword password \
  --targetHost hostName \
  --targetPort port \
  --targetBindDN bindDN \
  --targetBindPassword password
```

If any of these conditions are not satisfied, the `update` command will list all of the errors encountered for each server, and provide instructions on how to fix them.

Upgrade the server

Upgrading the server
About this task

This procedure assumes that an existing version of the server is stored at `PingData-server-old`. Make sure a complete, readable backup of the existing system is available before upgrading the server. Also, make sure there is a clear back-out plan and schedule.

Steps

1. Download the latest version of the server software and unzip the file.
2. Use the **`update`** command of the newly unzipped build to update the server. Make sure to specify the server instance that is being upgraded with the `--serverRoot` option. The server must be stopped for the update to be applied.

Copyright © 2025 Ping Identity Corporation

Reverting an update

If necessary, a server can be reverted to the previous version using the **`revert-update`** command. The command accesses a log of file actions taken by the **`update`** command to put the file system back to its prior state. If multiple updates have been run, you can run the **`revert-update`** command multiple times to revert to each prior update sequentially. For example, you can run the **`revert-update`** command to revert the server to its previous state, then run the command again to return it to its original state. The server is stopped during the revert-update process.

> **Note**
>
> Reverting an update is not supported for upgrades to version 7.0, because of the topology backend changes.

Use the `revert-update` command in the server root directory to revert back to the most recent version of the server:

```
$ PingData-server-old/revert-update
```

Reverting from version 7.x to a version earlier than 7.0

You can revert from version 7.0 or later to a pre-7.0 version using the **`revert-update`** command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 to 6.2.0.2 or later. These steps are listed when the **`update`** and **`revert-update`** commands are run as well. You might need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, you might need to rebuild the indexes. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the **`rebuild-index`** command to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the `logs/config-audit.log` file. If you want to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, you will need to set instance names for each server in the topology if they were not previously set. You can do this with the following **`dsconfig`** command:

  ```
  $ bin/dsconfig --bindDN "cn=Directory Manager" \
    --bindPassword secret \
    --no-prompt set-global-configuration-prop \
    --set instance-name:<name>
  ```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, you can run the **`revert-update`** command to return to the previous version.

  However, if new servers are added, then the restored `admin` backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.

- If new servers were added to the topology after the update, you must temporarily remove the new servers from the topology until all servers have been reverted to the previous version.

Copyright © 2025 Ping Identity Corporation

- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the `admin` backend) will need to know that the reverted server was downgraded to the `admin` backend. This is done by running the following **`dsconfig`** command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a primary server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made primary with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you want to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the `changelogDb/` and `db/changelog/` directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent startups.

Upgrading PingDataMetrics

Use the PingDirectory server's **`update`** tool to upgrade the current code version.

Click the following tabs to see instructions for the tasks you want to perform.

Upgrading servers in a topology

Upgrading servers in a topology

An update to the current release includes significant changes, and the introduction of a topology registry, which will store information previously stored in the admin backend (server instances, instance and secret keys, server groups, and administrator user accounts). For the admin backend to be migrated, the **`update`** command must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security options requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the configuration backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to true (such as the `cn=Directory Manager` user) that exists on every server can be used.

The **`update`** command will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The **`update`** command will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the configuration and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. After it has been set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server before the update:

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under `cn=cluster,cn=config` (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree primary. To synchronize the cluster-wide configuration data across all servers in the topology, run the **`config-diff`** command on each pair of servers to determine the differences, and use the **`dsconfig`** command to update each instance using the **`config-diff`** command's output. For example:

```
$ bin/config-diff --sourceHost hostName \
  --sourcePort port \
  --sourceBindDN bindDN \
  --sourceBindPassword password \
  --targetHost hostName \
  --targetPort port \
  --targetBindDN bindDN \
  --targetBindPassword password
```

If any of these conditions are not satisfied, the **`update`** command will list all of the errors encountered for each server, and provide instructions on how to fix them.

Upgrading the server

Upgrading the server
Before you begin

Make sure of the following:

- An existing version of the server is stored at `PingData-server-old`.
- A complete, readable backup of the existing system is available before upgrading the server.
- There is a clear back-out plan and schedule.

Steps

1. Download the latest version of the server software and unzip the file.
2. Use the **`update`** command of the newly unzipped build to update the server.
3. Specify the server instance that is being upgraded with the `--serverRoot` option.
4. Stop the server to apply the update.

Reverting an update

You can revert a server to the previous version using the **`revert-update`** command.

About this task

The **`revert-update`** command accesses a log of file actions taken by the **`update`** command to put the filesystem back to its prior state. If multiple updates have been run, the **`revert-update`** command can be used multiple times to revert to each prior update sequentially. For example, the **`revert-update`** command can be run to revert to the server's previous state, then run again to return to its original state. The server is stopped during the revert-update process.

> **Note**
> Reverting an update is not supported for upgrades to version 7.0 because of the topology backend changes.

Steps

1. Go to the server root directory.
2. To revert back to the most recent version of the server, use the `revert-update` command.

   Example:

   ```
   $ PingData-server-old/revert-update
   ```

Reverting from version 7.x to a version earlier than 7.0

Reverting from version 7.0 or later to a pre-7.0 version can be done using the `revert-update` command with some extra steps.

Copyright © 2025 Ping Identity Corporation

This is also the case when updating or reverting from a pre-6.2.0.2 version to 6.2.0.2 or later. These steps are listed when the **`update`** and **`revert-update`** commands are run as well. You might need to perform one or more of the following tasks, depending on your installation and configuration:

Processes for reverting from version 7.x to versions earlier than 7.0

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes might need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the **`rebuild-index`** command to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the `logs/config-audit.log` file. If you want to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following `dsconfig` command:

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
  --bindPassword secret \
  --no-prompt set-global-configuration-prop \
  --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the admin backend. As long as new servers are not added to the topology after this update, the **`revert-update`** command can be used to return to the previous version. However, if new servers are added, then the restored admin backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the admin backend) will need to know that the reverted server was downgraded to the admin backend. This is done by running the following **`dsconfig`** command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name  <Reverted server instance name>  \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a primary server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made primary with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

Copyright © 2025 Ping Identity Corporation

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you want to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the `changelogDb/` and `db/changelog/` directories in the reverted server root must be deleted after the revert has completed.

> **Note**
>
> When you start a server after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent startups.

Starting, stopping, and restarting the server

This section contains the following topics:

- Starting the server
- Starting the server at boot time
- Stopping the server
- Scheduling a server shutdown
- Restarting the server

Starting the server

You can start the server as a background or foreground process.

Click the following tabs to see the instructions for how you want to start the server.

As a background process

Starting the server as a background process

Use a terminal window to start the server as a background process.

Steps

- To start the server as a background process on UNIX or Linux systems, run the **`bin/start-server`** command without any options.

  An analogous command is in the `bat` folder on Microsoft Windows systems.

Copyright © 2025 Ping Identity Corporation

As a foreground process

Starting the server as a foreground process

Use a terminal window to run the server as a foreground process.

Steps

- To start the server as a foreground process, open a terminal window and enter `bin/start-server` with the `--nodetach` option.

  Example:

  ```
  $ bin/start-server --nodetach
  ```

Starting the server at boot time

By default, the server does not start automatically when the system is booted. Instead, you must start it manually with the **`bin/start-server`** command.

You can use the **`create-systemd-script`** utility to configure the server to start automatically when the system boots. If you prefer, you can also create the script manually.

Click the following tabs to see the instructions for the configuration you want to perform.

Copyright © 2025 Ping Identity Corporation

PingDirectory server

Starting the PingDirectory server at boot time

Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running the server.

   Example:

   ```
   $ bin/create-systemd-script \
        --outputFile /tmp/ping-directory.service \
        --userName ds
   ```

2. As a root user, copy the **`ping-directory.service`** configuration file into the `/etc/systemd/system` directory.

3. To read the new configuration file, reload **`systemd`**.

   Example:

   ```
   $ systemctl daemon-reload
   ```

4. To start the server, run the **`start`** command.

   Example:

   ```
   $ systemctl start ping-directory.service
   ```

5. To configure the server to start automatically when the system boots, run the **`enable`** command.

   Example:

   ```
   $ systemctl enable ping-directory.service
   ```

6. Sign off as root.

   To perform this task on an RC system, create the startup script with **`bin/create-rc-script`** and move it to the `/etc/init.d` directory.

   > **Note**
   >
   > Create symlinks to this script from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and from the /etc/rc0.d directory (starting with a "K" to ensure that the server is stopped).

Copyright © 2025 Ping Identity Corporation

PingDirectoryProxy server

Starting the PingDirectoryProxy server at boot time

Steps

1. Create the service unit configuration file in a temporary location, where "ds" is the user running the server.

   Example:

   ```
   $ bin/create-systemd-script \
        --outputFile /tmp/ping-directory-proxy.service \
        --userName ds
   ```

2. As a root user, copy the **`ping-directory-proxy.service`** configuration file into the `/etc/systemd/system` directory.

3. To read the new configuration file, reload **`systemd`**.

   Example:

   ```
   $ systemctl daemon-reload
   ```

4. To start the server, run the **`start`** command.

   Example:

   ```
   $ systemctl start ping-directory-proxy.service
   ```

5. To configure the server to start automatically when the system boots, run the **`enable`** command.

   Example:

   ```
   $ systemctl enable ping-directory-proxy.service
   ```

6. Sign off as root.

   To perform this task on an RC system, create the startup script with **`bin/create-rc-script`** and move it to the `/etc/init.d` directory.

   > **Note**
   >
   > Create symlinks to this script from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and /etc/rc0.d directory (starting with a "K" to ensure that the server is stopped).

Copyright © 2025 Ping Identity Corporation

PingDataSync server

Starting the PingDataSync server at boot time
About this task
Steps

1. Create the startup script. In this example, `ds` is the user.

```
$ bin/create-rc-script \
  --outputFile Ping-Identity-Sync.sh \
  --userName ds
```

2. Sign on as root and move the generated `Ping-Identity-Sync.sh` script into the `/etc/init.d` directory.
3. Create symlinks to it from the `/etc/rc3.d` directory (starting with an "S" to start the server) and the `/etc/rc0.d` directory (starting with a "K" to stop the server).

```
# mv Ping-Identity-Sync.sh /etc/init.d/
# ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc3.d/S50-Ping-IdentitySync.sh
# ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc0.d/K50-Ping-IdentitySync.sh
```

Stopping the server

The server provides the command, **`bin/stop-server`**, to stop the server. You can run it manually from the command line or within a script.

About this task

If the server has been configured to use a large amount of memory, then it might take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server might fail because the system does not yet have enough free memory. On UNIX systems, run the **`vmstat`** command and watch the values in the "free" column increase until all memory held by the server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process might take.

Steps

- Use the following command to shut down the server.

  Example:

```
$ bin/stop-server
```

Scheduling a server shutdown

You can schedule a server shutdown using the **`bin/stop-server`** command with the `--stopTime YYYYMMDDhhmmss` option.

Copyright © 2025 Ping Identity Corporation

About this task

The following step applies to PingDirectory, PingDirectoryProxy, and PingDataSync.

Steps

- Run the **`bin/stop-server`** command with the `--stopTime YYYYMMDDhhmmss` option.

  The server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2023 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, 20120606134500Z. The command also uses the `--stopReason` option, which writes the reason for the shutdown to the logs.

  > **Note**
  >
  > The **`bin/stop-server`** command must be run with the `--task` argument. If this argument is not provided, an error message displays.

  Example:

```
$ bin/stop-server --stopTime 20230606134500Z --task --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

Restarting the server

You can restart the server using the **`stop-server`** command with the `--restart` option.

About this task

Running this command is equivalent to shutting down the server, exiting the Java Virtual Machine (JVM) session, and then starting up again.

Steps

- Go to the server root directory, and run the **`bin/stop-server`** command with the `-R` or `--restart` option.

  Example:

```
$ bin/stop-server --restart
```

Support

https://support.pingidentity.com/

Introduction to the PingDirectory server

The PingDirectory server is a high-performance, extensible Lightweight Directory Access Protocol (LDAP) directory that provides seamless data management over a distributed system while meeting the constant performance demands for today's markets.

The PingDirectory server centralizes consumer and user identity management information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment.

The PingDirectory server can:

- Simplify administration
- Reduce costs
- Secure information in systems that scale for large numbers of users

For the latest information on PingDirectory server releases, see the Release Notes.

To learn more about PingDirectory server features and components, see:

- Server features
- Administration framework
- Server tools location

Copyright © 2025 Ping Identity Corporation

Server features

The PingDirectory server provides the following features and tools.

Full LDAP version 3 implementation

The PingDirectory server fully supports LDAP v3, which supports the Request For Comments (RFCs) specified in the protocol. It provides a feature-rich solution that supports the core LDAP v3 protocol in addition to server-specific controls and extended operations.

High availability

The PingDirectory server supports N-way multi-primary replication that eliminates single points of failure and ensures high availability for a networked topology. It allows you to store data across multiple machines and disk partitions for fast replication. It also supports replication in entry-balancing proxy server deployments.

Administration tools

The PingDirectory server provides a full set of command-line tools, an administrative console, and a Java-based setup tool to configure, monitor, and manage any part of the server.

The server has a task-based subsystem that provides automated scheduling of basic functions, such as:

- Backups
- Restores
- Imports
- Exports
- Restarts
- Shutdowns

The set of utilities includes a troubleshooting support tool that aggregates system metrics into a `.zip` file, which administrators can send to your authorized support provider for analysis.

Self-service account manager application

The Self Service Account Manager project, hosted at https://github.com/pingidentity/ssam, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes only and is not a supported application.

Delegated admin application

A Javascript-based web application can be installed for business users to manage identities stored in the PingDirectory server. The application provides delegated administration of identities for:

- Help desk or customer service representatives initiating a password reset and unlock
- An employee in HR updating an address stored within another employee profile
- An application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Copyright © 2025 Ping Identity Corporation

Security mechanisms

The PingDirectory server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry.

The server allows connections over SSL through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include:

- A privilege subsystem for fine-grained granting of rights
- A password policy subsystem that allows configurable password validators and storage schemes
- SASL authentication mechanisms to secure data integrity, such as:
  - PLAIN
  - ANONYMOUS
  - EXTERNAL
  - CRAM-MD5
  - Digest-MD
  - GSSAPI

The PingDirectory server supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. For more information, see the PingDirectory Security Guide.

Monitoring and notifications

The PingDirectory server supports monitoring entries using:

- PingDataMetrics server
- JConsole
- SNMP
- The administrative console

Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The PingDirectory server supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.

Powerful LDAP SDK

The PingDirectory server is based on a feature-rich LDAP SDK for Java. The LDAP SDK is a Java API standard that overcomes the limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

> **Note**
>
> For more information on the LDAP SDK for Java, see http://www.LDAP.com.

Copyright © 2025 Ping Identity Corporation

System for Cross-domain Identity Management (SCIM) extension

The PingDirectory server provides a SCIM servlet extension to facilitate moving users to, from, and between cloud-based software as a service (SaaS) applications in a secure and fast manner.

Directory REST API

The PingDirectory server provides a REST API as the native interface for client access. Instead of trying to manage directory hierarchy or requiring attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient. For more information, see the Developer portal.

Server SDK

The Server SDK is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for:

- PingDirectory server
- PingDirectoryProxy server
- PingDataSync server

The servers have a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

Administration framework

The PingDirectory server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances.

Administrators can configure changes locally or remotely:

- On a single server
- On all servers in a server group

Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the directory information tree (DIT). Administrators can tune the configuration and perform maintenance functions over LDAP using a suite of command-line tools or an administrative console (for configuration and monitoring). The PingDirectory server provides plugins to extend the functionality of its components.

Server tools location

The PingDirectory server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX or Linux machines and the `PingDirectory\bat` directory for Microsoft Windows machines.

The PingDirectory server, administrative console, and LDAP SDK for Java are distributed in `.zip` format. After extracting the file, you can access the **`setup`** utility in the server root directory, located at `PingDirectory`.

Copyright © 2025 Ping Identity Corporation

Before installing the PingDirectory server, see Preparing the operating system (Linux) for important information on setting up your machines. See Installing the PingDirectory server for information on installing a server instance using the `setup` utility. You can run this utility in either interactive command-line or non-interactive command-line. For information on modifying the configuration of a server instance or a group of servers using the command-line tools and the administrative console, see Configuring the PingDirectory server.

Getting started with the PingDirectory server

After you have set up your PingDirectory server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize the server's throughput.

> **Note**
>
> The URL is based on the host name and HTTPS port specified during installation, such as https://hostname.com:443/console.

Apply Server Configurations

Apply your server configuration changes individually or using a `dsconfig` batch file. The batch file defines the PingDirectory server configuration tool (`dsconfig`) commands necessary to configure your server instance. For more information on using batch files, see Using dsconfig batch mode.

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the `bin/migrate-sun-ds-config` command to migrate your configuration settings to this new server instance.

Import Data

Import user data using the `import-ldif` tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

Install and Configure the Delegated Admin Application

Install a Javascript-based web application for business users to manage identities stored in the PingDirectory server. The application provides delegated administration of identities for help desk or customer service representatives initiating a password reset and unlock, an employee in HR updating an address stored within another employee profile, or an application administrator updating identity attributes or group membership to allow application single sign-on (SSO) access.

Run Performance Tests

The PingDirectory server provides two tools for functional performance testing using in-house LDAP clients that access the server directly: `searchrate` to test search performance and `modrate` to test modification performance.

Copyright © 2025 Ping Identity Corporation

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
  --filter "(uid=user.[0-1999])" --attribute givenName --attribute sn \
  --attribute mail --numThreads 10

$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com" \
  --attribute description --valueLength 12 --numThreads 10
```

Directory server folder layout

After extracting the PingDirectory server's distribution file, you see the following folders and command-line utilities.

Layout of the PingDirectory server Folders

Directories/Files/Tools	Description
`License.txt`	Licensing agreement for the PingDirectory server.
`README`	`README` file that describes the steps to set up and start the PingDirectory server.
`bak`	Stores the physical backup files used with the **`backup`** command-line tool.
`bat`	Stores Windows-based command-line tools for the PingDirectory server.
`bin`	Stores UNIX/Linux-based command-line tools for the PingDirectory server.
`classes`	Stores any external classes for server extensions.
`collector`	Used by the server to make monitored statistics available to the PingDataMetrics server.
`config`	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.
`db`	Stores the Oracle Berkeley Java Edition database files for the PingDirectory server.
`docs`	Provides the product documentation.
`import-tmp`	Stores temporary imported items.
`ldif`	Stores any LDIF files that you might have created or imported.
`legal-notices`	Stores any legal notices for dependent software used with the PingDirectory server.
`lib`	Stores any scripts, jar, and library files needed for the server and its extensions.
`locks`	Stores any lock files in the backends.
`logs`	Stores log files for the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

Directories/Files/Tools	Description
`metrics`	Stores the metrics that can be gathered for this server and surfaced in PingDataMetrics server.
`resource`	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, `dsconfig` batch files, and other items for configuring or managing the server.
`revert-update`	The **`revert-update`** tool for UNIX/Linux systems.
`revert-update.bat`	The **`revert-update`** tool for Windows systems.
`setup`	The **`setup`** tool for UNIX/Linux systems.
`setup.bat`	The **`setup`** tool for Windows systems.
`scim-data-tmp`	Used to create temporary files containing System for Cross-domain Identity Management (SCIM) request data.
`uninstall`	The **`uninstall`** tool for UNIX/Linux systems.
`uninstall.bat`	The **`uninstall`** tool for Windows systems.
`update`	The **`update`** tool for UNIX/Linux systems.
`update.bat`	The **`update`** tool for Windows systems.
`Velocity`	Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.

Multiple backends

You can create multiple local database backends, each containing one or more different base distinguished names (DNs).

There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends.

The typical entry-balancing configuration involves two local database backends:

- One backend serves the global domain data that resides above the entry-balancing point.
- One backend is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, you can manage the data existing with each backend independently. Separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends can have the same base DN.

Copyright © 2025 Ping Identity Corporation

- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DNs on that backend must be subordinate to the base DN of the other backend.
- The total of all `db-cache-percent` values should be no more than 65-70% in most cases and should never exceed 100%.

Importing data

After installing the database, such as userRoot, import data into the database.

Steps

- To add a server to a replicating set:
    1. Perform a **`dsreplication enable`** operation.
    2. Import the database through the **`dsreplication initialize`** operation.
- To add a server to a non-replicating set or to add the first server of a future replicating set, import the data with the **`bin/import-ldif`** tool.

  For more information about the **`bin/import-ldif`** tool, see Importing and exporting data.

Generating sample data

The PingDirectory server provides LDIF templates to generate sample entries for initializing your server. You can generate the sample data with the **`make-ldif`** utility together with template files that come bundled with the `.zip` build, or you can use template files that you create yourself.

About this task

The templates create sequential entries for testing the PingDirectory server with a range of dataset sizes. The templates are located in the `config/MakeLDIF`.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the admin account full privileges. The templates also include the `uid=admin and ou=People` entries.

Steps

- To generate randomized sample data, use the `--randomSeed` option with the **`make-ldif`** command.

  Example:

  ```
  $ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \
    --ldifFile /path/to/data.ldif --randomSeed 0
  ```

  > **Note**
  >
  > If the `--randomSeed` option is used with the same seed value, the template always generates the same `.ldif` file.

  Result:

Copyright © 2025 Ping Identity Corporation

The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.

- To bypass the `make-ldif` command, use the `--templateFile` option with the `import-ldif` tool.

Importing data on the PingDirectory server using offline import

Steps

1. Create a `.ldif` file that contains entries or locate an existing file.The `import-ldif` tool requires a `.ldif` file, which conforms to standard LDIF syntax without change records. The `changeType` attribute is not allowed in the input LDIF. For information on adding entries to the PingDirectory server, see Managing Entries.
2. Stop the PingDirectory server.
3. To import data from an LDIF file to the PingDirectory server, use the `import-ldif` command.

   > **Tip**
   >
   > For assistance with the list of options, run `import-ldif --help`.

   In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. Entries rejected because of schema violation are written with the rejection reason to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the directory information tree (DIT) or if exclusion filters, such as `--excludeBranch`, `--excludeAttribute`, or `--excludeFilter` are used. The `--overwrite` option instructs `import-ldif` to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten, and the `--stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in an LDIF parsing error.

   Example:

   ```
   $ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --rejectFile
       rejects.ldif --skipFile skipped.ldif --overwrite --overwriteExistingEntries --stripTrailingSpaces
   ```

4. Restart the PingDirectory server.

Running the server as a Microsoft Windows service

The server can run as a Windows service, which enables you to sign out of a machine without stopping the server.

Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin\stop-server`.

   You cannot register a server while it is running.

Copyright © 2025 Ping Identity Corporation

2. To register the server as a service, from a Windows command prompt, run `bat\register-windows-service.bat`.
3. After registration, start the server from the Windows Services Control Panel or with the `bat\start-server.bat` command.

> **Note**
>
> Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>\config\wrapper-product.conf` file.

Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

Steps

1. To remove the service from the Windows registry, use the `bat\deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

Configuring log files for services

About this task

The log files are stored in `<server-root>\logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

Steps

1. These configurations can be changed in the `<server-root>\config\wrapper.conf` file.

Running the status tool

The PingDirectory server provides a `status` tool that outputs the current state of the server as well as other information, such as server version, java runtime environment statistics, operation processing times, work queue, and administrative alerts.

About this task

Copyright © 2025 Ping Identity Corporation

The `status` tool is located in the `bin` directory for UNIX and Linux or the `bat` directory for Windows.

Steps

1. Run the `status` command on the command line.

   The following code displays an example of the current server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type, and the current state of the work queue.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

          --- Server Status ---
Server Run Status:    Started 28/Mar/2012:10:47:17.000 -0500

Info     : 28/Mar/2012 10:47:14 -0500 : The Directory Server is starting
Info     : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started successfully
Info     : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48 hours Use the
--maxAlerts and/or --severity options to filter this list
```

> **Note**
>
> By default, the **`status`** command displays the alerts generated in the last 48 hours. To change this default setting, see step 2.

2. To limit the number of viewable alerts from the default 48 hours, use the `--maxAlerts` option.

Tuning the server

The PingDirectory server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup.

The default configuration and JVM settings are suitable for most deployments, but it is not uncommon in high-performance environments to make slight changes to the server's JVM settings as well as performance and resource-related configuration changes with the **`dsconfig`** tool. For these high-performance environments, tuning can achieve optimum throughput performance and disk space usage for the server and its tools.

About minimizing disk access

Minimizing disk access is critical to the PingDirectory server's performance.

Defining a Java Virtual Machine (JVM) heap size that can contain the entire contents of the database cache in memory minimizes read operations from disk and achieves optimal performance. The database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate in the transaction logs. During normal operation, the on-disk size of the database transaction logs does not represent the memory needed to cache the database.

Consider minimizing the size of the database based on the known characteristics of your data. Doing so reduces hard disk requirements and the memory requirements for the database cache. An example of this is the PingDirectory server automatically compacting common parent distinguished names (DN).

Finally, consider the write load on your server and its effect on the database. Write operations will always require an associated write-to-disk, but an environment that sustains a high load of write operations might consider tuning the background database cleaner to minimize the size of the database on disk.

If your backend DB environment is sensitive to write operations that take more than 500 milliseconds, you can reduce response time outliers by changing the **`fsync`** timeout value to 20 milliseconds. To do this, run the following command with the appropriate value for *<backend-name>*:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-backend-prop \
--backend-name  <backend-name>  \
--add "je-property:je.log.fsyncTimeout=20 ms"
```

Note

This change reduces the time that a thread will wait in an attempt to coalesce multiple concurrent requests to perform an **`fsync`**, which synchronizes the file system after a write or a transaction. When the timeout value is reached, these attempts expire.
This configuration change is set by default in PingDirectory 10.1 and later.

Memory allocation and database cache

Memory allocation and database cache comprise the basic components of the PingDirectory server footprint and logic behind the automated tuning of the **`setup`** tool.

The PingDirectory server's optimal performance is dependent on:

- The proper allocation of memory to the Java Virtual Machine (JVM) heap
- The number of processor cores in the system
- The correct combination of JVM options for optimized garbage collection

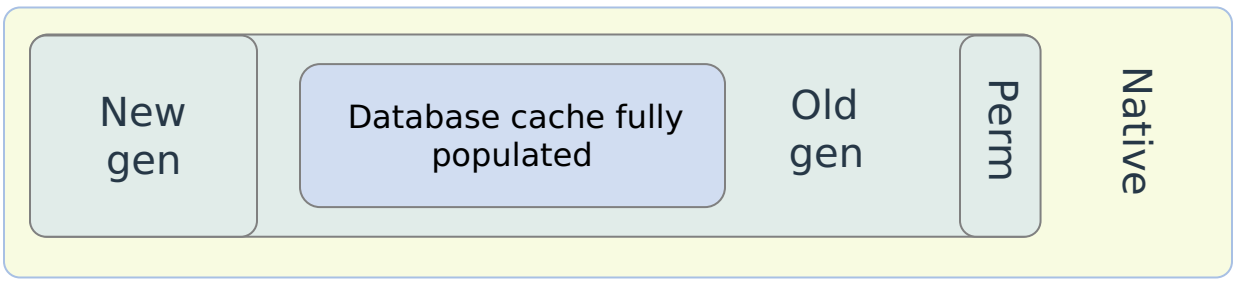
The **`setup`** tool for the PingDirectory server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system; however, in most production deployments, additional tuning might be required to meet the performance objectives for your system.

Often server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure and the expected database usage.

PingDirectory server process memory

The PingDirectory server consists mainly of a Java Virtual Machine (JVM) heap and a marginal amount of memory allocated by the JVM's execution of native code.

Although the JVM heap is referred to frequently as the maximum memory consumed by the PingDirectory server, the actual process size is slightly larger than the `Xmx` value because of the accumulation of small chunks of native code that Java requires for items such as SSL sockets.



Copyright © 2025 Ping Identity Corporation

Within the JVM heap, the principal memory components are the new and old generations. The new generation is a smaller area of memory where all data is initially allocated, with frequent garbage collection. Any data that's present long enough is promoted to the old generation for the longer term. The old generation is where the database cache eventually resides. The old generation's size isn't explicitly stated in the JVM options; it's computed from the leftover heap after defining the `MaxHeapSize` and new generation sizes.

A typical set of generation definitions for the JVM is as follows, where `mx` and `ms` values represent the heap size:

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX-NewSize=2g
```

Important

The `mx` and `ms` values should always be the same, and the `MaxNewSize` and `NewSize` values should be the same. This helps avoid negative changes in performance.
The **`setup`** and **`dsjavaproperties`** tools set `MaxNewSize` and `NewSize` values based on the results of extensive performance testing and shouldn't need to be changed.

Determining heap and database cache size

Define proper memory allocation of the PingDirectory server components using the **`setup`** command.

About this task

To define the proper memory allocation of the PingDirectory server's components:

Steps

1. Run the **`setup`** command.

   Note

   This must be done on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the **`setup`** tool allows.

2. To define schema and production database settings for the database import, use the **`import-ldif`** tool.

   Note

   After running **`import-ldif`**, the database is at its most optimized state on-disk with no inactive records. Over time, the on-disk representation of the database grows up to 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

3. After the database is imported, start the server and make any needed configuration changes.

   Example:

   Set the `prime-method` to `preload` on the `userRoot` backend configuration.

4. Restart the PingDirectory server and watch for a successful preload message.

Copyright © 2025 Ping Identity Corporation

Choose from:

- If preloading completes, proceed to step 6.
- If preloading does not complete, proceed to step 5.

5. If preloading does not complete, troubleshoot with the following steps:
    1. In the `config/java.properties` file, in the `start-server.java-args` entry, edit the entry to use larger values for `-Xmx` and `-Xms` arguments.
    2. Run the following command.

        ```
        bin/dsjavaproperties
        ```

    3. Restart the server and proceed to step 6.
6. After preload completes, run the `status` command to review the database cache utilization.

> **Note**
>
> A fully loaded database needs at least 10-20% cache headroom available for future growth, as in the following example.

Example:

```
             --- JE Environment ---
ID      : Cache Full : Cache   : On-Disk : Alert
---------:------------:--------:---------:------
userRoot : 30%       : 1.1 gb : 868.6mb : None
```

7. (Optional) To see the state of the database cache in more detail, run an `ldapsearch` on the backend monitor.

> **Note**
>
> In addition to the user configured backends, there might be backends for replication and changelog. The heap is shared among all backends. For information on how the heap amount allocated to each backend is calculated, seeAutomatic DB cache percentages.

Automatic DB cache percentages

Adjust the allocation of the DB cache percentage when setting up the PingDirectory server.

About this task

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured Java Virtual Machine (JVM) heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. Change the allocation if needed. When setting up the server:

Steps

1. Install the server with the necessary memory.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The server autotunes the size of the cache.

2. Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
3. Divide the server cache based on the expected size of the data in each backend.

Automatic memory allocation

If the Memory Tuning feature is enabled during setup, the `setup` algorithm determines the maximum Java Virtual Machine (JVM) heap size based on the total amount of available system memory. Otherwise, the PingDirectory server allocates a maximum JVM heap of 384 MB.

About this task

The server also allows you to specify the maximum heap size during the setup process. For more information, see JVM properties for server and command-line tools.

Steps

- To enable Memory Tuning during the setup process:

  Choose from:

  - Select the feature in interactive command-line mode.
  - Add the `--jvmTuningParameter` option using the `setup` tool in non-interactive command-line mode.
  - Regenerate the Java properties file with `bin/dsjavaproperties` and the `--jvmTuningParameter` options.

  > **Note**
  >
  > If Memory Tuning is selected, the server allocates the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

Allocated Max JVM Memory if Tuning is Enabled

Available Memory	Allocated JVM Memory
16 GB or more using a 64-bit JVM	The maximum JVM heap size is set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory, which should be the case for systems with up to 160 GB of memory, then the initial heap size is set to equal the maximum heap size.
6 GB–16 GB using a 64-bit JVM	Total system memory - 4 GB
4 GB–6 GB using a 64-bit JVM	2 GB
2 GB–4 GB	512 MB

Copyright © 2025 Ping Identity Corporation

Available Memory	Allocated JVM Memory
1 GB–2 GB	384 MB

Automatic memory allocation for the command-line tools

At setup, the PingDirectory server automatically allocates memory to each command-line utility based on the maximum Java Virtual Machine (JVM) heap size.

The server sets each command-line utility in the `config/java.properties` file with -`Xmx/Xms` values, depending on the expected memory needs of the tools.

Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file:

`.Online`

Typically requires minimal memory because the task is performed within the PingDirectory server's JVM.

`.Offline`

Can require the same amount of memory needed by the server. Examples include `import-ldif.offline` and `rebuild-index.offline`.

With large databases, some tools, such as **`ldap-diff`** and **`verify-index`**, might need more than the minimal memory. The following table lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

Default Memory Allocation to the Command-Line Tools

Command-Line Tools	Allocated JVM Memory
start-server, import-ldif (offline), rebuild-index (offline)	MaxHeapSize
backup (offline), dbtest export-ldif (offline), ldap-diff, restore (offline), scramble-ldif, summarize-access-log, verify-index	If Max System Memory is: • Greater than or equal to 16 GB: set heap to 3 GB • Greater than or equal to 8 GB: set heap to 1 GB • Greater than or equal to 4 GB: set heap to 512 MB • Under 4 GB: set heap to 256 MB

Database preloading

The ability to maintain the database contents in the database cache within the Java Virtual Machine (JVM) memory is key to the PingDirectory server's performance.

Copyright © 2025 Ping Identity Corporation

With a properly sized database cache, a priming method of preload directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, you can start the server with the `start-server --skipPrime` command. If the priming method is `none`, or the `--skipPrime` option is specified at startup, the database cache slowly builds as entries are accessed. This can take several days to reach optimal performance.

The preload priming method is suitable for nearly all PingDirectory server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The PingDirectory server database `prime-method` property configures how the caches get primed, what gets primed, such as data, internal nodes, system indexes, and where it gets primed, for example a database cache, file system cache, or both. The `prime-method` property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

Preload All Data

Prime the contents of the backend into the database cache.

Preload Internal Nodes Only

Prime only internal database structure information into the database cache, but do not prime any actual data. This corresponds to the cache-keys-only cache-mode.

Cursor Across Indexes

Use the `cursor-across-indexes` property to iterate through backend contents. This is similar to and might be slower than using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

Configuring database preloading

Use the `dsconfig` tool to set the database priming method.

If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they are performed. Changing the preloading option requires restarting the PingDirectory server. The following procedures show how to configure database preloading.

Configuring database preloading

You can configure database preloading to load the database contents from disk into memory when the PingDirectory server starts up.

Steps

1. Configure database preloading.

Copyright © 2025 Ping Identity Corporation

This eliminates the need for the server to gradually prime the database cache using client traffic and ensures that the server has optimal performance when it starts to receive client connections.

Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set prime-method:preload
```

2. To apply the changes, restart the PingDirectory server.
    1. Run **`bin/stop-server`**.
    2. Run **`bin/start-server`**.

Configuring multiple preloading methods

You can configure multiple preloading methods to achieve the benefits of preloading without delaying PingDirectory server startup.

Steps

1. Set **`prime-method`** to **`preload-internal-nodes-only`**, which caches all of the keys within the database, but not the values.

   The database values themselves can be cached in the background after the server has been started with the **`cursor-across-indexes`** option.

   Example:

   ```
   $ bin/dsconfig set-backend-prop \
     --backend-name userRoot \
     --add prime-method:preload-internal-nodes-only \
     --add prime-method:cursor-across-indexes \
     --set background-prime:true
   ```

2. To apply the changes, restart the PingDirectory server.
    1. Run **`bin/stop-server`**.
    2. Run **`bin/start-server`**.

Configuring system index preloading

You can configure system index preloading to reduce the PingDirectory server's startup time.

About this task

Some environments have many indexes configured though only a few are used for performance-sensitive traffic.

Steps

1. Preload only the necessary indexes into the database at startup.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload \
  --set prime-all-indexes:false \
  --set system-index-to-prime:dn2id \
  --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name mail \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name uid \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name entryUUID \
  --set prime-index:true
```

2. To apply the changes, restart the PingDirectory server.
    1. Run **`bin/stop-server`**.
    2. Run **`bin/start-server`**.

Databases on storage area networks, network-attached storage, or running in virtualized environments

Several considerations exist when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks.

A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property **`database-on-virtualized-or-network-storage`** can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property and, in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events might outweigh the penalty. The exact overhead of enabling **`database-on-virtualized-or-network-storage`** depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. A full backup strategy should be used instead if performance is unacceptable.

To enable **`database-on-virtualized-or-network-storage`** for each applicable backend, use the following command as an example, which references the configuration for the userRoot backend.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-global-configuration-prop \
  --set database-on-virtualized-or-network-storage:true
```

This should be set to `false` if the database is on a local disk.

Database cleaner

Production environments that have a high volume of write operations might require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted.

The PingDirectory server stores its Oracle Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labeled `nnnnnnnn.jdb`, where `nnnnnnnn` is an 8-digit hexadecimal number that starts at 00000000 and is increased by 1 for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (db) files.

The cleaner threads begin by scanning the records in each db file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active because of modifications or deletions, the cleaner threads leave it untouched. After the db file no longer has active records, the cleaner threads can either delete the file or rename the discarded file.

> **Note**
>
> Because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The local DB backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to 75, which indicates that database cleaning ensures that at least 75% of the total log file space is devoted to live data.

> **Note**
>
> This property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for db cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic might need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the PingDirectory server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the `dsconfig` tool by going to **Backend → Select Advanced Properties → db-num-cleaner-threads**.

Compacting common parent DNs

The PingDirectory server compacts entry distinguished names (DNs) by tokenizing common parent DNs.

About this task

Copyright © 2025 Ping Identity Corporation

Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage.

By default, PingDirectory generates tokens for the following:

- Base DNs for the backend, such as `dc=example,dc=com`
- Any `compact-common-parent-dn` values defined in the server configuration
- `ou=People,<base dn>`
- `ou=Groups,<base dn>`

The tokens are generated in this order. You can also define additional common base DNs to be tokenized.

Steps

- Use the following configuration to tokenize two branches: `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`.

  Example:

  ```
  $ bin/dsconfig set-backend-prop --backend-name userRoot \
    --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
    --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
  ```

Setting the import thread count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count can lead to improved import performance while selecting a value that is too large can actually cause import performance to degrade.

About this task

If minimizing LDIF import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the data set being imported.

Steps

- Use the **`dsconfig`** command to set the number of import threads.

  Example:

  ```
  $ bin/dsconfig set-backend-prop --backend-name userRoot --set import-thread-count:24
  ```

JVM properties for server and command-line tools

The PingDirectory server and tools refer to the `config/java.properties` file for Java Virtual Machine (JVM) options that include important memory settings.

The `java.properties` file sets the default Java arguments for the PingDirectory server and each command-line utility includes the default *<JAVA_HOME>* path.

Copyright © 2025 Ping Identity Corporation

The `java.properties` file is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if you selected the aggressive memory tuning option at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See Memory allocation and database cache for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (`start-server`) or command-line tools, the most common change required to `java.properties` is when you want to update the JVM version. A single edit applies the new JVM to all server and tool use.

Applying changes using dsjavaproperties

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the `bin/dsjavaproperties` utility.

The `dsjavaproperties` utility uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script, or `lib\set-java-home.bat` on Microsoft Windows systems, which is used by the PingDirectory server and all of its supporting tools to identify the Java environment and its JVM settings. During the process, `dsjavaproperties` calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated `set-java-home` script.

The `dsjavaproperties` utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the PingDirectory server compares the MD5 digest with the version stored in `set-java-home` and sends a message to standard error if the digests differ.

```
WARNING -- File /ds/{pingdir}
            /config/java.properties  has been edited without
running  dsjavaproperties  to apply the changes
```

Updating the Java version in the properties file

To change the version of Java that is used by the server and tools, edit the `config/java.properties` file and apply the change by invoking `bin/dsjavaproperties` with no command line options.

About this task

You must restart the PingDirectory server for the change to take affect.

Steps

- Inside `config/java.properties`, alter the value of `default.java-home` to point to the Java correct Java Runtime Environment (JRE).

  Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration.

  Example:

  ```
  $ bin/dsjavaproperties
  ```

Copyright © 2025 Ping Identity Corporation

Regenerating the Java properties file

The `dsjavaproperties` command provides an `--initialize` option that allows you to regenerate the Java properties file specifically if you set up the PingDirectory server using standard memory usage but opt for aggressive memory tuning after setup.

About this task

Rather than reconfigure the Java properties file by re-running `setup` or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file is renamed with a `.old` suffix.

Steps

- Run the `dsjavaproperties` command to regenerate the java properties file for aggressive memory tuning.

  Example:

  ```
  $ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
  ```

Tuning for disk-bound deployments

You can configure the PingDirectory server for a disk-bound configuration.

About this task

For best performance, configure the server to fully cache the DIT in the backend database cache. The server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set. When the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario.
- Use uncached attributes or entries as described in the following section.
- Use a PingDirectoryProxy server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

Steps

1. When installing the server, choose the **Aggressive** option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.
3. Set operating system `vm.swappiness` to 0 to protect the server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

Copyright © 2025 Ping Identity Corporation

Uncached attributes and entries

Although achieving optimal PingDirectory server performance requires that the entire data set be fully cached, there can be deployments in which fully caching the data set is not possible because of hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data.

The PingDirectory server already provides support for controlling caching on a per-database basis, such as to cache only certain indexes and system databases, but these features might not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the PingDirectory server provides two new options: the ability to exclude certain entries from the cache, and the ability to exclude certain attributes from the cache. The server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a large attribute and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it only includes internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database are included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of `uncached-id2entry`.

Backup and Restore

There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup successfully saves your database contents, including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration are properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

Replication

Replication does not propagate information about which portions of entries might have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

LDIF Import and Export

When LDIF content is imported into the server, the uncached attribute and uncached entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that might have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters or to include or exclude specific attributes.

Copyright © 2025 Ping Identity Corporation

Server Access Log

Server access log messages can include `uncachedDataAcessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAcessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

Uncached Entry and Attribute Properties

The PingDirectory server provides three new advanced properties on the local DB backend to control the caching mode for the `uncached-id2entry` database:

uncached-id2entry-cache-mode

Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended. Otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the PingDirectory Server Configuration Reference.

uncached-attribute-criteria

Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.

uncached-entry-criteria

Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

Configuring uncached attributes and entries

Configure uncached attributes and entries.

About this task

The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the PingDirectory Server Configuration Reference.

Steps

1. Run `dsconfig` to uncache entries that match the criteria.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig create-uncached-entry-criteria \
  --criteria-name "Fully Uncached l=austin" --type filter-based \
  --set enabled:true --set "filter:(l=austin)"
```

The filter uncaches all entries that have its location set to "austin", such as `l=austin`.

2. Run **`dsconfig`** to uncache attributes that match the criteria.

   The `--type simple` option indicates that the simple uncached attribute criteria be used to specify the attribute-type that should be uncached. For those entries that are fully stored in the `uncached-id2entry` database container, the uncached attribute is ignored.

   Example:

   In this example, the attribute-type criteria that should be uncached is `jpegPhoto`.

   ```
   $ bin/dsconfig create-uncached-attribute-criteria \
     --criteria-name "Uncached jpegPhoto" --type simple \
     --set enabled:true --set attribute-type:jpegPhoto
   ```

3. Set the uncached properties for the `userRoot` backend.

   Example:

   ```
   $ bin/dsconfig set-backend-prop \
     --backend-name userRoot \
     --set "uncached-entry-criteria:Fully Uncached l=austin" \
     --set "uncached-attribute-criteria:Uncached jpegPhoto"
   ```

4. Run the **`re-encode-entries`** tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains.

   The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend.

   Example:

   The following example initiates a task that re-encodes all fully-cached entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

   ```
   $ bin/re-encode-entries --hostname directory.example.com --port 389 \
     --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --backendID userRoot --skipFullyUncachedEntries \
     --skipPartiallyUncachedEntries --ratePerSecond 100
   ```

Copyright © 2025 Ping Identity Corporation

JVM garbage collection using CMS

To ensure reliable server performance with Java, the PingDirectory server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection.

Out of several garbage collection options, CMS is the ideal choice for consistent system availability. For the most part, the CMS collector runs as one or more background threads within the Java virtual machine (JVM), freeing up space in JVM Heap from an area called the old generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called `CMSInitiatingOccupancyFraction`. This percentage value, which applies to the Old Generation, is recommended for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the `CMSInitiatingOccupancyFraction` value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation because of an inability for CMS to keep up. Because CMS takes processing resources away from the PingDirectory server, do not set the `CMSInitiatingOccupancyFraction` at or below the expected database cache size, which would result in the constant running of CMS in the background. For a description of determining Old Generation size, see the section on Memory Footprint and Database Cache.

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM resorts to pausing all application processing to allow a full garbage collection. This event, called a "stop-the-world pause", does not break existing TCP connections or alter the execution of the PingDirectory server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the server generates an alert after the pause and records the pause time in the error log.

Because determining an ideal `CMSInitiatingOccupancyFraction` can be difficult, we warn if the PingDirectory server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, an administrator cannot determine the ideal occupancy threshold value in advance. To warn of any impending garbage collection pauses, the server calculates a recommended value for the `CMSInitiatingOccupancyFraction` property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, an administrative alert indicates the current state of the `CMSInitiatingOccupancyFraction` and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE severity=NOTICE msgID=458886
msg="PingDire Server
            8.0.0.0 (build 20120418135933Z, R6226) starting up"

... (more output) ...

[20/April/2012:10:35:53 -0500] category=UBID_EXTENSIONS severity=NOTICE
msgID=1880555580 msg="Memory-intensive PingDirectory server
components are configured to consume 71750382 bytes of memory:
['userRoot local DB backend' currently consumes 26991632 bytes and
can grow to a maximum of 64323584 bytes, 'changelog cn=changelog backend'
currently consumes 232204 bytes and can grow to a maximum of 2426798 bytes,
'Replication Changelog Database' currently consumes 376661 bytes and can
grow to a maximum of 5000000 bytes]. The configured value of
CMSInitiatingOccupancyFraction is 36 which is less than the minimum
recommended value (43) for the server's current configuration. Having
this value too low can cause the Concurrent Mark and Sweep garbage
collector to run too often, which can cause a degradation of throughput
and response time. Consider increasing the CMSInitiatingOccupancyFraction
value to at least the minimum value, preferably setting it to the
recommended value of 43 by editing the config/java.properties file,
running dsjavaproperties, and restarting the PingDirectory server.
If the server later detects that this setting actually leads to a
performance degradation, a separate warning message will be logged.
If this server has not yet been fully loaded with data, then you
can disregard this message"

[20/April/2012:10:35:53 -0500] category=CORE severity=NOTICE msgID=458887
msg="The PingDirectory server has started successfully"
```

The PingDirectory server only makes a recommendation if all of the backends are preloaded and the `CMSInitiatingOccupancyFraction` JVM property is explicitly set, which is done automatically. For example, if you installed the PingDirectory server and specified that the database be preloaded (or "primed") at startup, then the server can make a good recommendation when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value might be an inaccurately low value.

> **Note**
>
> The generated value for the PingDirectory server's property could change over time with each server build, Java release, or changes in data set. If the current value is close to the recommended value, then you do not need to change the property unless the server experiences a JVM pause.
> If the PingDirectory server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the property, run **`dsjavaproperties`**, and restart the server.

Determining the CMSInitiatingOccupancyFraction

Use the terminal to determine the `CMSInitiatingOccupancyFraction` value.

Steps

1. Retrieve the `prime-method` property for the backend.

   Example:

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
  --property prime-method
```

> **Note**
>
> If you set the `Preload Database at startup` option during the installation, then skip to step 3.

2. If the `prime-method` property was not configured, run **`bin/dsconfig`** to set the property to PRELOAD, and then restart the PingDirectory server to preload the database cache.

   Example:

   ```
   $ bin/dsconfig set-backend-prop --backend-name userRoot \
     --set prime-method:preload

   $ bin/stop-server
   $ bin/start-server
   ```

   Result:

   At startup, you see an administrative message if the current `CMSInitiatingOccupancyFraction` property is below the recommended value.

   > **Note**
   >
   > You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.

3. If you were unable to see the recommended `CMSInitiatingOccupancyFraction` property at startup presented in the previous step, pre-tune the value of the `CMSInitiatingOccupancyFraction` property to ensure that all of the data is imported into the server and preloading is enabled in the backend.

   1. Retrieve the recommended `CMSInitiatingOccupancyFraction` value by issuing the following search.

      Example:

      ```
      $ bin/ldapsearch --baseDN "cn=monitor" \
        "(objectclass=ds-memory-usage-monitor-entry)" \
        cms-initiating-occupancy-fraction \
        recommended-cms-initiating-occupancy-fraction-for-current-data-set
      ```

      > **Note**
      >
      > If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backends.

      Result:

      ```
      dn: cn=JVM Memory Usage,cn=monitor
      cms-initiating-occupancy-fraction:80
      recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
      ```

Copyright © 2025 Ping Identity Corporation

4. Open the `config/java.properties` file using a text editor and manually edit the `CMSInitiatingOccupancyFraction` property (or any other property) to its recommended value in the `start-server.java-args` property.
5. Save the file.

   The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.

   Example:

   ```
   start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
   -XX:NewSize=1g -XXParallelGCThreads=16 -XX:+UseConcMarkSweepGC
   -XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
   -XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
   -XX:CMSMaxAbortablePrecleanTime=3600000
   -XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
   -XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
   -XX:+UseBiasedLocking -XX:+UseLargePages
   -XX:+HeapDumpOnOutOfMemoryError
   ```

   The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. The `-XX:ParallelCMSThreads` should be limited to 8.
6. To apply the changes, run the **`bin/dsjavaproperties`** command.

   Example:

   ```
   $ bin/dsjavaproperties
   ```
7. Restart the PingDirectory server.

JVM garbage collection using ZGC

The Z Garbage Collector (ZGC) is a low-latency garbage collector that is well-suited for large Java Virtual Machine (JVM) heaps.

ZGC is a single-generation, region-based, NUMA-aware, compacting collector, and like G1, works concurrently with the JVM application. ZGC does not track how many collection cycles objects in the heap have survived. Because each region of the heap is concurrently scanned in each cycle, objects are not sorted into "new" or "old" generations. This collector is suitable for applications with large amounts of memory that require short pause times because it does not pause the execution of application threads for more than 10 ms.

The recommended JVM properties when using ZGC for garbage collection are:

```
-XX:+UseZGC -XX:ConcGCThreads=10 -XX:InitiatingHeapOccupancyPercent=80 -XX:MaxNewSize=2g -XX:NewSize=2g
```

In the JVM startup arguments, you should configure the heap space with at least 15-20 GB of headroom space left for the system RAM. For example, for a server with 62 GB RAM, the `xmx` and `xms` arguments in the `start-server.java-args` argument of the `java.properties` file should be set to 45 GB, expressed by `-Xmx45g -Xms45g`.

Configuring the PingDirectory server

Configure the PingDirectory server to meet the performance, hardware, operating system, and memory requirements for your production environment.

The out-of-the-box, initial configuration settings for the PingDirectory server provide an excellent starting point for most general-purpose server applications. However, additional tuning might be necessary to meet the needs of your production environment.

The PingDirectory server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the server provides command-line options and an administrative console for configuration purposes. The PingDirectory server also includes tools to create server groups to apply configuration changes to multiple servers at one time

About the configuration tools

You can access and modify the server configuration in two ways.

Administrative console

The server provides an administrative console for graphical server management and monitoring. The console functions are equivalent to the **`dsconfig`** tool for viewing or editing configurations.

All configuration changes using the administrative console are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands if you need to undo a configuration.

`dsconfig` *Command-line tool*

The **`dsconfig`** tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes:

- Interactive command-line mode
- Non-interactive command-line mode
- Batch mode

All configuration changes made using this tool are recorded in `logs/config-audit.log`.

About the dsconfig configuration tool

The **`dsconfig`** tool is the text-based management tool used to configure the underlying server configuration.

The **`dsconfig`** tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The **`dsconfig`** tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

To view the options for the dsconfig tool, change to the `PingDirectory/bin` directory, and enter `./dsconfig --help`. Example output is shown below.

Copyright © 2025 Ping Identity Corporation

```
./dsconfig --help

View and edit the Directory Server configuration.
This utility offers three primary modes of operation, the interactive mode, the non-interactive mode
and batch mode.  The interactive mode supports viewing and editing the configuration via an intuitive,
menu driven environment.  Running dsconfig in interactive command-line mode provides a user-friendly,
menu-driven interface for accessing and configuring the server. To start dsconfig in interactive
command-line mode, simply invoke the dsconfig shell script or batch file without any arguments.

The dsconfig non-interactive command-line mode provides a simple way to make arbitrary changes to the
Ping Identity Directory Server by invoking it on the command-line. If you want to use administrative
scripts to automate the configuration process, then run the dsconfig command in non-interactive mode.

The dsconfig tool provides a batching mechanism that reads multiple dsconfig invocations from a file
and executes them sequentially.  The batch file provides advantages over standard scripting in that it
minimizes LDAP connections and JVM invocations that normally occur with each dsconfig call.  You can
view the logs/config-audit.log file to review the configuration changes made to the Ping Identity
Directory Server and use them in the batch file.

Subcommands

  See the Usage section for instructions on viewing the list of supported subcommands.

Usage:  dsconfig  {options}
        where {options} include:

    --applyChangeTo [server-group|server-group-force|single-server]
        Controls whether changes apply to a single server or all servers in the configuration server group
    --offline
        Interact with the local configuration while the server is offline.  Not for use while the server
        is running
    -r, --reason {reason}
        A string describing the reason for the configuration change
    --help-classifications
        Display subcommands relating to connection and operation classification
    --help-core-server
        Display subcommands relating to core
    --help-database
        Display subcommands relating to backends, indexing, and caching
    --help-logging
        Display subcommands relating to logging, monitoring, and notifications
    --help-replication
        Display subcommands relating to replication
    --help-security
        Display subcommands relating to security and authorization
    --help-topology
        Display subcommands relating to topology
    --help-user-management
        Display subcommands relating to authentication and password management
    --help-web
        Display subcommands relating to web services and applications
    --help-subcommands
        Display all subcommands
```

Copyright © 2025 Ping Identity Corporation

```
  Configuration Options

    --advanced
        Allow the configuration of advanced components and properties

  LDAP Connection Options

    -Z, --useSSL
        Use SSL for secure communication with the server
    -q, --useStartTLS
        Use StartTLS to secure communication with the server
    --useNoSecurity
        Use no security when communicating with the server
    -h, --hostname {host}  [Default: localhost]
        Directory Server hostname or IP address
    -p, --port {port}  [Default: 389]
        Directory Server port number
    -D, --bindDN {bindDN}  [Default: cn=Directory Manager]
        DN used to bind to the server
    -w, --bindPassword {bindPassword}
        Password used to bind to the server
    -j, --bindPasswordFile {bindPasswordFile}
        Bind password file
    -o, --saslOption {name=value}
        SASL bind options (can be specified multiple times)
    -X, --trustAll
        Trust all server SSL certificates
    -P, --trustStorePath {truststorePath}  [Default: /Users/rowannabobo/Desktop/PingDirectory_9.2/config/
truststore]
        Certificate truststore path
    -T, --trustStorePassword {truststorePassword}
        Certificate truststore PIN
    -U, --trustStorePasswordFile {path}
        Certificate truststore PIN file
    --trustStoreFormat {trustStoreFormat}
        Certificate truststore format
    -K, --keyStorePath {keystorePath}
        Certificate keystore path
    -W, --keyStorePassword {keystorePassword}
        Certificate keystore PIN
    -u, --keyStorePasswordFile {keystorePasswordFile}
        Certificate keystore PIN file
    --keyStoreFormat {keyStoreFormat}
        Certificate keystore format
    -N, --certNickname {nickname}
        Nickname of the certificate for SSL client authentication

  Utility Input/Output Options

    -v, --verbose
        Use verbose mode
    -Q, --quiet
        Use quiet mode
    -n, --no-prompt
        Use non-interactive mode.  If data in the command is missing, you will not be prompted and the
```

Copyright © 2025 Ping Identity Corporation

```
        tool will fail
    -F, --batch-file {batchFilePath}
        Path to a file containing a sequence of dsconfig commands to run
    --batch-continue-on-error
        Force the execution of all commands in the batch file on the server even if prevalidation fails.
        Execution will also continue even if one of the commands fails.
        Please note that commands affecting multiple servers can still fail to execute unless the
        --applyChangeTo argument is provided with the value server-group-force. Only applies if the batch
        file argument is also supplied.
    --dry-run
        Validate configuration changes but do not apply them. This option can only be used along with the
        -F/--batch-file option
    --propertiesFilePath {propertiesFilePath}
        Path to the file that contains default property values used for command-line arguments
    --noPropertiesFile
        Specify that no properties file will be used to get default command-line argument values
    --script-friendly
        Use script-friendly mode

  General Options

    -V, --version
        Display Directory Server version information
    -?, -H, --help
        Display general usage information
    --help-ldap
        Display help for using LDAP options
    --help-sasl
        Display help for using SASL options
    --help-debug
        Display help for using debug options

Examples

  Start dsconfig in interactive mode:

    dsconfig

  Use non-interactive mode to change the amount memory used for caching database contents and to specify
  common parent DNs that should be compacted in the underlying database:

    dsconfig --no-prompt --bindDN uid=admin,dc=example,dc=com \
         --bindPassword password set-backend-prop --backend-name userRoot \
         --set db-cache-percent:40 \
         --add compact-common-parent-dn:ou=accts,dc=example,dc=com \
         --add compact-common-parent-dn:ou=subs,dc=example,dc=com

  Use batch mode to read and execute a series of commands in a batch file:

    dsconfig --bindDN uid=admin,dc=example,dc=com --bindPassword password \
         --no-prompt --batch-file /path/to/config-batch.txt

  List information about all available configuration properties for all objects, including inherited
properties:
```

Copyright © 2025 Ping Identity Corporation

```
    dsconfig list-properties --offline --inherited

  For examples and help with LDAP options see --help-ldap.  For help with SASL authentication, see --help-
sasl
```

Using dsconfig in interactive command-line mode

In interactive mode, the **`dsconfig`** tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running **`dsconfig`** in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory server.

Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.

   Result:

   You are prompted for connection and authentication information to the PingDirectoryProxy server, and then a menu displays the available operation types.

2. To accept the default values, press **Enter**.

   > **Note**
   >
   > In some cases, a default value is provided in square brackets. For example, [389] indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

Configuring the PingDirectory server using dsconfig interactive mode

Configure the PingDirectory server using the `dsconfig` command-line tool in interactive mode.

Steps

1. Launch the **`dsconfig`** tool in interactive command-line mode.

   Example:

   ```
   $ bin/dsconfig
   ```

2. Enter the LDAP connection parameters.

Copyright © 2025 Ping Identity Corporation

Choose from:

- Enter the PingDirectory server's host name or IP address.
- Press **Enter** to accept the default.

3. Enter the number corresponding to the type of LDAP connection that you are using on the PingDirectory server,, or press **Enter** to accept the default.

   The numbers for the LDAP connection type are 1 for LDAP, 2 for SSL, and 3 for StartTLS. The default entry is 1.

4. Enter the LDAP listener port number, or accept the default port.

   The default port is the port number of the server local to the tool.

5. Enter the user bind DN and the bind DN password.

   The default is `cn=Directory Manager`.

6. On the **Directory Server Configuration Console** main menu, enter a number corresponding to the configuration that you want to change.

   > **Note**
   >
   > The number might change between releases or within the same release, depending on the options selected, such as in cases where more expert level objects and properties are displayed.

7. In this example, select the number for Backend.
8. Set the `db-cache-percent` to 40%.

   The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the **`setup`** utility is sufficient.

9. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.
10. Select the backend to work with or press **Enter** to accept the default.

    In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`.

11. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
12. Enter the option to change the value, and then type the value for the `db-cache-percent` property.

    In this example, type `40` for 40 %.

13. To apply the changes, enter `f`.

    > **Note**
    >
    > Before you apply the change, the **`dsconfig`** interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building **`dsconfig`** script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent **`dsconfig`** non-interactive command, type `d`. For more information, see Getting the equivalent dsconfig non-interactive mode command.

14. In the **Backend management** menu, to quit the `dsconfig` tool, enter `q`.

Copyright © 2025 Ping Identity Corporation

Viewing dsconfig advanced properties

Configure `dsconfig` interactive mode to hide or display additional advanced properties.

About this task

> **Note**
>
> For most configuration settings, some properties are more likely to be modified than others.

Steps

1. Repeat steps 1–9 in Configuring the PingDirectory server using dsconfig interactive mode.
2. To display the advanced properties, from the **Local DB Backend properties** menu, enter `a`.

   Result:

   This toggles any hidden properties.

Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

Basic

Only includes the components that are configured most frequently.

Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

Copyright © 2025 Ping Identity Corporation

Steps

1. Using `dsconfig`, repeat steps 1–6 in Installing the PingDirectory server in interactive mode.
2. On the **PingDirectory Server configuration** main menu, enter the letter `o` to change the object level.

   Basic objects are displayed by default.
3. Enter a number corresponding to an object level of your choice.

   Choose from:

   - Enter `1` for Basic.
   - Enter `2` for Standard.
   - Enter `3` for Advanced.
   - Enter `4` for Expert.
4. Review the menu at the new object level.

   Additional configuration options for the server components are displayed.

dsconfig interactive administrative alerts

The **`dsconfig`** tool and the administrative console provide a feature that displays notifications for certain operations that require further administrative action to complete the process.

If you change a certain backend configuration property, the admin action appears in two places during a **`dsconfig`** interactive session:

- When configuring the property
- Before you apply the change

For example, if you change the `db-directory` property on the userRoot backend, such as specifying the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files, an admin action reminder displays during one of the steps.

The admin action alert also appears as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type the letter `f` to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: One or more configuration property changes require administrative action or confirmation/ notification. Those properties include: * db-directory: Modification requires that the PingDirectory server be stopped, the database directory manually relocated, and then the PingDirectory server restarted. While the PingDirectory server is stopped, the directory and files pertaining to this backend in the old database directory must be manually moved or copied to the new location. Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

Currently, only a small set of properties that display an admin action alert appear in **`dsconfig`** interactive mode and the administrative console. For more information on the properties, see the PingDirectory Server Configuration Reference, located in the server's `docs/config-guide` directory.

Copyright © 2025 Ping Identity Corporation

Using dsconfig in non-interactive mode

The **dsconfig** non-interactive command-line mode provides a simple way to make arbitrary changes to the server by invoking it from the command line.

Steps

1. To use administrative scripts to automate configuration changes, run the **dsconfig** command in non-interactive mode.

   Non-interactive mode is convenient for scripting applications.

   > **Note**
   >
   > If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. Use the **dsconfig** tool to update a single configuration object using command-line arguments to provide all of the necessary information.

   Example:

   The following shows the general format for the non-interactive command line.

   ```
   $ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
   ```

   > **Note**
   >
   > The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the PingDirectory server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **dsconfig** tool, as shown.
   >
   > ```
   > $ bin/dsconfig --no-prompt list-backends \
   >   --hostname server.example.com \
   >   --port 389 \
   >   --bindDN uid=admin,dc=example,dc=com \
   >   --bindPassword password
   > ```

3. If your system uses SASL GSSAPI (Kerberos), invoke **dsconfig** as shown.

   ```
   $ bin/dsconfig --no-prompt list-backends \
     --saslOption mech=GSSAPI \
     --saslOption authid=admin@example.com \
     --saslOption ticketcache=/tmp/krb5cc_1313 \
     --saslOption useticketcache=true
   ```

4. To always display the advanced properties, use the `--advanced` command-line option.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.
> Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

Configuring the Server using dsconfig non-interactive mode

Use `dsconfig` non-interactive mode to modify memory and specify parent distinguished names (DNs).

Steps

- To change the amount of memory used for caching database contents and to specify common parent DNs that should be compacted in the underlying database, use the **`dsconfig`** command in non-interactive mode.

  Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set db-cache-percent:40 \
  --add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

Viewing a list of dsconfig properties

Run `dsconfig` commands to view a list of properties, objects, property descriptions, and property information.

Steps

1. To view the list of all `dsconfig` properties, run the **`dsconfig`** command with the `list-properties` option.

   > **Note**
   >
   > Remember to add the LDAP connection parameters.

   Example:

```
$ bin/dsconfig list-properties
```

2. To view objects at and below the menu object level, use the **`dsconfig`** command with the `list-properties` option and the `--complexity <menu level>` option.

   Example:

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

3. If the server is offline, you can run the command with the `--offline` option without needing to enter the LDAP connection parameters.

   Example:

   ```
   $ bin/dsconfig list-properties --offline --complexity advanced --includeDescription
   ```

4. To review the property information provided with the server, view the `<server-root>/docs/config-properties.txt` file.

Getting the equivalent dsconfig non-interactive mode command

Although the **`dsconfig`** non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be time-consuming.

About this task

For quick and easy configuration, use an option to display the equivalent non-interactive command using **`dsconfig`** interactive mode. The command displays the equivalent **`dsconfig`** command to recreate the configuration in a scripted configuration or to enter any pending changes on the command line for another server instance more quickly.

> **Note**
>
> There are two other ways to get the equivalent **`dsconfig`** command. One way is by looking at the `logs/config-audit.log` file. It might be more convenient to configure the PingDirectory server the way you want and then get the **`dsconfig`** arguments from the log. Another way is to configure an option using the administrative console. The console shows the equivalent **`dsconfig`** command before applying the change.

To get the equivalent `dsconfig` non-interactive mode command:

Steps

1. Use **`dsconfig`** in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.
2. To view the equivalent non-interactive command, enter `d`.
3. View the equivalent command, and then press Enter to continue.

   Result:

   Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

   ```
   Command line to apply pending changes to this Local DB Backend: dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
   ```

   The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

Copyright © 2025 Ping Identity Corporation

Using dsconfig batch mode

Configure the server in `dsconfig` batch mode.

About this task

The PingDirectory server provides a **`dsconfig`** batching mechanism that reads multiple **`dsconfig`** invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each **`dsconfig`** call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with **`dsconfig`** in batch mode.

If a **`dsconfig`** command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the server. The **`dsconfig`** command supports a **`--batch-continue-on-error`** option that instructs **`dsconfig`** to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory server machines.

Steps

1. Create a text file that lists each **`dsconfig`** command with the complete set of properties that you want to apply to the server.

   > **Note**
   >
   > The items in this file should be in the same format as those accepted by the **`dsconfig`** command.
   > The batch file can have blank lines for spacing and lines starting with a pound sign (**`#`**) for comments.
   > The batch file also supports a "\" line continuation character for long commands that require multiple lines.

   Example:

Copyright © 2025 Ping Identity Corporation

```
# This  dsconfig  operation creates the exAccountNumber global attribute index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

Using the PingDirectory server or the PingDirectoryProxy server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on the PingDirectory server or the PingDirectoryProxy server.

This section explains how to set up an access token validator to handle this task.

Copyright © 2025 Ping Identity Corporation

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port>  \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

> **Note**
>
> In this example, the hostname verification method is set to `allow-all` and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
                        --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:client-id  \
  --set client-secret:client-secret
```

> **Note**
>
> Take the *client-id* and *client-secret* values from the PingFederate OAuth 2 client that will be used with the PingDirectory server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

   This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

Copyright © 2025 Ping Identity Corporation

```
{
    "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
    ],

    }
}
```

About recurring tasks and task chains

You can use the admin console to create recurring tasks and task chains to perform regular maintenance tasks for the PingDirectory server. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations.

Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

Create recurring tasks and add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

Copyright © 2025 Ping Identity Corporation

A recurring task includes:

- The task-specific object classes to include in the task entry
- The task-specific attributes to include in the task entry, if any
- Whether to alert on task start, success, or failure
- Any addresses to email on task start, success, or failure
- Whether to cancel an instance of the task if it is dependent upon another task and that task does not complete successfully

After you create a task, add one or more tasks to a task chain and schedule the chain.

A recurring task chain includes:

- An ordered list of the tasks to invoke
- The months, days, times, and time zones in which each task can be scheduled to start
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown
- The behavior to exhibit if the server is offline when the start time occurs

> **Note**
>
> Changing the schedule for an existing recurring task chain only takes effect the next time an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. Existing scheduled instances still run at the originally scheduled time. When that run is complete, the server schedules the next iteration according to the then-current schedule logic.
> You cannot cancel the existing scheduled instance to make the next instance run earlier. When you cancel an instance of a recurring task chain, the server automatically schedules the next instance for the next time that matches the scheduling criteria. It never schedules a new instance for earlier than or the same time as one that you manually canceled.

Creating a recurring task and task chain

Use `dsconfig` to create one or more tasks and then add them to a task chain for scheduling.

Steps

1. To create a task, use `dsconfig create-recurring-task`.

   Example:

   The following creates a backup task.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-recurring-task \
  --task-name backup-1 \
  --type backup \
  --set 'email-on-failure:admin1@company.com' \
  --set 'email-on-failure:admin2@company.com' \
  --set compress:true \
  --set encrypt:true \
  --set "retain-previous-full-backup-age:4 w" \
  --set retain-previous-full-backup-count:10
```

2. To create a task chain to schedule and run recurring tasks, use `dsconfig create-recurring-task-chain`.

   Example:

```
$ bin/dsconfig create-recurring-task-chain \
  --chain-name "backup chain" \
  --set recurring-task:backup-1 \
  --set scheduled-date-selection-type:selected-days-of-the-month \
  --set scheduled-day-of-the-month:last-day-of-the-month \
  --set scheduled-time-of-day:02:00
```

LDIF export as a recurring task

You can create a recurring task to schedule the export of LDIF data.

For new installations, the server exports LDIF data by default every day at 1:05 a.m. in the default time zone for the Java virtual machine (JVM), which is generally the time zone configured for the underlying system. At the scheduled time, the server exports the contents of each public backend to a file in the server root `ldif` directory.

> **Note**
>
> Public backends are non-administrative backends containing user-supplied data.

The server compresses and encrypts the LDIF exports if the global configuration is set to encrypt LDIF exports by default, which is enabled if encryption is configured during setup. The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release. However, the task chain is not enabled by default.

LDIF export can export multiple backends in the same recurring task. You can use the **`backend-id`** property to include multiple backends. You can use the **`exclude-backend-id`** property to exclude one or more backends. These optional properties are mutually exclusive:

- If the **`backend-id`** property has one or more values, only the backends with those IDs are exported.
- If the **`exclude-backend-id`** property has one or more values, all public backends except those listed are exported.
- If neither the **`backend-id`** property nor the **`exclude-backend-id`** property supply values, all public backends are exported.

Copyright © 2025 Ping Identity Corporation

Lockdown mode as a recurring task

You can create recurring tasks to move a server in and out of lockdown mode. Moving a server in and out of lockdown mode is useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server reports itself as unavailable and also rejects requests from any user that doesn't have the `lockdown-mode` privilege.

The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.
3. Run desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter lockdown mode and leave lockdown mode tasks each allow one optional property that you can use to supply a description for why that the server is being moved into this mode.

File retention recurring task

You can configure a recurring task to remove files in a specified directory that match a given pattern.

You can exclude files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files are removed before the most recent file.

If the file name pattern includes a `"${timestamp}"` element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the file's creation time, if available, or the last modified time, if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, the server uses lexicographic ordering to differentiate between them. Lexicographic ordering is applicable only for files with no `retain-file-age` property configured or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the `retain-file-age` value, then those files are retained.

When configuring a file removal task, you must specify at least one of the following properties:

- `retain-file-count`
- `retain-file-age`
- `retain-aggregate-file-size`

Using exec tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks.

About this task

The server restricts the kinds of commands that can be executed, and the access level of users who can execute them.

Copyright © 2025 Ping Identity Corporation

These safeguards and requirements include:

- The absolute path to the command to execute must be listed in the `<server-root>/config/exec-command-whitelist.txt` file.
- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following command enables this.

```
$ bin/dsconfig set-global-configuration-prop \
  --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the **`exec-task`** privilege. The server does not grant permission to run this task to any user by default, including root users.

The following configuration changes grant the **`exec-task`** privilege to a single root user, all root users, or a single non-root user:

Steps

- To grant the **`exec-task`** privilege to a single root user, run the following.

```
$ bin/dsconfig set-root-dn-user-prop --user-name "<username>" \
  --add privilege:exec-task
```

- To grant the **`exec-task`** privilege to all root users, run the following.

```
$ bin/dsconfig set-root-dn-prop \
  --add default-root-privilege-name:exec-task
```

- To grant the **`exec-task`** privilege to a single non-root user, run the following.

```
dn:  <userdn>
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

- Use the **`schedule-exec-task`** tool to create an exec task from the command line.

  Example:

  The following command schedules an exec task to run the **`verify-index`** tool to check the integrity of the **`cn`** index in the backend that hosts **`"dc=example,dc=com"`**, assuming that the server is installed in **`/ds`**.

Copyright © 2025 Ping Identity Corporation

```
$ bin/schedule-exec-task --hostname directory.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --promptForBindPassword \
  --waitForCompletion \
  --logCommandOutput \
  /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

Using custom rebranding

You can customize several visual elements of the console, including branding elements such as contact information or logos.

About this task

You can use the command line to configure the PingDirectory suite of products.

> **Note**
>
> Tomcat 10 currently has an issue where Spring applications (such as this console) will not run correctly. Use Tomcat 9 or earlier.

Steps

1. To customize the console, open the `application.yml` file and set *<branding.custom-folder>* to a local filepath that is not a subdirectory of the console application directory.

   This path should contain the elements for the console to display.

2. Set the custom branding filepath on any PingDirectory suite of products console with the following `dsconfig` command:

```
dsconfig set-web-application-extension-prop \
    --extension-name Console \
    --set init-parameter:branding.custom-folder=<path to folder>
```

Customizing text information

About this task

To customize text information, such as contact information or company names:

Steps

1. Make a copy of the `branding.properties.template` file and rename it to `branding.properties`.
2. Make the desired changes to the copy.
3. Place the copy in the folder specified by the *<branding.custom-folder>* setting.
4. Restart the console.

Copyright © 2025 Ping Identity Corporation

Customizing the color scheme or logos

About this task

To customize the color scheme or logos used by the console:

Steps

1. Make a copy of the `branding.css.template` file and rename it to `branding.css`.
2. Make the desired changes.
3. Place the copy in the folder specified by the <*branding.custom-folder*> setting.

Customizing the page icon

About this task

To customize the page icon used by the console:

Steps

1. Name the desired icon `favicon.ico`.

   > **Note**
   >
   > The icon must be in `.ico` format.

2. Place `favicon.ico` in the folder specified by the <*branding.custom-folder*> setting.

Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a primary and secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

> **Note**
>
> To remove a server from the topology, you must uninstall it with the uninstall tool.

Topology primary requirements and selection

A topology primary server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the primary sends a digest of its subtree contents. If the node's digest differs from the primary's, the server node knows it is not synchronized. The servers pull the entire subtree from the primary if they detect that they are not synchronized.

A server detects it is not synchronized with the primary under the following conditions:

- The server's subtree digest differs from the primary's digest at the end of its periodic polling interval.

Copyright © 2025 Ping Identity Corporation

- One or more servers have been added to or removed from the topology.

The primary of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a primary, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server primary. If a new server can be the primary and no other servers have indicated that they should be the primary, it will communicate its eligibility to the other servers. This ensures that all servers accept the same primary at approximately the same time, within a few milliseconds of each other. If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary.

  The primary server itself is considered while determining this majority.

- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as primaries, then a `multiple-servers-forced-as-masters` alarm is raised.

Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a primary because most of the servers are not available. A server with this setting enabled is assigned the role of primary if no suitable primary can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

Copyright © 2025 Ping Identity Corporation

`mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new primary selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable primary is found, the polling frequency adjusts to 100 milliseconds until a new primary is selected.

`mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the primary on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if primary selection is in progress at the time the update operation is received.

`mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current primary, if the primary is not known
- The instance name of the current primary or if a primary is not set, a description stating why a primary is not set
- A flag indicating which server thinks that it should be the primary
- A flag indicating which server is the current primary
- A flag indicating a server that was forced as primary
- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its primary or another node in the topology if the primary is unknown
- The amount of time in milliseconds that multiple primaries were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as primary
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

Copyright © 2025 Ping Identity Corporation

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary
- The number of successful operations processed by this server as primary
- The number of operations processed by this server as primary that failed to validate
- The number of operations processed by this server as primary that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the primary
- The maximum amount of time taken in milliseconds by this server to process an operation as the primary

Configure passphrase providers

Passphrase providers allow access to clear-text passphrases, application programming interface (API) keys, and other secrets through an extensible API that are needed for essential processing tasks.

These secrets can be used to:

- Access external services. For example, the PingDirectoryProxy server can use a clear-text secret for accessing the credentials needed for authentication to backend directories, and the PingDataSync server can use a secret for authentication to the synchronization source and destination servers.
- Access certificate key and trust stores.
- Reversibly encrypt passwords stored in the LDAP changelog. This allows PingDataSync to decrypt these passwords and send the clear-text value to the destination server.

The PingDirectory server supports the following passphrase providers:

Amazon Secrets Manager passphrase provider

Reads a passphrase from the Amazon AWS Secrets Manager service. The provider can only be used with string secrets, in which the Secrets Manager service returns the secret in the form of a JavaScript Object Notation (JSON) object, and not with secrets stored in binary form.

Azure Key Vault passphrase provider

Reads a passphrase from the Microsoft Azure Key Vault service.

Conjur passphrase provider

Reads a passphrase from a CyberArk Conjur instance.

Environment Variable passphrase provider

Reads a passphrase from a specified environment variable.

File-based passphrase provider

Reads a passphrase from a specified file. The contents of the file can be encrypted with a key from the server's encryption settings database.

Copyright © 2025 Ping Identity Corporation

Obscured-value passphrase provider

Reads a passphrase that is stored directly in the server configuration.

> **Important**
>
> Although this passphrase is encrypted, the encryption uses a hard-coded key that an attacker can use to obtain the clear-text value. As a result, you should not depend solely on this provider's obfuscation for keeping the passphrase secret.

Third-party passphrase provider

Reads a passphrase using a third-party implementation of the UnboundID server SDK. This provider supports the read-only `extension-class` property for specifying the Java class that extends or implements the SDK, and the `extension-argument` property for customizing the provider's behavior.

Vault passphrase provider

Reads a passphrase from a HashiCorp Vault instance.

For example, to create an Amazon Secrets Manager passphrase provider, define the new passphrase provider in the server configuration:

```
dsconfig create-passphrase-provider \
  --provder-name "Amazon Secrets Manager" \
  --type amazon-secrets-manager \
  --set enabled:true \
  --set aws-external-server:[AWS_EXTERNAL_SERVER_DN] \
  --set secret-id:[AWS_SECRET_ID] \
  --set secret-field-name:[SECRET_JSON_FIELD]
```

After you've created a passphrase provider, you must update the global configuration of the components that use the provider. For example, if you want to use the passphrase provider to obtain the PIN needed for accessing a certificate key store, you must set the `key-store-pin-passphrase-provider` property in the key manager configuration.

Using the Configuration API

The PingDirectory server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the application/json content type.

About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

Note

By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result:

The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Because of the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

The Configuration API and the dsconfig tool relationship

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types.

Copyright © 2025 Ping Identity Corporation

Property names are presented as hyphen case in **dsconfig** and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the **dsconfig list-connection-handlers** command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the **dsconfig** tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the attributes query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

Configuration API operations supported in REST APIs

HTTP Method	Description	Related dsconfig Example
GET	Lists the properties of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	• **get-backend-prop** • **list-backends** • **get-global-configuration-prop**
POST	Creates a new instance of an object when used with a relation parent path, such as `/config/backends`.	**create-backend**
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	• **set-backend-prop** • **set-global-configuration-prop**
PATCH	Updates the properties of an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	• **set-backend-prop** • **set-global-configuration-prop**
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	**delete-backend**

Copyright © 2025 Ping Identity Corporation

Note

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.
Object names, such as userRoot in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, %, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

GET example

This topic provides an example of a GET request and response concerning the userRoot backend for reference.

GET request

The following code example is a GET request for information about the **`userRoot`** backend.

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

GET response

The following code example is the response.

```

PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable dsconfig modify-[object] options
Set the single-valued `description` attribute to a new value.	`{ "op" : "replace", "path" : "description", "value" : "A new backend." }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --set "description:A new backend"`
Add a new value to the multi-valued `jeProperty` attribute.	`{ "op" : "add", "path" : "jeProperty", "value" : "je.env.backgroundReadLimit=0" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --add je-property:je.env.backgroundReadLimit=0`
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	`{ "op" : "remove", "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.cleaner.adjustUtilization=false`

Copyright © 2025 Ping Identity Corporation

Operation	PATCH request	Comparable dsconfig modify-[object] options
Second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	`{ "op" : "remove", "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.nodeMaxEntries=32`
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	`{ "op" : "remove", "path" : "id2childrenIndexEntryLimit" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit`

Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

           that had already hit the previous limit."
      }
    ]
  }
}
```

Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

Copyright © 2025 Ping Identity Corporation

Example

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
              Handler provides an implementation that uses syntax
              compatible with the Sun Java System Directory Server
              Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
              application-wide access control. The server's access
              control handler is defined through an extensible
              interface, so that alternate implementations can be created.
              Only one access control handler may be active in the server
                        at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-control-handler"
      }
    },
    {
 ...
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Copyright © 2025 Ping Identity Corporation

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
`filter`	Values can be simple SCIM filters, such as `id eq "userRoot"`, or compound filters like `meta.resourceType eq "Local DB Backend"` and `baseDn co "dc=exmple,dc=com"`.
`sortBy`	Specifies a property value by which to sort.
`sortOrder`	Specifies either `ascending` or `descending` alphabetical order.
`startIndex`	1-based index of the first result to return.
`count`	Indicates the number of results per page.

Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH.

With PUT, the server computes the differences between the object in the request with the current version in the server and performs modifications where necessary. The server never removes attributes that are not specified in the request. The API responds with the entire modified object.

Example

Sample request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Sample response:

    "writabilityMode": "enabled"
  }
```

Administrative actions

Updating a property might require an administrative action before changes can take effect.

If you need administrative actions to update a property, the server returns `200 Success`. Any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

Example

For example, changing the `jeProperty` of a backend results in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
    "required-actions": [
      {
       "property": "baseContextPath",
       "type": ""componentRestart",
       "synopsis": "In order for this modification to take effect, the component
                    must be restarted, either by disabling and re-enabling it, or
                    by restarting the server"
      },
      {
        "property": {
        "type": "other",
        "synopsis": "If this limit is increased, then the
                 contents of the backend must be exported to LDIF
                 and re-imported to allow the new limit to be used
                 for any id2children keys that had already hit the
                 previous limit."
      }
    ]
  }
```

Updating servers and server groups

You can configure servers as part of a server group so that configuration changes applied to a single server are applied to all servers in a group.

When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified.

Example

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

Configuration API responses

Clients of the API should examine the HTTP response code to determine the success or failure of a request.

The following are response codes and their meanings.

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the `urn:unboundid:schemas:configuration:messages:2.0` object.	List of objects, object properties, or administrative actions
204 No Content	The requested operation succeeded and no further information has been provided, as in the case of a DELETE operation.	None
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message
401 Unauthorized	User authentication is required. Some user agents, such as browsers, might respond by prompting for credentials. If the request specified credentials in an Authorization header, they are invalid.	None
403 Forbidden	The requested operation is forbidden, either because the user does not have sufficient privileges or some other constraint, such as an object is edit-only and cannot be deleted.	None
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message

Copyright © 2025 Ping Identity Corporation

Response Code	Description	Response Body
409 Conflict	The requested operation could not be performed because of the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referenced by another object.	Error summary and optional message
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None
500 Server Error	The server encountered an unexpected error. Report server errors to Customer Support.	Error summary and optional message

Note

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages can change, and their presence can depend on server configuration. Use the HTTP return code and the context of the request to create a client error message.

Example

The following is an example encoded error message.

```
{
 "schemas": [
   "urn:ietf:params:scim:api:messages:2.0:Error"
 ],
 "status": 404,
 "scimType": null,
 "detail": "The Local DB Index does not exist."
}
```

Generating a summary of configuration components

The `config-diff` tool generates a summary of the configuration in a local or remote directory server instance.

About this task

The `config-diff` tool is useful for comparing configuration settings on the server instance when troubleshooting issues or when verifying configuration settings on newly-added servers. The tool can interact with the local configuration regardless of whether the server is running.

Steps

- To generate a summary of configuration components, run `config-diff`

  Example:

Copyright © 2025 Ping Identity Corporation

`$ bin/config-diff` generates a summary of a local online server.

- To generate a comparison of the current configuration with the pre-installation configuration, run the following.

```
$ bin/config-diff --sourceLocal \
  --sourceBaseline \
  --targetLocal \
  --exclude differs-after-install \
  --outputFile configuration-steps.dsconfig
```

This comparison ignores any changes that could be made by the installer and writes the output to a file called `configuration-steps.dsconfig`.

You can use this file as the basis for a script to configure a new server identical to the local server.

- To view other available tool options, run `config-diff --help`.

Administrator account classes

The PingDirectory server provides three different classes of administrator accounts: root user, administrator, and global administrator.

Root user

The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set. For more information on default root privileges, see Default root privileges. The root user account is an entry that is stored in the server's configuration under `cn=Root DNs,cn=config` and bypasses access control evaluation. It can be created manually or with the `dsconfig` tool. This account has full access to the entire set of data in the directory information tree (DIT) and to the server configuration and its operations. One important difference between other vendors' servers and the PingDirectory server's implementation is that the root user's rights are granted through a set of privileges. This allows the PingDirectory server to have multiple root users on its system, but the normal practice is to set up administrator user entries. The root user has no resource limits by default.

Administrator

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators' entries typically have limited access to the entire set of data in the DIT, which is controlled by access control instructions. These entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology. In some cases, administrator user accounts might be unavailable when the server enters lockdown mode unless the administrator is given the lockdown mode privilege.

Global administrator

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at one time. Global administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend and are always mirrored across servers in a replication topology. These users can be assigned privileges like other administrator users but are typically used to manage the data under `cn=Topology,cn=config`.

Copyright © 2025 Ping Identity Corporation

Using separate administrator accounts

Each administrator should have their own account with their own credentials tailored to the level of access needed.

The `setup` utility only creates a single root user. Some directory servers from other vendors only support a single root account so all administrators are required to share that account. However, this is a bad practice for several reasons, including:

- It's difficult to audit the actions of individual administrators. With separate accounts for each administrator, it's easy to see who did what.
- Credentials have to be shared across multiple administrators. Shared credentials are at a greater risk of being leaked or compromised. With separate accounts for each administrator, each has its own credentials that are not shared with anyone else.
- If the credentials for that single root account are leaked or compromised (or if someone with legitimate access to those credentials leaves their position and no longer needs that access), then those credentials need to be changed. The new credentials need to be communicated to all of the administrators sharing that account, which can be difficult to do securely. If the new credentials are not communicated in advance of the change, then administrators who have not received them won't be able to manage the server. If the new credentials are communicated in advance of the change, then the old, potentially compromised credentials remain in effect for longer than necessary.
- Using a single root account makes it more difficult to use strong authentication, such as a certificate or two-factor authentication, in a secure manner. With separate accounts for each administrator, it's easier to use strong authentication in a secure manner.
- If there is only a single root account, then that account must have a level of access that permits everything that any administrator might need to do, even if all administrators don't need the same level of access. With separate accounts for each administrator, each can be given precisely the level of access that they need.

It might also be beneficial to remove or disable the account for the initial root user created by `setup` once all of the administrators have their own accounts.

Using separate accounts is mentioned in the following `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file, which provides an example for creating a topology admin user with various restrictions.

Copyright © 2025 Ping Identity Corporation

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts.  If you create a root user account, then it is only created
# in that one instance.  If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise.  They should be required to have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features).  You may also want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service.  For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you disable
# or remove the initial root user created during setup.  See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE:  Do not edit this file directly.  Changing this file could prevent it
# from being updated during a server upgrade.  If you want to alter the
# dsconfig commands below before applying the configuration changes, copy this
# file to another directory and edit that copy.
#

# Create a new topology administrator account.  In this example, the user will
# be able to read the configuration but will not be allowed to update it, and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration.  They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
     --user-name "[USER_NAME]" \
     --set "password:[PASSWORD]" \
     --set "first-name:[FIRST_NAME]" \
     --set "last-name:[LAST_NAME]" \
     --set "user-id:[USER_NAME]" \
     --set inherit-default-root-privileges:true \
```

Copyright © 2025 Ping Identity Corporation

```
    --set privilege:bypass-read-acl \
    --set privilege:-bypass-acl \
    --set privilege:-config-write \
    --set search-result-entry-limit:0 \
    --set time-limit-seconds:0 \
    --set look-through-entry-limit:0 \
    --set idle-time-limit-seconds:0 \
    --set require-secure-authentication:true \
    --set require-secure-connections:true \
    --set "allowed-authentication-type:SASL EXTERNAL" \
    --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

Unpredictable identifiers for server administrators

You can prevent online password guessing attacks by using unpredictable identifiers for users.

If an attacker doesn't know the name of the account, then it's another obstacle to overcome before they can authenticate as them.

An entry's DN is the most common identifier used to authenticate, as it's required for simple binds and is often used for SASL binds. For regular users, you should name accounts with the entryUUID attribute. However, this isn't feasible for root users or topology administrators because the configuration framework requires these entries to use `cn` as the naming attribute. Further, many SASL mechanisms allow identifying users with a username, which is correlated to the associated entry using an identity mapper, so using an unpredictable DN might not be enough to sufficiently interfere with an attacker's ability to target a server administrator.

The best way to obscure identifiers for root users and topology administrators is to choose unpredictable values for the `cn` attribute in their accounts and not include any predictable alternate bind DN values for those accounts. Although it is be possible to use randomly generated `cn` values, it should be sufficient to use more memorable strings as long as they aren't something an attacker is likely to guess even if they know the identities of those administrators.

Secure communication for server administrators

Requiring secure communication for server administrators is recommended to prevent unencrypted communication.

While you should only permit secure access to the server, many environments might still allow access to unencrypted communication. Unencrypted communication is potentially dangerous for any kind of client because it could be observed and altered by a malicious third party, but it's especially dangerous for administrative accounts. Even if the server is configured to allow some clients to issue insecure requests, you should ensure that administrative accounts always use secure communication.

The best way to require that a user only be permitted to communicate with the server over a secure connection is to include the `ds-auth-require-secure-connection` operational attribute in that user's entry with a value of `true`. Although the password policy configuration includes `require-secure-authentication`, and `require-secure-password` changes properties, those properties can only guarantee the safety of authentication credentials. They don't guarantee secure communication for other operations processed by that user. This is because it's possible to authenticate in a manner that the server considers secure, without exposing credentials to an observer, without using a secure connection such as using a SASL mechanism like GSSAPI.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> CRAM-MD5 and DIGEST-MD5 also currently fall into this category, but for this purpose they are no longer considered secure.

Although it's possible to enable this by default for root users and topology administrators, you shouldn't do so at the risk of affecting backward compatibility with existing deployments that expect to be able to use insecure communication for these accounts. If the server is configured to only accept secure connections, or to reject insecure requests, then this setting is not as necessary.

Managing root user accounts

The directory server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file, such as under `cn=Root DNs,cn=config`.

About this task

The root user is the LDAP-equivalent of a UNIX superuser account and inherits its read-write privileges from the default root privilege set.

Steps

- To create or update root users, use the `dscconfig` tool.

  Example:

  ```
  bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
    --set last-name:Smith \
    --set first-name:Joanne \
    --set user-id:jsmith \
    --set 'email-address:jsmith@example.com' \
    --set mobile-telephone-number:8889997777 \
    --set home-telephone-number:5556667777 \
    --set work-telephone-number:4445556666
  ```

  > **Note**
  >
  > Root user entries are stored in the server's configuration.

- To limit full access to all of the servers, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change.

  > **Note**
  >
  > Separate user accounts for each administrator make it possible to enable password policy functionality, such as password expiration, password history, and requiring secure authentication, for each administrator.

Default root privileges

The PingDirectory server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Managing access control for more information.

The following set of root privileges are available to each root user DN.

Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.

Copyright © 2025 Ping Identity Corporation

Privilege	Description
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The PingDirectory server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation can still be enforced for other types of operations.
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

Copyright © 2025 Ping Identity Corporation

Configuring administrator accounts

An administrator account is any account in the user backend that is assigned one or more privileges or is given access to read and write operations beyond that of a normal user entry.

The privilege mechanism is the same as that used for root distinguished name (DN) accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the directory information tree (DIT). You can grant fine-grained read and write access using the access control definitions available through the `aci` attribute. Administrator entries reside in the backend configuration, for example, `uid=admin,dc=example,dc=com`, and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts:

- The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges.

  > **Note**
  >
  > If you generated sample data at install, you can view an example `uid=admin` entry using **`ldapsearch`**.

- The second example shows a more realistic example where the user is part of the administrators group.

> **Note**
>
> Both examples are based on a simple DIT. Actual deployment cases depend on your schema.

Setting up a single administrator account

About this task

To create an example of a single, generic administrator account:

Steps

1. Create an LDIF file with an example administrator entry.

   Example:

   ```
   dn: uid=admin,dc=example,dc=com
   objectClass: person
   objectClass: inetOrgPerson
   objectClass: organizationalPerson
   objectClass: top
   givenName: Admin
   uid: admin
   cn: Admin User
   sn: User
   userPassword: password
   ```

2. To add the entry, use the **`ldapmodify`** tool.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. To add the access control instruction (ACI) to the root suffix or base DN to give full access to the new administrator, create another LDIF file.

> **Note**
>
> The ACI grants full access to all user attributes, but not to operational attributes. To grant access to operational attributes as well as user attributes, use `(targetattr = "*||+")` in the access control instruction.

Example:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr = "*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

4. To add the entry, use the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename admin.ldif
```

5. To verify the additions, use the `ldapsearch` tool.

Example:

In the following example, the first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"

$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base "(objectclass=*)" "+"
```

6. Add specific privileges to the administrator account, then to process the modify operation press CTRL-D.

Example:

For this example, add the `password-reset` privilege to the administrator account from the command line.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

Copyright © 2025 Ping Identity Corporation

Result:

```
Processing MODIFY request for uid=admin,dc=example,dc=com
MODIFY operation successful for DN uid=admin,dc=example,dc=com
```

7. Assign a password policy for the administrator account.

   Example:

   Create an `Admin Password Policy`, then add the password policy to the account.

```
$ bin/dsconfig create-password-policy \
  --policy-name "Admin Password Policy" \
  --set "description:Password policy for administrators" \
  --set password-attribute:userpassword \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set password-change-requires-current-password:true \
  --set force-change-on-reset:true \
  --set "max-password-age:25w 5d" \
  --set grace-login-count:3 \
  --no-prompt
```

8. To apply the password policy to the account, run the `ldapmodify` command.

   Example:

   Execute the `ldapmodify` command with a bind DN that has sufficient rights, such as a root DN, as in the following example.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password Policies,cn=config
```

Changing the administrator password

About this task

Root users are governed by the root password policy and by default, their passwords never expire. To change a root user password, use the `ldappasswordmodify` tool.

Steps

1. Open a text editor and create a text file containing the new password.

   Example:

   For this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

Copyright © 2025 Ping Identity Corporation

2. To change the root user's password, run `ldappasswordmodify`.

   Example:

   ```
   $ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager"\
     --bindPassword secret --newPasswordFile rootuser.txt
   ```

3. Remove the text file.

   Example:

   ```
   $ rm rootuser.txt
   ```

Setting up an administrator group

About this task

The following example shows how to set up a group of administrators that have access rights to the whole PingDirectory server.

> **Note**
>
> The example uses a static group using the `GroupOfUniqueNames` object class.

Steps

1. Create an LDIF file with an example administrator group.

   Example:

   For this example, name the file `admin-group.ldif`

   ```
   dn: ou=Groups,dc=example,dc=com
   objectClass: organizationalunit
   objectClass: top
   ou: Groups

   dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
   objectClass: groupofuniquenames
   objectClass: top
   uniqueMember: uid=user.0, ou=People, dc=example,dc=com
   uniqueMember: uid=user.1, ou=People, dc=example,dc=com
   cn: Dir Admins
   ou: Groups
   ```

2. To add the entries, use the `ldapmodify` tool.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename admin-group.ldif
   ```

Copyright © 2025 Ping Identity Corporation

3. To add the ACI to the root suffix or base DN to provide full access to the PingDirectory server to the new administrator, create another LDIF file.

   Example:

   For this example, name the file `admin-aci.ldif`.

   ```
   dn: dc=example,dc=com
   changetype: modify
   add: aci
   aci: (target="ldap:///dc=example,dc=com")
     (targetattr != "aci")
     (version 3.0; acl "allow all Admin group";
       allow(all) groupdn = "ldap:///cn=Dir Admins,ou=Groups,dc=example,dc=com";)
   ```

4. To add the ACI, use the `ldapmodify` tool.

   Example:

   ```
   $ bin/ldapmodify --filename admin-aci.ldif
   ```

5. To verify the additions, use the `ldapsearch` tool.

   Example:

   In the following example, the first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including ACIs, associated with the entry.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"

   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
     "(objectclass=*)" "+"
   ```

6. To add specific privileges to each administrator account, use an LDIF file.

   Example:

   For this example, name the file `admin-priv.ldif`.

   For this example, add the `password-reset` privilege to the `user.0` administrator account from the command line. To add the privilege, use the `ldapmodify` tool. Repeat the process for the other administrators configured in the administrator group.

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   changetype: modify
   add: ds-privilege-name
   ds-privilege-name: password-reset

   $ bin/ldapmodify --filename admin-priv.ldif
   ```

Copyright © 2025 Ping Identity Corporation

Result:

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

7. To assign a password policy for the administrator account, use an LDIF file. Save the file as `admin-pwd-policy.ldif`.

   Example:

   For example, create an `Admin Password Policy`, then add the password policy to the account. To apply the password policy to the account, use the **`ldapmodify`** tool.

   ```
   dn: uid=user.0,dc=example,dc=com
   changetype: modify
   add: ds-pwp-password-policy-dn
   ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password Policies,cn=config

   $ bin/ldapmodify --filename admin-pwd-policy.ldif
   ```

Configuring a global administrator

A global administrator is created when replication is enabled and is responsible for managing configuration server groups.

A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology where configuration changes to one server can be applied to all of the servers at a time.

Global administrators are stored in the topology registry. These entries are always mirrored between servers in a topology. Global administrators can be assigned privileges like other administrator users but are typically used to manage the data under `cn=topology,cn=config` and `cn=config`. You can create new or remove global administrators using the **`dsconfig`** tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

Creating a global administrator

Steps

1. To create a new global administrator, use the `create-topology-admin-user` option with **`dsconfig`**.

   Example:

   ```
   $ bin/dsconfig create-topology-admin-user \
     --user-name admin2 \
     --set alternate-bind-dn:cn=admin2 \
     --set password:rootPassword
   ```

2. To verify the creation of the new administrator, use the `list-topology-admin-users` option with **`dsconfig`**.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
--------------------:-------
admin               : generic
admin2              : generic
```

Removing a global administrator

Steps

1. To delete a global administrator, use the `delete-topology-admin-user` option with `dsconfig`.

   Example:

   ```
   $ bin/dsconfig delete-topology-admin-user --user-name admin2
   ```

2. To verify the deletion of the global administrator, use the `list-topology-admin-users` option with `dsconfig`.

   Example:

   ```
   $ bin/dsconfig list-topology-admin-users
   Topology Admin User : Type
   --------------------:------
   admin               : generic
   ```

Configuring server groups

The PingDirectory server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group.

About this task

After you have set up a server group, you can make an update on one server using `dsconfig`, then apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the `dsconfig` non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using `dsconfig` in interactive command-line mode, you are asked if you want to apply the change to a single server or to all servers in the server group.

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group, as outlined in Replication Configuration.

The following example procedure adds three PingDirectory server instances into the server group labeled "group-one".

Steps

1. Create a group called "group-one" using `dsconfig`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any PingDirectory server to the server group.

   If you have set up replication between a set of servers, these server entries are created by the `dsreplication enable` command.

   Example:

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server1

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server2

$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

   Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:group-one
```

4. Test the server group.

   In this example, enable the log publisher for each PingDirectory server in the group "server-group" by using the `--applyChangeTo server-group` option.

   Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first PingDirectory server instance.

   Example:

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

   Result:

```
Property : Value(s)
---------:---------
enabled : true
```

Copyright © 2025 Ping Identity Corporation

6. Repeat step 5 on the second and third PingDirectory server instances.
7. Test the server group by disabling the log publisher on the first PingDirectory server instance by using the `--applyChangeTo single-server`.

   Example:

   ```
   $ bin/dsconfig set-log-publisher-prop \
     --publisher-name "File-Based Audit Logger" \
     --set enabled:disabled \
     --applyChangeTo single-server
   ```

8. View the property on the first PingDirectory server instance.

   The first PingDirectory server instance should be disabled.

   Example:

   ```
   $ bin/dsconfig get-log-publisher-prop \
     --publisher-name "File-Based Audit Logger" \
     --property enabled
   ```

   Result:

   ```
   Property : Value(s)
   ---------:---------
   enabled : false
   ```

9. View the property on the second PingDirectory server instance.

   Repeat this step on the third PingDirectory server instance to verify that the property is still enabled on that server.

   Example:

   ```
   $ bin/dsconfig get-log-publisher-prop \
     --publisher-name "File-Based Audit Logger" \
     --property enabled
   ```

   Result:

   ```
   Property : Value(s)
   ---------:---------
   enabled : true
   ```

Client connection policy configuration

Client connection policies help distinguish what portions of the DIT the client can access.

Copyright © 2025 Ping Identity Corporation

They enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use is reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

When a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

About the client connection policy

Client connection policies are based on two factors.

Connection criteria

The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.

Evaluation order index

If multiple client connection policies are defined in the server, then each of them must have a unique value for the `evaluation-order-index` property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

When a client connection policy is assigned

A client connection policy can be associated with a client connection at the following times.

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs once at most for a client connection because StartTLS cannot be used more than once on a particular connection. You can not stop using StartTLS while keeping the connection active.

Copyright © 2025 Ping Identity Corporation

- After completing processing for a bind operation. This association occurs zero or more times for a client connection because the bind request can be processed many times on a given connection.

StartTLS and bind requests are subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. When they have completed, then subsequent operations are subject to the constraints of the new client connection policy assigned to that client connection. This policy might not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and only apply when the client reconnects.

All other types of operations are subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. The server does not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy is never re-evaluated for a search operation.

Restricting the type of search filter used by clients

You can restrict the types of search filters that a given client might be allowed to use to prevent the use of potentially expensive filters, like range or substring searches.

You can use the `allowed-filter-type` property to provide a list of filter types that can be included in the search requests from clients associated with the client connection policy. This setting is only used if search is included in the set of allowed operation types. This restriction only applies to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

You can use the `minimum-substring-length` property to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes is rejected. For example, you can configure the server to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting is only used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing short substrings can require the server to perform more expensive processing. The search requires more server effort to assemble a candidate entry list for short substrings because the server has to examine more index keys.
- Allowing short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server, a process known as "trawling". If a malicious user wants to obtain all the data from the server, it's easier to issue 26 requests like the following:

  `"(cn=a*)", "(cn=b*)", "(cn=c*)" … "(cn=z*)"`

  Than if the user is required to formulate requests like the following:

  `"(cn=aaaaa*)", "(cn=aaaab*)", "(cn=aaaac*)" … "(cn=zzzzz*)"`.

Resource limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources.

Copyright © 2025 Ping Identity Corporation

You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy can only be used to enforce additional restrictions on a client connection. You cannot use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties only impacts client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made continues to be subject to the configuration that was in place at the time it was associated with that policy.

Resource Limiting Properties

Property	Description
`maximum-concurrent-connections`	Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit is enforced. If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy, such as newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation, causes that connection to be terminated.
`terminate-connection`	Specifies that any client connection for which the client connection policy is selected, such as whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation, is immediately terminated. This property can be used to define criteria for connections that you do not want to be allowed to communicate with the PingDirectory server.
`maximum-connection-duration`	Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the PingDirectory server, regardless of the amount of activity on that connection. A value of "0 seconds" (default) indicates that no limit is enforced. If a connection associated with the client connection policy has been established for longer than this time, then it is terminated.

Copyright © 2025 Ping Identity Corporation

Property	Description
`maximum-idle-connection-duration`	Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the PingDirectory server without any requests in progress. A value of "0 seconds" (default) indicates that no additional limit is enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection is the smaller of the `maximum-idle-connection-duration` from the client connection policy and the idle time limit that would otherwise be in effect for that client. This property can be used to apply a further restriction on top of any value that might be enforced by the `idle-time-limit` global configuration property which defines a default idle time limit for client connections, or the `ds-rlim-idle-time-limit` operational attribute which might be included in a user entry to override the default idle time limit for that user.
`maximum-operation-count-per-connection`	Specifies the maximum number of operations that a client associated with the client connection policy is allowed to request. A value of zero (default) indicates that no limit is enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.
`maximum-concurrent-operations-per-connection`	Specifies the maximum number of operations that might be active at any time from the same client. This limit only applies to clients that use asynchronous operations with multiple outstanding requests at any given time. A value of zero (default) indicates that no limit is enforced. If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request is delayed or rejected based on the value of the `maximum-concurrent-operation-wait-time-before-rejecting` property.
`maximum-concurrent-operation-wait-time-before-rejecting`	Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection. A value of "0 seconds" (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection are immediately rejected. If an outstanding operation completes before this time expires, then the server might be allowed to process that operation. If the time expires, the new request is rejected.
`maximum-ldap-join-size-limit`	Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the `ds-rlim-ldap-join-size-limit` operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control has a "size limit exceeded" (integer value 4) result code.

Copyright © 2025 Ping Identity Corporation

Property	Description
`allowed-request-control`	Specifies the OIDs of the request controls that clients associated with the client connection policy are allowed to use. If any allowed-request-control OIDs are specified, then any request that includes a control not in that set is rejected. If no `allowed-request-control` values are specified (default), then any control whose OID is not included in the set of denied-request-control values is allowed.
`denied-request-control`	Specifies the OIDs of the request controls that clients associated with the client connection policy are not allowed to use. If there are any `denied-request-control` values, then any request containing a control whose OID is included in that set is rejected. If there are no `denied-request-control` values (default), then any request control is allowed if the `allowed-request-control` property is also empty, or only those controls whose OIDs are included in the set of `allowed-request-control` values are allowed if at least one `allowed-request-control` value is provided.
`allowed-filter-type`	Specifies the types of components that might be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set is rejected. The set of possible filter types include: • and • or • not • equality • sub-initial • sub-any • sub-final • greater-or-equal • less-or-equal • approximate-match • extensible-match By default, all filter types are allowed. **Note** No restriction is placed on the types of filters that might be used in searches with a base scope.

Copyright © 2025 Ping Identity Corporation

Property	Description
`allow-unindexed-searches`	**Specifies whether clients associated with the client connection policy are allowed to request searches that cannot be efficiently processed using the configured set of indexes.** **Note** Clients must still have the `unindexed-search` privilege, so this option does not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it might be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so. **By default, this has a value of "true", indicating that any client associated with the client connection policy that has the `unindexed-search` privilege is allowed to request unindexed searches.**
`minimum-substring-length`	**Specifies the minimum number of bytes, which might be present in any sub-Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit is enforced. This property might be used to prevent clients from issuing overly-vague substring searches that might require installing the PingDirectory server to examine too many entries over the course of processing the request.**
`maximum-search-size-limit`	**Specifies the maximum number of entries that might be returned from any single search operation requested by a client associated with this client connection policy.** **Note** This property only specifies a maximum limit and never increases any limit that might already be in effect for the client thought the `size-limit` global configuration property or the `ds-rlim-size-limit` operational attribute. **A value of zero (default) indicates that no additional limit is enforced on top of whatever size limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client is the smaller of the size limit from that search request, the `maximum-search-size-limit` from the client connection policy, and the size limit that would otherwise be in effect for that client.**

Defining the operation rate

Configure the maximum operation rate for individual client connections and collectively for all connections associated with a client connection policy.

Copyright © 2025 Ping Identity Corporation

If the operation rate limit is exceeded, the server can either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of fewer than twelve operations per second, but with bursts of up to one thousand operations per second.

Specify rate limit strings as a maximum count, followed by a slash and a duration. The count portion must contain an integer and can be followed by the following multipliers:

- k (to indicate that the integer should be interpreted as thousands)
- m (to indicate that the integer should be interpreted as millions)
- g (to indicate that the integer should be interpreted as billions)

The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w) and can be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client connection policy deployment example

In this example scenario, we assume the following:

1. Two external LDAP clients are allowed to bind to the server.
2. Client 1 should be allowed to open only one connection to the server.
3. Client 2 should be allowed to open up to five connections to the server.

For more information on this client connection policy deployment example, see the following topics:

- Define the connection policies
- How the policy is evaluated
- Configuring a client connection policy using the console
- Configuring a client connection policy using dsconfig
- Restricting server access based on client IP address

Copyright © 2025 Ping Identity Corporation

Define the connection policies

Set a per-client connection policy limit on the number of connections that can be associated with a particular client connection policy

Define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, you must create a third client connection policy that applies to unauthenticated clients because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Clients are not required to send a bind request as their first operation.

Define the following three client connection policies:

- Client 1 Connection Policy, which only allows client 1, with an evaluation order index of 1
- Client 2 Connection Policy, which only allows client 2, with an evaluation order index of 2
- Unauthenticated Connection Policy, which allows unauthenticated clients, with an evaluation order index of 3

Define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none so that it only applies to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This distinguished name (DN) can be full DN for the target user, or it can be the base DN for a branch that contains several users that you want treated in the same way.

> **Tip**
>
> To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the policy is evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy.

The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value are examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection is associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection is terminated.

So, in this example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

Copyright © 2025 Ping Identity Corporation

After the client performs a bind operation to authenticate to the server, then the client connection policies are re-evaluated. If Client 2 performs the bind, then the Client 1 Connection Policy does not match, but the Client 2 Connection Policy does, so the connection is re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server checks to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection is terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy because it is the client connection policy already assigned to the client connection. When the bind has completed, the server re-evaluates the client connection policy against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. When the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy because it has the lowest evaluation order index. The associated connection criteria do not match, so the Client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops, and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed because this is the client connection policy assigned to the client connection for Client 1. The connection is not re-evaluated before or after processing the search operation.

Configuring a client connection policy using the console

Configure a client connection policy using the PingDirectory administrative console.

Steps

1. In the administrative console, in the Core Server section, click Client Connection Policies.

   > **Tip**
   >
   > If you do not see **Client Connection Policies** on the menu, change the **Object Types** filter to **Standard**.

2. To add a new policy, click Add New.
3. Enter a Policy ID.

   If you want to base your new client connection policy on an existing policy, select it from the Template menu.

4. Configure the properties of the client connection policy, then to enable the policy, select Enabled.
5. Enter the order in which you want the new policy to be evaluated in the Evaluation Order Index box, and then click Continue.

   A policy with a lower index is evaluated before a policy with a higher index. The PingDirectory server uses the first evaluated policy that applies to a client connection.

Copyright © 2025 Ping Identity Corporation

6. Select the connection criteria that match the client connection for this policy.
    1. To change the criteria, click View and Edit.
    2. To add new criteria, click Select New.
    3. Select the operations allowed for clients that are members of this connection group.
    4. To make operations available to clients, use the Add and Remove buttons.
    5. Specify the extended operations that clients are allowed and denied to use.
7. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
8. Select the Include Backend Subtree Views check box if you want to automatically include the subtree views of backends configured in the PingDirectory server.

   You can also choose to include and exclude specific base DNs using the appropriate fields.
9. Save your changes.

   Choose from:
    - To review the `dsconfig` command equivalent and save your changes, click Confirm then Save.
    - To save your changes without first reviewing the `dsconfig` output, click Save Now.

Configuring a client connection policy using dsconfig

Configure a client connection policy using the `dsconfig` tool.

About this task

Configure a client connection policy using the `dsconfig` tool in interactive mode from the command line. You can access the Client Connection Policy menu on the Standard objects menu.

Steps

1. Use the `dsconfig` tool to create and configure a client connection policy.

   Specify the host name, connection method, port number, and bind distinguished names (DNs) described in previous procedures.
2. To change to the Standard objects menu, from the PingDirectory server main menu, enter `o`, and then enter the number for the Standard menu.
3. From the PingDirectory server main menu, enter the number associated with Client Connection Policy.
4. From the Client Connection Policy management menu, enter the number corresponding to Create a new connection policy.
5. To create a new client connection policy from scratch, enter `n`.
6. Enter a name for the new client connection policy.
7. To enable the connection policy, from the Enabled Property menu, select True.

Copyright © 2025 Ping Identity Corporation

8. To set the evaluation order for the policy, from the Evaluation-Order Property menu, enter a value between 0 and 2147483647.

   A client connection policy with a lower evaluation-order is evaluated before one with a higher number. For this example, enter `9999`.

9. From the Client Connection Policy menu, review the configuration.

   1. If you want to make any further modifications, enter the number corresponding to the property.
   2. To finish the creation of the client connection policy, enter `f`.

   Any changes that you make to the client connection policy do not apply to existing connections. They only apply to new connections.

Restricting server access based on client IP address

Two methods are available to limit client access to the PingDirectory server.

Connection Handlers

You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.

Client Connection Policies

For a more fine-grained approach, restrict access by configuring a new client connection policy. Then, create a new connection criteria and associate it with the connection policy. A connection criteria defines sets of criteria for grouping and describing client connections based on several properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy can be associated with zero or more connection criteria. Server components can use connection criteria to indicate which connections to process and what kind of processing to perform, such as to select connections and operations for filtered logging or to classify connections for network groups.

Restricting server access using the connection handlers

Use `dsconfig` to set the `allowed-client` property for the LDAP connection handler.

Steps

- Set the `allowed-client` property for the LDAP connection handler using `dsconfig`.

Copyright © 2025 Ping Identity Corporation

- Specify the address mask for the range of allowable IP addresses that can establish connections to the PingDirectory server.
- To configure the server using the `dsconfig` tool on the local host, specify the loopback address to 127.0.0.1.

Example:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set "allowed-client:10.6.1.*" \
  --set allowed-client:127.0.0.1
```

Restricting server access using client connection policies

A client-established connection to the PingDirectory server is associated with a client connection policy. Use client connection policies to restrict the kinds of requests that the client can issue and impose resource limits for that connection.

Steps

1. Create a simple connection criteria.

   Example:

   The following example uses the `dsconfig` tool in non-interactive mode. It allows only the PingDirectory server's IP address and loopback to have access.

   ```
   $ bin/dsconfig set-connection-criteria-prop \
     --criteria-name allowed-ip-addrs \
     --add included-client-address:10.6.1.80 \
     --add included-client-address:127.0.0.1
   ```

2. Assign the criteria to the client connection policy.

   Example:

   ```
   $ bin/dsconfig set-client-connection-policy-prop \
     --policy-name new-policy \
     --set connection-criteria:allowed-ip-addrs
   ```

   Result:

   After you have run the command, access is denied to remote IP addresses. The PingDirectory server does not require a restart.

3. Add a remote IP range to the criteria.

   > **Note**
   >
   > For the following example, add `10.6.1.*`.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addrs \
  --add "included-client-address:10.6.1.*"
```

Result:

Access from any remote servers is allowed. The PingDirectory server does not require a restart.

4. To restore default behavior, remove the criteria from the connection policy.

Example:

> **Tip**
>
> Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, bindPassword, with the `dsconfig` command.

Example:

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy --remove connection-criteria:allowed-ip-addrs
```

Result:

The PingDirectory server does not require a restart.

Automatically authenticating clients that have a secure communication channel

The PingDirectory server provides the option to automatically authenticate clients that have a secure communication channel, either SSL or StartTLS, and to present their own certificate.

About this task

By default, this option is disabled. When enabled, the net effect is as if the client issued a SASL EXTERNAL bind request on that connection.

> **Note**
>
> This option is ignored if the client connection is already authenticated, such as when using StartTLS, but the client had already performed a bind before the StartTLS request. If the bind attempt fails, the connection remains unauthenticated but usable. If the client subsequently sends a bind request on the connection, it's processed as normal, and any automatic authentication is destroyed.

Steps

- Run the following `dsconfig` command.

Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set "auto-authenticate-using-client-certificate:true"
```

Securing the Server with lockdown mode

The PingDirectory server provides tools to enter and leave lockdown mode if the server requires a security lockdown.

About this task

In lockdown mode, only users with the `lockdown-mode` privilege can perform operations Users who do not have the privilege are rejected. By default, root users have this privilege. You can give other administrators this privilege. Users with this privilege can configure lockdown mode as a recurring task.

Some configuration problems can lead to inadvertent exposure of sensitive information, such as an access control rule that cannot be properly parsed, and cause the server to place itself in lockdown mode. This ensures that an administrator can manually correct the problem. Lockdown mode does not persist across restarts.

Steps

- To perform some administrative operations and ensure that other client requests are not allowed to access any data in the server, manually place the server into lockdown mode.

  Result:

  Any client request to the PingDirectory server in lockdown mode receives an `Unavailable` response.

- To take the PingDirectory server out of lockdown mode, use either of the following options:
  - Use the `leave-lockdown-mode` command.
  - Restart the server.
- To start a server in lockdown mode, use the `start-server` `--lockdownMode` option.

Entering lockdown mode manually

Steps

- To enter lockdown mode, run `enter-lockdown-mode`.

  Example:

```
$ bin/enter-lockdown-mode
```

Leaving lockdown mode

Steps

- To leave lockdown mode, run `leave-lockdown-mode`.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/leave-lockdown-mode
```

Starting a server in lockdown mode

Steps

- To start a server in lockdown mode, run the `start-server` command with the `--lockdownMode` option.

  Example:

  ```
  $ bin/start-server --lockdownMode
  ```

Configuring maximum shutdown time

The PingDirectory server provides an option for administrators to set a maximum time for a shutdown process to take.

Before you begin

During shutdown, some database checkpointing and cleaning threads might remain active even after the default time period on systems with large or busy database backends. If checkpointing or cleaning is aborted prematurely, it can lead to significantly longer startup times for the PingDirectory server. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

About this task

Use the `dsconfig` tool to configure the maximum shutdown time to allow database operations to complete.

Steps

- To increase the maximum shutdown time for your system, choose from one of the following options.

  Choose from:

  - Run the `dsconfig` tool.

    > **Note**
    >
    > The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).
    > Include the LDAP or LDAPS connection parameters, such as host name, port, bindDN, and bindDN password, with the **`dsconfig`** command.

    ```
    $ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-time:6 m"
    ```

  - Change the `maximum-shutdown-time` property using the `dsconfig` tool in interactive mode. From the main menu, select Global Configuration, and then select the option to display advanced properties.

Copyright © 2025 Ping Identity Corporation

About working with referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the PingDirectory server but can be accessed on another server.

Use referrals when entries are located on another server. The PingDirectory server implements two types of referrals depending on the requirement:

Referral on Update plugin

The PingDirectory server provides a Referral on Update plugin to create any referrals for update requests, such as `add`, `delete`, `modify`, or `moddn` operations, on read-only servers. For example, given two replicated PingDirectory servers where one server is a primary with read-write capabilities, and the other is a read-only server. You can configure a referral for any client update requests on the second PingDirectory server to point to the primary server. For example, if a client application sends an add request on the second PingDirectory server, the PingDirectory server responds with a referral that indicates any updates should be made on the primary server. All read requests on the read-only server process normally.

Smart referrals

The PingDirectory server supports smart referrals that map an entry or a specific branch of a directory information tree (DIT) to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT send a referral to the server designated in the LDAP URL.

Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server.

LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax.

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

`ldap[s]`

Indicates the type of LDAP connection to the PingDirectory server. If the server connects over a standard, non-encrypted connection, then LDAP is used. If it connects over SSL, then LDAPS is used.

> **Note**
>
> Any search request initiated by means of an LDAP URL is anonymous by default unless an LDAP client provides authentication.

`hostname`

Specifies the host name or IP address of the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

`port`

Specifies the port number of the PingDirectory server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.

`base-dn`

Specifies the distinguished name (DN) of an entry in the directory information tree (DIT). The PingDirectory server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.

`attributes`

Specifies those attributes for which the PingDirectory server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.

`scope`

Specifies the scope of the search, which could be one of the following:

`base`

Only searches the specified base DN entry.

`one`

Only search one level below the specified base DN.

`sub`

Searches the base entry and all entries below the specified base DN.If no scope is provided, the server performs a base search.

`filter`

Specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses `+`.

Creating referrals

Create a smart referral by adding an entry with the referral and `extensibleObject` object classes or adding the object classes to a specific entry.

About this task

The referral object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a directory information tree (DIT) is located on another server.

To create a referral:

Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

Copyright © 2025 Ping Identity Corporation

Example:

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the `ldapmodify` command.

Example:

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

3. To verify the addition, search for a user.

Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4)"
```

Result:

```
SearchReference(referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

Modifying a referral

Run a modify command to modify a referral.

Steps

- To modify the `ref` attribute on the referral entry, run `ldapmodify` with the `manageDSAIT` control.

Example:

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

Deleting a referral

Run `ldapdelete` to delete a referral.

Steps

- To delete the referral entry, run `ldapdelete` with the `manageDSAIT` control.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/ldapdelete \
  --control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

Configuring a read-only server

The PingDirectory server provides a means to configure a hub-like, read-only server for legacy systems that require it.

About this task

The read-only PingDirectory server participates in replication but cannot respond to any update requests from an external client. You can configure the PingDirectory server by setting the writability mode to internal-only, which makes the server operate in read-only mode. The Read-only mode PingDirectory server can process update operations from internal operations but reject any write requests from external clients. Because the PingDirectory server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a primary server. The client must perform the operation again on the server named in the referral.

> **Note**
>
> For Implementers of third party extensions, many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any PingDirectory server using that extension will effectively respond to external update requests, even though the PingDirectory server is configured to operate in read-only mode, as described previously. One possible workaround is to split the extension into two extensions, one for reads and one for writes, and then to disable (or not to deploy) the write-only extension when configuring a PingDirectory server in read-only mode.

Steps

1. Install two replicating PingDirectory servers.

   For more information on various ways to set up your servers, see Enabling replication.

2. On the second server, run the `dsconfig` command to set the writability mode of the server to internal-only.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set writability-mode:internal-only
   ```

3. On the second server, run the `dsconfig` command to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to server1.example.com:1389.

   The referral itself is defined as a plugin of type `referral-on-update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
  --type referral-on-update \
  --set enabled:true \
  --set referral-base-url:ldap://server1.example.com:1389/ \
  --set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10.

   The resulting message is available in the server's access log.

   Example:

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

   Result:

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

Configuring HTTP access for the PingDirectory server

Although most clients communicate with the PingDirectory server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP.

There is an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

For more information, see the following topics:

- Configuring HTTP Servlet Extensions
- Configuring HTTP operation loggers
- Example HTTP log publishers
- Configuring HTTP connection handlers

Configuring HTTP Servlet Extensions

You must first configure one or more servlet extensions to use the HTTP connection handler.

Copyright © 2025 Ping Identity Corporation

Servlet extensions are responsible for obtaining Java servlets, using the Java Servlet 3.0 specification as described in JSR 315, and registering them to be invoked using one or more context paths. If you plan to deploy the System for Cross-domain Identity Management (SCIM) extension, follow the instructions in SCIM 2.0 servlet extension configuration. For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

Configuring web application servlet extensions

About this task

A web application can be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

Steps

- When deploying a web application from a directory, specify the location of the `web.xml` deployment descriptor if it is not in the standard location.
- Specify the directory used by the server for temporary files.

Result

At runtime, the web application has access to the server classes.

Configuring Java-based servlet extensions

About this task

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation.

Steps

- Use the **`manage-extension`** tool to install it.

  Example:

  ```
  $ bin/manage-extension --install/path/to/extension.zip
  ```

  The Java-based extension can then be configured for use in the server using **`dsconfig`** or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Web application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts might arise from use of different versions of commonly used JARs or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources that might require a dedicated Java virtual machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log might also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

Configuring Groovy-scripted extensions

Steps

1. For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory based on the package for those scripts after the `lib/groovy-scripted-extensions` directory.
2. Create a new Groovy Scripted HTTP Servlet extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

Configuring HTTP operation loggers

Interactions between servlet extensions and HTTP clients are generally not recorded in the server access log unless a servlet extension performs internal operations to interact with data held in the PingDirectory server.

About this task

To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in the following format.

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600]"GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request
- The RFC 1413 (ident) identity of the client

  Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity is always represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication or a dash to indicate that the request was not authenticated
- The time that the request was received
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used
- The integer representation of the HTTP status code for the response to the client

Copyright © 2025 Ping Identity Corporation

- The number of bytes included in the body of the response to the client

Steps

- To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object.
    1. Specify the path and name for the active log file.
    2. Specify the rotation and retention policies to manage the log files.

    > **Note**
    >
    > Properties for Common Log File HTTP Operation Log Publisher objects generally have the same meaning and use as they do for other kinds of loggers.

- To create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types, use the Server SDK.

Example HTTP log publishers

When troubleshooting HTTP connection handler issues, start with the logs to determine any potential problems.

About this task

The following examples walk you through how to use various `dsconfig` commands and their associated options to configure log files to use for troubleshooting connection handler issues.

The following section shows some `dsconfig` commands and their corresponding log files.

Steps

- To configure a default detailed HTTP Log Publisher with default log rotation and retention policies, use the `create-log-publisher` option with `dsconfig`.

    Example:

    ```
    $ bin/dsconfig create-log-publisher \
      --publisher-name "HTTP Detailed Access Logger" \
      --type detailed-http-operation \
      --set enabled:true \
      --set log-file:logs/http-detailed-access \
      --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
      --set "rotation-policy:Size Limit Rotation Policy" \
      --set "retention-policy:File Count Retention Policy" \
      --set "retention-policy:Free Disk Space Retention Policy" \
      --set "retention-policy:Size Limit Retention Policy"
    ```

    Result:

    The corresponding log file provides access information below. The log message contains the following elements:

    - The time that the request was received
    - The request ID issued by the client, including the IP address, port, HTTP method, and URL

Copyright © 2025 Ping Identity Corporation

- The authorization type, request content type, and status code
- The response content length
- The redirect URI
- The response content type

The HTTP log file shows the following.

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604 from="10.5.1.10:53269"
method="GET" url="https://10.5.1.129:443/Gimel/Users/uid=user.402914,ou=People,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.145 responseContentLength=1530 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.402914,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300605 from="10.5.1.10:53269"
method="PUT" url="https://10.5.1.129:443/Gimel/Users/uid=user.207585,ou=people,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.872 responseContentLength=1532 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.207585,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:11:31:18 -0600] RESULT requestID=4309872 from="10.5.1.10:3
```

- To configure a detailed HTTP Log Publisher with request and response header names and values, including the `Content-Type` request header, use the `set-log-publisher-prop` option with `dsconfig`.

> **Note**
>
> The `Content-Type` request header is suppressed by default.

Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "HTTP Detailed Access Logger" \
  --set log-request-headers:header-names-and-values \
  --remove suppressed-request-header-name:Content-Type \
  --set log-response-headers:header-names-and-values
```

Result:

The following is a log example of a query request by a SCIM Server using the property, `scim-query-rate`. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, HTTP method, content type, connection, user agent
- The response header for the access-control credentials

Copyright © 2025 Ping Identity Corporation

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307 from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?attributes=userName,title,

nection: keep-alive" requestHeader="User-Agent: DataSync-6.0.0.0 (Build
20121022173845Z, Revision 11281)" authorizationType="Basic" requestContentType="appli-
cation/json" statusCode=200 etime=10.615 responseContentLength=0
```

Configuring HTTP connection handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. HTTP connection handlers can be used to host web applications on the server.

Each HTTP connection handler should be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this does not prevent the entire directory server from starting. The server's `start-server` tool outputs any errors to the error log. This allows the server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include the following:

Copyright © 2025 Ping Identity Corporation

listen-address

Specifies the address on which the connection handler listens for requests from clients. If not specified, then requests are accepted on all addresses bound to the system.

listen-port

Specifies the port on which the connection handler listens for requests from clients. Required.

use-ssl

Indicates whether the connection handler uses SSL/TLS to secure communications with clients, such as whether it uses HTTPS rather than HTTP. If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

http-servlet-extension

Specifies the set of servlet extensions that are enabled for use with the connection handler. You can have multiple HTTP connection handlers listening on different address/port combinations with identical or different sets of servlet extensions. You must configure at least one servlet extension.

http-operation-log-publisher

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers are used.

key-manager-provider

Specifies the key manager provider that is used to obtain the certificate presented to clients if SSL is enabled.

trust-manager-provider

Specifies the trust manager provider that is used to determine whether to accept any client certificates presented to the server.

num-request-handlers

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads are automatically selected based on the number of CPUs available to the Java virtual machine (JVM).

web-application-extension

Specifies the web applications hosted by the server.

Configuring an HTTP connection handler

About this task

An HTTP connection handler has two dependent configuration objects:

- One or more HTTP servlet extensions
- An HTTP log publisher

Copyright © 2025 Ping Identity Corporation

The log publisher is optional, but in most cases, you should configure one or more logs to troubleshoot any issues with your HTTP connection.

> **Note**
>
> You must configure the HTTP servlet extension and log publisher before configuring the HTTP connection handler.

Steps

1. To configure your HTTP servlet extensions, use the `create-http-servlet-extension` option with `dsconfig`.

   Example:

   This example uses the `ExampleHTTPServletExtension` example in the Server SDK.

   ```
   $ bin/dsconfig create-http-servlet-extension \
     --extension-name "Hello World Servlet" \
     --type third-party \
     --set "extension-class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
     --set "extension-argument:path=/" \
     --set "extension-argument:name=example-servlet"
   ```

2. To configure one or more HTTP log publishers, use the `create-log-publisher` option with `dsconfig`.

   Example:

   This example configures two log publishers: one for common access and one for detailed access. Both log publishers use the default configuration settings for log rotation and retention.

   ```
   $ bin/dsconfig create-log-publisher \
     --publisher-name "HTTP Common Access Logger" \
     --type common-log-file-http-operation \
     --set enabled:true \
     --set log-file:logs/http-common-access \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"

   $ bin/dsconfig create-log-publisher \
     --publisher-name "HTTP Detailed Access Logger" \
     --type detailed-http-operation \
     --set enabled:true \
     --set log-file:logs/http-detailed-access \
     --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
     --set "rotation-policy:Size Limit Rotation Policy" \
     --set "retention-policy:File Count Retention Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"
   ```

3. To configure the HTTP connection handler, specify the HTTP servlet extension and log publishers using the `create-connection-handler` option with `dsconfig`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You can update some configuration properties later as needed, but for others, like `listen-port`, you must disable and then re-enable the HTTP Connection Handler for the change to take effect.

Example:

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. To monitor the connection handler, use the `ldapsearch` tool.

> **Note**
>
> By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE` by default.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

Configuring an HTTP connection handler for web applications

About this task

To host web applications on the server, use HTTP connection handlers.

Steps

1. To create the web application servlet extension, use the `create-web-application-extension` option with `dsconfig`.

Example:

```
$ bin/dsconfig create-web-application-extension \
  --extension-name "Hello Web Application" \
  --set "base-context-path:/hello-app" \
  --set "document-root-directory:/opt/hello-web-app"
```

2. To monitor the connection handler, use the `ldapsearch` tool.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE`.

Example:

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP correlation IDs

Correlation IDs make it easier to track log messages across a software system request that passes through multiple subsystems.

Scattered and intermingled log messages create challenges for tracing the request flow on distributed systems. A correlation ID can be assigned to a request and added to all associated operations as the request is processed. A correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP or HTTPS Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID might also be passed to the LDAP subsystem.

The correlation ID appears with associated requests in LDAP logs in the `correlationID` key for the following REST APIs:

- SCIM 1
- Delegated admin
- Consent
- Directory

The correlation ID is used as the default client request ID value in intermediate client request controls used by the following REST APIs:

- SCIM 2
- Consent
- Directory

Values related to the intermediate client request control appear in the LDAP logs in the `via` key and are forwarded to downstream LDAP servers when received by PingDirectoryProxy server. The correlation ID header is also added to requests forwarded by the PingDirectory gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest` `com.pingidentity.pingdata.correlation_id` attribute, as shown.

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Copyright © 2025 Ping Identity Corporation

Configuring HTTP correlation ID support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable or disable correlation ID support for the HTTPS Connection Handler, use the `set-connection-handler-prop` option with `dsconfig`.

  Example:

  This example shows how to enable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:true
  ```

  Example:

  This example shows how to disable correlation ID support.

  ```
  $ dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set use-correlation-id-header:false
  ```

- To customize the response header name for the correlation ID, use the `set-connection-handler-prop` option with `dsconfig`.

  > **Note**
  >
  > The server generates a correlation ID for every HTTP request and sends it in the response through the **`Correlation-Id`** response header.

  Example:

  This example changes the **`correlation-id-response-header`** property value to `X-Request-Id`.

  ```
  $ dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set correlation-id-response-header:X-Request-Id
  ```

- To designate the names of one or more HTTP request headers that contain an existing correlation ID value, use the `set-connection-handler-prop` option with `dsconfig`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This enables the server to integrate with a larger system consisting of every servers using correlation IDs. By default, the server generates a new, unique correlation ID for each HTTP request and ignores any correlation ID that might be set on the request.

Example:

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection Handler" \
  --set correlation-id-request-header:X-Request-Id \
  --set correlation-id-request-header:X-Correlation-Id \
  --set correlation-id-request-header:Correlation-Id \
  --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP correlation ID example

In this example, a request to the directory REST API is made and the correlation ID enables finding HTTP-specific log messages that also have LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `ee919049-6710-4594-9c66-28b4ada4b127`.

Copyright © 2025 Ping Identity Corporation

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
 Accept: /
 Accept-Encoding: gzip, deflate
 Authorization: Bearer ...
 Connection: keep-alive
 Host: localhost:1443
 User-Agent: HTTPie/0.9.9

 HTTP/1.1 200 OK
 Content-Length: 266
 Content-Type: application/hal+json
 Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
 Date: Fri, 02 Nov 2018 15:16:50 GMT
 Request-Id: 369

 {
      "_dn": "uid=user.86,ou=People,dc=example,dc=com",
      "_links": {
         "schemas": [
            {
              "href": "https://localhost:1443/directory/v1/schemas/inetOrgPerson"
            }
         ],
         "self": {
              "href": "https://localhost:1443/directory/v1/uid=user.86,ou=People,dc=example,dc=com"
         }
     },
     "mail": [
         "user.86@example.com"
     ]
 }
```

The correlation ID can be used to search the HTTP trace log for matching log records, as in the following example.

Copyright © 2025 Ping Identity Corporation

Configuring the PingDirectory server to use an HTTP proxy server

Some organizations configure their network so that internal systems cannot directly access the Internet, but instead must use an HTTP proxy server to access external services.

Copyright © 2025 Ping Identity Corporation

The PingDirectory server now supports using an HTTP proxy server in conjunction with the following components:

- The Amazon Key Management Service cipher stream provider
- The Amazon Secrets Manager cipher stream provider
- The Amazon Secrets Manager passphrase provider
- The Amazon Secrets Manager password storage scheme
- The Azure Key Vault cipher stream provider
- The Azure Key Vault passphrase provider
- The Azure Key Vault password storage scheme
- The PingOne pass-through authentication plugin
- The Pwned Passwords password validator
- The Twilio alert handler
- The Twilio OTP delivery mechanism
- The UNBOUNDID-YUBIKEY-OTP SASL mechanism handler

Setting up the server to use an HTTP proxy server involves two steps, which are described in the following sections.

1. Creating an HTTP proxy external server in the configuration.
2. Configuring the appropriate component(s) to use the HTTP proxy server.

Creating an HTTP proxy external server

An HTTP proxy external server configuration object provides information about a proxy server that should be used. At present, we only support HTTP proxy servers (which can handle both unencrypted HTTP and encrypted HTTPS connections), with or without authentication.

HTTP proxy external server definitions support the following configuration properties:

`server-host-name`

The resolvable name or IP address of the HTTP proxy server to use. This is required.

`server-port`

The port on which the HTTP proxy server is listening for connections. This is required.

`basic-authentication-username`

The username to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

`basic-authentication-passphrase-provider`

The passphrase provider to use to obtain the password to use if the proxy server requires authentication. This should be omitted if the proxy server does not require authentication.

Copyright © 2025 Ping Identity Corporation

For example, you can use a configuration change like the following to create an HTTP proxy external server that does not require authentication:

```
dsconfig create-external-server \
     --server-name "Example HTTP Proxy Server" \
     --type http-proxy \
     --set server-host-name:proxy.example.com \
     --set server-port:3128
```

Configuring server components to use the HTTP proxy external server

Merely defining an HTTP proxy external server in the configuration does not cause the server to use that proxy server for anything. Instead, you must indicate which components should use that proxy server.

This is necessary because you might only need to use an HTTP proxy server for certain components (for example, it might be necessary when accessing external web services, but not for services on the internal private network).

All of the components that support the use of an HTTP proxy server offer an `http-proxy-external-server` configuration property whose value should be the name of the appropriate HTTP proxy external server definition in the configuration. For example, to update the Pwned Passwords password validator to use the HTTP proxy server defined in the "Example HTTP Proxy Server" configuration object, use a configuration change like the following:

```
dsconfig set-password-validator-prop \
     --validator-name "Pwned Passwords" \
     --set "http-proxy-external-server:Example HTTP Proxy Server"
```

DNS caching

You can use two global configuration properties to control the caching of host name-to-numeric IP address or DNS lookup results returned from the name resolution services of the underlying operating system.

About this task

Steps

1. To configure these properties, use the `dsconfig` tool.

Global configuration properties and their descriptions

Global configuration property	Description
network-address-cache-ttl	Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. By default, it keeps resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.

Copyright © 2025 Ping Identity Corporation

Global configuration property	Description
network-address-outage-cache-enabled	Caches host name-to-IP address results in the event of a DNS outage. By default, this is set to true, meaning name resolution results are cached. Unexpected service interruptions might occur during planned or unplanned maintenance, network outages, or an infrastructure attack. This cache can allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

2. To reduce delays caused by unnecessary DNS lookups, follow these recommendations:
    1. Maintain a connection pool in the client app rather than opening new connections for each bind.
    2. Add appropriate records to DNS, including PTR records.
    3. Add `options timeout:1` or `options single-request` in the `/etc/resolv.conf` file.
    4. If IPv6 requests are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in server's `config/java.properties` file, so that running `bin/dsjavaproperties` and restarting the server no longer issues IPv6 PTR requests.

IP address reverse name lookups

The directory server performs numeric IP address-to-host name lookups.

Numeric IP address-to-host name lookups

The following are some of the numeric IP address-to-host name lookups:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- Java Management Extension (JMX): Creating a server socket
- Key Management: Generating a trust store
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- Simple Authentication and Security Layer (SASL) Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Configuring address masks

Address masks configured in Access control instructions (ACIs), connection handlers, connection criteria, and certificate handshake processing might trigger implicit reverse name lookups.

Copyright © 2025 Ping Identity Corporation

For more information about how address masks are configured in the server, see the following information for each server:

- ACI DNS: bind rules in Managing access control for the PingDirectory server and the PingDirectoryProxy server
- `ds-auth-allowed-address`: Restricting access through operational attributes in user entities for the PingDirectory server
- Connection Criteria: Restricting server access based on client IP address for the PingDirectory server and the PingDirectoryProxy server
- Connection Handlers: Restricting server access using the connection handlers for a configuration reference guide for all servers

Configuring traffic through a load balancer

To record the actual client's IP address to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingDirectory server.

By default, when a PingDirectory server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it logs incoming requests as originating with the intermediate HTTP server instead of the client that sent the request.

When you set the `use-forwarded-headers` property and enable an HTTP connection handler to use `Forwarded` or `X-Forwarded-*` headers, many intermediate HTTP servers add information about the original request that would otherwise be lost.

If `use-forwarded-headers` is set to `true`, the server uses the client IP address and port information in the `Forwarded` or `X-Forwarded-*` headers instead of the address and port of the entity that's sending the request (the load balancer). This client address information shows up in logs, such as in the `from` field of the `HTTP REQUEST` and `HTTP RESPONSE` messages.

> **Note**
>
> If both the `Forwarded` and `X-Forwarded-*` headers are included in the request, the `Forwarded` header takes precedence. The `X-Forwarded-Prefix` header only overrides the context path for HTTP servlet extensions, not for web application extensions.

Configuring traffic through a load balancer using `dsconfig`

About this task

To configure the directory server to get traffic through a load balancer and to record the actual client's IP address:

Steps

1. Edit the HTTP or HTTPS connection handler object and set `use-forwarded-headers` to `true` by running `dsconfig`.

   Example:

   ```
   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set use-forwarded-headers:true
   ```

2. To finalize the changes to the HTTP or HTTPS connection handler, use `dsconfig` to restart the connection handler.

Copyright © 2025 Ping Identity Corporation

Example:

```
dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:false

dsconfig set-connection-handler-prop \
    --handler-name "HTTPS Connection Handler" \
    --set enabled:true
```

3. To provide the `X-Forwarded-*` information to your load balancer, consult your provider's guide on configuring the load balancer settings.

Configuring traffic through a load balancer using the administrative console

About this task

To configure the PingDirectory server to get traffic through a load balancer and to record the actual client's IP address:

Steps

1. On the PingDirectory administrative console Configuration page, click Connection Handlers.
2. To edit your HTTP or HTTPS connection handler, in the Connection Handlers list, select the connection handler you want to edit.
3. To enable `Forwarded` headers, go to Use Forwarded Headers and select the Enabled check box.
4. Click Save.
5. To finalize the changes to the HTTP or HTTPS connection handler, use `dsconfig` to restart the connection handler.

   Example:

   ```
   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set enabled:false

   dsconfig set-connection-handler-prop \
       --handler-name "HTTPS Connection Handler" \
       --set enabled:true
   ```

   > **Note**
   >
   > Because disabling the connection handler brings down the administrative console, you must complete this step in the command line instead of the administrative console.

6. To provide the `X-Forwarded-*` information to your load balancer, consult your provider's guide on configuring the load balancer settings.

Copyright © 2025 Ping Identity Corporation

Working with the Referential Integrity plugin

Referential Integrity is a plugin mechanism that maintains the distinguished name (DN) references between an entry and a group member attribute. If you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the PingDataSync server.

Before you begin

By default, the Referential Integrity plugin is disabled. When enabled, the plugin performs integrity updates on the specified attributes, such as `member` or `uniquemember`, after a delete, modify DN, or a rename, such as subordinate `modifyDN`, operation is logged to the `logs/ referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Important points about the Referential Integrity plugin:

- Index all specified attributes that are configured for Referential Integrity.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas. You must manually enable the plugin on each replica.
- The plugin settings must be identical on all machines.
- If the Referential Integrity plugin is enabled and configured to operate in synchronous mode, subtree delete operations are not allowed. You must configure the plugin to operate in asynchronous mode by specifying a nonzero update interval for subtree delete operations to perform.

About this task

Enable the Referential Integrity plugin.

Steps

1. Determine the attributes needed for your system.

   By default, the `member` and the `uniquemember` attributes are set for the plugin.

2. To enable the Referential Integrity plugin, run the `dsconfig` tool.

   Example:

   ```
   $ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
     --set enabled:true
   ```

Working with the Unique Attribute plugin

The Unique Attribute plugin enforces uniqueness constraints on the values of one or more attributes across a portion of the PingDirectory server. The plugin checks for uniqueness before an add, modify, or modify distinguished name (DN) request and instructs the server to reject the request if a constraint violation is found.

About this task

Copyright © 2025 Ping Identity Corporation

By default, the plugin is disabled because it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, only on new `ADD`, `MODIFY`, or `MODDN` operations. To ensure that no such conflicts exist in the data, administrators can use the `identify-unique-attribute-conflicts` command.

> **Important**
>
> Ensure all attributes to enforce for uniqueness are indexed for equality in all backends. Use the LDAP SDK uniqueness request control for enforcing uniqueness on a per-request basis. For more information on the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control, see Use the server SDK and LDAP SDK. See the ASN.1 specification to implement support for it in other APIs.

You can enforce attribute uniqueness in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a PingDirectoryProxy server. In such environments, all servers have identical uniqueness configurations.

> **Note**
>
> It is not possible to prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts are detected after the changes have been replicated and then triggers administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers, such as environments that use entry balancing or that store different portions of the DIT on different servers, implement the Global Uniqueness Attribute plugin on the PingDirectoryProxy server instead of enabling the attribute uniqueness plugin on the PingDirectory server. For more information, see the PingDirectory Server Administration Guide and the PingDirectoryProxy Server Administration Guide.

To enable the Unique Attribute plugin:

Steps

1. Determine which attributes must be unique in your data.
2. To enable the plugin, run the `dsconfig` tool.

   By default, the plugin type property is set to `postsynchronizationadd`, `postsynchronizationmodify`, `postsynchronizationmodifydn`, `preoperationadd`, `preoperationmodify`, and `preopertionmodifydn`.

   Example:

   The following example checks for attribute uniqueness before an `ADD` operation using the `--set plugin-type:preoperationadd` option.

   ```
   $ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
     --set enabled:true
   ```

   1. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option.

Copyright © 2025 Ping Identity Corporation

Working with the Purge Expired Data plugin

Use the Purge Expired Data plugin to delete expired entries or attribute values and cleanup expired PingFederate Persistent Access Grants.

When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. For optimal performance, enable the Purge Expired Data plugin on multiple servers in a topology. For example, you can configure one server to delete data while others are searching for expired data.

Create and configure the Purge Expired Data plugin with the `dsconfig` tool. Configuration options include the base distinguished name (DN) and filter, the items to be purged, how to identify expired data, and the frequency for polling and purging. You must index the search for expired data. An alarm is raised if the server purging data falls behind the configured `max-updates-per-second`. Monitoring information is available in the Admin Console, or `cn=monitor`.

Configuring the Purge Expired Data plugin for expired entries

About this task

Use the Purge Expired Data plugin to delete all unverified account entries that have not been accessed in the past eight weeks. The is useful for the following scenarios:

- Accounts that potential customers started to create through an application's registration process but then did not complete.
- The phone number or email address that was provided during registration was not verified and should be allowed to be used by another account.

Steps

1. If necessary, enable the Last Access Time plugin:

   The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

   Example:

   ```
   $ bin/dsconfig set-plugin-prop \
     --plugin-name "Last Access Time" \
     --set enabled:true
   ```

2. To determine expiration order, create an index on the date attribute.

   The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering.

   Example:

   ```
   $ bin/dsconfig create-local-db-index \
     --backend-name userRoot \
     --index-name ds-last-access-time \
     --set index-type:ordering
   ```

3. If there is data present in the directory, rebuild the index.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/rebuild-index \
  --baseDN dc=example,dc=com \
  --index ds-last-access-time
```

4. Create the plugin that purges account entries `objectclass=account` that are not verified.

   Example:

   The following example purges account entries `verified=false` after eight weeks of inactivity.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Unvalidated Accounts" \
  --type purge-expired-data \
  --set enabled:true \
  --set datetime-attribute:ds-last-access-time \
  --set "expiration-offset:8 w" \
  --set "filter:(&(objectClass=account)(verified=false))"
```

Configuring the Purge Expired Data plugin for expired attribute values

About this task

Use the Purge Expired Data plugin to delete values of an attribute that have expired. For example, an application can track information about an employee's session and then expire the session after 24 hours. There can be multiple active sessions tracked across different devices with session information as shown in the following example.

In this example, the LDAP attribute is `sessioninfo` and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
"ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2 like Mac OS X; en-us)
AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367 Safari/531.21.10",
"creationTime" : "2018-03-31T13:10:15Z" }
```

Create the plugin to purge the JSON attribute values after 24 hours, rather than the entire session entry.

Steps

1. Create an index on the `creationTime` field of the `sessioninfo` attribute.

   Example:

```
$ bin/dsconfig create-json-attribute-constraints \
  --attribute-type sessioninfo \
  --set enabled:true
```

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type sessioninfo \
  --json-field creationTime \
  --set index-values:true \
  --set value-type:string
```

2. Create and enable the plugin.

   Example:

```
$ bin/dsconfig create-plugin \
  --plugin-name "Purge Old Session Data Plugin" \
  --type purge-expired-data \
  --set enabled:true \
  --set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
  --set datetime-attribute:sessioninfo \
  --set datetime-format:custom \
  --set datetime-json-field:creationTime \
  --set "expiration-offset:1 d" \
  --set purge-behavior:delete-json-attribute-values
```

Configuring uniqueness across attribute sets

Configure attribute uniqueness across a set of attributes using the `multiple-attribute-behavior` property.

About this task

To enable uniqueness across attribute sets:

Steps

- To configure the UID unique attribute plugin to apply across multiple attributes, use the `dsconfig` tool.

  The following table details the `multiple-attribute-behavior` property and the values it can take.

Copyright © 2025 Ping Identity Corporation

The `multiple-attribute-behavior` *property values, descriptions, and examples*

Value	Description	Example
`unique-within-each-attribute`	**If multiple attributes are specified, then uniqueness is enforced for all values of each attribute, but the same value might appear in different attributes in the same entry or in different entries.**	**For example, assume you have an existing entry that has attributes `telephoneNumber=123-456-7890` and `mobile=123-456-7891`.** **If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-within-each-attribute"` and add:** ◦ **An entry with a `telephoneNumber` value that matches the `telephoneNumber` attribute in the existing entry, then the add request fails.** ◦ **An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then the request fails.** ◦ **An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but differs from the values in the existing entry, then the add request succeeds.**

Copyright © 2025 Ping Identity Corporation

Value	Description	Example
`unique-across-all-attributes-including-in-same-entry`	If multiple attributes are specified, then uniqueness is enforced across all of those attributes. If a value appears in one of those attributes that value might not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries.	For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"` and add: ◦ An entry with a `telephoneNumber` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the add request fails. ◦ An entry with a `mobile` value that matches the `mobile` attribute in an existing entry, then the request fails. ◦ An entry with a `mobile` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then that fails. ◦ An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but differ from the values in an existing entry, then the add request fails.

Copyright © 2025 Ping Identity Corporation

Value	Description	Example
`unique-across-all-attributes-except-in-same-entry`	If multiple attributes are specified, then uniqueness is enforced across all of those attributes. So, if a value appears in one of those attributes, that value might not be present in any of the listed attributes in other entries. However, the same value might appear in multiple attributes in the same entry.	For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. You set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"` and add: ◦ An entry with a `telephoneNumber` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the add request fails. ◦ An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then the request fails. ◦ An entry with a `mobile` value, such as 123-456-7890, that matches the `telephoneNumber` attribute in an existing entry, then the request fails. ◦ An entry with a `telephoneNumber` value, such as 123-456-7891, that matches the `mobile` attribute in an existing entry, then the request fails. ◦ An entry with the same `telephoneNumber` and `mobile` attribute values, such as 123-456-7893, but that differs from the values in an existing entry, then the add request succeeds.

Example:

The `multiple-attribute-behavior` property is set to `unique-within-each-attribute`, which indicates that uniqueness is enforced for all values of each attribute, such as `telephoneNumber=123-456-7890` and `mobile=123-456-7891`, but the same value, such as either 123-456-7890 or 123-456-7891 might appear in different attributes in the same entry or in different entries.

Copyright © 2025 Ping Identity Corporation

```
$ dsconfig create-plugin \
  --plug-in "Unique telephoneNumber and mobile" \
  --type "unique-attribute" \
  --set "enabled:true" \
  --set "type:telephoneNumber" \
  --set "type:mobile" \
  --set "multiple-attribute-behavior:unique-within-each-attribute" \
  --no-prompt
```

Working with the Last Access Time plugin

Use the Last Access Time plugin to record the timestamp of the last activity targeting an entry. The plugin updates the `ds-last-access-time` attribute of the entry when accessing it using an `ADD`, `BIND`, `COMPARE`, `MODIFY`, `MODIFY DN`, or `SEARCH` operation.

Before you begin

Consider the following before using this plugin:

- An updated `ds-last-access-time` attribute value is replicated like any other change to an entry.
- The `ds-last-access-time` attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The `ds-last-access-time` value format is `yyyyMMddHHmmss.SSS'Z'`, which provides millisecond-level accuracy, such as `20131207144135.821Z`.
- The `ds-last-access-time` attribute can be indexed with a local database index. The ordering index type is the most relevant, but might require a higher index entry limit (default is 4000) to accommodate searches for entries that are not accessed for a long period of time. The ordering index type with a short time range or high index entry limit results in indexed search results for requests, such as `(ds-last-access-time>=20131207144135.821Z)`.

About this task

Use the plugin with the Directory Server Uncached Attribute Criteria or any application that needs to determine the last access time of an entry. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The `max-search-result-entries-to-update` property also prevents mass updates of `ds-last-access-time` when searches contain many results, but might not reflect end-user access.

Steps

- Enable the plugin on all servers that have the same configuration.

> **Important**
>
> For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

Copyright © 2025 Ping Identity Corporation

Working with pass-through authentication

The PingDirectory server provides support for passing through LDAP simple bind attempts to an external service for authentication processing, either instead of or in addition to the processing that it typically performs against the locally stored data.

Pass-through authentication can be useful when migrating to the PingDirectory server from a different type of datastore, especially when that datastore doesn't provide a means of directly migrating passwords.

The server provides pass-through authentication support for other LDAP servers (including Active Directory (AD), Oracle DSEE, OpenLDAP, and any other standards-compliant LDAPv3 server) and PingOne by default. You can also use the Server SDK to implement support for custom pass-through authentication handlers for interacting with other types of external services.

Configuration properties for pass-through authentication to LDAP servers

When used with the LDAP pass-through authentication handler, the pluggable pass-through authentication plugin can forward LDAP simple bind requests to another type of LDAP server for processing.

The following table contains the pluggable pass-through authentication plugin configuration properties.

Property	Description
`pass-through-authentication-handler`	The pass-through authentication handler that is used to interact with the external service. For passing through authentication to an LDAP directory server, create an LDAP pass-through authentication handler.
`included-local-entry-base-dn`	The base distinguished names (DNs) of subtrees containing local entries for which pass-through authentication is attempted. If this isn't provided, then all regular user entries (excluding root users and topology administrators) might be passed through.
`connection-criteria`	Optional connection criteria that can be used to indicate which clients can have their bind attempts passed through.
`request-criteria`	Optional request criteria that can be used to indicate which bind requests should be passed through.
`try-local-bind`	Indicates whether to try the bind attempt against the entry in the local server, only passing through to the external service if the local attempt fails. If this is `false`, then only pass-through authentication is used for applicable requests and local credentials aren't evaluated.

Copyright © 2025 Ping Identity Corporation

Property	Description
`override-local-password`	Indicates whether to pass through bind attempts for local accounts that have passwords. If this is set to `false`, bind attempts will only be passed through for accounts that don't have local passwords. This only applies if `try-local-bind` is `true`.
`update-local-password`	Indicates whether to update the password for the local account if authentication succeeds against the external service. This only applies if `try-local-bind` is `true`.
`update-local-password-dn`	The DN to use as the authorization identity when updating local passwords, which can be helpful if you want to synchronize other types of changes between the PingDirectory server and the external repository. If this isn't provided, an internal root account is used.
`allow-lax-pass-through-authentication-passwords`	Indicates whether to update the password for the local account even if it wouldn't have otherwise been accepted by the server (for example, if the password doesn't satisfy the configured set of password validators). This only applies if `update-local-password` is `true`.
`ignored-password-policy-state-error-condition`	Optionally allows pass-through authentication attempts to proceed against local accounts that are in certain states that don't allow them to authenticate locally (for example, if the account is locked or the password is expired).

The following table contains the LDAP pass-through authentication handler configuration properties.

Property	Description
`server`	The LDAP external servers to which bind attempts should be passed through.
`server-access-mode`	The mechanism that the server should use when choosing the order that the servers should be selected for pass-through authentication attempts.
`dn-map`	An optional mapping that can be used to construct the remote bind DN from the local PingDirectory server entry when authenticating to the external servers.
`bind-dn-pattern`	An optional pattern that can be used to construct the remote bind DN from the local PingDirectory server entry when authenticating to the external servers.

Copyright © 2025 Ping Identity Corporation

Property	Description
`search-base-dn`	The search base DN to use when searching for the corresponding entry in the external servers.
`search-filter-pattern`	An optional pattern you can use to construct a filter to search for the entry in the external servers that corresponds to an entry in the local PingDirectory server.
`initial-connections`	The initial number of connections to establish to each of the LDAP external servers.
`max-connections`	The maximum number of connections to maintain to each of the LDAP external servers.
`use-location`	Indicates whether to consider each server's location relative to the local PingDirectory server instance location when choosing the order that servers should be selected for pass-through authentication attempts.
`maximum-allowed-local-response-time`	The maximum length of time to wait for a response from an external server in the same location as the local PingDirectory server.
`maximum-allowed-nonlocal-response-time`	The maximum length of time to wait for a response from an external server in a different location from the local PingDirectory server.
`use-password-policy-control`	Indicates whether to include the password policy request control in bind requests forwarded to the external LDAP servers. This control can improve the server's ability to categorize authentication failures against the remote server, but not all types of LDAP servers support it. By default, the server includes the password policy request control if the server's root DSA-specific entry (DSE) advertises support for it.

At most one of the `dn-map`, `bind-dn-pattern`, and `search-filter-pattern` properties can be provided to indicate how the server should identify the entry in the remote server that corresponds to the entry in the local server. If none of these properties are provided, the local entry DN is used as the remote entry DN.

Configuring pass-through authentication to LDAP servers

To enable pass-through authentication to LDAP servers, create and configure at least one LDAP external server, a pass-through authentication handler, and a pluggable pass-through authentication plugin instance.

Copyright © 2025 Ping Identity Corporation

Steps

1. To create an LDAP external server, run `dsconfig create-external-server`.

   > **Note**
   >
   > If you already have an LDAP external server to use for pass-through authentication, proceed to step 2.

   Example:

   The following example creates two LDAP external servers.

   ```
   dsconfig create-external-server \
        --server-name ds1.example.com:636 \
        --type ldap \
        --set server-host-name:ds1.example.com \
        --set server-port:636 \
        --set connection-security:ssl \
        --set key-manager-provider:Null \
        --set trust-manager-provider:JKS \
        --set authentication-method:none

   dsconfig create-external-server \
        --server-name ds2.example.com:636 \
        --type ldap \
        --set server-host-name:ds2.example.com \
        --set server-port:636 \
        --set connection-security:ssl \
        --set key-manager-provider:Null \
        --set trust-manager-provider:JKS \
        --set authentication-method:none
   ```

2. To create an LDAP pass-through authentication handler, run `dsconfig create-pass-through-authentication-handler`.

   Example:

   ```
   dsconfig create-pass-through-authentication-handler \
        --handler-name LDAP \
        --type ldap \
        --set server:ds1.example.com:636 \
        --set server:ds2.example.com:636 \
        --set server-access-mode:round-robin
   ```

3. To create a pluggable pass-through authentication plugin instance, run `dsconfig create-plugin`.

   Example:

   ```
   dsconfig create-plugin \
        --plugin-name "Pluggable Pass-Through Authentication" \
        --type pluggable-pass-through-authentication \
        --set enabled:true \
        --set pass-through-authentication-handler:LDAP
   ```

Copyright © 2025 Ping Identity Corporation

The PingOne Pass-Through Authentication plugin

The PingOne Pass-Through Authentication plugin allows users to authenticate to the PingDirectory server with a password from PingOne and can optionally update the passwords in PingDirectory after successfully validating it in PingOne.

Although the PingDataSync server supports bidirectional synchronization between the PingDirectory server and PingOne, and it can synchronize password changes from PingDirectory to PingOne, it can't sync password changes from PingOne to PingDirectory. However, you can use the PingOne Pass-Through Authentication plugin to authenticate to the PingDirectory server with a PingOne password, and can optionally update the password in PingDirectory after successfully validating it in PingOne.

This plugin features a mandatory `try-local-bind` configuration property that enables one of the following modes of operation:

- When `try-local-bind` is `true`, the plugin attempts to authenticate locally first. It sends a request to PingOne only if the local bind attempt fails.
- When `try-local-bind` is `false`, the plugin attempts to authenticate with PingOne first.

The following table identifies and describes the configuration properties associated with the PingOne Pass-Through Authentication plugin.

The PingOne Pass-Through Authentication plugin properties and their descriptions

Property	Description	Required	Default
`api-url`	URL that the PingDirectory server uses to communicate with PingOne.	Yes	N/A
`auth-url`	URL that the PingDirectory server uses to authenticate to PingOne.	Yes	N/A
`oauth-client-id`	OAuth client ID that the PingDirectory server uses to authenticate to PingOne.	Yes	N/A
`oauth-client-secret`	OAuth client secret that the PingDirectory server uses to authenticate to PingOne.	Yes	N/A
`environment-id`	Identifier for the PingOne environment that contains the users for whom pass-through authentication is attempted.	Yes	N/A
`included-local-entry-base-dn`	If this value is set, authentication attempts are passed to PingOne only for users in a specified distinguished name (DN). If this value is set, only users who exist within a specified base DN allow their authentication attempts to be passed through to PingOne.	No	All public naming contexts (if not set)

Copyright © 2025 Ping Identity Corporation

Property	Description	Required	Default
`connection-criteria`	Reference to a connection criteria object to use to identify the bind requests to pass-through to PingOne based on the server's knowledge of the client expected to be the address, protocol, and security level. If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.	No	N/A
`request-criteria`	Reference to a request criteria object to use to identify the bind requests to pass through to PingOne, based on the contents of the request. If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.	No	N/A
`try-local-bind`	Indicates whether the PingDirectory server tries to process the bind locally before forwarding the bind request to PingOne. If this value is set to `true` and the bind succeeds locally, the PingDirectory server does not make a request to PingOne. If this value is set to `false`, the PingDirectory server ignores local credentials and attempts to authenticate only to PingOne.	Yes	`True`
`override-local-password`	Indicates whether the PingDirectory server attempts to bind to PingOne if the local account has a password. This property is used if `try-local-bind` is `true`. If it has a value of `false`, the plugin attempts to authenticate to PingOne only if the local user account doesn't have a password. If the local bind attempt fails while this value is set to `true`, the server tries to authenticate to PingOne even if the local account has a password.	Yes	`True`

Copyright © 2025 Ping Identity Corporation

Property	Description	Required	Default
`update-local-password`	Indicates whether the PingDirectory server attempts to set the password for the local user account, regardless of whether one is already set, when the local authentication attempt fails but the attempt to authenticate with PingOne succeeds. This property is used only if `try-local-bind` is `true`. If the on-premise PingDirectory server is the authoritative source for passwords, set this property to `false` and configure the PingDataSync server to synchronize password changes from the PingDirectory server into PingOne. If the passwords differ, either the local password or the password for PingOne allows the user to authenticate. If PingOne is the authoritative source for passwords, set this property to `true`. To ensure that a pass-through attempt to PingOne doesn't override local changes, make all password changes in PingOne.	Yes	`False`
`allow-lax-pass-through-authentication-passwords`	Indicates whether the PingDirectory server bypasses the normal password-validation process when setting the local password from PingOne. This property is used only when both `try-local-bind` and `update-local-password` are `true`. If this value is `true` when a local bind attempt fails but the authentication attempt with PingOne succeeds, the user's password is updated locally even if a local attempt to change the password to the same value is rejected because the password is considered too weak. If this value is `false`, pass-through authentication succeeds only if the authentication to PingOne succeeds, and if the password is accepted by the local password validators. If the PingOne password does not satisfy the configured set of password validators, the pass-through authentication attempt fails.	Yes	`True`
`ignored-password-policy-state-error-condition`	Set of zero or more password policy state error conditions that are ignored for pass-through authentication. For a list of values and their descriptions, see the following table.	No	N/A

Copyright © 2025 Ping Identity Corporation

Property	Description	Required	Default
`user-mapping-local-attribute`	Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne account. This property must include the same number of values as the `user-mapping-remote-json-field` property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an `AND` search in PingOne to locate the user account with all the values in the corresponding fields. The `entryDN` attribute can be used to represent the DN of the local entry.	Yes	N/A
`user-mapping-remote-json-field`	The name of a PingOne field used to map local user entries to the corresponding PingOne account. This property must include the same number and order of values as the `user-mapping-local-attribute` property.	Yes	N/A
`additional-user-mapping-scim-filter`	The System for Cross-domain Identity Management (SCIM) filter included in the search and used to identify the PingOne account that corresponds to the local user entry. If a value is provided for this property, it is used with the SCIM filter that was created to map the local user entry to a PingOne account. If a value is not provided for this property, no additional filter is used.	No	N/A

The following table identifies the values to use with the optional configuration property `ignored-password-policy-state-error-condition` and describes the scenarios in which a user is permitted to bind when using pass-through authentication.

Optional configuration property and the scenarios for use when using pass-through authentication

Property	Scenario in which a user can still bind by using pass-through authentication
`temporarily-locked-due-to-failures`	The account is locked temporarily because of too many failed attempts.
`permanently-locked-due-to-failures`	The account is locked permanently because of too many failed attempts.
`locked-due-to-idle-interval`	The account is locked because the user has not authenticated recently.
`locked-due-to-maximum-reset-age`	The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame.
`password-is-expired`	The password is expired.

Copyright © 2025 Ping Identity Corporation

ExampleConfiguring the PingOne Pass-Through Authentication plugin

To create and configure the PingOne Pass-Through Authentication plugin, run `dsconfig create-plugin` in a command similar to the following.

```
dsconfig create-plugin \
     --plugin-name "PingOne Pass-Through Authentication" \
     --type ping-one-pass-through-authentication \
     --set enabled:true \
     --set "api-url:<API URL>" \
     --set "auth-url:<Auth URL>" \
     --set "oauth-client-id:<Client ID>" \
     --set "oauth-client-secret:<Client Secret>" \
     --set "environment-id:<Environment ID>" \
     --set user-mapping-local-attribute:entryUUID \
     --set user-mapping-remote-json-field:externalId
```

Configuring pass-through authentication to custom services

The PingDirectory server provides support for passing through LDAP simple bind attempts to an external service for authentication processing, either instead of or in addition to the processing that it typically performs against the locally stored data. Use the Server SDK to implement support for custom pass-through authentication handlers for interacting with other types of external services.

About this task

To create a custom pass-through authentication handler, use the Server SDK. To configure your pass-through handler in the server:

Steps

1. Create an instance of a third-party pass-through authentication handler and set its `extension-class` property by running a command similar to the following.

   Example:

   ```
   dsconfig create-pass-through-authentication-handler \
        --handler-name "<Example Handler>" \
        --type third-party \
        --set extension-class:<com.example.ExamplePassThroughAuthenticationHandler>  \
        --set extension-argument:<argName1=argValue1>  \
        --set extension-argument:<argName2=argValue2>
   ```

   The third-party pass-through authentication handler supports the following configuration properties.

Copyright © 2025 Ping Identity Corporation

Property	Description
`extension-class`	The fully-qualified name of the Java class that provides the custom pass-through authentication handler implementation. This class must be a subclass of `com.unboundid.directory.sdk.ds.api.PassThroughAuthenticationHandler`.
`extension-argument`	An optional set of name-value pairs that provide arguments needed to configure the custom pass-through authentication handler.

2. (Optional) Set any further configuration needs, as determined by your custom implementation, through the `extension-argument` property.
3. After you have configured the third-party pass-through authentication handler, configure a pluggable pass-through authentication plugin instance to use it, using a command similar to the following.

   Example:

```
dsconfig create-plugin \
     --plugin-name "Pluggable Pass-Through Authentication" \
     --type pluggable-pass-through-authentication \
     --set enabled:true \
     -- set "pass-through-authentication-handler:<Example Handler>"
```

> **Note**
>
> For more information about the configuration properties for the pluggable pass-through authentication plugin, see Working with pass-through authentication.

Troubleshooting server performance issues

The following are the most common reasons that customers encounter performance issues and some suggestions for diagnosing and addressing these issues.

Slow password storage schemes

Slow password storage schemes are configurable schemes designed to use a lot of CPU and memory to thwart attackers, but they can affect legitimate operations like password validation and authentication.

The following password storage schemes are intentionally expensive:

- PBKDF2
- bcrypt
- scrypt
- Argon2

Copyright © 2025 Ping Identity Corporation

- The MD5, SHA-2-256 and SHA-2-512 variants of the crypt scheme

These schemes are designed to consume a significant amount of CPU, and memory in some cases, to increase the amount of resources an attacker must expend to crack a password if they happen to get access to the password's encoded representation. This same cost is also incurred for legitimate operations involving the password, including encoding clear-text passwords during account creation and password changes and when validating passwords during authentication. You can configure these schemes to adjust the amount of resources they consume, and you should configure them so that the resource consumption under expected peak load does not exceed the capacity of the topology.

Additionally, if you are initially populating the server using an LDIF import that contains clear-text passwords, using one of these schemes can cause the LDIF import to proceed at a small fraction of the rate that could be achieved with a faster storage scheme, such as one that uses a 256-bit or 512-bit salted SHA-2 digest. In such cases, you might import the data using a faster scheme and then change the configuration to make the desired scheme the new default, and mark the scheme used for import as deprecated. As a result, accounts with passwords encoded using the import scheme are automatically re-encoded with the new scheme the first time that the user successfully authenticates using that password.

Database size versus memory capacity

Best performance is achieved when the contents of the database can be fully cached in memory.

If possible, the amount of memory allocated to PingDirectory server should be large enough so that all of the data can fit in the database cache. Memory sizing estimates appear at the end of the output when you run the `import-ldif` tool.

If the amount of data that needs to be stored exceeds the available memory capacity of the individual systems on which the server runs, there are a couple options:

- Break up the data into segments that are small enough to be fully cached on their own, and use PingDirectoryProxy server's entry balancing functionality to make them appear as a single logical set.
- Tune the server so that the most frequently accessed information can be served from memory while disk access might be required for other data. In disk-bound deployments, you can use backend configuration options such as cache mode, uncached attribute criteria, and uncached entry criteria to help prioritize what data should remain in memory versus what can be retrieved from disk.

Large number of access control rules

As the number of access control rules increases, so does the potential costs of determining whether a client is allowed to request a given operation and of paring down search result entries based on the data that the client is permitted to access.

The server might need to re-evaluate all access control rules after certain update operations, including modify DN operations, to determine whether these are affected by the change.

In many cases, deployments with an extremely large number of access control rules, especially those with large numbers of branches in which the same structure might be repeated across each of these branches, might be able to leverage parameterized access control instructions (ACIs) to dramatically reduce the number of access control rules that need to be defined and evaluated. In other cases, it is possible to refactor the access control configuration to achieve the same effect but with far fewer rules.

Large static groups

PingDirectory server supports large static groups with hundreds of thousands of members or more, but these can have a significant impact on performance. Consider replacing large static groups with dynamic groups.

Copyright © 2025 Ping Identity Corporation

It can be expensive in terms of system resources to update the large static group to add or remove members because each update requires rewriting the entire entry. It can also be expensive to decode the entry when retrieving it from the database, even if it is held in the database cache, and to return the list of members to a client in search results.

If possible, consider replacing large static groups with dynamic groups. Dynamic groups automatically determine their membership based on criteria defined in LDAP URLs. A dynamic group consumes little memory and disk space and does not need to be altered as entries are created, updated, and removed. In some cases, it is possible to use virtual static groups in conjunction with dynamic groups to create entries that behave like static groups for read operations. This lets you maintain compatibility with applications that only understand static groups but use dynamic groups behind the scenes to determine membership.

If it is not possible to eliminate large static groups, you can enable the static group entry cache. While this does not reduce the performance impact of updating large static groups, it can make it much more efficient to access those groups for read operations.

Large index ID sets

Indexes store data that make it possible to quickly retrieve matching entries during a search. As the size of an ID set increases, so does the potential resource cost of accessing the ID set.

Each index record maps an index key to a list of the entry IDs for the entries that match that key. If you have an equality index for a given attribute, there is a key for each unique value for that attribute and the values for each key of the IDs of the entries that contain that value. For substring indexes, there can be multiple keys for the same attribute value (one for each unique six-character substring within the value), and the same substring can apply to many different values of the same attribute.

For an attribute index, you can store ID sets in one of two ways that each affect performance differently:

- In the regular (non-exploded) case, each index key occurs once, and the value of this key is the entire list of IDs for entries that match the key. The ID set for a non-exploded index key can be retrieved quickly because only a single database read is required. However, as the size of the ID set grows, the cost of updating it grows because it is necessary to replace the entire set, which requires larger amounts of disk I/O and can place an increased burden on the database cleaner.
- In the exploded case, the same key can be stored multiple times (one for each entry that matches that key), with each instance of the key associated with a different entry ID. Updating the ID set for an exploded key is always fast because the writes are small, but the cost of reading the ID set increases with the number of IDs.

You can also use composite indexes. These offer many advantages over attribute indexes and when they can be used. Some of these advantages, such as the ability to configure a base DN or combinations of attributes, do not have any effect on performance with regard to large ID sets. They use a hybrid of the exploded and non-exploded approaches to maintaining the ID set, such that a large set can be split into multiple pieces, but each piece can have up to 5000 IDs rather than just one. This means that retrieving a large ID set from a composite index can be thousands of times cheaper than retrieving the same ID set from an exploded attribute index. Updating a large ID set in a composite index should be cheaper in terms of systems resources than updating the same ID set in a non-exploded attribute index because the write is much smaller.

Copyright © 2025 Ping Identity Corporation

In environments with performance problems related to very large index ID sets, you might consider the following options as a way to help improve performance:

- Consider reducing the index entry limit for that index. The index entry limit specifies the maximum number of IDs that an ID set can have for an index key.
    - If a key matches more entries than this limit, the server stops maintaining the index for that key, and attempts to access it behave as if it were unindexed, while the index continues to be maintained for keys matching smaller numbers of entries. If you don't have searches that depend only on those keys, then this is an excellent way of eliminating the cost of maintaining large ID sets. It isn't logical to set the index entry limit to a value that is a large percentage of the total number of entries in the server. In such cases, there might not be a significant performance difference between indexed and unindexed search performance, but there would be no need to maintain the associated large ID sets.
- If there are cases in which you need a large index entry limit, then consider increasing the limit only for that index, rather than increasing the default limit for all indexes in the backend.
    - The `index-entry-limit` property in the backend applies to all indexes that don't specify their own limit, but each index also offers an `index-entry-limit` property that, if set, overrides the index entry limit configured for the backend. As such, if you need a higher index entry limit for a particular index, set a higher limit just for that one index instead of raising the default limit for all indexes in the backend.
- For attribute indexes with keys matching a large number of entries, consider converting it to a composite index when possible.
    - Composite indexes can completely replace equality and ordering attribute indexes, and they can support "starts with" substring searches, regardless of whether they have "contains" or "ends with" components. Composite indexes can't currently replace approximate match indexes or substring searches that don't have a "starts with" component.
- Consider eliminating any unnecessary substring indexes.
    - As previously noted, substring indexes are more likely to have large ID sets than equality, ordering, or approximate match indexes because substring keys are generally smaller and any given substring key can apply to multiple attribute values. It's also not commonly understood that equality attribute indexes and equality composite indexes are used for substring searches with a "starts with" component. As such, a substring index is not used for substring searches with a "starts with" unless there isn't an equality index for that attribute.
    - If a substring index is defined for an attribute that isn't targeted by substring searches, or that is only targeted by substring searches that contain a "starts with" component (regardless of whether it also includes "contains" or "ends with" components), then that substring index is not necessary and can be removed. You can use access logs to determine the types of searches that clients are performing, and the `summarize-access-log` and `search-logs` tools might help with that.
- If a substring index is needed for a given attribute, then consider increasing the substring length for that index.
    - By default, the server creates a separate substring key for each unique six-character substring in an attribute value, and there might be cases in which the same six-character substring appears in several different values. If that occurs and causes substring keys to have large ID sets, then increasing the substring length for that index reduces the number of values that might share the any given key and can reduce the number of IDs associated with that key.

Copyright © 2025 Ping Identity Corporation

- As a last resort, consider tuning the exploded index threshold for an index (the number of entries that an ID set needs to have for a given key before it will transition from a non-exploded set to an exploded one) based on the expected usage for that index.
    - If search performance is more important than update performance for an attribute with large ID sets, then raising the exploded index threshold helps keep the ID set stored as a monolithic block of IDs. On the other hand, if update performance is more important than search performance, then lowering the exploded index threshold might help.

Missing indexes

Maintain indexes to determine if an index is missing.

Maintaining unneeded indexes can have a detrimental effect on performance, but it can also be detrimental if a needed index is missing.

The best way to identify expensive searches processed in the server is to examine the access logs for search operations with a high `etime` (elapsed processing time) value. After you identify these search operations, you can filter out any of these operations that do not need to be fast. For example, you might have applications that generate reports by performing inefficient searches, such as searches to retrieve all entries, and it is usually more acceptable for those searches to be slow.

For any remaining searches that are slow or that should be faster, the best way to understand why the search is expensive is to issue a search with the same base DN, scope, and filter, but request only the `debugsearchindex` attribute.

> **Note**
>
> `debugsearchindex` is a special attribute that makes the server return debug information about the index processing that is being performed in the course of evaluating the search, and how long it took to complete each step of the evaluation.

From this output, you can see which indexes were used and which could not be used because there was either no applicable index or the index entry limit had been exceeded for the target key. You can see expensive accesses to exploded indexes and identify indexes you want to add, indexes that can benefit from being converted to composite indexes, or indexes where you might need to increase the index entry limit. Alternatively, you can determine a different way to perform the search so that it does not depend on components that are unindexed or that match a large number of entries.

Configuring the PingDirectory server for Oracle compatibility

Configure the PingDirectory server for Oracle compatibility.

About this task

For companies that are migrating from an Oracle server to the PingDirectory server, the PingDirectory server provides a `dsconfig` batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to an Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the PingDirectory server's configuration with the necessary `dsconfig` commands by uncommenting the example commands listed in the file and then running the `dsconfig` command specifying the batch file.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This batch file is not comprehensive and must be used together with the **`migrate-sun-ds-config`** tool, located in the `bin` folder, or `bat` folder for Windows systems, during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Oracle server to a Ping Identity server.

Another useful tool is the **`migrate-ldap-schema`** tool in the `bin` folder, or `bat` folder for Windows systems, which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server are added to the targeted instance or written to a schema file.

Steps

1. From the PingDirectory server's root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder.

   You can use a text editor to view the file.

2. Read the file completely.

3. Apply any changes to the file by removing the comment symbol at any **`dsconfig`** command example, and then applying the **`dsconfig`** command specifying the batch file.

   Example:

   ```
   $ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
     --bindPassword "password" --batch-file /path/to/dsconfig/file
   ```

4. Run the **`migrate-ldap-schema`** tool to move the schema definitions on the source server to the destination Ping Identity server.

   Example:

   ```
   $ bin/migrate-ldap-schema
   ```

5. Run the **`migrate-sun-ds-config`** tool to see what differences exist in the Ping Identity configuration versus the Oracle configuration.

6. On the PingDirectory server, run the following command.

   Example:

   ```
   $ bin/migrate-sun-ds-config
   ```

7. Test the server instance for further settings that might not have been set with the batch file, the **`migrate-ldap-schema`** tool, or the **`migrate-sun-ds-config`** tool.

8. If you notice continued variances in your configuration, contact your authorized support provider.

Copyright © 2025 Ping Identity Corporation

Supporting unindexed search requests

By default, the PingDirectory server denies all unindexed search requests, except for those issued by the bind distinguished names (DNs) that have the `unindexed-search` privilege.

About this task

This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the `unindexed-search` privilege to allow any client to perform an unindexed search.

Steps

1. Set the `disabled-privilege` global configuration property to `unindexed-search` as follows.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set disabled-privilege:unindexed-search
   ```

2. If you choose to allow unindexed searches, cap the maximum number of concurrent unindexed search requests using the `maximum-concurrent-unindexed-searches` global configuration property.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set maximum-concurrent-unindexed-searches:2
   ```

3. Limit unindexed search privileges for particular clients using the `allow-unindexedsearches` property of the client connection policy.

   For more information about configuring client connection policies, see Client connection policy configuration.

Syncing passwords to PingOne

To sync passwords with PingOne, the PingDirectory server maps the `userPassword` attribute to the `password` attribute through a direct attribute mapping. (IBM Security Directory and the IBM Tivoli Directory servers return the `userPassword` attribute value as `userPassword;binary`.)

About this task

To sync passwords from thePingDirectory server to PingOne:

Steps

- To create a direct attribute mapping, run the following.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-attribute-mapping \
--map-name PingDirectory_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:userPassword
```

The PingDataSync server can synchronize passwords that have been encrypted by PingDirectory server or a hashed version of the password, depending on how an administrator chooses to store passwords on PingDirectory server.

- To sync passwords from a generic relational database management system (RDBMS), create a direct attribute mapping with the `from-attribute` being whichever attribute the RDBMS uses to store the password.

> **Note**
>
> RDBMS passwords cannot be encrypted and should be hashed with a scheme that PingDirectory server recognizes.

> **Important**
>
> The PingDataSync server cannot synchronize passwords between PingOne systems, because PingDataSync cannot retrieve passwords from PingOne.

Example:

In the following example, the RDBMS uses the `dbPassword` attribute to store the password.

```
dsconfig create-attribute-mapping \
--map-name Generic_RDBMS_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:dbPassword
```

Single sign-on with the administrative console

The OpenID Connect (OIDC) protocol enables single sign-on (SSO) with the PingDirectory server administrative console using either PingOne, PingFederate, or a custom authorization server.

Overview of OpenID Connect

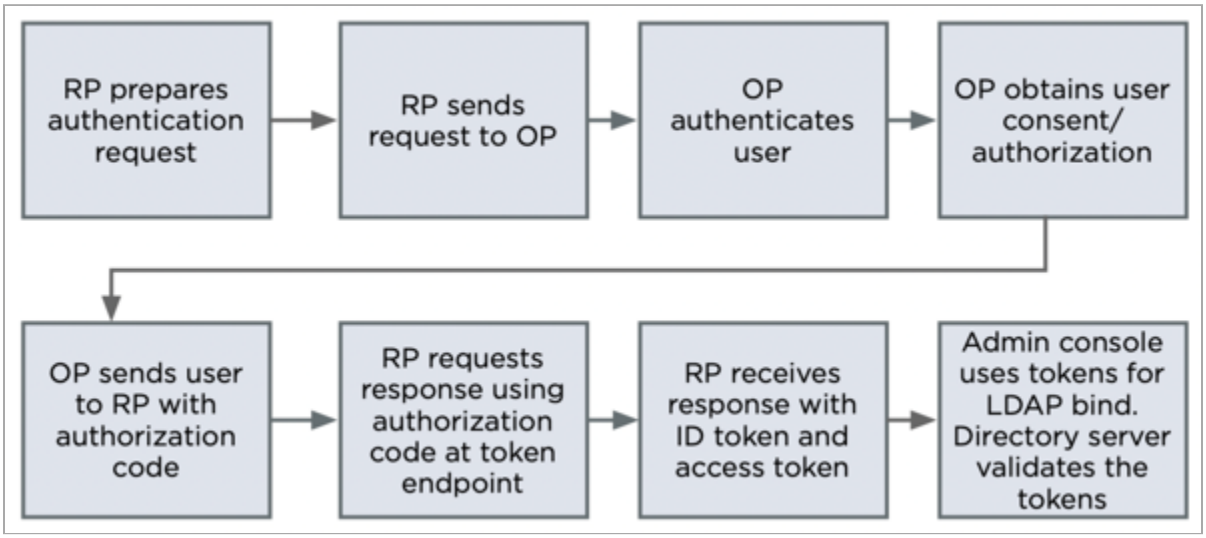
OIDC is a protocol that allows a client application called a relying party (RP) to confirm that a user is who they say they are by contacting an authorization server called an OpenID Provider (OP).

The authorization code flow

The PingDirectory server administrative console uses the authorization code flow implementation of the protocol.

The following is the basic authorization code flow where the PingDirectory server administrative console acts as the RP in steps 1-7, the managed server acts as the RP in step 8, and PingOne, PingFederate, or your custom authorization server acts as the OP.

Copyright © 2025 Ping Identity Corporation



1. The PingDirectory server administrative console (RP) prepares an authentication request containing the desired request parameters.
2. The administrative console (RP) sends the request to the authorization server.
3. The authorization server (OP) authenticates the user.
4. The authorization server (OP) obtains user consent/authorization.
5. The authorization server (OP) sends the user back to the administrative console with an authorization code.
6. The administrative console (RP) requests a response using the authorization code at the token endpoint.
7. The administrative console (RP) receives a response that contains an ID token and access token in the response body.
8. The administrative console attempts to use the tokens to perform an Lightweight Directory Access Protocol (LDAP) bind with the server (RP) through the OAUTHBEARER SASL mechanism. While establishing this LDAP bind, the server (RP) validates the tokens.

Configuring OIDC with the PingDirectory server administrative console

The authorization server must be configured with the following settings.

Copyright © 2025 Ping Identity Corporation

Configuration requirement	Description
An OIDC client with a client ID, client secret, and a Redirection URI.	The client ID and client secret are used by the authorization server to confirm that the authentication and token requests are coming from a valid source. Set the redirection URI value to `https://<hostname>:<HTTPS_port>/console/oidc/cb`, where `https://<hostname>:<HTTPS_port>/console/` is where you access the console. **Note** The redirection URI value is used by the authorization server in steps 3 and 5 when sending the end user back to the RP. If the value is incorrect, the authorization server displays an error.
The authorization server must be able to return an ID token that maps to a user on the managed PingDirectory server.	The `sub` field in the ID token must be mappable.

The PingDirectory server administrative console must be configured with the following settings in the `application.yml` file, which is located in `PingDirectory/tmp/console/webapp/WEB-INF/classes`.

Note

If doing this in DevOps, none of these settings will have any effect and the changes must be done through the profile.

application.ymlconfiguration name	Embedded console setting name	Settings required
`PingData.SSO.OIDC.enabled`	SSO Enabled	`true`. Necessary for the console to start the OIDC login flow. **Note** If SSO Enabled is set to `false`, the console asks for a username and password.
`PingData.SSO.OIDC.issuerUri`	OIDC Issuer URI	Allows the client to use OIDC discovery to determine the correct addresses to send the authentication request to in step 2 and the token request in step 6.
`PingData.SSO.OIDC.clientID`	OIDC Client ID	Value obtained from the authorization server. This is sent in the authentication request in step 2.

Copyright © 2025 Ping Identity Corporation

application.ymlconfiguration name	Embedded console setting name	Settings required
`PingData.SSO.OIDC.clientSecret`	OIDC Client Secret	Value obtained from the authorization server. This is sent in the token request in step 6.
`ldap.server`	LDAP Server	Set to the managed PingDirectory server's hostname and LDAPS port. Used in step 8 when the administrative console attempts to perform an LDAP bind to the managed PingDirectory server using the OAUTHBEARER SASL mechanism.

The managed PingDirectory server must be configured with the ability to accept LDAPS connections and with the following additional configuration properties.

Configuration requirement	Description
A configured ID token validator	• For PingOne SSO: the PingOne ID token validator. • For PingFederate SSO or a general OIDC provider: the OIDC ID token validator. **Note** The ID token validator must be configured with an identity mapper that is able to map the `sub` value in the token to an LDAP user on the server.
A configured OAUTHBEARER SASL mechanism	Set the mechanism's ID token validator configuration property to the previously configured OIDC ID token validator. **Note** The OAUTHBEARER SASL mechanism is used in step 8 when the PingDirectory server processes the LDAP bind.

Setting up SSO to the PingDirectory administrative console

- To set up SSO using PingOne, refer to Setting up SSO to PingDirectory from PingOne.
- To set up SSO using PingFederate, refer to Setting up SSO to PingDirectory from PingFederate.
- To set up SSO using a generic OP, refer to Setting up SSO to PingDirectory from a generic OpenID Connect provider.

Copyright © 2025 Ping Identity Corporation

Setting up SSO to PingDirectory from PingOne

To set up single sign-on (SSO) access from the PingOne admin console to the PingDirectory admin console, configure PingOne and PingDirectory and test the sign-on experience.

> **Tip**
>
> You can use groups to organize user identities, as explained in Groups in the PingOne documentation. You can also set access to applications, as explained in Application access control in the PingOne documentation.

Steps

- To set up SSO to the PingDirectory admin console from PingOne, follow the steps detailed in Setting up SSO to PingDirectory in the PingOne documentation.

  Result:

  You have succesfully done the following:

  - Set up a matching user between PingOne and the PingDirectory environments that allows the server's `All Admin Users` identity mapper to map the PingOne ID token to a PingDirectory server LDAP user.
  - Set up the OpenID Connect (OIDC) client.
  - Satisfied the configuration requirements for both the PingDirectory admin console and PingDirectory server.

    > **Note**
    >
    > The OIDC client and the PingDirectory configuration properties are both outlined in more detail in Single sign-on with the admin console.

Setting up SSO to PingDirectory from PingFederate

You can set up single sign-on authentication to the PingDirectory administrative console using PingFederate as the authorization server.

To increase your control over who can access the PingDirectory administrative console, you can configure single sign-on (SSO) using PingFederate as the OpenID Connect (OIDC) provider. Migrating authorization to PingFederate enables you to manage administrative access to PingDirectory more effectively in environments where you already rely on PingFederate workflows.

To set up SSO authentication to the administrative console:

1. Complete the steps for Configuring PingFederate for SSO.
2. Complete the steps for Configuring PingDirectory for SSO.

Configuring PingFederate for SSO

Before you begin

- You must have a working PingFederate instance to serve as the OpenID Connect (OIDC) provider.

Copyright © 2025 Ping Identity Corporation

- To complete these steps, you must have an HTML form adapter instance. You can find details in Configuring an HTML Form Adapter instance in the PingFederate documentation.

About this task

To create an OIDC client and configure PingFederate as an authorization server, follow these steps.

Steps

1. Configure an access token manager.
    1. Go to Applications > OAuth > Access Token Management.
    2. Click Create New Instance.
    3. Enter or select the access token management instance properties as shown in the following table.

> **Important**
>
> Use the **Extend the contract** field to add the `admin_role` and `sub` attributes. Learn more about Defining the access token attribute contract in the PingFederate documentation.
> Configure other values as needed or leave the default values in place.

Tab	Property	Value
Type	Instance Name	`jwt`
	Instance ID	`jwt`
	Type	JSON Web Tokens
Instance Configuration	Certificates	Add your signing certificate and give it a key ID.
	Token Lifetime	`120`
	Use Centralized Signing Key	False
	JWS Algorithm	RSA using SHA-256
	Active Signing Certificate Key ID	Enter the key ID you assigned to your signing certificate.
	Enable Token Revocation	False
	Include Key ID Header Parameter	True
	Include X.509 Thumbprint Header Parameter	False
	Default JWKS URL Cache Duration	`720`

	Check Session Validation Status	False
	Check Session Revocation Status	False
	Update Authentication Session Activity	False
Access Token Attribute Contract	Attribute	`admin_role`
	Attribute	`sub`
	Default Subject Attribute	USER_KEY
Access Control	Restrict Allowed Clients	False

4. Click Save.

2. Create an OIDC policy.

    1. Go to Applications > OAuth > OpenID Connect Policy Management.

    2. Click Add Policy.

Copyright © 2025 Ping Identity Corporation

3. Enter or select the OIDC policy properties as shown in the following table.

> **Note**
>
> Configure other values as needed or leave the default values in place.

Tab	Property	Value
Manage Policy	Policy ID	`jwtOIDCpolicy`
	Policy Name	`jwtOIDCpolicy`
	Access Token Manager	Select the jwt access token manager you previously created.
	ID Token Lifetime	`5`
	Include Session Identifier in ID Token	True
	Include User Info in ID Token	True
	Include State Hash in ID Token	False
	Return ID Token on Refresh Grant	False
	Reissue ID Token during Hybrid Flow	False
Attribute Contract	Attribute	`sub`
	Attribute	`admin_role`
Attribute Scopes	openid	`admin_role`
Contract Fulfillment	admin_role	Select Access Token in the Source menu and admin_role in the Value menu.
	sub	Select Access Token in the Source menu and sub in the Value menu.

4. Click Save.

3. Create a policy contract grant mapping.

    1. Go to Authentication > OAuth > Policy Contract Grant Mapping.

    2. In the Policy Contract menu, select your authentication policy contract and click Add Mapping.

    3. On the Attribute Sources & User Lookup tab, click Next.

Copyright © 2025 Ping Identity Corporation

4. On the Contract Fulfillment tab, for both the User_Key and User_Name, select Authentication Policy Contract for the Source and subject for the Value.
5. Complete any other configuration, as needed, and save the mapping.

4. Create an access token mapping between your authentication policy contract and the access token manager you previously created.

> **Important**
>
> If needed, create an authentication policy contract. The `sub` attribute is required.

1. Go to Applications > OAuth > Access Token Mappings.
2. On the Access Token Mappings page, in the Context menu, select your authentication policy contract.
3. In the Access Token Manager menu, select the jwt access token manager you previously created.
4. Click Add Mapping.
5. On the Attribute Sources & User Lookup tab, click Next.
6. On the Contract Fulfillment tab, do the following:
   - For the `admin_role` attribute, select Text for the Source and enter `fullAdmin` for the Value.
   - For the `sub` attribute, select Authentication Policy Contract for the Source and subject for the Value.
7. Complete any other configuration, as needed, and save the mapping.

5. Create an OIDC client.

1. Go to Applications > OAuth > Clients and click Add Client.
2. Enter or select the client application properties as shown in the following table.

> **Note**
>
> Configure other values as needed or leave the default values in place.

Property	Value
Client ID	`PingDirectoryConsole`
Client Name	`PingDirectoryConsole`
Description	`Client for the PingDirectory administrative console`
Client Authentication	Select Client Secret.
Client Secret	Select the Change Secret check box and enter a password, or click Generate Secret and note the generated secret value.

Copyright © 2025 Ping Identity Corporation

Property	Value
Redirect URLs	Enter `https://<hostname>:<port>/console/oidc/cb`, supplying the hostname and port values for your PingDirectory server instance. **Note** To obtain the PingDirectory administrative console port value, run `bin/status`.
Bypass Authorization Approval	Select Bypass.
Allowed Grant Types	Select Authorization Code.
Default Access Token Manager	Select jwt.
OpenID Connect > ID Token Signing Algorithm	Select RSA using SHA-256.
OpenID Connect > Policy	Select the OIDC policy you previously created.

3. Click Save.

6. Create an OAuth set authentication selector.

    1. Go to Authentication > Policies > Selectors.
    2. On the Selectors page, click Create New Instance.
    3. Enter or select the authentication selector properties as shown in the following table.

Tab	Property	Value
Type	Instance Name	`PD Console Selector`
	Instance ID	`PDConsoleSelector`
	Type	OAuth Client Set Authentication Selector
Authentication Selector	Clients	Select the OIDC client you previously created.

    4. Complete any other configuration, as needed, and save the selector.

7. Create and save an authentication policy by following steps 1-11 of Creating an authentication policy.

Copyright © 2025 Ping Identity Corporation

> **Important**
>
> In step 9, for the **Yes** option on the selector, select your HTML form adapter instance from the **IdP Adapters** menu.

Result

You have completed the PingFederate SSO configuration.

Configuring PingDirectory for SSO

Before you begin

You must have a working PingDirectory server instance that accepts LDAPS connections. This server will host the administrative console being configured for SSO.

About this task

To enable administrators to use PingFederate to sign on to the PingDirectory administrative console using SSO and configure PingDirectory to accept access and ID tokens from PingFederate, follow these steps.

Steps

1. **Create administrator accounts in PingDirectory.**
    1. **Make a list of the accounts that should have administrative access.**
    2. **For each account in the previous list, run the following command:**

    ```
    $ bin/dsconfig create-root-dn-user \
      --user-name <Username>  \
      --set first-name:<Given Name>  \
      --set last-name:<Family Name>
    ```

    Creating these administrators allows the `All Admin Users` identity mapper to map the PingFederate ID token to a PingDirectory LDAP user.
2. **Create an HTTP external server by running the following command:**

    ```
    $ bin/dsconfig create-external-server \
      --server-name PingFederateHttpServer \
      --type http \
      --set base-url:https://<PingFederate_server>:9031 \
      --set hostname-verification-method:allow-all
    ```

    Creating the HTTP external server enables an HTTP connection to PingFederate.
3. **Create an OIDC ID token validator by running the following command:**

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-id-token-validator \
  --validator-name PingFedTokenValidator \
  --type openid-connect \
  --set enabled:true \
  --set "identity-mapper:All Admin Users" \
  --set issuer-url:https://<PingFederate_server>:9031 \
  --set evaluation-order-index:1 \
  --set allowed-signing-algorithm:RS256 \
  --set openid-connect-provider:PingFederateHttpServer \
  --set jwks-endpoint-path:https://<PingFederate_server>:9031/pf/JWKS
```

Note

Set the `openid-connect-provider` value to the name of the HTTP external server you previously created.

Creating the ID token validator enables PingDirectory to validate the OIDC ID token it receives from PingFederate.

4. **Create a SASL mechanism handler by running the following command:**

```
$ bin/dsconfig create-sasl-mechanism-handler \
  --handler-name PingFedSASLHandler \
  --type oauth-bearer \
  --set enabled:true \
  --set id-token-validator:PingFedTokenValidator
```

Note

Set the `id-token-validator` value to the name of the OIDC ID token validator you previously created.

Creating the SASL mechanism handler enables PingDirectory to accept the access token it receives from PingFederate.

5. **Configure the Console web application extension.**

    1. **Run `bin/dsconfig`.**
    2. **Enter the number for the Web Application Extension configuration.**

    Note

    This option is only shown for the **Advanced** objects configuration menu. If needed, enter option **o** and change the configuration menu level.

    3. **To show existing web application extensions, enter `3`.**
    4. **To edit the Console web application extension, press enter.**
    5. **Configure the Console's properties as shown in the following table.**

    Note

    Configure other values as needed or leave the default values in place.

Copyright © 2025 Ping Identity Corporation

Property	Value
sso-enabled	true
oidc-client-id	Enter the client ID you provided for the PingFederate client application you previously created.
oidc-client-secret	Enter the client secret you provided for the PingFederate client application you previously created.
oidc-issuer-url	Enter the PingFederate OIDC token issuer URL. **Note** This value should match the value you provided for the `issuer-url` argument when creating the OIDC token validator.
ldap-server	This value should already be set, but you can confirm it by running `bin/status` on the PingDirectory server hosting the administrative console for SSO connections.

6. Enter `f` after you complete your configurations.

Configuring the Console web application extension enables the PingDirectory administrative console to accept ID token credentials for SSO from an OIDC ID token issued by your trusted PingFederate authorization server.

6. Restart PingDirectory.

7. Go to the PingDirectory administrative console URL.

> **Note**
> The URL takes the form `https://<PingDirectory_server>:<HTTP_port>/console/` . If needed, you can run `bin/status` to find this information.

Result:

You should be redirected to the PingFederate sign-on form.

Troubleshooting:

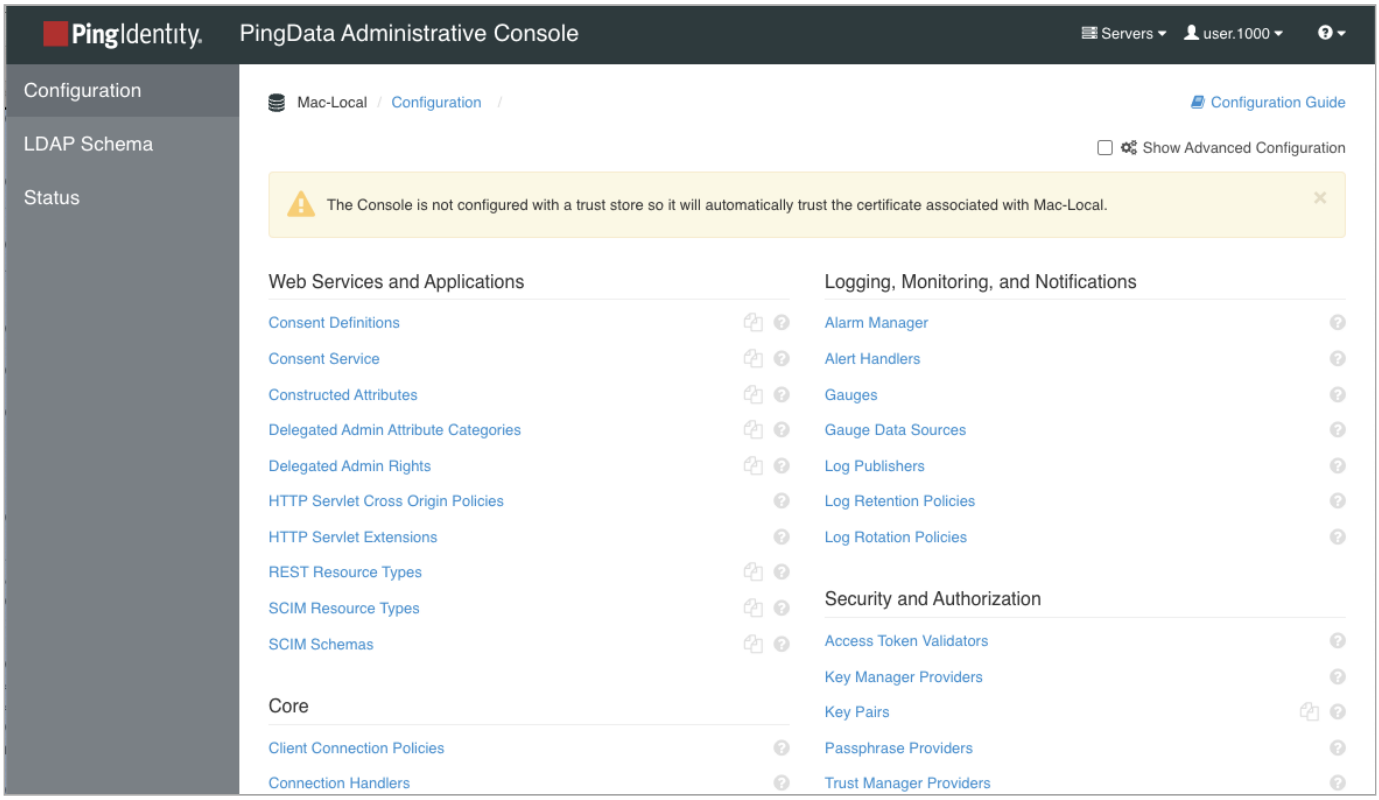
If you have previous administrative console sessions, close your browser tabs and retry or use your browser's privacy mode.

8. Enter the credentials for one of the administrator accounts you created in step 1.

Result:

You should be signed on to the PingDirectory administrative console.

Copyright © 2025 Ping Identity Corporation



Setting up SSO to PingDirectory from a generic OpenID Connect provider

To set up single sign-on (SSO) access to the PingDirectory administrative console from your OpenID Connect (OIDC) provider, configure the OIDC provider and PingDirectory and test the sign-on experience.

Before you begin

Ensure that you have:

- A PingDirectory server that accepts LDAPS connections

  This server will host the administrative console that is being configured for SSO.

- An OIDC provider that supports OIDC discovery

About this task

For more information on the configuration properties you are setting up with this task, see Single sign-on with the administrative console.

Steps

1. Configure your OIDC provider to access the PingDirectory administrative console:
   1. Set the redirect URL to `https://<hostname>:<port>/console/oidc/cb` where `<hostname>` and `<port>` are for the PingDirectory server.
   2. Set the JSON web token (JWT) signing algorithm.
   3. Record the client ID, client secret, and issuer URL for use in step 5.

Copyright © 2025 Ping Identity Corporation

2. Create a token validator on the PingDirectory server by running a command similar to the following.

   Example:

   ```
   dsconfig create-id-token-validator \
        --validator-name "OpenID Token Validator" \
        --type openid-connect \
        --set enabled:true \
        --set "identity-mapper:All Admin Users" \
        --set evaluation-order-index:1 \
        --set issuer-url:<OIDC_Provider_Issuer_URL>
        --set allowed-signing-algorithm:<JWT_signing_algorithm>
   ```

   Provide your own values for `<OIDC_Provider_Issuer_URL>` and `<JWT_signing_algorithm>`, where the algorithm is the one you set in the previous step.

   Although not shown in the example, the command must also set the properties in one of the rows in the following table.

Properties	Descriptions
`openid-connect-provider` and `jwks-endpoint-path`	An OpenID Connect provider, which refers to an HTTP External Server, and a JWKS (JSON web key set) endpoint path
`signing-certificate`	A signing certificate

3. To create an LDAP user in `cn=Root DNs,cn=config` that the OIDC provider can send an ID token for, use the following `dsconfig` command.

   If, in the previous step, you use the `All Admin Users` identity mapper and the ID token validator's `subject-claim-name` is `sub` (the default), then the `sub` value of the ID token that the OIDC provider sends must be the `cn` of an admin user on the PingDirectory server. For example, assume the OIDC provider sends an ID token with the claim `sub=admin-user`. Then, there must be an LDAP user in `cn=Root DNs,cn=config` or in `cn=Topology Admin Users,cn=topology,cn=config` who has `cn=admin-user`.

   ```
   dsconfig create-root-dn-user --user-name admin-user
   ```

4. Create a SASL mechanism handler on the PingDirectory server to use the validator you just created by running a command similar to the following.

   Example:

   ```
   dsconfig create-sasl-mechanism-handler \
        --handler-name OAUTHBEARER \
        --type oauth-bearer \
        --set enabled:true \
        --set "id-token-validator:OpenID Token Validator" \
        --set require-both-access-token-and-id-token:false
   ```

Copyright © 2025 Ping Identity Corporation

5. Run the following command, substituting values for the ID, secret, and issuer URL.

```
dsconfig set-web-application-extension-prop \
     --extension-name Console \
     --set sso-enabled:true \
     --set oidc-client-id:<OIDC_Client_ID>  \
     --set oidc-client-secret:<OIDC_Client_Secret>  \
     --set oidc-issuer-url:<OIDC_Provider_Issuer_URL>
```

6. To finalize your changes, disable and re-enable the HTTPS Connection Handlers with the following commands.

```
dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set enabled:false

dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set enabled:true
```

7. Test the sign on.

   Result:

   The administrative console should open.

Using the administrative console

You can configure and maintain the PingDirectory server through the embedded administrative console.

- Signing on to and configuring the administrative console
- Single sign-on with the administrative console
- Working with the schema
- Managing tasks
- Monitoring with the administrative console

Signing on to and configuring the administrative console

After you install the PingDirectory server, access the administrative console to verify the configuration and manage the server.

About this task

The administrative console is designed primarily for system configuration, which includes the creation of new schema elements like attribute types and objectClasses. Most entry-monitoring tasks, such as searching and modifying, must be executed with the built-in command-line tools. Learn more in Managing entries.

Copyright © 2025 Ping Identity Corporation

You can find more information in Configuring a global administrator.

Steps

1. Start the PingDirectory server.

   ```
   $ bin/start-server
   ```

2. To access the administrative console, go to https://*<host>*:*<port>*/console/login.

   <host> is the host name of the server, and *<port>* is the port on which the server accepts connections from HTTPS clients. The host name and port were configured during installation.

   > **Note**
   >
   > The `<port>` is different for PingDirectory and each of its add-ons. The console that you access is specific to the add-on for which you are using it.

3. In the Username and Password fields, enter the root user DN credentials.

   > **Note**
   >
   > The root user distinguished name (DN) or the common name of a root user DN is required to sign on to the administrative console. For example, if the DN created when the server was installed is `cn=Directory Manager`, you can use `directory manager` to sign on to the administrative console.

4. Click Sign In.

   To set up an SSO connection to the administrative console, see Single sign-on with the administrative console.

   To run the administrative console in an external container, such as Tomcat, see Deploying the administrative console.

Setting the administrative console session timeout window

About this task

Copyright © 2025 Ping Identity Corporation

The default session timeout for the administrative console is 24 hours. You can adjust your session length to suit your organization's needs.

> **Note**
>
> When the session duration is exceeded, all inactive users are logged off automatically.

To change the default session timeout value:

Steps

1. To configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds, set the value as an `init` parameter either in the console or on the command line:

   Choose from:

   - Use the administrative console:

     1. Ensure that the Show Advanced Configuration check box is selected.

        
     2. In the Web Services and Applications list, select Web Application Extensions.
     3. In the Web Application Extension list, select Console.
     4. In the Init Parameter field, enter the desired timeout duration value in seconds.
     5. Click Save.

   - Use the command line to run the following:

     ```
     dsconfig set-web-application-extension-prop --no-prompt \
             --extension-name Console \
             --add init-parameter:server.sessionTimeout=<value in seconds>
     ```

2. To save your changes, restart the HTTP Connection Handler or the server:

   Choose from:

   - Restart the HTTP Connection Handler:

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:false

dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:true
```

- Restart the server using `bin/stop-server` with the `-R` or `--restart` option:

```
bin/stop-server --restart
```

Deploying the administrative console

To administer multiple servers from a single console instance, you can use Docker or a Java application server, such as Tomcat or Jetty, to run the administrative console as a standalone instance. Running the console as a standalone instance also allows you to make changes to the console without restarting the directory server's HTTPS connection handlers.

For more information on deployment options, click the following tabs.

Copyright © 2025 Ping Identity Corporation

Use Docker to run a standalone console

Using Docker to run a standalone administrative console
About this task

The administrative console is available as a standalone Docker image on Docker Hub. To see a `docker-compose` example that deploys a PingDirectory container with a corresponding console, see the PingDirectory getting started demo.

> **Note**
>
> The Ping Identity Helm charts also include support for the administrative console, which you should use when deploying the console in Kubernetes.

Steps

- **To connect with a PingDirectory server that is deployed in Docker, run the administrative console image in a local Docker deployment.**

  The network you use must match the network used by the PingDirectory server's container.

  Example:

  The following example deploys the standalone console image in a local Docker deployment with the console listening on port `8443` using the `pingnet` network:

  ```
  docker run \
      --name pingdataconsole \
      --publish 8443:8443 \
      --network pingnet \
      --detach \
      pingidentity/pingdataconsole:edge
  ```

  > **Important**
  >
  > You can change the first port in the `--publish` line based on what port you want to use on your local machine, but you shouldn't change the second port. To access the console outside of Docker on port `9443`, for example, use `9443:8443`.

- **To access the console, go to https://<*hostname*>:<*port*>/console/login and enter the following credentials.**

Copyright © 2025 Ping Identity Corporation

Field	Credential
Server	`<PingDirectory container name>:<LDAPS port>` **Note** The name of the server you enter on the sign-on page must match the name of the PingDirectory container you are trying to connect to along with the LDAPS port of that container. For example, use `pingdirectory:1636` to connect to a standalone PingDirectory Docker container on the same network.
Username	`administrator`
Password	`2FederateM0re`

Copyright © 2025 Ping Identity Corporation

Set up the console in a Tomcat environment

Setting up the administrative console on a Tomcat environment
Before you begin

To set up a standalone console, you need the `admin-console.war` file from the PingDirectory server's `resource/admin-console.zip` archive.

About this task

You can use the `.war` file with Java application servers, such as Tomcat or Jetty. The following example uses Tomcat as the server environment.

> **Note**
> Because Tomcat server version 10 has a defect with Spring Boot applications, use Tomcat 9 instead.

Steps

1. Download the Tomcat 9 `.zip` archive from the Apache Tomcat downloads page.
2. Extract the `.zip` archive.
3. To set up the Tomcat server, follow the instructions in the `RUNNING.txt` file from the extracted directory.
4. To keep the Tomcat server information from being exposed, in the `Host` section of the `Tomcat_directory/conf/server.xml` file, add the following line:

   ```
   <Valve className="org.apache.catalina.valves.ErrorReportValve" showReport="true"
   showServerInfo="false" />
   ```

   > **Note**
   > This information is sourced from the Smart Scanner website, where you can learn more about this Tomcat server vulnerability.

5. Copy the `admin-console.war` file into the `webapps` folder in the Tomcat root directory.
6. To start the Tomcat server, run `startup.sh` or `startup.bat` from the `bin` folder of the Tomcat root directory.

   Result:

   Tomcat automatically extracts the console from the compressed `.war` file into an exploded application directory and starts running the console.

7. To access the console, use the `admin-console` path from the Tomcat server path.

   By default, the path to access the console is `localhost:8080/admin-console`.

Configuring the administrative console

About this task

After you have deployed the PingDirectory administrative console, you can configure it.

Steps

1. Disable the embedded administrative console using `dsconfig` or the administrative console to configure connection handlers:

   Choose from:

   - To use `dsconfig`, run `dsconfig set-connection-handler-prop`:

     ```
     dsconfig set-connection-handler-prop \
         --handler-name "<HTTPS Connection Handler>"  \
         --reset web-application-extension
     ```

     > **Note**
     >
     > Replace *<HTTPS Connection Handler>* with the name of the connection handler hosting the administrative console.

   - To use the administrative console, open the console:

     1. On the Configuration page, go to Connection Handlers.
     2. In the Connection Handlers list, select the HTTP or HTTPS connection handler that is hosting the administrative console.
     3. Go to Web Application Extension and click the arrows to move Console from the Selected column on the right to the Available column on the left.

2. To finalize your changes, restart the HTTPS Connection Handler using `dsconfig`:

   Example:

   ```
   dsconfig set-connection-handler-prop \
       --handler-name "<HTTPS Connection Handler>" \
       --set enabled:false

   dsconfig set-connection-handler-prop \
       --handler-name "<HTTPS Connection Handler>" \
       --set enabled:true
   ```

3. Configure the administrative console's `application.yml` file.

   You can configure the standalone PingDirectory server administrative console by modifying the `/tmp/Console/WEB-INF/classes/application.yml` file. To see the different configuration settings listed in the default `application.yml` file included with the administrative console and what they do, expand the following table.

Copyright © 2025 Ping Identity Corporation

Setting	Description
`spring.*`	You can find information about these properties in the Spring API docs. You should not modify them.
`management.server.base-path`	Controls the prefix of the Spring Boot Actuator endpoints of the console application. You should not modify this setting.
`logging.level.*`	Controls the severity level of messages logged about these packages.
`log.console`	If this is set to `true`, the console logs messages to a file.
`log.file`	If logging is enabled, this specifies the file that the console will log to.
`PingData.SSO.OIDC.enabled`	If this is set to `true`, the console attempts to use OpenID Connect (OIDC) single sign-on (SSO) to bind to the managed server. If `false`, the console asks for a username and password.
`PingData.SSO.OIDC.issuer-uri`	The issuer URI to the OIDC provider.
`PingData.SSO.OIDC.client-id`	The client ID used with the OIDC provider.
`PingData.SSO.OIDC.client-secret`	The client secret used with the OIDC provider.
`PingData.SSO.OIDC.trust-store-file`	The file path to the trust store used when communicating with the OIDC provider.
`PingData.SSO.OIDC.trust-store-type`	The type of trust store specified by `PingData.SSO.OIDC.trust-store-file`.
`PingData.SSO.OIDC.trust-store-pin`	Specifies the password used with the trust store specified by `PingData.SSO.OIDC.trust-store-file`.
`PingData.SSO.OIDC.trust-store-pin-environment-variable`	Specifies the environment variable containing the password used with the trust store specified by `PingData.SSO.OIDC.trust-store-file`.
`PingData.SSO.OIDC.strict-hostname-verification`	If this is set to `true`, the console requires a matching host name on the OIDC provider certificate.
`PingData.SSO.OIDC.trust-all`	If this is set to `true`, the console accepts any OIDC provider certificate.

Copyright © 2025 Ping Identity Corporation

Setting	Description
`PingData.SSO.OIDC.username-attributes`	The LDAP attribute containing the username of the user the console is logging in as when using SSO.
`login.hide-server`	If this is set to `true`, the 'server' field is hidden on the sign on page.
`ldap.server`	Auto-populates the 'server' field on the sign-on page. If `login.hide-server=true`, this value determines which directory server the console tries to bind to.
`ldap.init-user`	Auto-populates the `user` field on the sign-on page.
`ldap.init-password`	Auto-populates the `password` field on the sign-on page.
`ldap.trust-store-file`	The file path to the trust store used when binding to the directory server.
`ldap.trust-store-type`	Specifies the type of trust store specified by `trust-store-file`.
`ldap.trust-store-pin`	Specifies the password used with the trust store specified by `trust-store-file`.
`ldap.trust-store-pin-environment-variable`	Specifies the environment variable containing the password used with the trust store specified by `trust-store-file`.
`ldap.file-servlet-name`	Specifies the name of the file servlet on the managed directory server to use when fetching generated `collect-support-data` (CSD) or server profiles.
`ldap.csd-task-enabled`	If this is set to `true`, the console has a button that has the managed directory server run a `collect-support-data` task.
`ldap.csd-destination-folder`	The file path to the folder where the managed directory server stores generated CSD files after running the `collect-support-data` task.
`ldap.profile-destination-folder`	The file path to the folder where the managed directory server stores generated server profiles after running the `generate-server-profile` task. **Important** Do not change this property.

Copyright © 2025 Ping Identity Corporation

Setting	Description
`branding.custom-folder`	The file path to the folder that holds custom `branding.properties`, `branding.css`, and `favicon.ico` files. If empty, default Ping Identity branding is used instead.
`configuration.complexity`	Determines the maximum complexity level for shown configuration objects. The possible values are `basic`, `standard`, `advanced`, and `expert`.
`server.sessionTimeout`	The amount of time a web session can remain idle before the user must sign on again. The time is set in seconds unless you use a time interval (h for hours or m for minutes). If not specified, the default is 24 hours.

> **Note**
>
> After modifying the `application.yml` file, you must restart the console for your changes to take effect.

4. Select servers to manage in the administrative console:
    1. To use the `application.yml` file to select a server for the administrative console to manage:
        1. Set the `ldap.server` property to the address of the LDAP server to bind to.
        2. Restart the console using the following command:

```
dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:false

dsconfig set-connection-handler-prop \
    --handler-name "<HTTPS Connection Handler>" \
    --set enabled:true
```

    2. To switch between managed servers in a single topology while signed on to the administrative console, in the Servers list, select the server that you want to manage.

    3. To select a server when SSO is not enabled and the `login.hide-server` property in `application.yml` is `false`:
        1. If you are signed on to the console, sign off of your current session.

Copyright © 2025 Ping Identity Corporation

2. Change the Server field value on the console sign-on page to the address of the LDAP server you want to manage.

4. To select a server when SSO is enabled, enter the console URL with the `ldap-hostname` and `ldaps-port` query parameters specified when accessing the console:

   ```
   https://<hostname>:<port>/console/login?ldap-hostname=<ldap.host>&ldaps-port=<ldaps-port>
   ```

   Example:

   In the following example URL, *<hostname>* is `localhost`, *<port>* is `443`, *<ldap.host>* is `ldap.host`, and *<ldaps-port>* is `636`:

   ```
   https://localhost:443/console/login?ldap-hostname=ldap.host&ldaps-port=636
   ```

Working with the schema

A schema is the set of PingDirectory server rules that define the structures, contents, and constraints of a directory information tree (DIT).

The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its PingDirectory server objects.

The PingDirectory server includes a default set of read-only schema files that define the core properties for the server. The administrative console provides a schema editor to view existing schema definitions and add new custom schema elements to your DIT.

> **Note**
>
> Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file results in an `Unwilling to Perform` result.

About the schema editor

The administrative console provides a user-friendly graphical editor with tabs to manage any existing schema components related to the directory information tree (DIT).

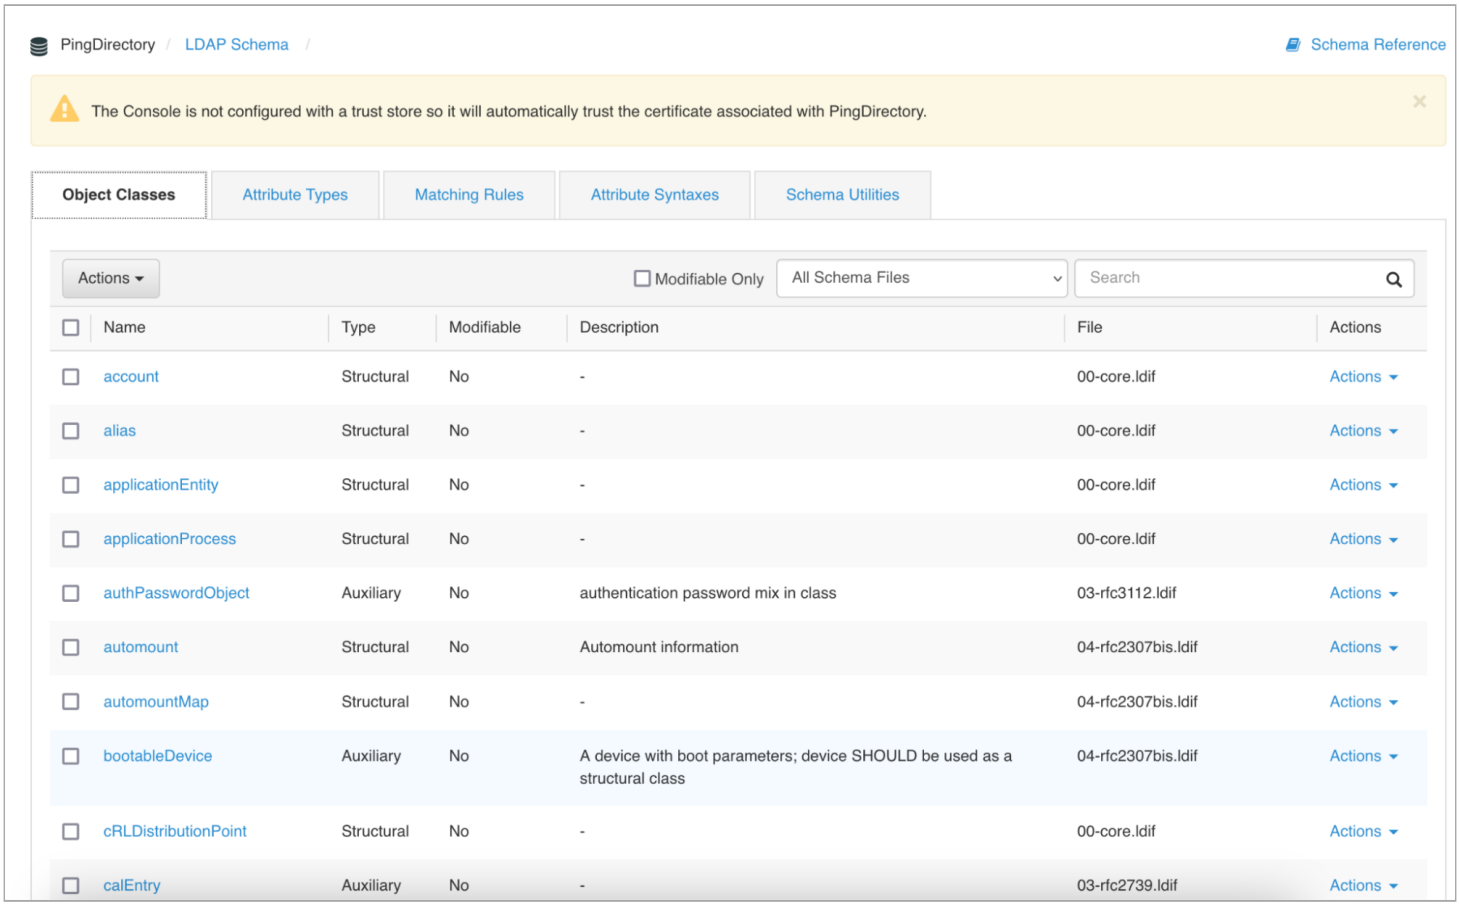
The list of existing schema components that can be managed includes:

- Object classes
- Attributes
- Matching rules
- Attribute syntaxes
- Schema utilities

Copyright © 2025 Ping Identity Corporation

The following list describes the tabs of the Schema Editor page:

- The Object Classes and Attribute Types tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.
- The Matching Rules and Attribute Syntaxes tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements.
- The Schema Utilities tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules.
- The Utilities tab supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.



Example schema editor page

The schema editor provides two views for each definition:

- The Properties View that breaks down the schema definition by its properties and shows any inheritance relationships among the attributes.
- The LDIF View that shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

Copyright © 2025 Ping Identity Corporation

Using the schema editor utilities

The schema editor provides a Schema Utilities tab where you can import new schema elements from a file and check schema compliance.

About this task

If you are importing a schema file, the system automatically checks for compliance before the import. If the definition doesn't meet schema compliance, the system displays an error message. However, you should check if your file is compliant with your schema before importing it.

To check schema compliance using the schema editor:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click LDAP Schema.
3. In the schema editor, click the Schema Utilities tab.
4. Add your schema definition using one of two methods:

   Choose from:

   - To have the system check an LDIF file, click Import Schema Elements and select a file to upload.
   - Copy and paste a new schema definition into the field.
5. Click Validate Entries.

   Result:

   If there is a problem with your definition, you see an error message.

Modifying the schema

You can create new attribute types or object classes in the schema editor.

When extending the schema, you should not modify native schema elements. Click the corresponding tab for the task that you want to perform.

Copyright © 2025 Ping Identity Corporation

Creating an attribute type

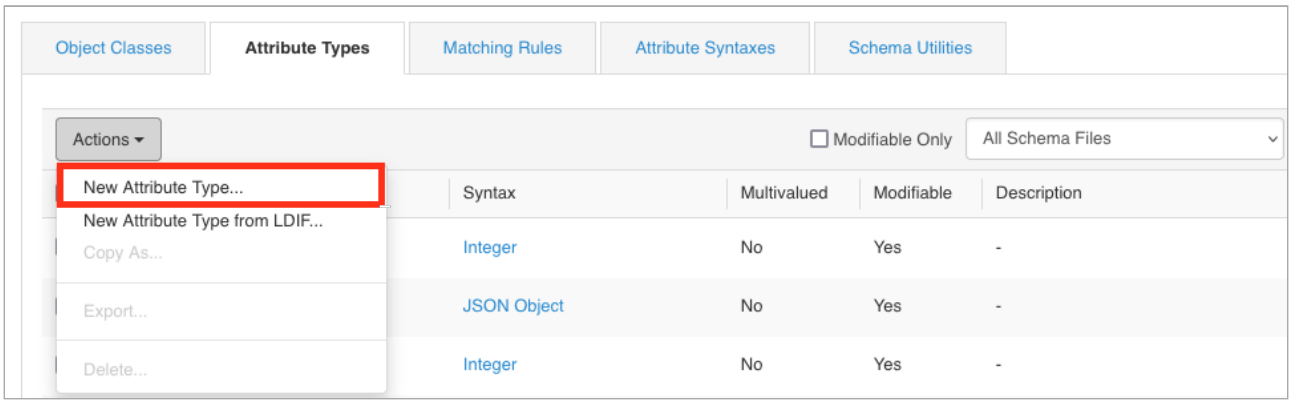
Creating a new attribute type using the schema editor

About this task

You can create attribute types for any new properties that logically belong to objects in your directory. To create a new attribute type:

Steps

1. **Start the administrative console.**
2. **In the top-level navigation menu, select LDAP Schema.**
3. **Click the Attribute Types tab, and then in the Actions list, select New Attribute Type.**



4. **Enter the properties for the new attribute types according to the help text.**
5. **Click Save.**

Copyright © 2025 Ping Identity Corporation

Creating an object class

Creating a new object class using the schema editor
Before you begin

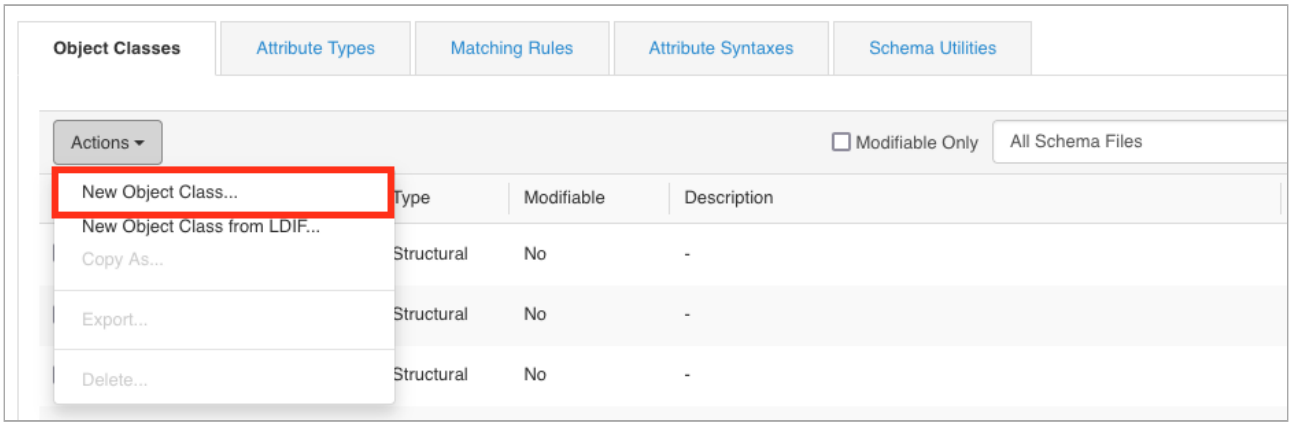
Make sure that any attributes that are part of the new object class are defined before creating the object class.

About this task

Creating a new object class is similar to creating a new attribute. To create a new object class:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, select LDAP Schema.
3. Click the Object Classes tab, and then in the Actions list, select New Object Class.



4. Enter the properties for the new object class.
5. In the Attributes box, filter the types of attributes required for the new object class. Click the right arrow to move it into the Required or the Optional box.

> **Note**
>
> All custom attributes appear at the bottom of the list in the **Attributes** box.

Copyright © 2025 Ping Identity Corporation

Modifying a schema definition

Modifying a schema definition
About this task

You can only edit schema definitions in the PingDirectory server that are read-write. The schema elements indicated by the Modifiable column in the schema editor's tables can be modified.

To modify a schema definition:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click Schema.
3. Click the Object Classes tab.
4. Select the object class that you want to modify, and then click Actions → Edit.

5. Make your changes and click OK.

Copyright © 2025 Ping Identity Corporation

Deleting a schema definition

Deleting a schema definition
About this task

You can only delete schema definitions in the PingDirectory server that are read-write. In general, you can only remove schema definitions in the Custom folder of the schema editor. Ensure that the schema element you are deleting is not currently in use.

To delete a schema definition:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click Schema.
3. Click the Object Classes tab.
4. Select the object class that you want to remove, and then in the Actions list, select Delete.

Result:

The Confirmation dialog box opens.

5. To delete the schema element, click Yes.

Managing tasks

The PingDirectory server has a tasks subsystem that allows you to schedule basic administrative operations.

Although the server provides a full suite of command line tools, several of these operations can be executed directly from the administrative console. See the following:

- Collecting support data from the administrative console
- Generating the server profile from the administrative console
- Creating a file based access log publisher
- About recurring tasks and task chains
- Scheduling LDIF export as a recurring task

Copyright © 2025 Ping Identity Corporation

Collecting support data from the administrative console

You can collect support data to aggregate data and send it to a support provider.

About this task

PingDirectory servers provide information about their current state and any problems encountered. If a problem occurs, run the Collect Support Data tool. The tool aggregates all relevant support files into a `.zip` file that can be sent to a support provider for analysis. The tool also runs data-collector utilities, such as `jps`, `jstack`, and `jstat`, plus other diagnostic tools for the operating system.

The tool can only archive portions of certain log files to conserve space so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

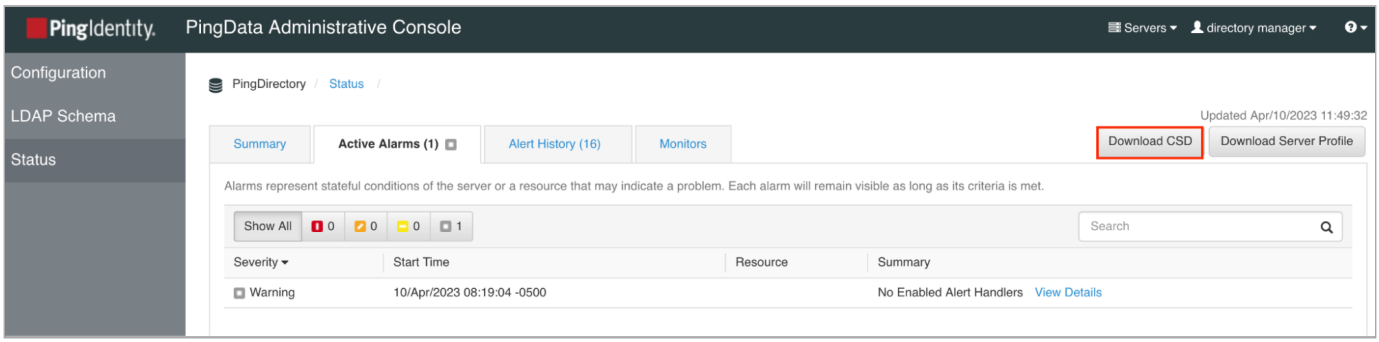
The data collected by the Collect Support Data tool can vary between systems. The data collected includes the configuration directory, summaries and snippets from the logs directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

> **Important**
>
> The Collect Support Data task is not recommended on directory servers running in a Docker container because this container has limited memory. If running the Collect Support Data task exhausts the container's memory, then the server will crash.

To run this tool from the administrative console:

Steps

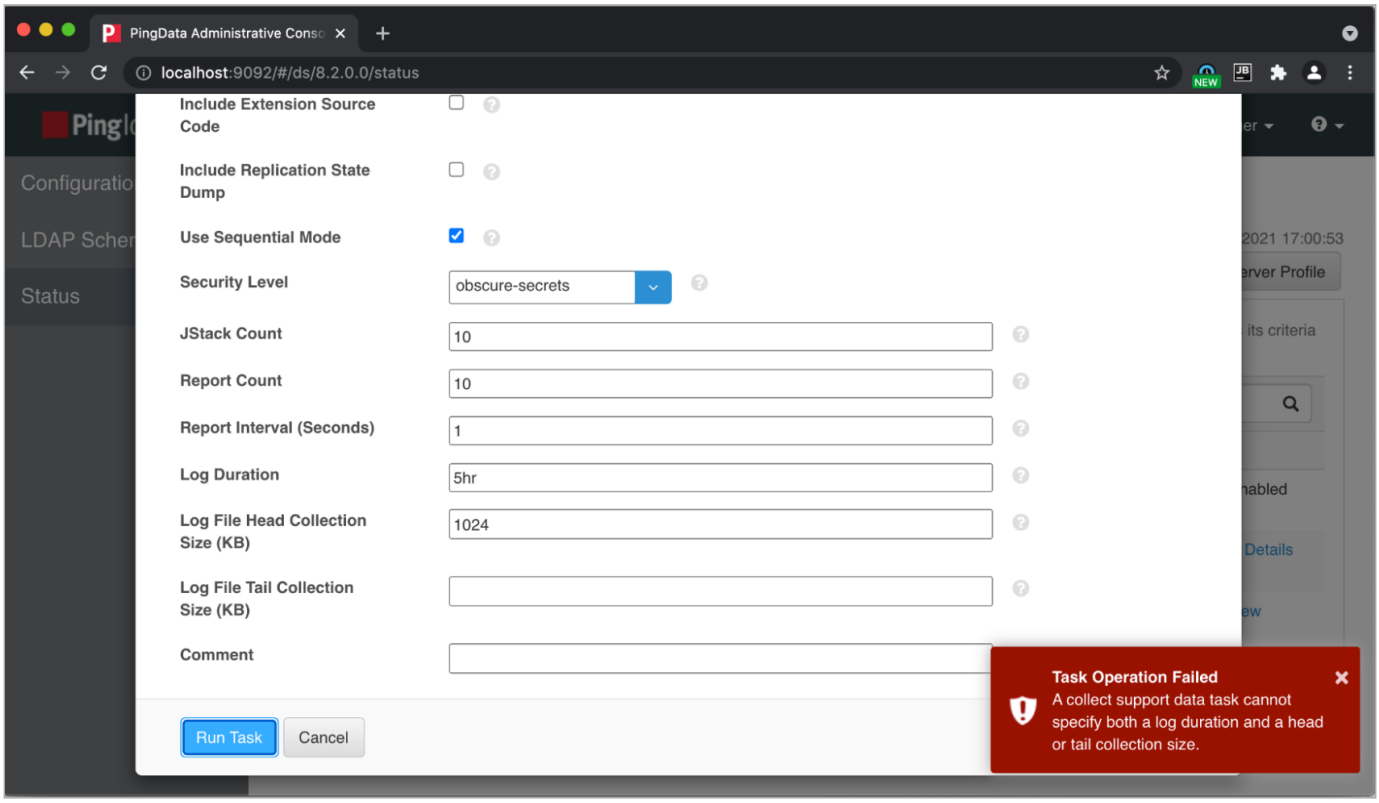
1. Start the administrative console.
2. In the top-level navigation menu, select Status.
3. Click Download CSD.



4. In the Collect Support Data window, populate the properties according to the help text.
5. Click the Run Task button.

> **Note**
>
> If there is any issue with scheduling the task, an error message displays in the bottom-right corner of the page. Resolve the issue as described to proceed.

Copyright © 2025 Ping Identity Corporation



6. If the task is scheduled successfully, a confirmation message appears in the bottom-right corner of the page.
7. Wait for the task to complete.

   This can take several minutes.
8. After the task is complete, the generated files are automatically downloaded to the `<directory>/csd-files` directory.

> **Note**
>
> When the administrative console sends a request to the PingDirectory server to generate the support files, the `<directory>/csd-files` is the default path for storing the resultant file package. This default path can be modified in the `<directory>/console/WEB-INF/classes/application.yml` directory.

Generating the server profile from the administrative console

Run the Download Server Profile task to generate a format for setting up and configuring new server instances.

About this task

A server profile defines a format for the configuration of a server by combining the following files into a single, concrete structure:

- `dsconfig`
- Initial DIT
- Setup arguments

Copyright © 2025 Ping Identity Corporation

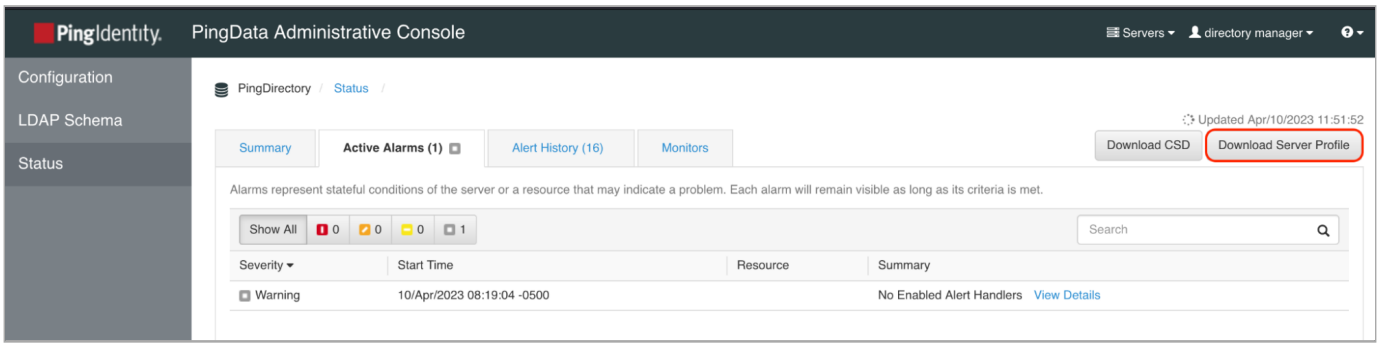
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks–like Docker, Kubernetes, and Ansible–is reduced considerably. For more information, see Server profiles.

To run this tool from the administrative console:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, select Status.
3. Click Download Server Profile.



4. In the Generate Server Profile window, enter path values according to the help text.
5. Click the Run Task button.
6. Wait for the task to complete.

   This can take several minutes.
7. After the task is completed, the server profile is downloaded to the `<directory>/profile-files` directory.

> **Note**
>
> When the administrative console sends a request to the PingDirectory server to generate the server profile, `<directory>/profile-files` is the default path for storing the resultant file package. This default path can be modified in the `<directory>/console/WEB-INF/classes/application.yml` directory.

Creating a file based access log publisher

The PingDirectory server supports different types of log publishers that can be used to provide monitoring information for operations, access, debug, and error messages that occur during normal server processing.

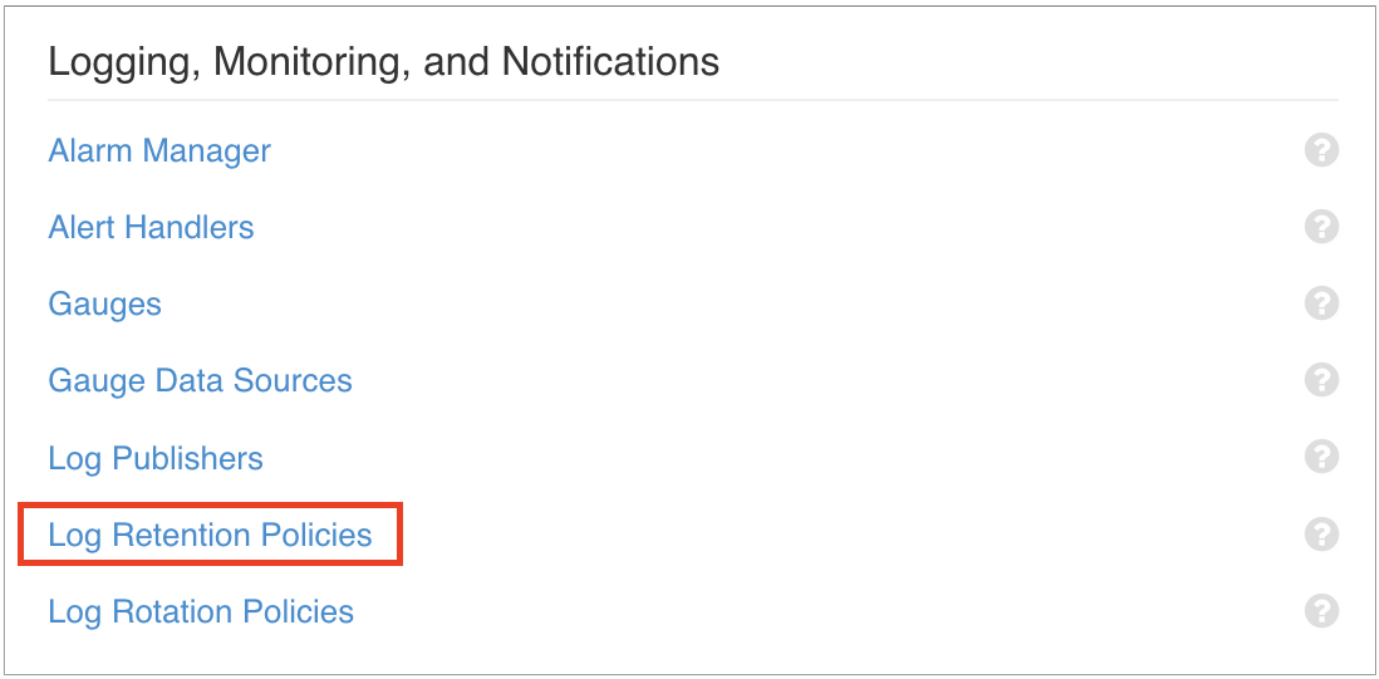
About this task

Copyright © 2025 Ping Identity Corporation

The server provides a standard set of default log files as well as mechanisms to configure custom log publishers with their own log rotation and retention policies. The filed based access log publisher publishes access messages with information about the operations processed by the server. For more information, see Types of log publishers.

Steps

1. Start the administrative console.
2. In the main menu, select Configuration, and in the Logging, Monitoring, and Notifications section, select Log Retention Policies.



3. In the New Log Retention Policy list, select your desired policy and fill out the fields according to the help text.
4. Click Save.
5. Return to the Logging, Monitoring, and Notifications section and select Log Rotation Policies.
6. In the New Log Rotation Policy list, select your desired policy and fill out the fields according to the help text.
7. Click Save.
8. Return to the Logging, Monitoring, and Notifications section and select Log Publishers.
9. In the New Log Publisher list, select File Based Access Log Publisher.
10. Fill out the fields according to the help text. In the Rotation Policy field of the Log File Management section, select your desired rotation policy in the Available list, and click the Add Value button to activate the policy.
11. Repeat step 10 for the Retention Policy field.
12. Click Save.

Copyright © 2025 Ping Identity Corporation

About recurring tasks and task chains

You can use the admin console to create recurring tasks and task chains to perform regular maintenance tasks for the PingDirectory server. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations.

Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

Create recurring tasks and add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry
- The task-specific attributes to include in the task entry, if any
- Whether to alert on task start, success, or failure
- Any addresses to email on task start, success, or failure
- Whether to cancel an instance of the task if it is dependent upon another task and that task does not complete successfully

After you create a task, add one or more tasks to a task chain and schedule the chain.

A recurring task chain includes:

- An ordered list of the tasks to invoke
- The months, days, times, and time zones in which each task can be scheduled to start
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown
- The behavior to exhibit if the server is offline when the start time occurs

> **Note**
>
> Changing the schedule for an existing recurring task chain only takes effect the next time an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. Existing scheduled instances still run at the originally scheduled time. When that run is complete, the server schedules the next iteration according to the then-current schedule logic.
> You cannot cancel the existing scheduled instance to make the next instance run earlier. When you cancel an instance of a recurring task chain, the server automatically schedules the next instance for the next time that matches the scheduling criteria. It never schedules a new instance for earlier than or the same time as one that you manually canceled.

Scheduling LDIF export as a recurring task

You can create an LDIF export recurring task and add it to a recurring task chain to automate the export with a custom schedule.

About this task

Copyright © 2025 Ping Identity Corporation

For new installations, the server exports LDIF data by default every day at 1:05 a.m. in the default time zone for the Java Virtual Machine (JVM), which is generally the time zone configured for the underlying system. At the scheduled time, the server exports the contents of each public backend to a file in the `<server-root>/ldif` directory.

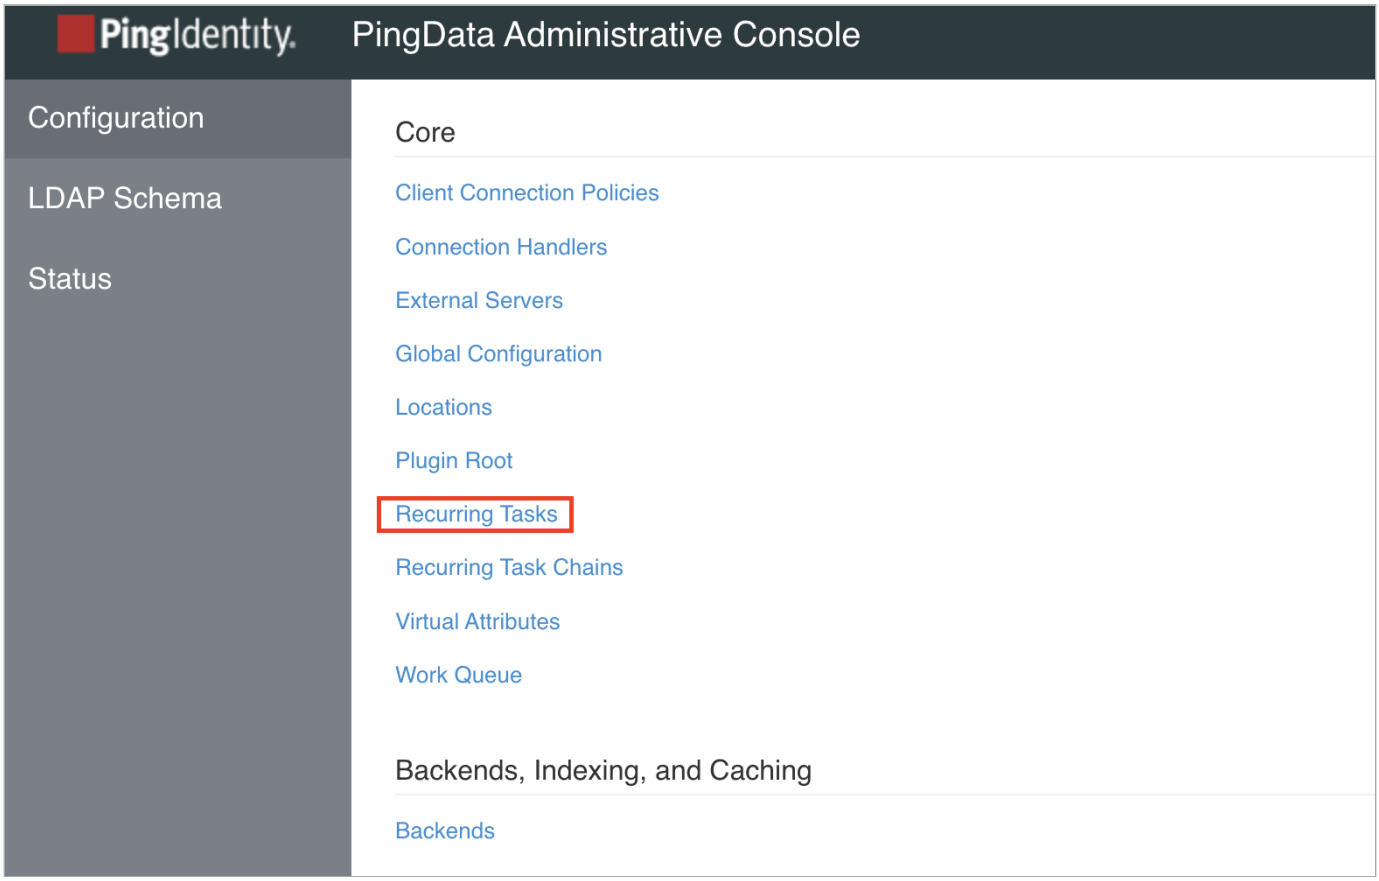
> **Note**
>
> Public backends are non-administrative backends containing user-supplied data.

If the global configuration is set to encrypt LDIF exports by default, the server compresses and encrypts the LDIF exports. If encryption is configured during server setup, LDIF exports are encrypted by default. The LDIF exports are rate-limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days. The recurring task chain is created in instances that are updated to this release. However, the task chain is not enabled by default.

To create a recurring LDIF export task:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, select Configuration, and in the Core section, select Recurring Tasks.

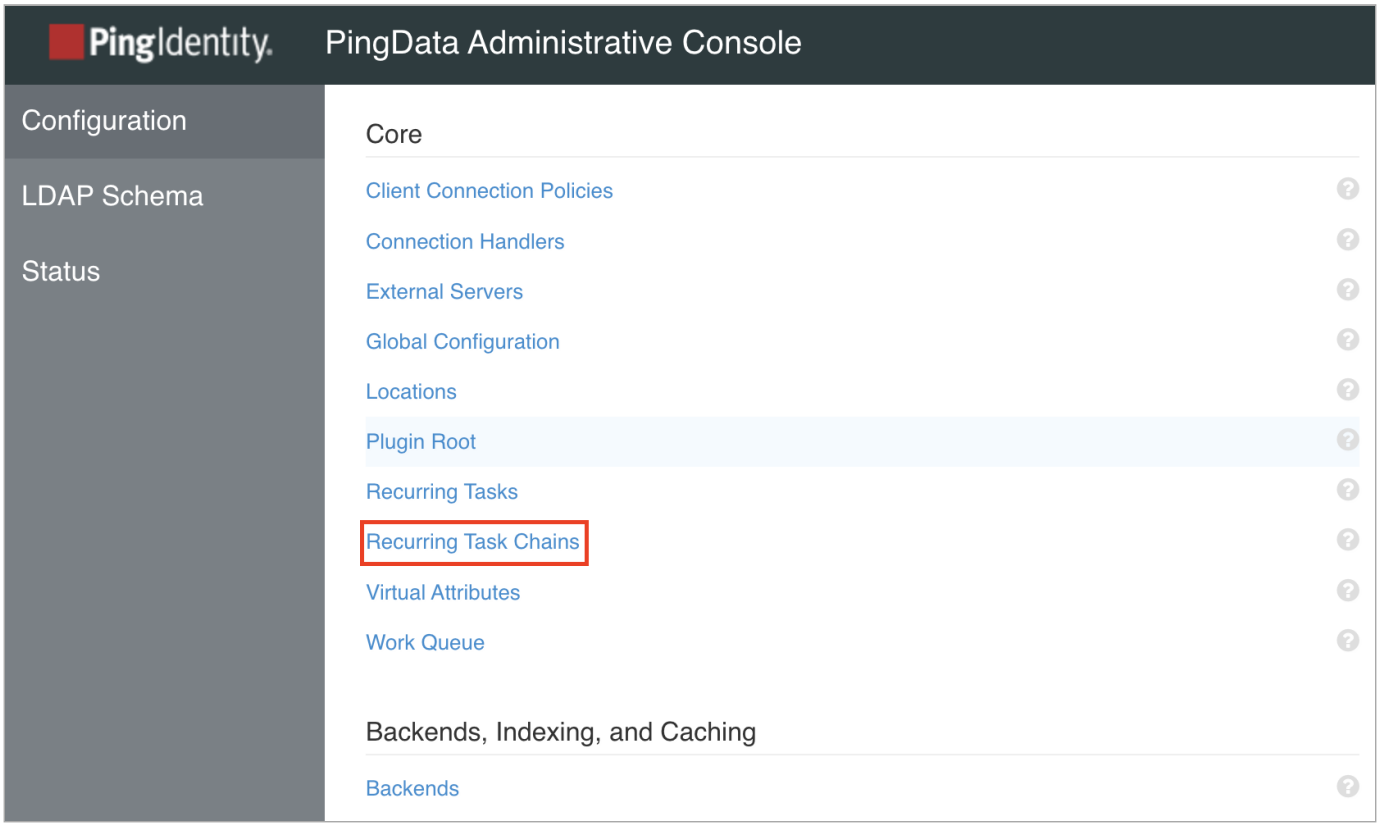


3. In the New Recurring Task list, select LDIF Export Recurring Task.
4. In the Name field, enter the desired name of the task.
5. Populate the rest of the task's properties according to the help text.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You must configure a value for either the **Retain Previous LDIF Export Count** field, which specifies the minimum number of previous LDIF exports preserved after a new export, or the **Retain Previous LDIF Export Age** field, which specifies the minimum age of previous LDIF exports preserved after a new export. If each of these properties has a value, then only LDIF exports failing to satisfy both criteria are candidates for removal.

6. Click Save.
7. In the Core section, in the Configuration menu, click Recurring Task Chains.



8. Click New Recurring Task Chain.
9. In the Name field, enter the desired name of the task chain.
10. In the Recurring Task section, select your newly created recurring task and any other tasks you want to schedule.
11. Enter the scheduling details according to the help text.
12. Click Save.

Monitoring with the administrative console

The administrative console can be used to monitor items, such as disk space usage, active operations in the server, and alarms raised.

About this task

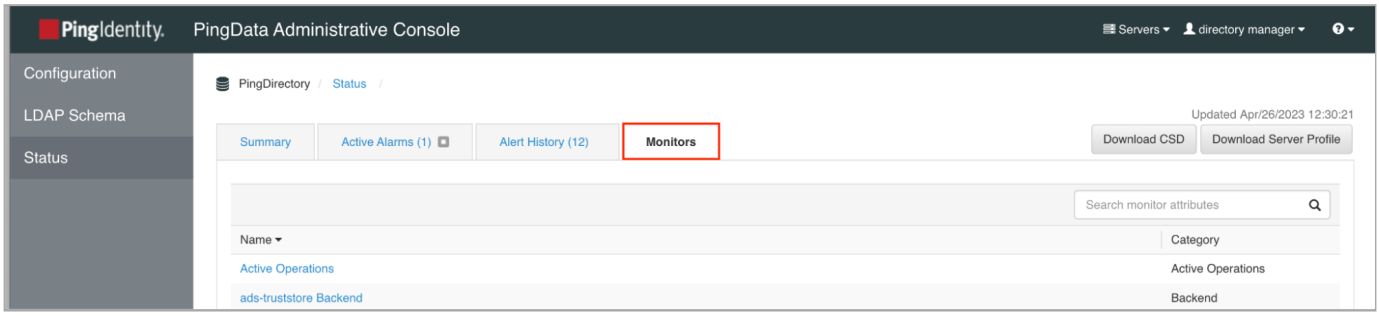
Copyright © 2025 Ping Identity Corporation

The console provides a status option that accesses the server's monitor content.

To view the monitor dashboard:

Steps

1. In your browser, go to http://<*server-name*>:<*port*>/console.
2. Enter the root user distinguished name and password. Click Login.
3. In the top-level navigation menu, select Status.
4. Click the Monitors tab.



Result

The Monitors page opens, and you can monitor your server by selecting a monitor attribute.

Removing the administrative console

You can remove the administrative console from your PingDirectory deployment.

About this task

You can configure and operate the PingDirectory server without the administrative console by using the command-line interface (CLI). There aren't any server functions available from the administrative console that aren't also available through the CLI.

Steps

Follow these steps to remove the administrative console from your PingDirectory deployment:

1. Stop the server.

   Example:

   ```
   $ bin/stop-server
   ```

2. Remove the `console.war` file from the `webapps` directory.
3. Edit the `config/config.ldif` file as follows:
   1. In the `dn: cn=HTTPS Connection Handler,cn=Connection Handlers,cn=config` section, remove the following line:

Copyright © 2025 Ping Identity Corporation

```
ds-cfg-web-application-extension: cn=Console,cn=Web Applications,cn=config
```

2. In the `dn: cn=Console,cn=Web Applications,cn=config` section, remove the following lines:

```
objectClass: ds-cfg-console-web-application-extension
objectClass: ds-cfg-web-application-extension
objectClass: top
cn: Console
ds-cfg-description: The Administrative Console
ds-cfg-log-file: logs/webapps/console.log
```

3. Save your changes.

4. Restart the server.

Example:

```
$ bin/start-server
```

Result:

You have successfully removed the administrative console from your PingDirectory deployment.

> **Note**
>
> Upgrading the server after removing the administrative console restores the `console.war` file but doesn't affect the console configurations that you removed from `config.ldif`. The administrative console won't run with these configurations removed. Optionally, you can remove `console.war` after completing a server upgrade.

Configuring Soft Deletes

PingDirectory server 3.2.4 and later supports a soft-delete feature.

This feature preserves a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

About soft deletes

Soft deletes preserve a deleted entry's attribute and uniqueness characteristics so it can be undeleted or permanently removed at a later date.

The standard implementation of an LDAP server allows adding, renaming, modifying, searching, comparing, and deleting one or more entries. By specification, the `delete` operation permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. The `delete` operation severs any associations such as references and group memberships. Meta attributes, such as operational attributes, which can be unique to an entry like `entryUUID`, are lost or different if the same entry is re-added to the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

There are cases where a company might want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company might want to retain account and subscriber entries for their users who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, can be tracked and recovered while a user is deleted or when the user returns as an active customer. Soft deletes facilitate this use-case.

A delete request can result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class to the entry, `ds-soft-delete-entry`, which saves the entry in a hidden state. All active references and group memberships are then removed. While in this hidden state, clients cannot access soft-deleted entries under normal operating conditions. Only clients with the `soft-delete-read` privilege can interact with soft-deleted entries.

To allow soft deletes, the PingDirectory server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted, but a different John Smith was added to the user accounts system, both entries can reside in the DIT without conflict. One entry would exist in a soft-deleted state and the other in an active state. The PingDirectory server extends this capability by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an `undelete` operation. The same uniqueness constraints that apply when adding a new user to the PingDirectory server are enforced when a soft-deleted entry is undeleted. In the previous example, John Smith was soft-deleted, but a different John Smith with the same `uid` as the original John Smith was later added to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators must modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular `delete` operation on it. This operation, called a hard delete, permanently removes a soft-deleted entry from the server. You can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The PingDirectory server provides tool arguments that can use the soft delete request control, the hard delete request control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating PingDirectory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, make sure all servers in the replication cluster support soft deletes and have identical soft delete configurations.

General tips on soft deletes

Administrators should be aware of the following tips about soft deletes:

- The LDAP SDK and Server SDK both fully support soft-deletes.
- There is little performance difference between retrieving a regular entry and a soft-deleted entry. However, there might be a performance impact when a search operation has to match criteria, such as `uid=john.smith`, for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it might take the server more time to retrieve and try to match the criteria before it can return the results.

Copyright © 2025 Ping Identity Corporation

- The soft delete feature fully supports uncached attributes and uncached entries. For more information, see Uncached attributes and entries.
- Soft-deletion is allowed for leaf nodes only. Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- There are two available state options for soft-deletes:
    - Administrators can permanently delete a soft-deleted entry or undelete the entry.
    - Administrators cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.
- Soft-deleted users have no privileges. Soft-deleted users do not have the ability to bind to the PingDirectory server or have authentication access. They cannot change their passwords and cannot undelete themselves. Soft-deleted entries also cannot be used as an authorization identity using the proxied authorization or immediate client control. The soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry retains the same privileges it originally had before being soft deleted. One possible exception to this are privileges assigned by virtual attributes that no longer match the newly-undeleted entry. Those entries do not retain their original privileges.
- Soft-deleted entries might not be accessible from alternate access methods like SCIM.
- Soft-deleted entries can be modified but not renamed. Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrator has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a `modify DN` operation results in an `UNWILLING_TO_PERFORM` result code.
- Replication has access to the LDAP operations with soft delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers and is then replicated, this results in a replication conflict. For maximum compatibility, all servers in a replication cluster should support soft deletes and have identical soft delete configuration.
- Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- There are no special configuration steps to configure soft deletes on the PingDirectoryProxy server. The soft-deleted entry is routed directly to the underlying PingDirectory server. There is one exception: in an entry-balancing deployment, the PingDirectoryProxy server is responsible for routing the soft-deleted entry to the PingDirectory server containing the originally soft-deleted item. As with standard entry-balanced deployments, it is not possible to use `moddn` to undelete an entry to a different PingDirectory server.
- The default behavior includes soft-deleted entries as part of the `export-ldif` operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- The soft delete feature can be used with users who have proxied authorization privileges.
- For customers using the PingDataSync server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular `delete` operation, and an actual undelete operation appears in the changelog as a regular `add` operation.

Copyright © 2025 Ping Identity Corporation

- References to a deleted DN are not restored by the referential integrity plugin when you undelete a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin removes this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin does not add the entry back to the group.
- The soft delete policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`, that perform the purging of soft-deleted entries. For more information, see Configuring Soft-Delete Automatic Purging.
- The root user account, such as `cn=Directory Manager`, has access to all of the controls needed to run the soft delete operations by default. For non-root users, you must grant access to these soft delete controls using access control rules. An example is shown in step 1 of Configuring a user to use soft or hard delete controls. The following soft delete controls are available to non-root users:

Soft delete request control

Allows the user to perform a soft delete operation. The object identifier (OID) for the control is 1.3.6.1.4.1.30221.2.5.20.

Soft delete response control

Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.

Hard delete request control

Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.

Undelete request control

Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.

Soft-deleted entry access request control

Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24.

> **Note**
>
> A bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the soft-deleted entry access request control. For example, if a user can successfully run **`dump-dns`** or **`ldap-diff`**, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents through the output of one of those tools.

Configuring soft deletes on the server

Steps

- Use any of the following methods to configure soft deletes on the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

Method	Description
Using a soft-delete policy and global configuration property	Configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete requests. To enter a soft delete request, the `ldapmodify` or `ldapdelete` command requires the `--useSoftDelete` option. A delete request that does not have the `--useSoftDelete` option is treated as a hard delete, which permanently removes the entry. For more information, see Configuring soft deletes as a global configuration.
Using connection criteria	Configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria have their deletes processed as soft deletes. For more information, see Configuring soft deletes by connection criteria.
Using request criteria	Configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria have their deletes processed as soft deletes. For more information, see Configuring soft deletes by request criteria. **Note** You can define both connection criteria and request criteria. When both criteria exist within a soft-delete policy, connection criteria is processed first, then request criteria.

Configuring soft deletes as a global configuration

Configure the soft delete feature by creating a soft delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft delete requests.

About this task

For this configuration, use the `--useSoftDelete` option used with the `ldapmodify` or `ldapdelete` commands to send the delete using the soft delete request control. Without the `--useSoftDelete` option, any delete is processed as a hard delete.

To configure soft deletes as a global configuration:

Steps

1. Configure a soft delete policy using the `dsconfig` command.

Copyright © 2025 Ping Identity Corporation

The soft delete configuration requires a soft delete policy, which enables the feature on the server.

Example:

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy
```

2. Configure the soft delete as a global configuration property using the `dsconfig` command.

   This command sets up the soft delete controls necessary to send them as a request.

   Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

Configuring a user to use soft or hard delete controls

To use soft deletes, a user must have access to the appropriate controls. By default, only the Directory Manager has access to these controls.

About this task

The user must also have the `soft-delete-read` privilege. Access control instructions (ACIs) allow the user to:

- Modify target entries
- Use the soft delete and undelete controls
- Use the soft-deleted entry access control to modify soft-deleted entries
- Use the hard delete request control to permanently delete an soft-deleted entry

The `uid=admin,dc=example,dc=com` user that is installed with the sample data during setup already has an ACI giving it access to user entries as follows.

```
(targetattr="*")(version 3.0; acl "Grant full access for the admin user";
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Steps

1. Add the following ACIs to the base suffix or other point in the directory information tree (DIT) to restrict the scope as required.

   Example:

Copyright © 2025 Ping Identity Corporation

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; acl "Allow admins to use the Soft Delete Request Control and Soft Delete Response
Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; acl "Allow admins to use the Hard Delete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; acl "Allow admins to use the Undelete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)

(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; acl "Allow admins to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

2. Add the `ds-privilege-name` attribute to the user with the value `soft-delete-read`.

   Example:

```
$ ./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
# Successfully connected to localhost:1389.

dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete

# Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
# Result Code:  0 (success)
# Soft Delete Response Control:
#      OID:  1.3.6.1.4.1.30221.2.5.21
#      Soft-Deleted Entry DN:  entryUUID=8dbe8cb4-1aa3-41c5-88ec-a6280eeff918+uid=user.
10,ou=People,dc=example,dc=com
```

Searching for soft deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent deleted entries. The updated `ldapsearch` tool supports these types of searches.

About this task

There are three different ways to search for soft-deleted entries.

Steps

- To perform a base-level search on a soft-deleted entry by distinguished name (DN), run the `ldapsearch` command and specify the base DN of the specific soft-deleted entry that you are searching for.
- To filter your search by `ds-soft-delete-entry` object class, run a search for all soft-deleted entries with the `ldapsearch` command with a filter on the `ds-soft-delete-entry` object class.
- To return soft-deleted entries, use the soft-delete-entry-access-control with the LDAP search.

Copyright © 2025 Ping Identity Corporation

The `ldapsearch` tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:

- Return only soft-deleted entries.
- Return non-deleted entries along with soft-deleted entries.
- Return only soft-deleted entries in undeleted form.

Running a base-level search on a soft-deleted entry

Use the command line to run a base-level search on a soft-deleted entry.

Steps

- Run the `ldapsearch` command using the base distinguished name (DN) of the specified soft-deleted entry.

  Example:

```
$ bin/ldapsearch \
  --baseDN entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
  --searchScope base "(objectClass=*)"
```

  Result:

```
# Soft-deleted entry DN:
# entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.

```

Running a filtered search by soft-delete-entry object class

Retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

Copyright © 2025 Ping Identity Corporation

Steps

- Run the `ldapsearch` command to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class.

  Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  "(objectclass=ds-soft-delete-entry)"
```

Running a search using the soft delete entry access control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the soft delete entry access control.

About this task

You can use the `--control` option with the soft delete entry access control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual soft delete entry access control OID, `1.3.6.1.4.1.30221.2.5.24`.

Steps

1. To return only soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries`.

   Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries without-non-deleted-entries \
  --searchScope sub "(objectclass=*)"
```

2. To return non-deleted entries along with soft-deleted entries, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries`.

   Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries with-non-deleted-entries \
  --searchScope sub "(objectclass=*)"
```

3. To return only soft-deleted entries in undeleted form, run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form`.

   Some applications require access to all entries in the server, including both active and soft-deleted entries.

   Example:

   The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". The object class, `ds-soft-delete-entry`, is also not displayed.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries deleted-entries-in-undeleted-form \
  --searchScope sub "(ds-soft-delete-from-dn=*)"

# Soft-deleted entry DN:
# entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c+uid=user.14,ou=People,dc=exam-
ple,dc=com
dn: uid=user.14,ou=People,dc=example,dc=com
objectClass: top

```

Undeleting a soft-deleted entry using the same RDN

When you decide to undelete a soft-deleted entry, if the original Relative Distinguished Name (RDN), such as `uid=user.1`, is still available, you can perform the undelete using that same RDN.

About this task

To undelete a soft-deleted entry, use **`ldapmodify`** with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the distinguished name (DN) that the entry is undeleted to, and the `ds-undelete-from-dn` attribute, which is the entry that is undeleted from. An undelete requires the `add` changetype so that the entry can be re-added to the server.

Steps

- To undelete a soft-deleted entry using the same RDN, run the command **`ldapmodify`** with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore.

  Example:

  The first DN is the entry to undelete to and the `ds-undelete-from-dn` is the soft-delete entry to undelete from.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.1,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Result:

The `--allowUndelete` option sends the soft undelete request control to the server.

Undeleting a soft-deleted entry using a new RDN

In some cases, you can allocate the original Relative Distinguished Name (RDN), `uid=user.1`, to a new user. This is permitted when the entry is in a soft-deleted state. To properly undelete this entry, you must specify a new RDN value you can use to restore the entry.

About this task

In this case, specifying the RDN of `uid=user.5` undeletes the original entry, but with the new distinguished name (DN) in the following example, and the `uid` attribute on the entry is updated with the new value of `user.5`. All other attributes of the users entry, including the `entryUUID`, remain unchanged.

To undelete a soft-deleted-entry using a new RDN:

Steps

1. Run the command `ldapmodify` to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`.

   > **Note**
   >
   > If you specify a DN that already exists in the PingDirectory server as a normal entry, this leads to an `entry already exists` error. Ensure the DN that you are undeleting the entry to does not already exist.

   Example:

   ```
   $ bin/ldapmodify --allowUndelete
   dn: uid=user.5,ou=People,dc=example,dc=com
   changetype:add
   ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
   ```

2. To view the results, run `ldapsearch`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dn: uid=user.5,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.
uid: user.5
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
employeeNumber: 1
initials: AKA
givenName: Aartjan
pager: +1 197 025 3730
mobile: +1 890 430 9077
cn: Aartjan Aalders
sn: Aalders
telephoneNumber: +1 094 100 7524
street: 59748 Willow Street
homePhone: +1 332 432 4295
l: Green Bay
mail: user.3@maildomain.net
st: TN
entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4
```

Result:

The RDN and the `uid` attribute has changed.

Modifying a soft-deleted entry

Modify a soft-deleted entry the same as a regular entry using the `ldapmodify` tool. The entry remains hidden in its soft-deleted state after the change.

About this task

Soft-deleted entries can be modified like any regular entry. The only restriction is that you cannot change the distinguished name (DN) or run a `moddn` operation. To move a soft-deleted entry from one machine to another, use the `move-subtree` command and specify the DN of the soft-deleted entry.

> **Note**
>
> To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

Steps

- To modify a soft-deleted entry, run the `ldapmodify` command and specify the soft-deleted DN.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
# Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.
1,ou=People,dc=example,dc=com
# MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.
1,ou=People,dc=example,dc=com
```

Hard deleting a soft-deleted entry

Use this section for instructions on hard deleting a soft-deleted entry from the server when soft-deleted entries are configured as global configuration for requests or configured using a connection or request criteria.

About this task

Consider the following when hard deleting a soft-deleted entry:

Steps

- To permanently remove a soft-deleted entry from the server, run `ldapdelete` on the soft-deleted entry for soft-deleted entries.
- To hard delete a soft-deleted entry, use `ldapdelete` with the `--useHardDelete` option.

  The Hard Delete Request Control works with soft deletes. It applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running `ldapdelete` with the Hard Delete Request Control, such as using the `--useHardDelete` option, guarantees that any entry permanently deletes.

Hard deleting a soft-deleted entry (global configuration)

About this task

Permanently remove a soft-deleted entry from the PingDirectory server.

Steps

- To permanently remove a soft-deleted entry, run `ldapdelete` on the soft-deleted entry.

  Example:

  The following example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
  entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You cannot soft-delete an already soft-deleted entry. If you use the **`--useSoftDelete`** subcommand with the **`ldapdelete`** operation on a soft-deleted entry, an error message generates. `DELETE operation failed. Result Code: 53 (Unwilling to Perform) Diagnostic Message: DELETE operation failed.`

Hard deleting a soft-deleted entry (connection or request criteria)

About this task

Permanently remove a soft-deleted entry from the PingDirectory server.

Steps

- To permanently remove a soft-deleted entry run **`ldapdelete`** with the **`--useHardDelete`** subcommand on the soft-deleted entry.

  Example:

  The following example assumes that you configured soft deletes using a connection or request criteria.

  ```
  $ bin/ldapdelete --useHardDelete \
    entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
  ```

Configuring soft deletes by connection criteria

Use this section for instructions on enabling and disabling soft deletes with connection criteria.

The PingDirectory server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria.

To configure soft deletes:

- Define the connection criteria used in a client connection policy.
- Configure the soft delete connection criteria in the soft-delete policy.

Enabling soft deletes by connection criteria

Before you begin

Configure a soft-delete policy and global configuration, as shown in Configuring Soft Deletes as a Global Configuration.

Steps

1. Create a connection criteria using **`dsconfig`** and name it `Internal Applications`.

   Example:

   In the following example the soft delete connection criteria is configured for a member of a line of business (LOB) applications group connecting from the 10.8.1.0 network.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Internal Applications" \
  --type simple \
  --set included-client-address:10.8.1.0/8 \
  --set "all-included-user-group-dn:cn=LOB Applications,ou=Groups,dc=example,dc=com"
```

2. Set the `auto-soft-delete-connection-criteria` property to the soft-delete connection criteria you created in step 1.

   Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-connection-criteria:Internal Applications"
```

Disabling soft deletes by connection criteria

About this task

Disable soft deletes by connection criteria.

Steps

- Reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

  Example:

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-connection-criteria
```

Configuring soft deletes by request criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria are treated as a soft delete.

The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria.

> **Note**
>
> Both a soft delete by connection criteria and a soft delete by request criteria can be present in a soft delete policy.

Enabling soft deletes by request criteria

Before you begin

Configure a soft-delete policy and global configuration.

Steps

1. To configure request criteria for soft deletes, use the `create-request-criteria` option with `dsconfig`.

Copyright © 2025 Ping Identity Corporation

Example:

In this example, the soft delete request criteria is configured for an external delete request from a member of the internal applications group matching an entry with object class `inetorgperson` with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name "Soft Deletes" \
  --type simple \
  --set "description:Requests for soft delete" \
  --set operation-type:delete \
  --set operation-origin:external-request \
  --set "connection-criteria:Internal Applications" \
  --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
  --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

2. In the soft delete policy you previously created, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

   Example:

   ```
   $ bin/dsconfig create-soft-delete-policy \
     --policy-name default-soft-delete-policy \
     --set "auto-soft-delete-request-criteria:Soft Deletes"
   ```

Disabling soft deletes by request criteria

Steps

- To disable soft deletes by request criteria, reset the soft delete policy.

  Example:

  ```
  $ bin/dsconfig set-soft-delete-policy-prop \
    --policy-name default-soft-delete-policy \
    --reset auto-soft-delete-request-criteria
  ```

Configuring soft-delete automatic purging

By default, PingDirectory server retains soft-deleted entries indefinitely.

For companies that want to set up automatic purging of soft-deleted entries, the server provides two configurable properties on the soft delete policy: the maximum retention time for all soft-deleted entries and the retained number of soft-deleted entries.

> **Note**
>
> These changes take effect without requiring a server restart.

Copyright © 2025 Ping Identity Corporation

Configuring soft-delete automatic purging

About this task

To enable automatic purging, you can change the retention time, the retained number of entries, or both. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), can be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc.

> **Note**
>
> After you configure the properties, the changes take effect immediately without the need for a server restart. The server deletes all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward, according to the new policy.

Steps

1. To retrieve the name of the soft delete policy in effect, use the `get-global-configuration-prop` option with `dsconfig`.

   Example:

   In this example, the soft delete policy is called `default-soft-delete-policy`.

   ```
   $ bin/dsconfig get-global-configuration-prop \
     --property soft-delete-policy
   ```

2. To set the retention time or retained number of soft-deleted entries, use the `set-soft-delete-policy-prop` option with `dsconfig`.

   Example:

   This example shows how to set the retention time for soft-deleted entries.

   ```
   $ bin/dsconfig set-soft-delete-policy-prop \
     --policy-name default-soft-delete-policy \
     --set "soft-delete-retention-time:52 w"
   ```

   Example:

   This example shows how to set the retained number of soft-deleted entries.

   ```
   $ bin/dsconfig set-soft-delete-policy-prop \
     --policy-name default-soft-delete-policy \
     --set soft-delete-retain-number-of-entries:1000000
   ```

3. If it has not been assigned yet, assign the soft delete policy to the global configuration.

   Example:

   This example assigns `default-soft-delete-policy` to the global configuration.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

Disabling soft-delete automatic purging

About this task

The change takes effect immediately without the need of a server restart. If the server is in the middle of an automatic soft-delete purging, it might continue to purge entries until the next time it evaluates the soft delete policy.

Steps

- To disable soft-delete automatic purging, use the `set-soft-delete-policy` option with `dsconfig`.
- To reset the soft delete policy properties that control automatic purging, use the `set-soft-delete-policy-prop` with `dsconfig`.

  Example:

  This example resets the `soft-delete-retention-time` and `soft-delete-retain-number-of-entries` properties.

  ```
  $ bin/dsconfig set-soft-delete-policy-prop \
    --policy-name default-soft-delete-policy \
    --reset soft-delete-retention-time \
    --reset soft-delete-retain-number-of-entries
  ```

Soft and hard delete processes

See the following tables for the results of actions taken during the soft and hard delete processes.

If no automatic soft delete criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes.

Action	Result
Delete	Performs a hard delete on the entry.
Delete with the Soft Delete Request Control	Performs a soft delete on the entry.
Delete of a soft-deleted entry	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Soft Delete Request Control	Not allowed. Generates an `UNWILLING_TO_PERFORM` error.

Copyright © 2025 Ping Identity Corporation

Action	Result
Delete with a Hard Delete Request Control	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Hard Delete Request Control.	Performs a hard delete on the entry.

If soft delete connection or request criteria is configured

The following table summarizes the resulting actions of a `DELETE` operation for soft deletes configured by connection criteria or request criteria.

Action	Result
Delete not matching criteria	Performs a hard delete on the entry.
Delete matching criteria	Performs a soft delete on the entry.
Delete of a soft-deleted entry not matching criteria	Performs a hard delete on the entry.
Delete of a soft-deleted entry matching criteria	Performs a hard delete on the entry.
Delete not matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete with Soft and Hard Delete Request Controls	Not allowed. Generates an `UNWILLING_TO_PERFORM` error.

Soft delete controls and tool options

See the following tables for summaries of soft delete controls and tools.

Soft delete OIDs

The following table shows the Object Identifier (OID) for each soft delete control. The soft delete OIDs are defined in the LDAP SDK generated API documentation.

Copyright © 2025 Ping Identity Corporation

OID Type	OID
Soft Delete Request Control	1.3.6.1.4.1.30221.2.5.20
Soft Delete Response Control	1.3.6.1.4.1.30221.2.5.21
Hard Delete Request Control	1.3.6.1.4.1.30221.2.5.22
Soft Undelete Request Control	1.3.6.1.4.1.30221.2.5.23
Soft Delete Entry Access Control	1.3.6.1.4.1.30221.2.5.24

Soft delete tool options

The following table shows the new tool options available for the soft delete operations.

Operation	Options
`ldapdelete` / `ldapmodify`	`--useSoftDelete/-s`. Process `DELETE` operations with the Soft Delete Request Control, whereby entries are renamed and hidden instead of being permanently deleted. The PingDirectory server must be configured to allow soft deletes. **Note** Any entries in the LDIF file with the changetype of `delete` are processed as a soft-delete request.
`ldapdelet`	`--useHardDelete`. Process `DELETE` operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The PingDirectory server must be configured to allow soft deletes.

Copyright © 2025 Ping Identity Corporation

Operation	Options
`ldapsearch`	`--includeSoftDeletedEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}`. Process search operations with the soft delete entry access control. Soft delete search options are as follows: ***with-non-deleted-entries*** Returns all entries matching the search criteria with the results, including non-deleted and soft-deleted entries. ***without-non-deleted-entries*** Returns only soft-deleted entries matching the search criteria. ***deleted-entries-in-undeleted-form*** Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form. Users must have access to the Soft Delete Entry Access Control to search for soft-deleted entries.
`ldapmodify`	`--allowUndelete`. Process `ADD` operations, which include the `ds-undelete-from-dn` attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the `ADD` operation. The PingDirectory server must be configured to allow soft deletes to process any undelete requests and the client user must have the `soft-delete-read` privilege.

Soft delete OID symbolic names using with the --control/-J option

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

Control	Symbolic Name
Soft Delete Request Control	softdelete
Hard Delete Request Control	harddelete
Soft Undelete Request Control	undelete
Soft Delete Entry Access Control	softdeleteentryaccess

Monitor soft deletes

The server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

Copyright © 2025 Ping Identity Corporation

New monitor entries

Two new monitor entries are present for a backend monitor entry.

Administrators see the following additional monitor entries on `cn=userRoot Backend,cn=monitor`:

`ds-soft-delete-entry-operations-count`

Displays the number of soft deletes performed on the backend since server startup.

`ds-undelete-operations-count`

Displays the number of undeletes performed on the backend since server startup.

`ds-backend-soft-deleted-entry-count`

Displays the current number of soft-deleted entries in the database.

`ds-auto-purged-soft-deleted-entry-count`

Displays the current number of soft-deleted entries purged since the backend or server was restarted.

Monitoring soft deletes

Monitor soft deletes using the `ldapsearch` command.

Steps

- Run `ldapsearch` on the `cn=userRoot Backend,cn=monitor` branch using a search criteria targeting the `ds-backend-monitor-entry` object class.

  Example:

  ```
  $ bin/ldapsearch --baseDN "cn=userRoot Backend,cn=monitor" \
    --searchScope sub "(objectclass=ds-backend-monitor-entry)"
  ```

  Result:

  ```
  dn: cn=userRoot Backend,cn=monitor
  objectClass: top
  objectClass: ds-monitor-entry
  objectClass: ds-backend-monitor-entry
  objectClass: extensibleObject
  cn: userRoot Backend
  ds-backend-id: userRoot
  ds-backend-base-dn: dc=example,dc=com
  ds-backend-is-private: FALSE
  ds-backend-entry-count: 200001
  ds-backend-soft-deleted-entry-count: 1000
  ds-soft-delete-operations-count: 40
  ds-undelete-operations-count: 20
  ds-auto-purged-soft-deleted-entry-count: 0
  ds-base-dn-entry-count: 200001 dc=example,dc=com
  ds-backend-writability-mode: enabled
  ```

Copyright © 2025 Ping Identity Corporation

Access logs

The access log records the LDAP operations corresponding to soft delete and undelete for `DELETE`, `SEARCH`, `MODIFY`, and `ADD` operations with the related soft-deleted values.

The access log does not require any configuration for soft delete.

`DELETE` *(soft-delete) operations*

The access log displays the following.

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

`SEARCH` *operations for soft-deleted entries*

The access log displays the following.

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

`MODIFY` *operations of soft-deleted entries*

The access log displays the following.

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

`ADD` *(soft-undelete) operations*

The access log displays the following.

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

Audit logs

The audit log captures any `MODIFY` and `DELETE` operations of soft-deleted entries.

These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry distinguished name (DN).

Copyright © 2025 Ping Identity Corporation

```
# 14/May/2012:10:57:09.054 -0500; conn=30; op=1
# ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: delete
```

For any `MODIFY` changes made, the log displays the LDIF, the modifier's name, and update time.

```
# 14/May/2012:10:58:33.566 -0500; conn=33; op=1
# dn: entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: modify
# replace: homePhone
# homePhone: +1 003 428 0966
#-
# replace: modifiersName
# modifiersName: uid=admin,dc=example,dc=com
#-
# replace: modifyTimestamp
# modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time, and creator's name.

```
# 14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn: entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
# 14/May/2012:11:00:14.055 -0500; conn=36; op=1
# dn: entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
ple,dc=com
# changetype: delete
```

Configuring the file-based audit log for soft deletes

Configure the file-based audit log for soft deletes.

Steps

1. Enable the audit log if it is disabled.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
--set enabled:true
```

2. View the audit log.

   The `soft-delete-entry-audit-behavior` property is set to `commented` by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

   Example:

```
# 11/May/2012:15:33:17.552 -0500; conn=13; op=1
# ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: delete
```

Changelog

You can configure the changelog to capture soft-delete changes to entries so that external clients, such as PingDataSync server, can access these changes.

The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

All soft-delete operations appear in the changelog as regular DELETE operations. When a soft delete occurs, the resulting changelog entry includes a `ds-soft-delete-entry-dn` operational attribute with the value of the soft-deleted entry DN. PingDataSync Server recognizes the `ds-soft-delete-entry-dn` attribute and does nothing with it.

The changelog backend `soft-delete-entry-included-operation` property determines whether MODIFY or DELETE operations of soft-deleted entries appear in the changelog. This property is disabled by default.

Configuring soft deletes on the changelog backend

Steps

1. To configure soft deletes on the changelog backend, run the following.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.

3. To review the changelog for the soft-deleted entry, run the following.

```
$ bin/ldapsearch --baseDN cn=changelog \
  "(objectclass=*)" "+"
```

   Result:

Copyright © 2025 Ping Identity Corporation

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863

```

Disabling soft deletes as a global configuration

To disable soft deletes on your PingDirectory server, reset the global configuration property and the remove the soft-delete policy.

About this task

From that point, PingDirectory processes all deletes as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present disabling after the global configuration remain in the server as latent entries.

> **Note**
>
> Be sure to include the LDAP bind parameters for your system when running each of these commands.

Steps

1. To reset the global configuration property, run the following `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
   ```

2. To reset the global configuration property, run the following `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-policy
   ```

Copyright © 2025 Ping Identity Corporation

Importing and exporting data

The PingDirectory server supports import or export of the database backends in LDIF.

You can use the `bin/import-ldif` and `bin/export-ldif` tools to create or export database backends for online or offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt, or digitally sign the data.

Importing data

The PingDirectory server provides initialization mechanisms to import database files.

The `import-ldif` command line tool imports data from an LDIF file. You can import all or a portion of the entries contained in the LDIF file, including a subset of the entries, a subset of the attributes within entries, or both. The command also supports importing data that has been compressed, encrypted or digitally signed, or both.

You can run the `import-ldif` utility with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, is removed from service and data held in that backend is not available to clients.

The `import-ldif` tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. You must include this option when performing an import into a backend with a branch that already contains entries. If a branch contains just a single base entry, the `--overwriteExistingEntries` option is not required.

Validating an LDIF file

Before importing data, you can validate an import file using the PingDirectory server's `validate-ldif` tool.

About this task

The tool binds to the PingDirectory server locally or remotely and validates the LDIF file to determine whether it violates the server's schema. Elements that do not conform to the schema are rejected and written to standard output. You can specify the output filepath to which the rejected entries and reasons for their rejection are written. The `validate-ldif` tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

Steps

- To validate an LDIF file, run the `validate-ldif` tool.

  > **Note**
  >
  > Make sure the server is online before running this command.

  To process large files faster, you can set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
  --rejectFile rejectedEntries
```

1. (Optional) To view the arguments, use the `--help` option.

Result:

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

About the database cache estimate

After successful completion of an import, the `import-ldif` command lists detailed information about the database cache usage characteristics of the imported data set.

To guide decisions for changing Java virtual machine (JVM) size and database-cache-percent for the backend, the current server configuration is considered along with the capabilities of the underlying hardware.

The `/logs/tools` directory contains additional files that describe the database cache characteristics in more detail.

Tracking skipped and rejected entries

During import, skip entries if they do not belong in the specified backend or if they are part of an excluded base distinguished name (DN) or filter.

Steps

- To write skipped entries to a specified file, use the `--skipFile {path}` option on the command line.

  You can add a comment indicating why the entries were skipped.

- To write information about rejected entries and the reasons for rejection to a specified file, use the `--rejectFile {path}` option.

  You can reject an entry if:

  - It violates the server's schema constraints.
  - Its parent entry does not exist.
  - Another entry already exists with the same DN.
  - It was rejected by a plugin.

Running an offline import

To import LDIF data encoded with the UTF-8 character set, run the `import-ldif` tool offline.

This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated with a MakeLDIF template.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You do not need to authenticate as an administrator when performing offline LDIF imports.

Performing an offline import

Steps

1. Confirm the PingDirectory server is offline.
2. To import data from an LDIF file, use the `import-ldif` command.

   Do not specify any connection arguments when running the command.

   Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a compressed file

Steps

1. Confirm the PingDirectory server is offline.
2. To import data from a compressed gzip formatted file, use the `import-ldif` command.

   > **Note**
   >
   > You must include the `--isCompressed` option to indicate that the input file is compressed.
   > Do not specify any connection arguments when running the command.

   Example:

```
$ bin/import-ldif --backendID userRoot --isCompressed \
  --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
  --skipFile /path/to/skip.ldif
```

Performing an offline LDIF import using a MakeLDIF template

Steps

1. Confirm the PingDirectory server is offline.
2. Use the `import-ldif` command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF` directory.

   Do not specify any connection arguments when running the command.

   Example:

   The following example uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

Copyright © 2025 Ping Identity Corporation

```
$ bin/import-ldif --backendID userRoot \
  --templateFile config/MakeLDIF/example.template
```

Running an online LDIF import

You can run LDIF imports while the server is online from another remote server.

The online import is similar to the offline import, except that you must provide information about how to connect and authenticate to the target server.

To schedule an LDIF file to begin importing at a specific time, use the `--task` and `--start YYYYMMDDhhmmss` options of the `import-ldif` tool.

You can also specify email addresses of users to notify when the import process completes. You can notify them regardless of success or failure or only if the import fails.

Performing an online LDIF import

Steps

1. Confirm the PingDirectory server is online.
2. To import data from an LDIF, use the `import-ldif` command.

   Example:

   ```
   $ bin/import-ldif --task --hostname server1 --port 389 \
     --bindDN uid=admin,dc=example,dc=com --bindPassword password \
     --backendID userRoot --ldifFile userRoot.ldif
   ```

Scheduling an online import

Steps

1. Confirm the PingDirectory server is online.
2. To import data from an LDIF file at a scheduled time, use the `import-ldif` command.

   > **Note**
   >
   > To specify a time in the UTC time zone, include a trailing `Z`. Otherwise, the time zone defaults to the time zone configured on the server.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/import-ldif --task \
  --hostname server1 \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password \
  --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --start 20111026010000 \
  --completionNotify import-complete@example.com \
  --errorNotify import-failed@example.com
```

Result:

```
Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM CDT
```

3. To confirm that you successfully scheduled your import task, use the `manage-tasks` command to view a summary of all tasks on the system.

   Example:

   ```
   $ bin/manage-tasks --summary
   ```

   Result:

   ```
   ID                  Type   Status
   ------------------------------------------------
   2011102617321510 Import Waiting on start time
   ```

4. To monitor the progress of this task, use the `manage-tasks` tool.

   > **Note**
   >
   > Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the PingDirectory server.

   Example:

   ```
   $ bin/manage-tasks --info 2011102617321510
   ```

   Result:

Copyright © 2025 Ping Identity Corporation

```
Task                    Details
-------------------------------------------------------
ID                      2011102617321510
Type                    Import
Status                  Waiting on start time
Scheduled Start Time    Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed     None
Dependency Action       None
Email Upon Completion   admin@example.com
Email Upon Error        admin@example.com

Import        Options
---------------------------
LDIF File        /path/to/data.ldif
Backend ID      userRoot
```

Canceling a scheduled import

Steps

- To cancel the scheduled task, run the `manage-tasks` tool.

  Example:

  ```
  $ bin/manage-tasks --cancel 2011102417321510
  ```

Adding entries to an existing PingDirectory server

To add entries to an existing PingDirectory server while preserving operational attributes such as `createTimestamp` or `modifiersName`, attach the `Ignore No User Modification` control to the request.

About this task

The `Ignore No User Modification` control allows modification of certain attributes that have the `No User Modification` constraint.

The `Ignore No User Modification` only applies to `ADD` requests. If you use the control to modify an existing entry, it results in an operational attribute change and fail.

To append entries to an existing PingDirectory server, perform the following steps:

Steps

- Run the `ldapmodify` command with the `Ignore No User Modification` control.

  Example:

  The Object Identifier (OID) for the control is `1.3.6.1.4.1.30221.2.5.5`.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
  --filename change-record.ldif
```

Filtering data import

The `import-ldif` command lets you include or exclude specific attributes and entries during an import.

The `import-ldif` arguments are summarized in the following table.

Inclusion and Exclusion Arguments for import-ldif

Argument	Description
`--includeBranch`	Base distinguished name (DN) of a branch to include in the LDIF import. Can be specified multiple times.
`--excludeBranch`	Base DN of a branch to exclude from the LDIF import. Can be specified multiple times.
`--includeAttribute`	Attribute to include in the LDIF import. Can be specified multiple times.
`--excludeAttribute`	Attribute to exclude from the LDIF import. Can be specified multiple times.
`--includeFilter`	Search filter to identify entries to include in the LDIF import. Can be specified multiple times.
`--excludeFilter`	Search filter to identify entries to exclude from the LDIF import. Can be specified multiple times.
`--excludeOperational`	Exclude operational attributes from the LDIF import.
`--excludeReplication`	Exclude replication attributes from the LDIF import.
`--excludeSoftDelete`	Exclude soft delete entries from the LDIF import.

Exporting data

The PingDirectory server `export-ldif` command line tool exports data from the server backend to an LDIF file for backups, exporting data to other applications, or reinitializing servers in a replicated topology.

The `export-ldif` tool supports the `--task` argument, which initiates the export process from within the PingDirectory server. When `export-ldif` is run as a task, extra information is available:

- Output from the export process is included in the error log.
- There is a task entry (accessible below the `cn=tasks` base distinguished name (DN)) with information about the success or failure of the export along with log messages.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> An **`ldif-export`** task can be run from the server system or a remote system. Even if it's run from a remote system, the exported LDIF file is still written to the server system.

The `export-ldif` tool exports a point-in-time snapshot of the backend that is guaranteed to provide a consistent state of the database in LDIF. If necessary, you can re-import with `import-ldif`. The data exported by `export-ldif` can include all or some of the entries (a subset of the entries, or a subset of the attributes within entries, or both) contained in the backend. You accomplish this by specifying branches, filters, and attributes to include or exclude. You can compress, encrypt, or digitally sign the exported LDIF.

> **Tip**
>
> You can configure LDIF exports as recurring tasks with **`dsconfig create-recurring-task`**. You can schedule them to run by adding them to a recurring task chain.

Performing an export

Export data to an LDIF file.

Steps

- To export data to an LDIF file, run the `export-ldif` tool.

  Example:

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

Performing an export from specific branches

Steps

- To export data to an LDIF file under a specific branch from the userRoot backend of the local PingDirectory server into a compressed file, run the `export-ldif` tool.

  Example:

  In addition to including a specific branch, the following command excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --compress \
  --includeBranch ou=people,dc=example,dc=com --excludeOperational \
  --wrapColumn 80
```

Encrypting LDIF exports and signing LDIF files

You can encrypt data during an LDIF export and digitally sign the LDIF file.

Copyright © 2025 Ping Identity Corporation

The PingDirectory server provides features to encrypt data during an LDAP Data Interchange Format (LDIF) export using the `export-ldif` `--encryptLDIF` option. It also allows the encrypted LDIF file to be imported on the same instance, or another server in the same replication topology, using the `import-ldif` tool. You can use a `--doNotEncrypt` argument to force an LDIF export to be unencrypted even if automatic encryption is enabled. The `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the LDIF file can be written to disk.

You can use the `export-ldif` tool with the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to specify which key to use for encrypting the export. The `import-ldif tool` automatically detects encryption and compression and has `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile` options as well.

The PingDirectory server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the `export-ldif` `--sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the `import-ldif` `--isSigned` option.

> **Note**
>
> There is little added benefit to signing and encrypting the same data because encrypted data cannot be altered without destroying the ability to decrypt it.

Encrypting an LDIF export

Steps

- To encrypt the data during an export to an output LDIF file, run the `export-ldif` tool with the `--encryptLDIF` option.

  Example:

  The following command runs an offline export of the `userRoot` backend and encrypts the file when written to an output file called `data.ldif`.

  ```
  $ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
    --encryptLDIF
  ```

Importing an encrypted LDIF file

Use the `import-ldif` tool to import an encrypted LDIF file.

About this task

You can import an encrypted LDIF file into the same instance from which it was exported or into another server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not connected to the instance from which it was exported.

Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from Encrypting an LDIF export.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The command imports the `data.ldif` file and decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

Example:

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --overwriteExistingEntries
```

Signing an export

Steps

- To digitally sign the data during an export to an output LDIF file, run the `export-ldif` tool with the `--sign` option.

  Example:

  The following command runs an offline export of the `userRoot` backend and signs the content when written to an output file called `data.ldif`.

  ```
  $ bin/export-ldif --backendID userRoot \
    --ldifFile /path/to/data.ldif --sign
  ```

Importing a signed LDIF file

Steps

- To import the signed LDIF file (`data.ldif`) from Signing an export, run the `import-ldif` tool with the `--isSigned` option.

  The tool imports the `data.ldif` file and checks the signature of the contents while overwriting the existing contents to the `userRoot` backend.

  > **Note**
  >
  > The command requires the `--isSigned` option, which instructs the tool that the contents of the LDIF file are signed.

  Example:

  ```
  $ bin/import-ldif --backendID userRoot \
    --ldifFile /path/to/data.ldif \
    --overwriteExistingEntries --isSigned
  ```

Copyright © 2025 Ping Identity Corporation

Filtering data exports

The `export-ldif` command is analogous to the `import-ldif` command to provide a way to include or exclude specific attributes or entries during an export.

Inclusion and Exclusion Arguments for export-ldif

Argument	Description
`--includeBranch`	Base distinguished name (DN) of a branch to include in the LDIF export (can be specified multiple times).
`--excludeBranch`	Base DN of a branch to exclude from the LDIF export (can be specified multiple times).
`--includeAttribute`	Attribute to include in the LDIF export (can be specified multiple times).
`--excludeAttribute`	Attribute to exclude from the LDIF export (can be specified multiple times).
`--includeFilter`	Filter to identify entries to include in the LDIF export (can be specified multiple times).
`--excludeFilter`	Filter to identify entries to exclude from the LDIF export (can be specified multiple times).
`--excludeOperational`	Exclude operational attributes from the LDIF export.
`--excludeReplication`	Exclude replication attributes from the LDIF export.
`--excludeSoftDelete`	Exclude soft delete entries from the LDIF export.

Scrambling data files

The PingDirectory server `transform-ldif` tool provides backward compatibility with the former `scramble-ldif` tool, with additional functionality for configuring input and output files.

The `transform-ldif` tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data lets you:

- Obscure the values of certain attributes so that it's difficult to determine the original values in the source data.
- Preserve the characteristics of the associated attribute syntax.

This process is repeatable, so if the same value appears multiple times, it yields the same scrambled representation each time. You can apply scrambling to both LDIF entries and LDIF change records.

Copyright © 2025 Ping Identity Corporation

The process of scrambling data is not the same as encryption. Only use scrambling to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is `userPassword` and its value starts with a schema name surrounded by curly braces, such as `{SSHA256}XrgyNdl3fid7KYdhd/Ju47KJQ5PYZqlUlyzxQ28f/QXUnNd9fupj9g==`, the schema name is left unchanged and the rest of the value is treated like a generic string.
- If the attribute is `authPassword` and its value contains at least two dollar signs, such as `SHA256$QGbHtDCi1i4=$8/X7XRGaFCovC5mn7ATPDYlkVoocDD06Zy3lbD4AoO4=`, the portion up to the first dollar sign (which represents the name of the encoding schema) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either `TRUE` or `FALSE`. Scrambling Boolean values is not repeatable because the determination to use a value of `TRUE` or `FALSE` is random. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of relative distinguished name (RDN) components for any attributes to be scrambled.

  For example, if you configure the tool to scramble both the `member` and `uid` attributes, and an entry has a member attribute with a value of `uid=john.doe,ou=People,dc=example,dc=com`, that member value is scrambled in a way that only obscures the `john.doe` portion but leaves the attribute names and all values of non-scrambled attributes intact.
- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization is over a time range that is double the difference between the time the **`transform-ldif`** tool launches and the timestamp is scrambled. For values where that time difference is less than one day, one day is added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit is nonzero.
- If an attribute has an octet string syntax, it's scrambled as follows:
  - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each byte that represents a uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
  - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
  - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
  - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
  - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.
- If an attribute has a value that represents a valid JavaScript Object Notation (JSON) object, the resulting value is also a JSON object. All field names are left intact, and only the values of those fields can be scrambled. If the `--scrambleJSONField` argument is provided, only the specified fields have values scrambled. Otherwise, the values of all fields are scrambled. Field values are scrambled as follows:
  - Null values aren't scrambled.
  - Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.

Copyright © 2025 Ping Identity Corporation

- Number values have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
- String values are replaced with a randomly-selected generic string.
- Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
- JSON values have scrambling applied as appropriate for their fields.

- If an attribute does not match any of the previous criteria, it is scrambled as follows:
  - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
  - Each ASCII digit is replaced with a randomly-selected ASCII digit.
  - All other characters are left unchanged.

Example

The following example reads from an LDIF file named `original.ldif`, scrambles the values of the `telephoneNumber`, `mobile`, and `homeTelephoneNumber` attributes, and writes the results to `scrambled.ldif`.

```
$ bin/transform-ldif --sourceLDIF original.ldif \
  --targetLDIF scrambled.ldif \
  --scrambleAttribute telephoneNumber \
  --scrambleAttribute mobile \
  --scrambleAttribute homeTelephoneNumber \
  --randomSeed 0
```

Backing up and restoring data

PingDirectory server provides efficient `backup` and `restore` command line tools that support full backups.

You can schedule backups using either the UNIX-based `cron` scheduler or PingDirectory server's task-based scheduler.

The PingDirectory server can run backups while it is online and processing other requests, so there is no need to shut down the server or place it in read-only mode before starting a backup.

About backing up and restoring data

Administrators should make a comprehensive backup strategy and schedule that consist of daily, weekly, and monthly backups. The plan should include:

- Full backups of the PingDirectory server data, configuration, and backends
- A backup plan for the underlying file system

This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> You can use `dsconfig create-recurring-task` to configure backups as recurring tasks and schedule those tasks as part of a recurring task chain.

If you back up more than one backend, the `backup` tool creates a subdirectory within a specified backup directory for each backend. If you back up only a single backend, then the backup files are placed in the specified directory. A single directory can only contain files from one backend, so you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including:

- The server product name
- The server version
- The backend ID
- The set of base distinguished names (DNs) for the backend
- The Java class used to implement the backend logic

The backup descriptor also includes information about the Berkeley DB Java edition version and information about the attribute and virtual list view (VLV) indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors.

You can choose to ignore warnings using the `ignoreCompatibilityWarnings` option to the `restore` tool. Errors always cause the restore operation to fail.

For example, restoring a newer backup into an older version of the server results in a warning. Restoring an older backup into a new version of the server does not result in a warning, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly the major, minor, point, and patch version numbers.

Both the `backup` and `restore` tools provide encryption options that can be used to specify which key to use for encrypting the backup:

- `--promptForEncryptionPassphrase`
- `--encryptionPassphraseFile`
- `--encryptionSettingsDefinitionID`

For backups encrypted with an encryption settings definition or an internal topology key, the server automatically determines the correct key.

Alternately, you can use the `--doNotEncrypt` argument to force a backup to be unencrypted even if automatic encryption is enabled.

If necessary, you can use the `--maxMegabytesPerSecond` argument to impose a limit on the rate at which the backup can be written to disk.

Copyright © 2025 Ping Identity Corporation

Retaining backups

The backup tool can use the `--retainPreviousFullBackupCount` or `--retainPreviousFullBackupAge` arguments to identify which previous backups to preserve.

Any other backups in that directory are removed. A new backup is always preserved. However, older backups in the same directory are eligible to be removed.

If you include the `--retainPreviousFullBackupCount` argument, that number of the most recent previous full backups are preserved and any other previous full backups are removed. A value of zero can be specified for the `--retainPreviousFullBackupCount` argument so that only the most recent backup is preserved and all previous backups are removed.

If you include the `--retainPreviousFullBackupAge` argument, its value must be a duration represented as an integer followed by a time unit. Any full backups created longer ago than that duration are eligible to be removed.

If you include both the `--retainPreviousFullBackupCount` and `--retainPreviousFullBackupAge` arguments, then only backups that don't satisfy either condition are deleted.

The `remove-backup` tool also supports the `--retainFullBackupCount` and `--retainFullBackupAge` arguments to delete any backups outside the provided retention criteria.

Listing the available backups on the system

Use the `restore` tool to list the backups in a `backup` directory.

Steps

- To list the existing backups in a specific backup directory, run the following command.

```
$ bin/restore --listBackups --backupDirectory  </mybackups>
```

Result:

```
[13:26:21] The console logging output is also available in '/ds/PingDirectory/logs/ tools/
restore.log'

Backup ID:         20120212191715Z
Backup Date:       12/Feb/2012:13:17:19 -0600
Is Compressed:     false
Is Encrypted:      false
Has Unsigned Hash: false
Has Signed Hash:   false
```

Backing up all backends

Use `backup` to save the all of the server's backends.

About this task

The `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

Copyright © 2025 Ping Identity Corporation

Steps

- To back up all backends and compress the backups, run the following.

```
$ bin/backup --backUpAll --compress --backupDirectory  </path/to/backup>
```

Backing up a single backend

Use the `--backendID` argument to specify a single backend to back up.

Steps

- To back up the `userRoot` directory and compress the backup, use the following command.

```
$ bin/backup --backendID userRoot --compress --backupDirectory  </path/to/backup>
```

Performing an offline restore

Use the `restore` command to restore a backed up backend.

About this task

Only a single backend can be restored at a time.

The PingDirectory server must be shut down before performing an offline restore.

> **Note**
>
> The server root directory should never be restored from a file system backup or snapshot.

Steps

1. To stop the PingDirectory server run the following command.

```
$ bin/stop-server
```

2. To restore a saved backup, run the following command.

```
$ bin/restore --backupDirectory  </path/to/backup/userRoot>
```

3. To start the server, run the following command.

```
$ bin/start-server
```

Copyright © 2025 Ping Identity Corporation

Assigning an ID to a backup

Use the `--backupID` argument to assign an ID to a backup.

Steps

- To back up the userRoot directory, run the following command.

```
$ bin/backup --backupDirectory  </path/to/backups/>userRoot \
  --backendID userRoot --backupID weekly
```

The `--backupID` argument identifies the backup being created as "weekly".

Result:

The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

Scheduling an online backup

About this task

You can schedule a backup to run as a task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss'" format. If the option has a value of `0`, then the task is scheduled for immediate execution. Because you can't run recurring tasks, you must run daily operations using cron or another system that can submit the task.

For online (remote) backups, you can conduct the backup operation while the PingDirectory server is online if you provide information about how to connect and to authenticate to the target PingDirectory server.

Steps

- To schedule the backup to occur at a specific time, use the task-based `--start YYYYMMDDhhmmss` option.

> **Note**
>
> To specify a time in the UTC time zone format, add a trailing `Z` to the time. Otherwise, the time is treated as a local time in the time zone configured on the server.

Example:

```
$ bin/backup --backUpAll --task --start 20111025010000 \
  --backupDirectory /path/to/backup --completionNotify admin@example.com \
  --errorNotify admin@example.com
```

Result:

```
Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM CDT
```

Scheduling an online restore

About this task

Copyright © 2025 Ping Identity Corporation

To perform an online restore, use the Tasks subsystem and enter connection and authentication information and an optional start time.

> **Note**
>
> The server must be online.

The Tasks subsystem allows you to schedule certain operations, such as `import-ldif`, `backup`, `restore`, `start-server`, and `stop-server`.

Steps

- Schedule an online restore.

  Example:

  ```
  $ bin/restore --task --start 20111025010000 \
    --backupDirectory /path/to/backup/userRoot \
    --completionNotify admin@example.com --errorNotify admin@example.com
  ```

  You can schedule a restore to run as a task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in `YYYYMMDDhhmmss` format. If the option has a value of `0`, then the task is scheduled for immediate execution. You can't run recurring tasks, so you must run daily operations using cron or another system that can submit the task.

  > **Note**
  >
  > To specify a time in the UTC time zone, add a trailing `Z` to the time. If you do not specify a time, the configured time zone on the server will be set to a local time.
  > The backend is unavailable while the restore is in progress.

Encrypting a backup

About this task

To encrypt a backup:

Steps

- Go to the server root directory and use the `backup` tool to back up the single backend, `userRoot`, and encrypt it with the `--encrypt` option.

  Example:

  ```
  $ bin/backup --encrypt --backendID userRoot --compress --backupDirectory /path/to/backup
  ```

Signing a hash of the backup

Run the `backup` tool to backup a backend and generate and digitally sign the hash of the backup contents.

Steps

- To backup the single backend from the server root directory, run the `backup` tool.

Copyright © 2025 Ping Identity Corporation

Choose from:

- To generate and digitally sign the hash of the backup contents, run the `-signHash` option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID userRoot \
  --backupDirectory /path/to/backup
```

- To only generate a hash of the backup contents, run `backup` with the `--hash` option.

Restoring a backup

You can use the `restore` command to restore a backup created with the `backup` command.

About this task

You can only restore a single backend at a time, and that backend will be offline for the duration of the restore process. The directory containing the backup used for the restoration includes a `backup.info` file with information about the backup, including when the backup was generated and whether the backup is compressed, signed, or encrypted.

You can use the `restore` command for the following data recovery scenarios:

Steps

- To restore a single backend in a replicated topology, run the `dsreplication initialize` command.

  This command streams the contents of the backend database from the source to the destination and ensures that the server receives the most up-to-date version of the data.

- To restore a backup in a non-replicated instance, run the `restore` command and specify the path to the directory containing the backup.

  Example:

```
$ bin/restore --backupDirectory /path/to/backup
```

- To restore a backup to a point-in-time:

  1. Run `dsreplication pre-external-initialization` on a server in the topology.
  2. Choose the required `baseDN`.
  3. Stop the server.
  4. Restore that server to your desired point-in-time backup.
  5. Re-start the server.
  6. Run `dsreplication initialize-all`.
  7. Initialize all other servers in the topology from the restored server.
  8. Run `dsreplication post-external-initialization` on the restored server.

Copyright © 2025 Ping Identity Corporation

- If all of your servers have been compromised:

    1. Build a directory server.
    2. Restore from the latest backup.
    3. If available, use the `extract-data-recovery-log-changes` command to replay changes in the data recovery log.

       For more information, see Reverting or replaying changes.
    4. Add and initialize new directory servers from the one that you just restored.

Moving or restoring a user database

Part of any disaster recovery involves the restoration of the user database from one server to another.

You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. A plan is the best insurance against significant downtime or data loss in the event of an unrecoverable database issue.

> **Note**
>
> The server root directory should never be restored from a file system backup or snapshot. External backup methods, such as virtual machine (VM) snapshots, are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

Regular backup from local replicated PingDirectory server

Take a backup from a local replicated PingDirectory server and restore to the failed server. This is more recent than any other backup you have.

Restore the most recent backup

Restore the most recent backup from a local server. In some cases, this might be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it takes longer for replication to play back changes.

Contact support

If all else fails, contact your authorized support provider and they can work with you, and possibly in cooperation with the Oracle Berkeley DB JE engineers, to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

Using VM snapshots

Although VM snapshots are not recommended for disaster recovery, remember the following in case you must use them:

- Snapshotting the VM should never result in a corrupted PingDirectory server.
- Shutting down the DB before snapshotting is only recommended for speeding up recovery time.

Copyright © 2025 Ping Identity Corporation

Comparing the data in two PingDirectory servers

The PingDirectory server provides an `ldap-diff` tool to compare the data on two LDAP servers to determine any differences that they might contain.

The differences are identified by first issuing a subtree search on both servers under the base distinguished name (DN) using the default search filter `(objectclass=*)` to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format that could be used to modify the content of the source server so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted, such as `"^attrToExclude"`. The `@objectClassName` notation is used to compare only attributes that are defined for a given `objectclass`.

The `ldap-diff` tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives caused by replication delays. By default, it re-checks each entry twice, pausing two seconds between checks. You can configure these settings with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it lists any exceptions in comments in the output file.

The PingDirectory server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry.

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For PingDirectory servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. You can customize the memory used by the `ldap-diff` tool by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

If you do not want to use a subtree search filter, you can use an input file of DNs for the source, target, or both. The format of the file can accept various syntaxes for each DN.

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
# The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHRoaW5ncyB0byBkbyB0aGFuIHNlZSB3aGF0IHRoaXMgc2F5cw==
# There was a blank line above dn: cn=this is the final entry.
```

Copyright © 2025 Ping Identity Corporation

> **Caution**
>
> Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation because manual updates to the servers risk introducing additional replication conflicts.

Comparing two PingDirectory servers using ldap-diff

Steps

1. Use `ldap-diff` to compare the entries in two PingDirectory server instances.

   Ignore the `userpassword` attribute because of the one-way password hash used for the password storage scheme.

   Example:

   ```
   $ bin/ldap-diff --outputLDIF difference.ldif \
     --sourceHost server1.example.com --sourcePort 1389 \
     --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
     --targetHost server2.example.com --targetPort 2389 \
     --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
     --baseDN dc=example,dc=com --searchFilter "(objectclass=*)" "^userpassword"
   ```

2. Open the output file in a text editor to view any differences.

   The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and adds from the perspective of the source server as the authoritative source.

   Example:

Copyright © 2025 Ping Identity Corporation

```
# This file contains the differences between two LDAP servers.
#
# The format of this file is the LDIF changes needed to bring server
# ldap://server1.example.com:1389 in sync with server
# ldap://server2.example.com:2389.
#
# These differences were computed by first issuing an LDAP search at both
# servers under base DN dc=example,dc=com using search filter (objectclass=*)
# and search scope SUB to first retrieve the DNs of all entries. And then each
# entry was retrieved from each server and attributes: [^userpassword] were
# compared. # # Any entries that were out-of-sync were compared a total of 3 times
# waiting a minimum of 2 seconds between each attempt to account for replication
# delays.
#
# Comparison started at [24/Feb/2010:10:34:20 -0600]
# The following entries were present only on ldap://server2.example.com:2389 and
# need to be deleted. This entry existed only on ldap://server1.example.com:1389
# Note: this entry might be incomplete. It only includes attributes:
# [^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
# objectClass: person
# objectClass: inetOrgPerson
... (more attributes not shown) ...
# st: DC
dn: uid=user.200,ou=people,dc=example,dc=com
changetype: delete

# The following entries were present on both servers but were out of sync.

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999
-
delete: mobile
mobile: +1 009 471 1808

# The following entries were missing on ldap://server2.example.com:2389 and need
# to be added. This entry existed only on ldap://server2.example.com:2389
# Note: this entry might be incomplete. It only includes attributes:

# [^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
# Comparison completed at [24/Feb/2010:10:34:25 -0600]
```

Copyright © 2025 Ping Identity Corporation

Comparing configuration entries using config-diff

Steps

- Use `config-diff` to compare PingDirectory server configurations and produce a `dsconfig` batch file needed to align the source with the target.

  Example:

  The following example compares the current configurations of server1 and server2. The changes necessary to align server1's configuration with server2 are written to the console. The same credentials are used to connect to both servers.

  ```
  $ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory Manager" \
    --sourceBindPassword password --targetHost server2
  ```

  You can find more information about runtime options in Available command-line tools or the `config-diff` tool help.

  Important

  The `config-diff` tool doesn't support connecting to different versions over LDAP. To compare configurations between servers of different versions:

  1. Copy the `config/config.ldif` file from the lower-version server to the higher-version server.
  2. Run one of the following commands on the higher-version server:
     - If the higher-version server is the source:

       ```
       $ bin/config-diff --sourceLocal \
         --targetFile "<lower-version config.ldif file>"
       ```

     - If the higher-version server is the target:

       ```
       $ bin/config-diff --targetLocal \
         --sourceFile "<lower-version config.ldif file>"
       ```

Comparing entries using source and target DN files

Steps

- To compare the entries in two PingDirectory server instances, use `ldap-diff`.

  In the following example, the utility uses a single distinguished name (DN) input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute because of the password storage scheme that uses a one-way hashing algorithm.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldap-diff --outputLDIF difference.ldif \
  --sourceHost server1.example.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
  --targetHost server2.example.com --targetPort 2389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
  --baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
  --targetDNsFile input-file.ldif "^userpassword"
```

Comparing PingDirectory servers for missing entries only using ldap-diff

Steps

- To compare two PingDirectory servers and return only those entries that are missing on one of the servers, use `ldap-diff` with the `--missingOnly` option.

  This can significantly reduce the runtime for this utility.

  Example:

  ```
  $ bin/ldap-diff --outputLDIF difference.ldif \
    --sourceHost server1.example.com --sourcePort 1389 \
    --sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
    --targetHost server2.example.com --targetPort 2389 \
    --targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
    --baseDN dc=example,dc=com --searchFilter "(objectclass=*)" "^userpassword" \
    --missingOnly
  ```

Reverting or replaying changes

The PingDirectory server provides support for an audit logger that records information about the changes to data within the server.

The data is formatted as LDIF, and it can be replayed with tools such as `ldapmodify` or `parallel-update`. The data includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made, such as by a malicious or defective client, it can obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export, such as concurrent database corruption across all instances, it can recover changes that might not otherwise be available.
- Automating the process of identifying changes made in one topology that can be replayed into another topology, such as to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem.
- Analytics and reporting purposes.

Copyright © 2025 Ping Identity Corporation

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the `extract-data-recovery-log-changes` tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

The data-recovery log

The `setup` tool automatically creates an audit logger for data recovery purposes in `logs/data-recovery`. The log is always compressed, and it is encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the `logs/data-recovery` directory so that they are isolated from other log files. The active log file is named `data-recovery.gz.encrypted` while rotated files are named `data-recovery.{timestamp}.gz.encrypted`.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.
- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file easily fits into the `extract-data-recovery-log-changes` tool's memory.
- The server retains rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server also retains no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which can provide information about the downstream client.

The `extract-data-recovery-log-changes` tool

The `extract-data-recovery-log-changes` tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the `ldapmodify` or parallel-update. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The `extract-data-recovery-log-changes` tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes are converted to a form that reverts the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin, content type, or alterations.

The following is a sample command to revert all changes by user `uid=malicious,ou=People,dc=example,dc=com` between noon and 2 pm on October 15, 2018.

Copyright © 2025 Ping Identity Corporation

```
$ bin/extract-data-recovery-log-changes \
  --auditLogFile logs/data-recovery/data-recovery.201810161234.567.gz.encrypted \
  --outputFile revert-malicious-user-changes.ldif \
  --direction revert \
  --startTime 201810151200.000 \
  --endTime 201810151359.999 \
  --includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

Working with groups

LDAP groups are special types of entries that represent collections of users. This section provides an overview of PingDirectory server group concepts and procedures on setting up and querying groups in the server.

Groups are often used by external clients to control who has access to a particular application or features. Internally, they might be used by the server to control its behavior. Groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. There are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group
- To determine the set of groups in which a specified user is a member
- To determine the set of all users that are members of a particular group

Overview of groups

The PingDirectory server provides three types of groups: static, dynamic, and virtual static groups.

A description of each group type follows:

Static groups

A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its structural object class. Static groups are ideal for small, infrequently changing elements. When the membership list grows, static groups become more difficult to manage because any change in a member base distinguished name (DN) must then be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

The PingDirectory server also supports nested groups, in which a parent group entry contains child attributes whose DNs reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughput, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.

Dynamic groups

A dynamic group has its membership list determined by search criteria using an LDAP URL. Dynamic groups solve the scalability issues for static groups because searches are efficient, constant-time operations. However, searches that range over a large set of data might affect performance.

Copyright © 2025 Ping Identity Corporation

Virtual static groups

A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Avoid using virtual static groups for applications that need to retrieve the entire membership list because the process for constructing the entire membership list can be expensive.

About the isMemberOf and isDirectMemberOf virtual attribute

PingDirectory server can generate either `isMemberOf` or `isDirectMemberOf` virtual attributes in user entries.

The existence of static, nested, dynamic, and virtual static groups can make it complex to work with groups in the server because the ways you interact with them are so different. Static groups can use three different structural object classes, not counting the auxiliary class for virtual static groups, which can further complicate things. PingDirectory server's virtual attributes simplify the group-related determination process for consistency across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of distinguished names (DNs) of all groups, including static, nested, dynamic, and virtual static groups, in which the associated user is a member. The value of the `isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who have been granted the privilege can see them. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. You should restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

The `rewrite-search-filters` `isMemberOf` configuration property

The `rewrite-search-filters` property allows `isMemberOf` searches targeting dynamic groups to be processed more efficiently because you can substitute the filter of the dynamic group into the original search filter. This speeds up paged searches across a large dynamic group.

The following table shows the three possible settings for the `rewrite-search-filters`.

Setting	Description
`always`	Always enhance search filters to include the dynamic group filter components. **Note** This often speeds up searches on dynamic groups, but in rare cases can make search processing slower. An example is if the dynamic group filter matches many entries, but the dynamic group base distinguished name (DN) and scope do not.

Copyright © 2025 Ping Identity Corporation

Setting	Description
`within-group-scope`	**The default value. Enhances search filters to include dynamic group filter components only when the base DN and scope of the dynamic group.** **Note** Although this doesn't improve performance for search requests whose scope is larger than that of the dynamic group, it should never lead to slower dynamic group search processing
`never`	**Never enhance search filters to include the dynamic group filter components.**

To use the `rewrite-search-filters` configuration property:

- **To set the `rewrite-search-filters` configuration property to the desired setting, run `dsconfig`.**

```
dsconfig set-virtual-attribute-prop --name isMemberOf --set rewrite-search-filters:<always | never |
within-group-scope>
```

- **To optionally keep the server from archiving configurations where only this attribute is changing, you can declare the `rewrite-search-filter` attribute as insignificant by running `dsconfig`.**

```
dsconfig set-backend-prop --backend-name config --add insignificant-config-archive-attribute:ds-cfg-
rewrite-search-filters
```

Determine if a user is a member of a specified group

To determine if a user is a member of a specified group using the `isMemberOf` virtual attribute, perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this base-level search.

Search Parameter	Value
Base DN	`uid=john.doe,ou=People,dc=example,dc=com`
Scope	`base`
Filter	`(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)`
Requested Attributes	`1.1`

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

Copyright © 2025 Ping Identity Corporation

Determine the set of all groups in which a user is a member

To determine the set of all groups in which a user is a member, retrieve the user's entry with a base-level search and include the `isMemberOf` attribute.

Search Parameter	Value
Base DN	`uid=john.doe,ou=People,dc=example,dc=com`
Scope	`base`
Filter	`(objectclass=*)`
Requested attributes	`isMemberOf`

Determine the set of all members for a specified group

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries.

Search Parameter	Value
Base DN	`ou=People,dc=example,dc=com`
Scope	`sub`
Filter	`(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)`
Requested Attributes	`cn, mail`

The `isDirectMemberOf` virtual attribute can be used in the previous examples in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

> **Note**
>
> If this filter targets a dynamic group using an unindexed search, then this might be an expensive operation. However, it is not more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries. Otherwise, it would be required to retrieve the static group and then perform a separate search for each member's entry.

Using static groups

A static group contains an explicit membership list where each member is represented as a distinguished name (DN)-valued attribute.

Copyright © 2025 Ping Identity Corporation

There are three types of static groups supported for use in the PingDirectory server: groupOfNames, groupOfUniqueNames, and groupOfEntries. A description for each follows:

groupOfNames

A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members.

RFC 4519 requires that the `member` attribute is in an entry. The PingDirectory server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

groupOfUniqueNames

A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members

RFC 4519 requires that the `uniquemember` attribute is in an entry. The PingDirectory server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class.

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Test Group
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
uniquemember: uid=user.3,ou=People,dc=example,dc=com
```

groupOfEntries

A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members

This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the PingDirectory server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class.

Copyright © 2025 Ping Identity Corporation

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfEntries
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

Creating static groups

Using an LDIF file, you can configure a static group. Static groups contain a membership list of explicit distinguished names (DNs) specified by the `uniquemember` attribute.

Creating a static group

About this task

To create a static group:

Steps

1. Open a text editor and create a group entry in LDIF.
    1. Include the `groupOfUniquenames` object class and `uniquemember` attributes.
    2. (Optional) If you did not have `ou=groups` set up in your server, add it in the same file.
    3. Save the file.

       Example:

       In the following example, the file is named `static-group.ldif`.

       This example LDIF file creates two groups: `cn=Development` and `cn=QA`.

Copyright © 2025 Ping Identity Corporation

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Development,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Development
ou: groups
uniquemember: uid=user.14,ou=People,dc=example,dc=com
uniquemember: uid=user.91,ou=People,dc=example,dc=com
uniquemember: uid=user.180,ou=People,dc=example,dc=com

dn: cn=QA,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: QA
ou: groups
uniquemember: uid=user.0,ou=People,dc=example,dc=com
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
```

2. To add the group entries to the server, use the `ldapmodify` tool.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename static-group.ldif
   ```

3. To verify the configuration, use the virtual attribute `isDirectMemberOf` that checks membership for a non-nested group.

   The virtual attribute is disabled by default, but you can enable it using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set enabled:true
   ```

4. To determine if a user is a member of a certain group, use `ldapsearch` to search the `isDirectMemberOf` virtual attribute.

   Example:

   This example inquires if `uid=user.14` is a member of the `cn=Development` group.

   This example assumes that the administrator has the privilege to view operational attributes.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isDirectMemberOf
   ```

   Result:

Copyright © 2025 Ping Identity Corporation

```
dn: uid=user.14,ou=People,dc=example,dc=com
isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

5. Use the group as a target in access control instructions (ACI).

    1. Open a text editor and create an `aci` attribute in an LDIF file.
    2. Save the file.
    3. To add the file, use the `ldapmodify` tool.

        Example:

        In this example, the file is named `dev-group-aci.ldif`.

        ```
        dn: ou=People,dc=example,dc=com
        changetype: modify
        add: aci
        aci: (target ="ldap:///ou=People,dc=example,dc=com")
          (targetattr != "cn || sn || uid")
          (targetfilter ="(ou=Development)")
          (version 3.0; acl "Dev Group Permissions";
            allow (write) (groupdn = "ldap:///cn=Development,ou=groups,dc=example,dc=com");)
        ```

        > **Note**
        >
        > You can create a similar ACI for the QA group, which is not shown in the previous example, but is shown in the example for step 1.

6. To add the file, use the `ldapmodify` tool.

    Example:

    ```
    $ bin/ldapmodify --filename dev-group-aci.ldif
    ```

Adding a new member to a static group

Steps

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the new user.

    Example:

    This example adds a new `uniquemember`: `user.4`.

    ```
    dn: cn=QA,ou=Groups,dc=example,dc=com
    changetype: modify
    add: uniquemember
    uniquemember: uid=user.4,ou=People,dc=example,dc=com
    ```

Copyright © 2025 Ping Identity Corporation

Removing a member from a static group

Steps

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute.

  Example:

  This example removes the DN of `user.1`.

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

Searching static groups

The following section provides a description of how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group.

Determining if a user is a static group member

Steps

- To determine if a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the distinguished name (DN) of the specified user.

  > **Note**
  >
  > For best performance, include a specific attribute list, using either `cn`, or a `1.1` request that no attributes be returned, so that the entire member list is not returned.

  Example:

  This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the `groupOfNames` static group "`cn=Test Group,ou=Groups,dc=example,dc=com`".

Base DN	`cn=Test Group,ou=Groups,dc=example,dc=com`
Scope	`base`
Filter	`(member=uid=john.doe,ou=People,dc=example,dc=com)`
Requested attributes	`1.1`

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
  --searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com)" "1.1"
```

Result:

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

- If you do not know if the membership attribute for the specified group is `member` or `uniqueMember`, then revise the filter to allow either attribute.

  Example:

  This example adjusts the filter from the previous step's example to expand the membership attribute to allow for `member` and `uniqueMember` attributes.

  ```
  (|(member=uid=john.doe,ou=People,dc=example,dc=com)
  (uniqueMember=uid=john.doe,ou=People,dc=example,dc=com))
  ```

Determining the static groups to which a user belongs

Steps

- To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the directory information tree (DIT).

  > **Tip**
  >
  > Configure the search filter to match any type of static group in which the specified user is a member.

  Example:

  The following table contains the search criteria to determine the set of all static groups in which the user `uid=john.doc,ou=People,dc=example,dc=com` is a member.

Base DN	`dc=example,dc=com`
Scope	`sub`
Filter	`(|(&(objectClass=groupOfNames)(member=uid=john.doe,ou=People,dc=example,dc=com))(&(objectClass=groupOfUniqueNames)(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com))(&(objectClass=groupOfEntries)(member=uid=john.doe,ou=People,dc=example,dc=com)))`
Requested attributes	`1.1`

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
  "(|(&(objectClass=groupOfNames)
  (member=uid=john.doe,ou=People,dc=example,dc=com)) \
  (&(objectClass=groupOfUniqueNames)\
  (uniqueMember=uid=john.doe,ou=People,dc=example,dc=com)) \
  (&(objectClass=groupOfEntries) \
  (member=uid=john.doe,ou=People,dc=example,dc=com)))" "1.1"
```

Result:

Entries returned from the search represent each static group in which the specified user is a member.

> **Note**
>
> A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes gives the same results. You can also use the virtual attributes with virtual static groups.

Determining the members of a static group

Steps

- To determine all of the members for a static group, retrieve the group entry, including the membership attribute.

> **Tip**
>
> To retrieve attributes from member entries, search all users whose `isMemberOf` attribute contains the group DN, returning the attributes desired.
> To retrieve additional information about the members, such as attributes from member entries, issue a separate search for each member to retrieve the user entry and the desired attributes.

Example:

This table contains the search criteria to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`.

Base DN	`cn=Test Group,ou=Groups,dc=example,dc=com`
Scope	`base`
Filter	`(objectClass=*)`
Requested attributes	`member uniqueMember`

Example:

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
  --searchScope base "(objectclass=*)" uniqueMember
```

Result:

The returned entry includes the DNs of all users that are members of that group.

Copyright © 2025 Ping Identity Corporation

Using dynamic groups

Dynamic groups contain a set of criteria to identify members rather than maintaining an explicit list of group members.

If a new user entry is created, or if an existing entry is modified so that it matches the membership criteria, then the user is considered a member of the dynamic group. Similarly, if a member's entry is deleted, or if it is modified so that it no longer matches the group criteria, then the user is no longer considered a member of the dynamic group.

In the PingDirectory server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL is used in the process of making the determination, and any other elements present in the URL are ignored.

Example

For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of contractor are considered members of the group.

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that fewer than 80,000 entries have the `employeeType` of contractor, you must create the following index definition to evaluate the dynamic group.

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
  --index-name employeeType --set index-entry-limit:80000 \
  --set index-type:equality
```

Creating dynamic groups

Configure a dynamic group in the same manner as static groups using an LDIF file.

About this task

Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

Steps

1. Use `ldapsearch` to verify that `uid=user.15` is not part of any group.
    1. Assume that `uid=user.15` is not part of any group.

       You add the user to the dynamic group in a later step.

       Result:

       ```
       dn: uid=user.15,ou=People,dc=example,dc=com
       ```

Copyright © 2025 Ping Identity Corporation

2. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the engineering department.

   Example:

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.0)" ou isMemberOf
   ```

   Result:

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   ou: Engineering
   ```

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.15)" ou
```

2. Open a text editor, and then create a dynamic group entry in LDIF. Save the file as `add-dynamic-group.ldif`.

   The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute.

   Example:

   ```
   dn: cn=eng-staff,ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: groupOfURLs
   ou: groups
   cn: eng-staff
   memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
   ```

3. Use `ldapmodify` to add the group entry to the server.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
   ```

4. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

   Example:

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
   ```

   Result:

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
   ```

5. Run the following command to return the DNs of entries that are part of the `cn=eng-staff` dynamic group and sort them in ascending order by the `sn` attribute.

Copyright © 2025 Ping Identity Corporation

If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For larger databases, it is not practical to run a database-wide search for all users as there can be a performance hit on the PingDirectory server.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
  "(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

6. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry.

   This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry is automatically added to the `eng-staff` dynamic group.

   Example:

   ```
   $ bin/ldapmodify
   dn: uid=user.15,ou=People,dc=example,dc=com
   changetype: modify
   add: ou
   ou: Engineering
   ```

7. Use `ldapsearch` to check if the user is part of the `cn=eng-staff` dynamic group.

   Example:

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.15)" isMemberOf
   ```

   Result:

   ```
   dn: uid=user.15,ou=People,dc=example,dc=com
   isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
   ```

Searching dynamic groups

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

Determining if a user is a dynamic group member

Steps

- To determine whether a user is a member of a specific dynamic group, run a base-level search to verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL.

Copyright © 2025 Ping Identity Corporation

> **Tip**
>
> You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side is more complicated. While possible, especially in clients able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

Example:

This table contains the search criteria to determine if the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the desired member URL.

Base DN	`uid=john.doe,ou=People,dc=example,dc=com`
Scope	`base`
Filter	`(ou=Engineering)`
Requested Attributes	`1.1`

Example:

```
$ bin/ldapsearch --baseDN "uid=john.doe,ou=People,dc=example,dc=com" \
  --searchScope base "(ou=Engineering)" "1.1"
```

> **Note**
>
> The search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member.

Result:

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

Determining the dynamic groups to which a user belongs

Steps

- **To determine the set of all dynamic groups in which a user is a member, perform a search to find all dynamic group entries defined in the server using a subtree search with a filter of `(objectClass=groupOfURLs)`.**

> **Tip**
>
> You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups.

Example:

The following table contains the search criteria to determine the set of all dynamic groups defined in the `dc=example,dc=com` tree.

Copyright © 2025 Ping Identity Corporation

Base DN	`dc=example,dc=com`
Scope	`sub`
Filter	`(objectClass=groupOfURLs)`
Requested Attributes	`memberURL`

Example:

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(objectClass=groupOfURLs)" "memberURL"
```

Result:

Each entry returned is a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

Determining the members of a dynamic group

Steps

- To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL.

> **Note**
>
> The set of requested attributes should reflect the attributes desired from the member user entries or "1.1" if no attributes are needed.

Example:

This table contains the search criteria to retrieve the list of all members of the group `dc=example,dc=com` with the `cn` and `mail` attributes.

Base DN	`dc=example,dc=com`
Scope	`sub`
Filter	`(employeeType=contractor)`
Requested Attributes	`cn, mail`

Example:

> **Caution**
>
> This search might be extensive if the associated filter is not indexed or if the group contains a large number of members.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" \
  --searchScope sub "(employeeType=contractor)" "cn, mail"
```

Using dynamic groups for internal operations

Use dynamic groups for internal operations, such as Access control instruction (ACI) or component evaluation.

The PingDirectory server performs the `memberurl` parsing and internal LDAP search. However, the internal search operation cannot be performed with access control instructions applied to it.

For example, the following dynamic group represents an organization's employees within the same department.

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
  (&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example,dc=com` entry, as in the following example.

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
  (version 3.0; acl "Grant write access to employeeType" ;
    allow (all) groupdn="ldap:///cn=department 202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example,dc=com`.

Using virtual static groups

Virtual static groups make it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with them as a static group.

About this task

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. The PingDirectory server provides a third type of group: a virtual static group, which references another group and provides access to the members of that group as if it was a static group.

Copyright © 2025 Ping Identity Corporation

Steps

- To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`.

  > **Note**
  >
  > It should include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members.
  > You must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group.

  Example:

  This example creates a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group.

  ```
  dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
  objectClass: top
  objectClass: groupOfNames
  objectClass: ds-virtual-static-group
  cn: Virtual Static Sales Group
  ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
  ```

- To enable a configuration object for the virtual static member attribute, use the `set-virtual-attribute-prop` option with `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
    --set enabled:true
  ```

  > **Note**
  >
  > A configuration object for this virtual attribute is in the server configuration but is disabled by default.
  > If you want to use virtual static groups with the `groupOfUniqueNames` object class, enable the `Virtual Static uniqueMember` virtual attribute in the same way.

Creating virtual static groups

If your application only supports static groups but has scalability issues, using a virtual static group is a possible solution.

About this task

A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. Do not use it if an application accesses the full list of group members because of the performance expense at constructing the list.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you have a small database and an application that requires that the full membership list be returned, enable the `allow-retrieving-membership` property for the Virtual Static `uniqueMember` virtual attribute using the **`dsconfig`** tool.

To create a virtual static group:

Steps

1. In a text editor, create a group entry in LDIF, and then save the file.

   Example:

   In this example, the entry contains the `groupOfUniqueNames` object class, but in place of the `uniquemember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class.

   In this example, the file is named `add-virtual-static-group.ldif`.

   ```
   dn: cn=virtualstatic,ou=groups,dc=example,dc=com
   objectclass: top
   objectclass: groupOfUniqueNames
   objectclass: ds-virtual-static-group
   ou: groups
   cn: virtual static
   ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
   ```

2. To add the virtual static group entry to the server, use the **`ldapmodify`** tool.

   Example:

   ```
   $ bin/ldapmodify -h server1.example.com -p 389 -D "uid=admin,dc=example,dc=com" \
     -w password -a -f add-virtual-static-group.ldif
   ```

3. To enable the Virtual Static `uniqueMember` attribute, use the `set-virtual-attribute-prop` option with **`dsconfig`**.

   > **Note**
   >
   > This attribute is disabled by default.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static uniqueMember" \
     --set enabled:true
   ```

4. To determine if a user is part of a virtual static group, use **`ldapsearch`**.

   Example:

   In Creating dynamic groups, the example sets up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. This example determines if `uid=user.0` is part of the virtual static group using the `isMemberOf` virtual attribute.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager" \
  -w secret -b dc=example,dc=com" "(uid=user.0)" isMemberOf
```

Example:

The following example determines if `uid=user.0` is part of the virtual static group without using the `isMemberOf` virtual attribute in the **`ldapsearch`**.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
  -b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
  "(&(objectclass=groupOfUniqueNames) \
  (uniquemember=uid=user.0,ou=People,dc=example,dc=com))"
```

Result:

Using the `isMemberOf` virtual attribute returns the following.

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

> **Note**
>
> You should see the returned `cn=virtualstatic` entry if successful.

5. (Optional) To try searching for a user that is not part of the `cn=eng-staff` dynamic group, use **`ldapsearch`**.

   Example:

   This example searches for `uid=user.20`.

   ```
   $ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
     -b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
     "(&(objectclass=groupOfUniqueNames) \
     (uniquemember=uid=user.20,ou=People,dc=example,dc=com))"
   ```

   Result:

   No entries are returned.

Searching virtual static groups

Virtual static groups behave like static groups, so the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group.

The process for determining all virtual static groups in which a user is a member is similar to the process for standard static groups in which a user is a member. The query provided in the static groups discussion returns virtual static groups in addition to standard static groups because the structural object class of a virtual static group is the same as the structural object class for a static group.

Copyright © 2025 Ping Identity Corporation

You can retrieve a list of all members of a virtual static group in the same way as a standard static group: retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default.

To make the configuration change to allow full membership retrieval, update the virtual attribute used to expose membership.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
  --set allow-retrieving-membership:true
```

Note

This can be an expensive operation, so you should leave the option to allow retrieving virtual static group membership as disabled unless it is required.

Creating nested groups

PingDirectory server supports nested groups where the distinguished name (DN) of an entry that defines a group is included as a member in the parent entry.

About this task

The following example shows a nested static group, such as `cn=Engineering Group`, that has `uniquemember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=Groups,dc=example,dc=com
uniquemember: cn=QA,ou=Groups,dc=example,dc=com
```

By default, nested group support is enabled on the PingDirectory server.

The PingDirectory server uses a group cache to support nested groups without the performance hit. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for the following reasons:

- LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them.
- Supporting nested groups in LDAP clients is not trivial, and many PingDirectory server-enabled applications that can interact with groups do not provide any support for nesting.

Copyright © 2025 Ping Identity Corporation

Tip

Disable this support if:

- Nesting support is not needed in your environment.
- Nesting support is only required for clients but is not needed for server-side evaluation, such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server might need to make a membership determination.

To create nested static groups:

Steps

1. **Open a text editor, and create a group entry in LDIF.**
    1. **Include the `groupOfUniquenames` object class and `uniquemember` attributes.**
    2. **If you did not have `ou=groups` set up in your server, then add it in the same file.**
    3. **Save the file as `nested-group.ldif`.**

    Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

    Example:

    The following example shows how to set up a nested static group, which is a static group that contains `uniquemember` attributes whose values contain other groups (static, virtual static, or dynamic).

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. **To add the group entry, use `ldapmodify`.**

    Example:

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. **Using the `isMemberOf` virtual attribute that checks the group membership for an entry, verify the configuration.**

    By default, the virtual attribute is enabled. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group.

    Example:

Copyright © 2025 Ping Identity Corporation

In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf

dn: uid=user.14,ou=People,dc=example,dc=com
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

4. In a text editor, create an Access control instruction (ACI) in LDIF. Save the file as `eng-group-aci.ldif`.

> **Tip**
>
> Use the group as a target in ACI.

Example:

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
  (targetattr != "cn || sn || uid")
  (targetfilter ="(ou=Engineering Group)")
  (version 3.0; acl "Engineering Group Permissions";
    allow (write) (groupdn = "ldap:///cn=Engineering Group,ou=groups,dc=example,dc=com");)
```

5. Add the file using the `ldapmodify` tool.

Example:

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

> **Note**
>
> When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support nesting by including the members of another group with a filter in the member URL. For example, if you have two groups, `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL.
>
> ```
> cn=dynamic1,ou=groups,dc=example,dc=com
> objectClass: top
> objectClass: groupOfURLs
> memberURL: ldap:///dc=example,dc=com??sub?
> (isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
> ```
>
> The members included from the other group using this method are not considered nested members and are returned even when using `isDirectMemberOf` when retrieving the members.

Copyright © 2025 Ping Identity Corporation

Maintaining referential integrity with static groups

The PingDirectory server automatically updates references to an entry whenever that entry is removed or renamed in the referential integrity process.

About this task

If a user entry is deleted, the referential integrity plugin removes that user from any static groups in which the user was a member. This is not necessary for dynamic groups because no explicit membership is maintained. Similarly, if a modify distinguish name (DN) operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

In the default configuration, the referential integrity processing performs synchronously. Because the necessary cleanup work must complete before the response to the original operation returns, the throughput and response time of delete and modify DN operations might be adversely impacted. To alleviate this performance impact, change the configuration to use a non-zero update interval. As a result, the referential integrity process uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

Performing referential integrity processing in a background thread can introduce a race condition that might adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. For example, if referential integrity processing has not yet been completed for the delete, then newly-established group memberships might be removed along with those that existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then the client attempts to re-establish those memberships can fail if the referential integrity processing has not removed the previous membership. Use the default synchronous behavior unless the performance impact associated with synchronous referential integrity processing is unacceptable or clients might be affected by delayed referential integrity processing.

Other configuration attributes for this plugin include:

Referential integrity plugin configuration attributes and their descriptions

Configuration attribute	Description
`attribute-type`	This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the `member` and `uniqueMember` attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
`base-dn`	This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. By default, If no values are provided then entries within all public naming contexts will be included.

Copyright © 2025 Ping Identity Corporation

Configuration attribute	Description
`log-file`	This attribute specifies the path to a log file that can be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.
`update-interval`	This attribute specifies the maximum length of time that a background thread can sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

By default, referential integrity support is disabled. To enable the support:

Steps

- Use the `dsconfig` tool as shown.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

> **Note**
>
> The internal operations of the referential integrity plugin are not replicated. In a replicated topology, you must enable the referential integrity plugin on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see Configuring the Server in PingDirectory Server Administration Guide.

Monitoring the group membership cache

At startup, the PingDirectory server logs information about the group membership cache's memory consumption.

The hard-coded cache contains information about the group memberships for internal processing, such as Access control instructions (ACIs). By default, the group membership cache is enabled.

The information about this cache logs to the standard output log `server.out` and the standard error log. When using groups, use the log information to tune the server for best performance. At startup, the server logs a message to the `server.out` log.

Copyright © 2025 Ping Identity Corporation

The following is a sample standard output log.

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The following is a sample error log.

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and 1000002
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

Using the entry cache to improve the performance of large static groups

The PingDirectory server provides an entry cache implementation, which allows for fine-grained control over entries that are held in the cache.

You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

For most circumstances, use the PingDirectory server without an entry cache. In most cases, the server efficiently retrieves and decode entries from the database. The database cache is more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

Entry caches with large static groups

If the PingDirectory server contains large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, enable an entry cache that holds only large static groups.

In servers containing large static groups, define an entry cache to hold only those large static groups. To define this entry cache, include a filter that matches only group entries, as shown in the following example.

```
(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfEntries))
```

The filter contains a minimum value count so that only groups with a large number of members, such as those with at least 100 `member` or `uniqueMember` values are included. By default, the PingDirectory server entry cache implementation with these settings is disabled. To use this implementation, you must enable these settings.

Enabling the entry cache

Steps

- To enable the entry cache, use the `dsconfig` tool.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry Cache" \
  --set enabled:true
```

Creating your own entry cache for large groups

Steps

- To create your own entry cache for large groups, use the `dsconfig create-entry-cache` subcommand.

  Example:

```
# bin/dsconfig create-entry-cache --type fifo \
  --set enabled:true \
  --set cache-level:10 \
  --set max-entries:175000 \
  --set "include-filter:(objectClass=groupOfUniqueNames)" \
  --set min-cache-entry-value-count:10000 \
  --set min-cache-entry-attribute:uniquemember
```

Monitoring the entry cache

Steps

- To monitor the memory consumed by your entry cache, use the `entry-cache-info` property in the periodic stats logger.
  - To retrieve the monitor entry over LDAP, issue a search on `baseDN="cn=monitor"` using `filter="(objectClass=ds-fifo-entry-cache-monitor-entry)"`.

    > **Note**
    >
    > By default, the entry cache memory is set to 75% with a maximum of 90%.

    Example:

Copyright © 2025 Ping Identity Corporation

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
objectClass: extensibleObject
cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory. Entries can be
added to the cache until the overall JVM memory usage reaches the configured limit of
75%. Cache has 174999 remaining entries before reaching the configured limit of 175000.
```

Tuning the index entry limit for large groups

The PingDirectory server uses indexes to improve database search performance and to provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

About this task

You can specify an index entry limit property that defines the maximum number of entries allowed to match a given index key before the server no longer maintains it.

Steps

- When the index keys have reached the default limit of 4000, rebuild the indexes using the `rebuild-index` tool.

  Example:

  ```
  $ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
  ```

Copyright © 2025 Ping Identity Corporation

- For PingDirectory server environment directories containing more than 4000 groups with the same structural object class, such as more than 4000entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries, increase the index entry limit for the `objectClass` attribute so that it has a value larger than the maximum number of group entries of each type by setting the `index-entry-limit` property in the command line.

  > **Note**
  >
  > For most PingDirectory server environments, the default index entry limit value of 4000 entries is sufficient. However, group-related processing might be necessary to increase the index entry limit.

  Example:

  ```
  $ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
    --index-name objectClass --set index-entry-limit:175000
  ```

- As an alternative, create a separate backend to hold these group entries so that an unindexed search in that backend yields primarily group entries.

  > **Note**
  >
  > If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type can be expensive.

- For directories in which any single user is be a member of more than 4000 static groups of the same type, increase the index entry limit for the `member` or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member.

  > **Note**
  >
  > If you do not increase the limit, searches to retrieve the set of all static groups in which the user is a member can be unindexed and therefore expensive.

Summary of commands to search for group membership

The following summary of commands show the fastest way to retrieve direct or indirect member distinguished names (DNs) for groups.

- To retrieve direct member, non-nested DNs of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

  ```
  $ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com" "(objectClass=*)" uniqueMember member
  ```

- To retrieve direct member entries or non-nested under `dc=example,dc=com` of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

  ```
  $ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com" "(isDirectMemberOf=cn=group.
  1,ou=Groups,dc=example,dc=com)"
  ```

Copyright © 2025 Ping Identity Corporation

This is useful when attributes from member entries are used in the filter or being returned.

- To retrieve group DNs in which user `uid=user.2,ou=people,dc=example,dc=com` is a direct member or non-nested, static groups, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com" "(objectClass=*)" isDirectMemberOf
```

- To retrieve all member entries under `ou=people,dc=example,dc=com` of group `cn=group.1,ou=groups,dc=example,dc=com`, run the following.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com" "(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com)"
```

- To retrieve the group DNs in which user `uid=user.2,ou=people,dc=example,dc=com` is a member, run the following.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com" "(objectClass=*)" isMemberOf
```

Migrating Oracle groups

The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups.

You can migrate Oracle static and dynamic groups to PingDirectory server groups. For more information about the differences in access control evaluation between Oracle and the PingDirectoryserver, see Migrating ACIs from Oracle to the PingDirectory server.

Migrating static groups

About this task

PingDirectory server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, you can import static groups without modification.

You can enable a First-In, First-Out (FIFO) entry cache to cache group-to-user mappings, which improves performance when accessing large entries at the expense of greater memory consumption. PingDirectory server provides an out-of-the-box FIFO entry cache object for this purpose. You must enable this object using `dsconfig` as described in Using the entry cache to improve the performance of large static groups.

To migrate static groups:

Steps

1. To enumerate any schema differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-ldap-schema` tool.
2. To enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment, use the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema or configuration changes recorded by the tools in steps 1 and 2.

Copyright © 2025 Ping Identity Corporation

4. Import the existing users and groups using the `import-ldif` tool.
5. From the PingDirectory server root directory, open the `docs/sun-ds-compatibility.dsconfig` file using a text editor.
6. Go to the FIFO Entry Cache section.
    1. Read the accompanying comments.
    2. To enable the corresponding `dsconfig` command, delete the comment character ("#").

    Example:

    ```
    $ bin/dsconfig set-entry-cache-prop \
      --cache-name "Static Group Entry Cache" --set enabled:true
    ```
7. To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

    Example:

    ```
    $ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --set enabled:true
    ```

Next steps

If the PingDirectory server is part of a replication topology, enable the Referential Integrity plugin for each replica.

Migrating static groups to virtual static groups

About this task

In many cases, using virtual static groups in place of static groups can produce marked performance gains without having to update client applications. Migrating to virtual static groups varies depending on the original directory information tree (DIT), but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

For this task, consider the following:

- The common membership trait for all members of the `All Users` group is the parent distinguish name (DN) `ou=People,dc=example,dc=com`.
- In other cases, a common attribute might need to be used. For example, groups based on the location of its members could use the `l` location or `st` state attribute.
- The common case of an `All Users` group, which contains all entries under the parent DN `ou=People,dc=example,dc=com`.
- When implemented as a virtual static group, this group can have a large membership set without incurring the overhead of a static group.

To migrate Oracle Directory Server Enterprise Edition static groups to virtual static groups:

Steps

1. Create a dynamic group.

Copyright © 2025 Ping Identity Corporation

Example:

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

2. Create a virtual static group that references the dynamic group.

   Example:

   ```
   dn: cn=All Users,ou=Groups,dc=example,dc=com
   objectClass: top
   objectClass: groupOfUniqueNames
   objectClass: ds-virtual-static-group
   cn: All Users
   ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
   ```

3. To populate the `All Users` group with `uniqueMember` virtual attributes, enable the `Virtual Static uniqueMember` virtual attribute.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static uniqueMember" \
     --set enabled:true
   ```

4. To confirm that the virtual static group is correctly configured, check a user's membership in the group.

   Example:

   ```
   $ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
     --searchScope base "(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)" 1.1
   ```

   Result:

   ```
   dn: cn=All Users,ou=Groups,dc=example,dc=com
   ```

5. If a client application requires it, enable the ability to list all members of a virtual static group.

   By default, this feature is disabled.

   Example:

   ```
   $ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static uniqueMember" \
     --set allow-retrieving-membership: true
   ```

Copyright © 2025 Ping Identity Corporation

> **Tip**
>
> You can implement the virtual static group using the `groupOfNames` object class instead of `groupOfUniqueNames`. To do this, update the `Virtual Static member` configuration object instead of the `Virtual Static uniqueMember` configuration object.

Migrating dynamic groups

About this task

The PingDirectory server supports dynamic groups with the `groupofURLs` object class. In general, you can import dynamic groups without modification.

To migrate dynamic groups:

Steps

1. To enumerate any schema differences between the Oracle Directory Server Enterprise Edition (DSEE) deployment and the Ping Identity deployment, run the `migrate-ldap-schema` tool.
2. To enumerate any configuration differences between the DSEE deployment and the Ping Identitiy deployment, run the `migrate-sun-ds-config` tool.
3. Import or configure any necessary schema and configuration changes recorded by the tools used in steps 1 and 2.
4. Import the existing users and groups using the `import-ldif` tool.

Working with indexes

The PingDirectory server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the PingDirectory server.

Overview of indexes

The PingDirectory server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the directory information tree (DIT).

Indexes are associated with attributes and stored in database index files, which are managed separately for each base distinguished name (DN) in the PingDirectory server. The PingDirectory server automatically creates index files when you initialize a base DN or run the `dsconfig` tool to create a local DB backend. During modify operations, the PingDirectory server updates the database index files.

> **Note**
>
> If you enable encryption on the server, indexes will be encrypted.

The PingDirectory server comes with the following types of indexes:

Copyright © 2025 Ping Identity Corporation

Default system indexes

Ensures that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.

Default Local DB indexes

Created for each database suffix. Modify the index to meet your system's requirements using the `dsconfig` tool.

Local DB VLV indexes

Allows a client to request the server to send search results using the virtual list view (VLV) control.

Filtered Indexes

Provides the ability to index an attribute, but only for entries that match a specified filter based on an equality index. You can only use the filtered index for searches containing your specified filter. The filtered index can be maintained independently of the equality index for the attribute even if a normal equality index is not maintained for the attribute.

General tips on indexes

Important critical indexes

The PingDirectory server has several built-in indexes on the local DB backend that are critical to internal server processing and should never be removed.

```
aci, ds-entry-unique-id, objectClass
```

> **Tip**
>
> You can define a composite index with a filter pattern of `"(objectClass=?)"` and use it in place of the `objectClass` equality attribute index. The composite index is more performant in cases where many entries have the same object class values.
> In most cases, you should avoid setting the index entry limit too high for the `objectClass` index. In a typical directory of users and groups, you should set the index entry limit for indexes covering the `objectClass` type higher than the total number of groups in the server but lower than the number of users.

Built-in indexes for efficient queries

The PingDirectory server has built-in indexes on the local DB backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. You can remove the `mail` and `uid` indexes, but these attributes are referenced from the Password Modify Extended Operation and their removal causes problems with components, such as the Exact Match Identity Mapper. If you remove the `mail` or `uid` indexes, additional configuration changes might be necessary to ensure that the server starts properly. You can safely remove the `cn`, `givenName`, `mail`, `sn`, and `telephoneNumber` indexes if clients do not query on these attributes. This reduces the size of the database both on disk and in memory.

Copyright © 2025 Ping Identity Corporation

Using composite indexes for performance

When exploded attribute index keys exceed the index entry limit, background cleanup processing can sometimes significantly impact server performance. To avoid this performance impact, in cases where you expect index keys will match a large number of entries, use composite indexes instead of attribute indexes.

Composite indexes don't have the performance and scalability issues that attribute indexes have when working with large ID sets, and they don't require the same expensive cleanup processing for keys that exceed the index entry limit.

For example, you can use a composite index with a filter pattern of `"(givenName=?)"`:

- To replace an attribute index on the `givenName` attribute for the equality and ordering index types
- To process substring searches that contain at least a subInitial (that is, "starts with") component

You can also use a composite index with a filter pattern of `"(cn=?)"` to replace a substring index on the `cn` attribute.

Online rebuilds

When an online index rebuild is in progress, the data in that backend is available and writable although the index being rebuilt is not used. Searches that attempt to use that attribute might be unindexed.

Index rebuild administrative alert

The PingDirectory server generates an administrative alert when the rebuild process begins and ends. It has a degraded-alert-type of `index-rebuild-in-progress` so that a PingDirectoryProxy server can avoid using the PingDirectory server while the rebuild is in progress.

System indexes cannot be rebuilt

The contents of the backend must be exported and re-imported in order to rebuild system indexes. For more information, see the list of System indexes.

Indexing certain attributes

Ensure that the following recommendations are used when setting up the indexes:

- Do not use equality and substring indexes for attributes that contain binary data.
- Avoid approximate indexes for attributes containing numbers, such as telephone numbers.

Unindexed searches

Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, you should prevent applications from performing unindexed searches so that searches that are not indexed would be rejected rather than tying up a worker thread. Ways to achieve this include the following:

- Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.

Copyright © 2025 Ping Identity Corporation

- To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user is only permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search privilege` allows a client to request an unindexed search without this control.
- You can use the Reject Unindexed Search request control to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of privileges. For information about these controls, see the LDAP SDK. These capabilities are also available with the `ldapsearch` tool.
- Make sure that `allow-unindexed-searches` property is set to false in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow undindexed searches, set the `allow-unindexed-searches-with-control` property to true. If `allow-unindexed-searches` is false but, `allow-unindexed-searches-with-control` is true, the policy only permits an unindexed search if the request includes the Permit Unindexed Search request control. For more information, see the LDAP SDK and the `ldapsearch` tool.
- Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them are active at any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

  To change the maximum number of concurrent unindexed searches, use the `dsconfig` tool to set a value for the number. A default value of "0" represents no limit on the number of concurrent unindexed searches.

  ```
  $ bin/dsconfig set-global-configuration-prop \
    --set maximum-concurrent-unindexed-searches:2
  ```

Index entry limit

The PingDirectory server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must rebuild the indexes using the `rebuild-index` tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JRE backend index entry limit configuration, such as 4000.

To change the default index entry limit, use the `dsconfig` tool, as in the following example.

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name cn --set index-entry-limit:5000
```

Rebuild index vs. full import

Expect a limited amount of database growth because of the existence of old data when running `rebuild-index` versus doing a full import of your database.

Index types

The PingDirectory server supports several types of indexes to quickly find entries that match search criteria in LDAP operations.

Copyright © 2025 Ping Identity Corporation

Entry IDs

The PingDirectory server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs.

Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files.

Entry IDs can look like the following:

- `id2entry`
- `dn2id`
- `dn2uri`
- `id2children`
- `id2subtree`

Index types

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the `uid` attribute has an equality matching rule and thus has an equality index maintained by the PingDirectory server. The following table describes the index types.

PingDirectory server index types

Index Type	Description
Approximate	Used to efficiently locate entries that are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.
Equality	Used to efficiently locate entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule.
Filtered	Uses a defined search filter for a specific attribute. This is an offshoot of the equality index, but you can maintain it independently of the equality index for a specific attribute.
Ordering	Used to efficiently identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.
Presence	Used to efficiently locate entries that have at least one value for a specified attribute. There is only one presence index key per attribute.
Substring	Used to efficiently locate entries that contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.

Copyright © 2025 Ping Identity Corporation

System indexes

The PingDirectory server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

System Indexes

Index	Description
dn2id	Allows quick retrieval of distinguished names (DNs). The `dn2id` database has one record for each entry. The key is the normalized entry DN and the value is the entry ID.
id2entry	Allows quick retrieval of entries. The `id2entry` database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.
referral	Allows quick retrieval of referrals. The referral database called `dn2uri` contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the `ref` attribute for that entry.
id2children	Allows quick retrieval of an entry and its children. The `id2children` database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.
id2subtree	Allows quick retrieval of an entry's subtree. The `id2subtree` database provides a mapping between an entry's unique identifier and the unique identifiers in its subtree.

Viewing the system indexes

Steps

- To view the system and user indexes, use the **`dbtest`** command.

  Example:

  ```
  $ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID userRoot
  ```

  The index status indicates whether or not an index is trusted. An untrusted index requires rebuilding.

Managing local DB indexes

To modify the local database (DB) indexes to meet your system's requirements, use the **`dsconfig`** tool. If you are using the **`dsconfig`** tool in interactive command-line mode, access the Local DB Index menu from the Basic object menu.

Viewing the list of local DB indexes

Steps

- To view the default list of indexes, run **`dsconfig`** with the `list-local-db-indexes` option.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

Result:

```
Local DB Index     : Type    : index-type
-------------------:---------:--------------------
aci                : generic : presence
cn                 : generic : equality, substring
ds-entry-unique-id : generic : equality
givenName          : generic : equality, substring
mail               : generic : equality
member             : generic : equality
objectClass        : generic : equality
sn                 : generic : equality, substring
telephoneNumber    : generic : equality
uid                : generic : equality
uniqueMember       : generic : equality
```

Viewing a property for all local DB indexes

Steps

- To view a property assigned set for all local DB indexes, run `dsconfig` with the `--property` option.

  Repeat the option for each property that you want to list.

  Example:

  In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

  ```
  $ bin/dsconfig list-local-db-indexes --property index-entry-limit \
    --property prime-index --backend-name userRoot
  ```

Viewing the configuration parameters for local DB index

Steps

- To view the configuration setting of a local DB index, run `dsconfig` with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

  > **Tip**
  >
  > To view the advanced properties, add the `--advanced` option to your command.

  Example:

  ```
  $ bin/dsconfig get-local-db-index-prop --index-name aci \
    --backend-name userRoot
  ```

Copyright © 2025 Ping Identity Corporation

Modifying the configuration of a local DB index

About this task

To modify an index, run the `dsconfig` tool. Any modification or addition of an index requires rebuilding the indexes. In general, an index only needs to be built once after it has been added to the configuration.

> **Note**
>
> If you add an index and then import the data using the **`import-ldif`** tool, the index is automatically rebuilt. If you add an index and then add the data using a different method, you must rebuild the index using the **`rebuild-index`** tool.

Steps

1. To modify an index, run **`dsconfig`** with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties.

   Example:

   This example updates the `prime-index` property, which loads the index at startup. To access this command, use the `--advanced` option.

   ```
   $ bin/dsconfig set-local-db-index-prop --index-name uid \
     --backend-name userRoot --set prime-index:true
   ```

2. To view the index and verify the change, run **`dsconfig`** with the `get-local-db-index-prop` option.

   Example:

   ```
   $ bin/dsconfig get-local-db-index-prop --index-name uid \
     --backend-name userRoot
   ```

3. Stop the server.

   > **Note**
   >
   > Although you can rebuild an index with the server online, it is not recommended.

   Example:

   ```
   $ bin/stop-server
   ```

4. To rebuild the index, run the **`rebuild-index`** tool.

   Example:

   ```
   $ bin/rebuild-index --baseDN dc=example,dc=com --index uid
   ```

5. Restart the server.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/start-server
```

Creating a new local DB index

Steps

1. To create a new local DB index, run `dsconfig` with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type:` *<value>* options.

   Example:

   ```
   $ bin/dsconfig create-local-db-index \
     --index-name roomNumber --backend-name userRoot \
     --set index-type:equality
   ```

2. To view the index, run `dsconfig` with the `get-local-db-index-prop` option.

   Example:

   ```
   $ bin/dsconfig get-local-db-index-prop \
     --index-name roomNumber --backend-name userRoot
   ```

3. Stop the PingDirectory server.

   > **Note**
   >
   > Although you can rebuild an index with the server online, it is not recommended.

   Example:

   ```
   $ bin/stop-server
   ```

4. To rebuild the index, run the `rebuild-index` tool.

   Example:

   ```
   $ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
   ```

5. Restart the PingDirectory server.

   Example:

   ```
   $ bin/start-server
   ```

Copyright © 2025 Ping Identity Corporation

Deleting a local DB index

About this task

Check that no plugin applications are using the index before deleting it.

> **Note**
>
> When the index is deleted, the corresponding index database is also deleted. The disk space is reclaimed after the cleaner threads begin.

Steps

- To remove an index from the database, run `dsconfig` with the `delete-local-db-index` option.

  Example:

```
$ bin/dsconfig delete-local-db-index \
  --index-name roomNumber --backend-name userRoot
```

Composite indexes

A PingDirectory server composite index can generate from multiple pieces of information, such as a combination of multiple filter components or a combination of filter components and a base distinguished name (DN), or from a single piece of information.

> **Note**
>
> Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

To improve the performance of searches in directories with a large number of entries, especially with a large number of non-leaf entries, use equality composite indexes to combine a mandatory equality filter pattern with an optional base DN pattern.

Equality composite indexes offer two advantages over existing equality attribute indexes in the these types of deployments, a base DN pattern and index pages.

Base DN pattern

If a directory environment has many branches, but searches are often done within specific individual branches, use the base DN pattern to make search processing more efficient. The server only needs to search entries within a target branch.

For example, if the directory contains an `"ou=Customers,dc=example,dc=com"` branch with separate branches below that for sets of customers, such as `"ou=ACME,ou=Customers,dc=example,dc=com"` and `"ou=SHOPCO,ou=Customers,dc=example,dc=com"`, you can define a composite index with a filter pattern of `"(sn=?)"` and a base DN pattern of `"ou=?,ou=Customers,dc=example,dc=com"`. Then use a search with a filter of `"(sn=Smith)"` and a base DN of `"ou=ACME,ou=Customers,dc=example,dc=com"` to narrow the search to the Smiths in the ACME branch.

Copyright © 2025 Ping Identity Corporation

Index Pages

If many entries have the same value for a specific attribute, you can use composite indexes to break large ID sets up across multiple pages, unlike a traditional attribute index.

Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index returns either:

- One Smith record whose value is a block that contains all 50,000 of the matching entry IDs when the index isn't exploded.

> **Note**
>
> The exploded form is efficient for writing, for example, adding or removing a Smith involves just that one entry ID, but it is expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

- 50,000 Smith records that each have a value of the matching entry ID when the index is exploded.

> **Note**
>
> The non-exploded form is efficient for searching because all of the entry IDs return in a single read, but it is expensive for writing. If a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten.

Composite indexes break up the block of entry IDs across multiple pages, a page size of up to 5000. If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, the composite index returns 10 blocks of 5,000 IDs. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value, such as `givenName` or `sn`. Do not use a equality composite index for an attribute with very few entries with the same value, such as `id` or `mail`. For attributes in which all of the values match a small number of entries, use an equality attribute index.

Rebuilding indexes

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

- To rebuild a composite index, use the **`rebuild-index`** tool. The index name must be preceded by `composite.`

```
bin/rebuild-index --index composite.thisIndexName
```

> **Note**
>
> For the exact name to use in rebuilding the index, run the **`dbtest`** tool with the `list-database-containers` option and `--backendID` property.
>
> ```
> bin/dbtest list-database-containers --backendID {backendID}
> ```

Define the following properties when configuring a composite index.

Copyright © 2025 Ping Identity Corporation

Composite Index Properties	Description
`index-filter-pattern` (required)	Specifies a single-valued filter property used to identify a portion of the index criteria. You can only specify this at the time that the index definition is created.
`index-base-dn-pattern` (optional)	Specifies a single-valued DN property that indicates that the index is scoped to a specific subtree or subtree pattern. You can only specify this at the time the index definition is created.

JSON indexes

JSON indexing is similar to general attribute indexing. Where a general attribute can be indexed several ways and requires a separate database for each index type, with JSON indexing, there is a single database for each JSON field to use for different JSON filter types.

This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field. The corresponding database entry value is a list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator based on the data type for the target field that enables iterating through values in a logical order to facilitate inequality and subInitial searches.

When the JSON field constraint indicates to index a JSON field, JSON indexes are automatically created. Learn more about Configuring JSON attribute constraints.

View indexes with the following command.

```
$ bin/dbtest list-index-status \
  --backendID userRoot \
  --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

`equals`

Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. Depending on the nature of the search filter, the ID list might contain references to entries that do not actually match the filter, such as if the field is a string and if the filter is configured to use case-sensitive matching.

`equalsAny`

Identifies entries that have a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.

`greaterThan/lessThan`

Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, but it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.

Copyright © 2025 Ping Identity Corporation

`substring`

Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes:

- Add, delete, modify, and modify distinguish name (DN) operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The `rebuild-index` tool and corresponding backend code make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The `verify-index` tool also works with JSON indexes to make it possible to check their validity.
    - When rebuilding a JSON index with the `rebuild-index` tool, the attribute name must be followed by `.json`. Optionally, you can also add `.<fieldName>`, where `<fieldName>` is replaced by the name of the JSON field.

```
bin/rebuild-index --index  <attributeName>.json.<fieldName>
```

> **Note**
>
> For the exact name to use in rebuilding the index, run the **`dbtest`** tool with the `list-database-containers` option and `--backendID` property.
>
> ```
> bin/dbtest list-database-containers --backendID {backendID}
> ```

- Matching entry count control and `debugsearchindex` return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

> **Note**
>
> Exploded indexes and the entry balancing global index do not support JSON objects.

Working with local DB VLV indexes

Local database (DB) virtual list view (VLV) indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter.

The client can navigate through the list by passing a context back to the server with the virtual list view control. The local DB VLV index can be used only when the client request contains the VLV control and the client has been authorized with an access control instruction (ACI) with a **`targetcontrol`** of 2.16.840.1.113730.3.4.9.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> A client request, which includes a virtual list view control, can be successfully processed without a matching local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV since the server has to retrieve each entry twice.

Viewing the list of local DB VLV indexes

Steps

- To view the default list of indexes, use `dsconfig` with the `list-local-db-vlv-indexes` option.

  Example:

  In this example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-vlv-indexes --backend-name userRoot
```

Creating a new local DB VLV index

Steps

1. Use `dsconfig` with the `create-local-db-vlv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options.

   > **Note**
   >
   > If you do not set any property values, the default values are assigned.

   Example:

```
$ bin/dsconfig create-local-db-vlv-index \
  --index-name givenName --backend-name userRoot --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree --set filter:"(objectclass=*)" \
  --set sort-order:givenName
```

2. Rebuild the index using the `rebuild-index` tool.

   > **Note**
   >
   > You must add the `vlv.` prefix to the index name to rebuild the VLV index.

   Example:

   The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
```

Copyright © 2025 Ping Identity Corporation

Modifying a VLV index's configuration

Steps

1. Use `dsconfig` with the `set-local-db-vlv-index-prop` option and the `--index-name` and `--backend-name` properties.

   Example:

   In this example, update the `base-dn` property.

   ```
   $ bin/dsconfig set-local-db-vlv-index-prop --index-name givenName \
     --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
   ```

2. Rebuild the index using the `rebuild-index` tool.

   > **Note**
   >
   > You must add the prefix `vlv.` to the index name.

   Example:

   The following command can be run with the server on or offline with the addition of the `--task` and connection options.

   ```
   $ bin/rebuild-index --baseDN dc=example,dc=com --index vlv.givenName
   ```

Rebuilding a VLV index

When rebuilding specific non-attribute indexes, it is important to include any appropriate prefixes or postfixes with the index name to avoid errors.

Steps

- When rebuilding a VLV index with the `rebuild-index` tool, the index name must be preceded by `vlv.`

  ```
  bin/rebuild-index --index vlv.thisIndexName
  ```

  > **Note**
  >
  > For the exact name to use in rebuilding the index, run the `dbtest` tool with the `list-database-containers` option and `--backendID` property.
  >
  > ```
  > bin/dbtest list-database-containers --backendID {backendID}
  > ```

Deleting a VLV index

About this task

Copyright © 2025 Ping Identity Corporation

Delete a VLV index using the `dsconfig` tool. Before deleting it, check that the index is not being used in any plugin applications.

Steps

1. To remove a VLV index from the database, use `dsconfig` with the `delete-local-db-vlv-index` option.

   Example:

   ```
   $ bin/dsconfig delete-local-db-vlv-index --index-name givenName \
     --backend-name userRoot
   ```

2. To verify the deletion, try to view the VLV index.

   Example:

   ```
   $ bin/dsconfig get-local-db-vlv-index-prop --index-name givenName \
     --backend-name userRoot
   ```

Working with filtered indexes

The PingDirectory server filtered index is useful when client search requests consisting of a compound `&` filter with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

About this task

Filtered indexing is primarily useful for cases in which clients frequently issue searches with `&` filters that meet the following criteria:

- The `&` filter itself matches a small number of entries, but each of the individual components can match a large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that does not change.
- The filter must be narrowed to a base distinguished name (DN) for data structures with many branches or if indexed attribute values appear in a large number of entries.

For an example, consider the following use case process. A database contains several thousand company profiles and each company profile is represented by many entries. The `(objectClass=company)` filter matches a small set of entries per company and can exceed the index entry limit because there are many companies. Also, the `(companyDomain=example.com)` filter matches many of the entries for the company with domain `example.com` and can also result in an unindexed search. The more narrow filter `(&(objectClass=company)(companyDomain=example.com))` also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the `companyDomain` attribute with a static filter of `(objectClass=company)` in the `equality-index-filter` property of the index.

When configuring a filtered index, define the following properties.

Copyright © 2025 Ping Identity Corporation

Filtered Index Properties and their descriptions

Filtered Index Properties	Description
`equality-index-filter`	Specifies a search filter that can be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index is maintained for the associated attribute, but only for entries that match the provided filter. The index is used only for searches containing an equality component with the associated attribute type used with this filter.
`maintain-equality-index-without-filter`	Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute does not indexed for equality by itself but only in conjunction with the defined equality index filters.

Steps

- Define the `equality-index-filter` filter index property.
- Define the `maintain-equality-index-without-filter` filter index property.

> **Note**
>
> Maintain the filtered index independently from the equality filter for that attribute. Use the filtered index only for searches containing the equality component with the associated attribute type used with this filter. When configuring a filtered index, be aware of the **`equality-index-filter`** and **`maintain-equality-index-without-filter`** properties of the index.

Result:

The searches are configured and built with the **`rebuild-index`** tool or **`import-ldif`** tool.

This example shows the result of searches built with filters based on the use case process described above with the following index.

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))(&(objectClass=company)
(companyDomain=example.org)))
```

Creating a filtered index

Steps

1. To create a filtered index, use the **`dsconfig`** tool.

   The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined `"(objectclass=company)"`.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
  --index-name companyDomain --set maintain-equality-index-without-filter:true \
  --set index-type:equality --set equality-index-filter:"(objectclass=company)"
```

2. After you have created the index, rebuild the indexes.

    1. Stop the PingDirectory server using `bin/stop-server`.

    2. Run the `rebuild-index` tool.

        Example:

        ```
        $ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
        ```

3. Start the PingDirectory server using `bin/start-server`.

Tuning indexes

The PingDirectory server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system.

To process high write load operations, the server supports an optional expanded index database using an exploded format. To view the current state of the server's indexes and make adjustments to the index databases, the PingDirectory server automatically generates an Index Summary Statistics table after each LDIF import or index rebuild. To determine the key data size for the indexes, the `dbtest` tool includes an index histogram. This section describes each of these tools.

About the exploded index format

The `index-entry-limit` backend configuration property specifies the maximum number of entries kept in an index record before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search.

> **Note**
>
> Because composite indexes are much more efficient than exploded indexes when dealing with large numbers of identical keys, use composite indexes for data sets where large numbers of entries (several thousand or more) share the same value for an indexed attribute.

If any index keys have already reached this limit, you must rebuild these indexes before they can use a new limit. If you configure `index-entry-limit` to be greater than 50000, any keys with more than 50000 entries are stored in a separate database in an expanded, or exploded, format.

All keys with less than 50000 entries continue to be stored in one database in a consolidated format so that changes to the key require rewriting all the entry IDs matching the key. All keys with more than 50000 entries and less than the `index-entry-limit` are stored in a separate database in an exploded format so that changes to the key require writing to the updated entry ID only.

Copyright © 2025 Ping Identity Corporation

If you increase the `index-entry-limit` to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it is stored in a separate database where each key is stored with its entry ID individually. The consolidated format is efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is efficient for high volumes of write operations because it avoids large on-disk growth.

About monitoring index entry limits

Index keys that have reached their limit require indexes to be rebuilt before they can use a new limit. To avoid a potentially costly rebuild, there are several ways to monitor index limits.

In certain cases, it's acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and applications frequently need to find entries of a specific type. However, the top objectClass key doesn't need to be indexed because it appears in every entry in the server.

Select an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `--listKeysNearestIndexEntryLimt` argument of the `verify-index` tool lists a specified number of keys that are closest to the limit without having exceeded it. Make the index entry limit larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if you need to adjust the index entry limit needs to be adjusted.

The `--listKeysExceedingIndexEntryLimit` argument of the `verify-index` tool lists all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has been exceeded that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key, with additional room for future growth. Then, run the `rebuild-index` tool or export to LDIF and re-import.

The server provides other methods for determining if index keys have exceeded or are close to exceeding the index entry limit, including:

- When performing an LDIF import, the tool includes an Index Summary Statistics section that provides usage information for each index, including:
  - The number of keys for which the index entry limit has been exceeded.
  - The number of keys for which the number of matching entries falls within several predefined buckets, such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries.
- During a search operation, if the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation includes an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- During a search operation, if the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are greater than 80 percent of it, the access log message for that operation includes an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field can appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80%of the index entry limit.

Copyright © 2025 Ping Identity Corporation

- If a search operation request includes either the `debugsearchindex` attribute or the matching entry count request control with debugging enabled, the debug information includes any indexes accessed that have exceeded the index entry limit or that are within 80% of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered since the backend was brought online, or since the index entry limit was changed in several different categories. These monitor attributes include:

  `ds-index-exceeded-entry-limit-count-since-db-open`

  The number of index keys for which the number of matching entries has crossed the index entry limit because of a write operation.

  `ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open`

  The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80% of the index entry limit.

  `ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open`

  The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

  `ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open`

  The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80% of the index entry limit.

  `ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open`

  The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

About the dbtest Index Status table

The `dbtest` tool has a `list-all --analyze` option that generates the current status of all of the databases on your system, including all index databases.

The table shows the following information:

- Type
- Entry count (the number of records in the database)
- Index status
  - `TRUSTED` indicates the indexes are up-to-date.
  - `UNTRUSTED` indicates the index needs rebuilding.
- Each key's total data size
- Each key's average data size

Copyright © 2025 Ping Identity Corporation

- Each key's maximum data size

> **Note**
>
> Any indexes that are in exploded format are also listed in this table.

```
Index Name                          Index Type  JE Database Name                                                  Index Status

cn.substring                        Index       dc_example_dc_com_cn.substring                                    TRUSTED
sn.equality                         Index       dc_example_dc_com_sn.equality                                     TRUSTED
sn.substring                        Index       dc_example_dc_com_sn.substring                                    TRUSTED
telephoneNumber.equality            Index       dc_example_dc_com_telephoneNumber.equality                        TRUSTED
mail.equality                       Index       dc_example_dc_com_mail.equality                                   TRUSTED
ds-entry-unique-id.equality         Index       dc_example_dc_com_ds-entry-unique-id.equality                     TRUSTED
```

dbtest output including index databases

Configuring the index properties

By default, the `index-entry-limit` value is 4000, meaning the server stops maintaining index values for keys that match more than 4000 entries. You can change the value with the `dsconfig` tool.

About this task

Before running the following commands, be aware that you must do an index rebuild on the system, which requires a system shutdown unless the command is run as a task.

To configure the index properties:

Steps

1. Run `dsconfig` with the `set-backend-prop` subcommand.
2. Set the `index-entry-limit` to 5000. Confirm that you want to apply the changes.

   By default, this value is set to 4000.

   > **Note**
   >
   > Remember to include the bind parameters for your system.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set index-entry-limit:5000 \
One or more configuration property changes require administrative action
or confirmation/notification. Those properties include:
* index-entry-limit: If any index keys have already reached this limit,
indexes must be rebuilt before they will be allowed to use the new limit.
Setting a large limit (greater than 10,000) could have a big impact on
write performance and database growth on disk.
Continue? Choose 'no' to return to the previous step (yes / no) [yes]: yes
```

3. Stop the server.

   Example:

   ```
   $ bin/stop-server
   ```

4. Rebuild the index.

   Example:

   ```
   $ bin/rebuild-index --baseDN dc=example,dc=com \
     --index cn --index givenName --index objectClass \
     --index sn --maxThreads 10
   ```

5. View the Index Summary Statistics table, which automatically displays to system out after running the `rebuild-index` command.

   You can also access the table at `logs/tools/rebuild-index-summary.txt`.

   Example:

   ```
            --- Index Summary Statistics ---
   Index                                 : Limit : >Limit : Max    : 1-9    : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
   --------------------------------------:-------:--------:--------:--------:-------:---------:-----------:-------------:--------------
   dc_example_dc_com_cn.equality         : 5000  :        : 1      : 100001 :       :         :           :             :
   dc_example_dc_com_cn.substring        : 5000  : 9      : 15401  : 131746 : 22372 : 545     : 39        : 3           :
   dc_example_dc_com_givenName.equality  : 5000  :        : 16     : 3788   : 4817  :         :           :             :
   dc_example_dc_com_givenName.substring : 5000  : 8      : 23809  : 7039   : 12062 : 483     : 42        : 3           :
   dc_example_dc_com_objectClass.equality : 5000  : 4      : 100003 : 3      :       :         :           :             : 4
   dc_example_dc_com_sn.equality         : 5000  :        : 8      : 13419  :       :         :           :             :
   dc_example_dc_com_sn.substring        : 5000  : 9      : 15401  : 33967  : 7055  : 459     : 39        : 3           :

   The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
   (2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
   maximum entry count for any key in the index. The remaining columns provide the number of keys
   whose entry count falls in the range indicated in the column heading
   ```

6. Repeat steps 1-4 to make more adjustments to your indexes.

7. Restart the server.

   Example:

   ```
   $ bin/start-server
   ```

About the Index Summary Statistics table

The PingDirectory server automatically generates an Index Summary Statistics table, which you can use to determine the optimal configuration for your system's indexes.

The table only generates when you run the `rebuild-index` tool in offline mode. The table generates after any LDIF import or an index rebuild. It is written to system out and to `logs/tools/rebuild-index-summary.txt`.

The table displays the following information:

- The current index entry limit set by the `index-entry-limit` property on the local database configuration
- The number of keys whose entry count exceeds this limit, if any
- The maximum entry count for any key in the index
- A histogram of the number of keys whose entry falls within a range of values

The following image is an example of the Index Summary Statistics table for the `sn.equality` and the `sn.substring` indexes.

In this figure, there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```
          --- Index Summary Statistics ---
Index                          : Limit : >Limit : Max   : 1-9    : 10-99 : 100-999 : 1000-9999 : 10000-99999
-------------------------------:-------:--------:-------:--------:-------:---------:-----------:------------
dc_example_dc_com_sn.equality  : 4000  :        : 2     : 100000 :       :         :           :
dc_example_dc_com_sn.substring : 4000  : 7      : 13419 : 150814 : 7109  : 407     : 36        : 6
```

Example of an Index Summary Statistics Table

Managing entries

The PingDirectory server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

The following sections describe how to work with entries:

- Searching entries
- Working with the matching entry count control
- Adding entries
- Deleting entries using ldapdelete
- Deleting entries using ldapmodify
- Modifying entries using ldapmodify
- Working with the parallel-update tool
- Working with the watch-entry tool

Copyright © 2025 Ping Identity Corporation

- Working with LDAP transactions

Searching entries

The PingDirectory server provides an `ldapsearch` tool to search for entries or attributes within your server.

The `ldapsearch` tool requires the LDAP connection parameters to bind to the server, including the `baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search.

base

Searches only for the specified entry.

one

Searches only the children of the entry and not the entry itself.

sub

Searches the entry and its descendants.

The `ldapsearch` tool provides basic functionality specified by the RFC 2254 and provides additional features that use the PingDirectory server's control mechanisms.

> **Note**
>
> For more information, run the `ldapsearch --help` function.

Searching the root DSE

The root DSA-specific entry (DSE) is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls.

About this task

Specifically, the root DSE entry provides information about the supported LDAP3 controls, Simple Authentication and Security Layer (SASL) mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

The PingDirectory server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. After you set this property, the associated attribute types are recreated and re-registered as user attributes in the schema (in memory, not on disk). After you set the property, you can use `ldapsearch` without "+" to view the root DSE.

Steps

1. To set the `show-all-attributes` property to TRUE, run the `dsconfig` tool.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

2. Run the `ldapsearch` tool to view the root DSE entry on the PingDirectory server.

> **Note**
>
> To display the operational attributes in the entry, use `+`.

Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

Searching all entries in the PingDirectory server

Steps

- To search all entries in the PingDirectory server, run the `ldapsearch` tool.

> **Note**
>
> The filter `"(objectclass=*)"` matches all entries. If you do not specify the `--searchScope` subcommand, it defaults to a search scope of `sub`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(objectclass=*)"
```

Searching for an access control instruction

Steps

- To search the `dc=example,dc=com` base distinguished name (DN) entry, run the `ldapsearch` tool.

> **Note**
>
> The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an access control instruction (ACI).

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci
```

Result:

The system displays the following ACI information.

Copyright © 2025 Ping Identity Corporation

```
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
aci: (targetattr="")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

Searching for the schema

Steps

- To search the `cn=schema` entry, run the `ldapsearch` tool.

> **Note**
>
> The base distinguished name (DN) is specified as `cn=schema`, and the filter `"(objectclass=*)"` matches all entries. The command uses a special attribute "+" to return all operational attributes.

Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" "+"
```

Searching for a single entry using base scope and base DN

Steps

- To search for a single entry, run the `ldapsearch` tool and specify the base scope and DN.

Example:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
  --searchScope base "(objectclass=*)"
```

Searching for a single entry using the search filter

Steps

- To search for a single entry, specify the `sub` scope and a search filter that describes a single entry.

Example:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub "(uid=user.14)"
```

Copyright © 2025 Ping Identity Corporation

Searching for all immediate children for restricted return values

Steps

- To search for all immediate children of restricted return values, run the `ldapsearch` tool.

> **Note**
>
> The special attribute "+" returns all operational attributes.

Example:

In this sample, the immediate children are `ou=People,dc=example,dc=com`, and the restricted returned values are `sn` and `givenName`.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope one '(objectclass=*)' sn givenName "+"
```

Searching for all children of an entry in sorted order

Steps

- To search for all children of an entry in the appropriate subtree and sort the results by one or more attributes, run the `ldapsearch` command and include the `--sortOrder` option.

Choose from:

  - To sort the results in ascending order, supply an attribute name for the value of `--sortOrder`.
  - To sort the results in descending order, supply an attribute name preceded by a `-` for the value of `--sortOrder`.
  - To sort the results by multiple attributes, supply the attribute names for the value of `--sortOrder` as follows:
    - List the attributes in the order in which you want to sort the results.
    - Separate the attributes with commas.
    - Remember to prepend `-` to any attributes that represent a descending sort.

Example

For this example, the `ldapsearch` command searches for children in the `ou=People,dc=example,dc=com` subtree and sorts them first by `sn` (ascending) and then by `givenName` (descending):

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

Copyright © 2025 Ping Identity Corporation

Limiting the number of returned search entries and search time

Steps

- To search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree, specify a compound filter.

  Example:

  In the following example, no more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes.

  ```
  $ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
    --searchScope sub --sizeLimit 200 --timeLimit 5 \
    "(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
  ```

Getting information about how indexes are used in a search operation

Before you begin

The PingDirectory server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT).

Steps

- To search for how indexes are used in a search operation, you can either:

  Choose from:

  - Issue a search request with the desired base distinguished name (DN), scope, and filter, and request that the server return the special `debugsearchindex` attribute using the `ldapsearch` command.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --hostname ds.example.com \
 --port 389 --bindDN uid=admin,dc=example,dc=com \
 --bindPassword password \
 --baseDN dc=example,dc=com \
 --searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
 dn: cn=debugsearch
 debugsearchindex: 0.040 ms - Beginning index processing for search
     request with base DN 'dc=example,dc=com', scope wholeSubtree,
     and filter (&(givenName=John)(sn=Doe)).
 debugsearchindex: 0.067 ms - Unable to optimize the AND filter
     beyond what the client already provided.
 debugsearchindex: 0.834 ms - Candidate set obtained for single-key
     filter (givenName=John) from index dc_example_dc_com_givenName.equality.
     Candidate set:  CandidateSet(isDefined=true, isExploded=false,
     isResolved=true, size=2, originalFilter=(givenName=John),
     remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
 debugsearchindex: 0.030 ms - Final candidate set for filter (givenName=John)
     obtained from an unexploded index key in dc_example_dc_com_givenName.equality.
     Since the scope of the search includes the entire entry container, there is
     no need to attempt to further pare down the results based on the search scope.
     Candidate set:  CandidateSet(isDefined=true, isExploded=false, isResolved=true,
     size=2, originalFilter=(givenName=John), remainingFilter=null,
     matchingEntryCountType=UNEXAMINED_COUNT)
 debugsearchindex: 0.020 ms - Short-circuiting index processing for AND filter
     (&(givenName=John)(sn=Doe)) after evaluating single-key component
     (givenName=John) because the current ID set size of 2 is within the
      short-circuit threshold of 5.
 debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for AND filter
     (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe).  Even though
     there is still more of the filter to evaluate, the current candidate set is
     within the short-circuit threshold of 5, so no additional index processing will
     be performed to try to pare down the results based on the remaining filter or the
     search scope.  Candidate set:  CandidateSet(isDefined=true, isExploded=false,
     isResolved=true, size=2, originalFilter=(&(givenName=John)(sn=Doe)),
     remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
 debugsearchindex: 0.016 ms - Completed all index processing.  Candidate set:
     CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
     originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
     matchingEntryCountType=UPPER_BOUND)
```

Note

Users must have access to the **`debugsearchindex`** operational attribute and the **`cn=debugsearch`** portion of the DIT with the following command.

```
$ bin/dsconfig set-access-control-handler-prop \
 --add "global-aci:(targetattr=\"debugsearchindex\")(target=\"ldap:///cn=debugsearch\")
    (version 3.0; acl \"Allow members of the Index Debugging Users group
    to request the debugsearchindex operational attribute \"; allow
    (read,search,compare) groupdn=\"ldap:///cn=Index Debugging
    Users,ou=Groups,dc=example,dc=com\";)"
```

- **Issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to `true` using `ldapsearch`.**

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --hostname ds.example.com --port 389 \
 --bindDN uid=admin,dc=example,dc=com --bindPassword password \
 --baseDN dc=example,dc=com \
 --searchScope sub --matchingEntryCountControl examineCount=0:debug "(&(givenName=John)(sn=Doe))"
 Upper Bound on Matching Entry Count:  2
 Matching Entry Count Debug Messages:
 * naw-desktop:1389 - 0.104 ms - Beginning index processing for search request with
    base DN 'dc=example,dc=com', scope wholeSubtree, and filter (&(givenName=John)(sn=Doe)).

    unindexedFilterPortion=(sn=Doe))
 * naw-desktop:1389 - Constructing an UPPER_BOUND response with a count of 2
```

Working with the matching entry count control

You can use the `ldapsearch` command with the `--matchingEntryCountControl` option to determine the count of entries that match a search filter.

You must grant users access to this control by invoking OID `1.3.6.1.4.1.30221.2.5.36` with the following command:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-access-control-handler-prop \
 --add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
   (version 3.0; acl \"Allow members of the Index Debugging Users group to
   use the matching entry count request control \"; allow (read)
   groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com\";)"
```

You can use an `examineCount` control for searches that are at least partially indexed to determine whether to return an examined count, an unexamined count, or an upper bound count. The following factors determine what the search returns:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. You can also use indexes to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if you can use indexes to identify the entry IDs for all entries that match the search criteria.

  > **Note**
  >
  > The candidate list could also include entries that either don't match the filter or are outside the scope of the search.

- A search is unindexed if it's not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count except that all of the candidate entries are examined to determine whether the search would return them to the client.

  An examined count might be less than an unexamined count if the set of matching entries includes those that the search would remove, including special entries, such as LDAP subentries, replication conflict entries, or soft-deleted entries, and entries excluded through access control evaluation.
- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it doesn't do.
- If a search is fully indexed, the result is an examined count or an unexamined count.

  If `alwaysExamine` is true and `examineCount` is greater than or equal to the number of candidates, the result is an examined count. If `alwaysExamine` is false, or if the number of candidates exceeds `examineCount`, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count.

  The `alwaysExamine` flag isn't relevant in this case. If `examineCount` is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.
- If a search is unindexed, the result is either an examined count or an unknown count.

  If `allowUnindexed` is true, the server processes the unindexed search, which can be very expensive. Instead of getting the matching entries back, the server returns the examined count. If `allowUnindexed` is false, the server returns an unknown count. If `allowUnindexed` is true, the requester needs to have the `unindexed-search` privilege to get the exact count.

Example

Copyright © 2025 Ping Identity Corporation

The following example demonstrates an `ldapsearch` using the `--matchingEntryCountControl` option:

```
$./ldapsearch \
  --bindDN "cn=directory manager" \
  --bindPassword password \
  --baseDN dc=example,dc=com \
  --matchingEntryCountControl examineCount=100:alwaysExamine:allowUnindexed:debug \
  "(objectclass=inetOrgPerson)"
```

Adding entries

Depending on the number of entries that you want to add to your PingDirectory server, you can use the `ldapmodify` tool for small additions.

The `ldapmodify` tool provides two methods for adding a single entry:

- Using an LDIF file
- Using the command line

The attributes must conform to your schema and contain the required object classes.

Adding requests with the `ignore-no-user-modification` control enables a client to include attributes that are not normally allowed from external sources, such as the `userPassword` attribute, which is a user-modifiable attribute. An add request with the `ignore-no-user-modification` control allows a one-time exception to the password policy, even if the requesting client does not have the `bypass-pw-policy` privilege. This exception enables specifying pre-encoded passwords.

> **Note**
>
> When adding an entry, the server can ensure that the entry's relative distinguished name (RDN) is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated `entryUUID` value. An LDAP client written with the LDAP SDK for Java can use the **`NameWithEntryUUIDRequestControl`** to explicitly indicate which add requests should be named in this way or the **`ldapmodify`** tool with the **`--nameWithEntryUUID`** argument.
> The **`auto-name-with-entry-uuid-connection-criteria`** and **`auto-name-with-entry-uuid-request-criteria`** global configuration properties can be used to identify which add requests should be automatically named this way.
> You can also use the uniqueness request control with **`ldapmodify`** for enforcing uniqueness on a per-request basis. Provide at least one of the **`uniquenessAttribute`** or **`uniquenessFilter`** arguments with the request. For more information about this control, see the LDAP SDK documentation and the **`com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl`** class for using the control.

Adding an entry using an LDIF file

Use the `ldapmodify` tool to add an entry from an LDIF file.

Steps

1. Open a text editor and create an entry that conforms with your schema.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The PingDirectory server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

Example:

The following example adds the entry in the file and saves the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith
employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. To add the entry specified in the LDIF file, run the `ldapmodify` tool.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename add-user.ldif
   ```

   Result:

   A confirmation message of the new addition appears. If the command is successful, you'll see generated success messages with the "#" symbol.

   ```
   # Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
   # ADD operation successful for DN uid=user.2000,ou=People,dc=example,dc=com
   ```

Adding an entry using the changetype LDIF directive

About this task

Copyright © 2025 Ping Identity Corporation

RFC 2849 specifies LDIF directives that you can use within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine `add` and `modify` in one file.

Steps

1. Open a text editor and create an entry that conforms with your schema.

   Example:

   This example uses `changetype: add` to add the following entry in the file and saves the file as `add-user2.ldif`.

   ```
   dn: uid=user.2001,ou=People,dc=example,dc=com
   changetype: add
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
   postalCode: 50563
   description: This is the description for Seely Dorm.
   uid: user.2001
   userPassword: pleasantry
   employeeNumber: 2001
   initials: SPD
   givenName: Seely pager: +1 596 665 3344
   mobile: +1 039 686 4949
   cn: Seely Dorm
   sn: Dorm
   telephoneNumber: +1 097 257 7542
   street: 100 Apple Street
   homePhone: +1 214 521 4883
   l: Cincinnati
   mail: user.2001@maildomain.net
   st: OH
   ```

2. To add the entry specified in the LDIF file, run the `ldapmodify` tool.

   Example:

   In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

   ```
   $ bin/ldapmodify --filename add-user2.ldif
   ```

   Result:

   A confirmation message displays confirming the addition.

Adding multiple entries in a single file

About this task

Copyright © 2025 Ping Identity Corporation

Add multiple entries in your LDIF file by separating each distinguished name (DN) and its entry with a blank line from the next entry.

Steps

1. Open a text editor and create some entries that conform to your schema.

   Example:

   For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

   ```
   dn: uid=user.2003,ou=People,dc=example,dc=com
   objectClass: top
   objectClass: person
   objectClass:
   organizationalPerson
   objectClass: inetOrgPerson
   ...(similar attributes to previous examples)...

   dn: uid=user.2004,ou=People,dc=example,dc=com
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   ...(similar attributes to previous examples)...
   ```

2. To add the entries specified in the LDIF file, run the `ldapmodify` tool.

   Example:

   This example uses the short form arguments for the `ldapmodify` tool.

   ```
   $ bin/ldapmodify -h server.example.com -p 389 \
     -D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif
   ```

   The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype are treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those begining with "#") for each addition.

   Result:

   ```
   # Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
   # ADD operation successful for DN uid=user.2003,ou=People,dc=example,dc=com
   # Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
   # ADD operation successful for DN uid=user.2004,ou=People,dc=example,dc=com
   ```

Copyright © 2025 Ping Identity Corporation

Deleting entries using ldapdelete

You can delete an entry using the `ldapdelete` tool.

> **Note**
>
> Ensure that there are no child entries below the entry because that can create an orphaned entry.

Back up your system before removing any entries.

Deleting an entry using ldapdelete

Steps

1. To delete an entry, run the `ldapdelete` command.

   Example:

   The following example deletes the `uid=user.14` entry.

   ```
   $ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
   ```

Deleting multiple entries using an LDIF file

About this task

To generate a file of distinguished names (DNs) to delete from the PingDirectory server:

Steps

1. To search for all entries in a branch and return the DNs of the subentries, run the following command.

   Example:

   For this example, the search is for all entries in the `ou=Accounting` branch.

   ```
   $ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
                        "ou=Accounting,ou=People,dc=example,dc=com" --outputFile /usr/local/entry_dns.txt
   ```

2. Run the `ldapdelete` command with the file to delete the entries.

   Example:

   The following command uses the `--continueOnError` option, which continues deleting through the whole list even if an error is encountered for a DN entry.

   ```
   $ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueOnError
   ```

Copyright © 2025 Ping Identity Corporation

Deleting entries using ldapmodify

About this task

You can use the LDIF changetype directive to delete an entry from the PingDirectory server using the `ldapmodify` tool.

> **Note**
>
> You can only delete leaf entries.

Steps

1. Delete an entry using the `ldapmodify` tool.
    1. From the command line run the `ldapmodify` tool with the `changetype:delete` option.
    2. Enter the distinguished name (DN) and press `Enter` to go to the next line.
    3. Enter the `changetype` directive.
    4. Press `Ctrl+D` twice to enter the end-of-file (EOF) sequence (UNIX) or `Ctrl+Z` (Windows).

        Example:

        ```
        $ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN "uid=admin,dc=example,dc=com" --
        bindPassword password
        dn:uid=user.14,ou=People,dc=example,dc=com
        changetype: delete
        ```

Modifying entries using ldapmodify

You can use the `ldapmodify` tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value.

If you have more than one change, you can separate them using the `-` (dash) symbol.

Modifying an attribute from the command line

Steps

1. To locate a specific entry, run the `ldapsearch` tool.

    Example:

    ```
    $ bin/ldapsearch -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
      -w password -b dc=example,dc=com "(uid=user.2004)"
    ```

2. To change attributes from the command line, run the `ldapmodify` command.
    1. Specify the modification using the `changetype:modify` directive and then specify which attributes are to be changed using the `replace` directive.

Copyright © 2025 Ping Identity Corporation

Example:

In this example, we change the telephone number of a specific user entry.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

3. Process the request:

   Choose from:

   - For Unix EOF escape sequence, enter `ctrl+d` twice.
   - For Windows, enter `ctrl+z`.

Modifying multiple attributes in an entry from the command line

Steps

1. To locate a specific entry, run the `ldapsearch` tool.

   Example:

   ```
   $ bin/ldapsearch -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
     -w password -b dc=example,dc=com "(uid=user.2004)"
   ```

2. To change attributes from the command line, use the `ldapmodify` command.

   1. Specify the modification using the `changetype:modify` subcommand.
   2. Specify the attributes to change using the `add` and `replace` subcommand.

      Example:

      In this example, we add the `postOfficeBox` attribute and change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-").

      ```
      $ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" -w password
      dn: uid=user.2004,ou=People,dc=example,dc=com
      changetype: modify
      add: postOfficeBox
      postOfficeBox: 111
      -
      replace: mobile
      mobile: +1 039 831 3737
      -
      replace: telephoneNumber
      telephoneNumber: +1 097 453 8232
      ```

Copyright © 2025 Ping Identity Corporation

3. Process the request.

   Choose from:

   - For Unix, enter `ctrl+d` twice.

     This is the Unix EOF escape sequence.

   - For Windows, enter `ctrl+z`.

Adding an attribute from the command line

Steps

1. Run the `ldapmodify` tool from the command line interface.
2. Specify the modification using the `changetype:modify` subcommand.
3. Specify which attributes to add using the `add` option.

   Example:

   In this example, we add another value for the `cn` attribute, which is multi-valued.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
cn: Sally Tea Tree
```

4. To process the request, enter `ctrl+d` twice.

   This is the UNIX EOF escape sequence.

> **Note**
>
> An error might occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's `objectclass` requirements.
> Remove any trailing spaces after the attribute value.

Adding an attribute using the language subtype

About this task

The PingDirectory server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

Steps

1. Run the `ldapmodify` tool from the command line interface.
2. Specify the modification using `changetype:modify`.
3. Specify which attributes to add using the `add` option.

Copyright © 2025 Ping Identity Corporation

Example:

In this example, we add another value for the `lang` attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

4. To process the request, enter `ctrl+d` twice.

   This is the UNIX EOF escape sequence.

Adding an attribute using the binary subtype

About this task

The PingDirectory server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that you can store in an entry. The operation must specifically match the subtype for successful operation. You must use the version directive with a value of "1" for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

Steps

1. To add an attribute with a binary subtype, run the `ldapmodify` tool from the command line interface.
2. Specify the modification using `changetype:modify`.
3. Specify which attributes to add using the `add` option.

   Example:

   The attribute in this example points to the filepath of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
  -w password
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

Deleting an attribute

Steps

1. To delete an attribute, run the `ldapmodify` tool with the LDIF `delete` subcommand.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
  -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: employeeNumber
```

Deleting one value from an attribute with multiple values

About this task

Use the LDIF `delete` subcommand to delete a specific attribute value from an attribute.

Steps

1. Run the `ldapmodify` tool from the command line.
2. Specify the modification using `changetype:modify`.
3. Specify the attribute pair that you want to delete using `delete`.

   Example:

   The following sample assumes you have multiple values of `cn` in an entry, such as `cn: Sally Tree`, `cn: Sally Tea Tree`. This sample keeps `cn:Sally Tree` and deletes the `cn: Sally Tea Tree`.

   ```
   $ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
     -w password
   dn: uid=user.2004,ou=People,dc=example,dc=com
   changetype: modify
   delete: cn
   cn: Sally Tea Tree
   ```

Renaming an entry

Rename an entry by changing the relative distinguished name (RDN) of an entry.

About this task

> **Note**
>
> You cannot rename an RDN if it has children entries because this violates the LDAP protocol.

Steps

1. Run the `ldapmodify` tool to rename an entry.
   1. Run the `changetype`, `newrdn`, and `deleteoldrdn` directives.

      Example:

      The following command changes `uid=user.14` to `uid=user.2014` and uses the `changetype`, `newrdn`, and `deleteoldrdn` directives.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

Moving an entry within a PingDirectory server

Run the `ldapmodify` tool to move an entry from one base distinguished name (DN) to another base DN.

Before you begin

- Assign access control instructions (ACIs) on the parent entries.
  - The source parent entry must have an ACI that allows export operations: `allow(export)`.
  - The target parent entry must have an ACI that allows import operations: `allow(import)`.

About this task

For more information on access control instructions, see Overview of access control.

Steps

1. To move an entry from one branch to another, run the `ldapmodify` tool.

   Example:

   In this example, an entry moves from the `ou=contractors` branch to the `ou=People` branch.

   ```
   $ bin/ldapmodify
   dn: uid=user.14,ou=contractors,dc=example,dc=com
   changetype:moddn
   newrdn: uid=user.2014
   deleteoldrdn: 0
   newsuperior: ou=People,dc=example,dc=com
   ```

2. Specify the modification using `changetype:moddn`.

Moving an entry from one machine to another

About this task

The PingDirectory server provides the `move-subtree` tool to move a subtree or one entry on one machine to another.

The `move-subtree` tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. After the entries are moved, they are no longer present on the source server.

> **Note**
>
> The subtree or entry must exist on the source server and cannot be present on the target server. The source server must also support the `real attributes only` request control. The target server must support the `Ignore NO-USER-MODIFICATION` request control.

Copyright © 2025 Ping Identity Corporation

Steps

- To move an entry, such as `uid=test.user,ou=People,dc=example,dc=com`, from the source host to the target host, run the `move-subtree` tool.

  Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
  --entryDN uid=test.user,ou=People,dc=example,dc=com
```

Moving multiple entries from one machine to another

About this task

The `move-subtree` tool provides the ability to move multiple entries listed in a distinguished name (DN) file from one machine to another. Lines that begin with the octothorpe character (#) and empty lines will be ignored. You can prefix entry DNs with `dn:`, but long DNs can'tt be wrapped across multiple lines.

Steps

1. In a text editor, create a new text file, enter a list of DNs, one DN per line, and then save the file.

   You can also use the `ldapsearch` command with the special character `"1.1"` to create a file containing a list of DNs that you want to move.

   Example:

   The following example searches for all entries that match `"(department=Engineering)"` and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

2. To specify the file of DNs to move from one machine to another, run the `move-subtree` tool with the `--entryDNFile` option.

   Example:

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
  --entryDNFile /path/to/file/test-dns.ldif
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If an error occurs with one of the DNs in the file, the output message shows the error. The `move-subtree` tool keeps processing the remaining DNs in the file.
>
> ```
> An error occurred while communicating with the target server: The entry
> uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry with that name
> already exists
> Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
> source.example.com:389 to target.example.com:389
> Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
> source.example.com:389 to target.example.com:389
> ```

Working with the parallel-update tool

The PingDirectory server provides a **`parallel-update`** tool, which reads change information (`add`, `delete`, `modify`, and `modify DN`) from an LDIF file and applies the changes in parallel.

This tool is a multi-threaded version of the **`ldapmodify`** tool that is designed to process a large number of changes as quickly as possible.

The **`parallel-update`** tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries, such as modifying an entry after it has been added or adding a child after its parent.

The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file, such as if the change to add a parent entry is provided later in the LDIF file than a change to add a child entry.

After the tool applies the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table.

Processing Statistic	Description
Attempts	Number of update attempts
Successes	Number of successful update attempts
Rejects	Number of rejected updates
ToRetry	Number of updates that will be retried
AvgOps/S	Average operations per second
RctOps/S	Recent operations per second Total number of operations from the last interval of change updates
AvgDurMS	Average duration in milliseconds

Copyright © 2025 Ping Identity Corporation

Processing Statistic	Description
RctDurMS	Recent duration in milliseconds Total duration from the last interval of change updates

Running the parallel-update tool

Steps

1. Create an LDIF file with your changes.

   Example:

   The third change in this example generates a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

   ```
   dn:uid=user.2,ou=People,dc=example,dc=com
   changetype: delete

   dn:uid=user.99,ou=People,dc=example,dc=com
   changetype: moddn
   newrdn: uid=user.100
   deleteoldrdn: 1

   dn:uid=user.101,ou=People,dc=example,dc=com
   changetype: add
   objectClass: person
   objectClass: inetOrgPerson
   objectClass: organizationalPerson
   objectClass: top
   postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
   postalCode: 49843
   description: This is the description for Ziggy Zad.
   uid: user.101
   userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

   dn:uid=user.100,ou=People,dc=example,dc=com
   changetype: modify
   replace: st
   st: TX
   -
   replace: employeeNumber
   employeeNumber: 100
   ```

2. To apply the changes in the LDIF file to a target server, run `parallel-update` with the `--ldifFile` and `--rejectFile` options.

   > **Note**
   >
   > The `--ldifFile` and `--rejectFile` options are required.

   Example:

Copyright © 2025 Ping Identity Corporation

In this example, there are ten concurrent threads. The optimal number of threads depends on your underlying system.

```
$ bin/parallel-update --hostname 127.0.0.1 \
  --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

Result:

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS
-------- --------- ------- ------- -------- -------- -------- ---------
       4         3       1       0        3        3       26       26
All processing complete Attempted 4 operations in 1 seconds
```

3. View the rejects files for any failed updates.

   Result:

   The following sample elaborates on the rejected file.

```
# ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed for
# the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

Working with the watch-entry tool

The PingDirectory server provides a `watch-entry` tool that demonstrates replication or synchronization latency by watching an LDAP entry for changes.

About this task

You can directly modify attributes with the `watch-entry` tool.

> **Note**
>
> If the LDAP entry changes, the background of modified attributes will briefly be red.

Steps

- Run the `watch-entry` tool.

Copyright © 2025 Ping Identity Corporation

Example:

This example connects to `server.example.com` as `uid=admin,dc=example,dc=com` and watches entry `uid=kate,ou=people,dc=example,dc=com` for changes.

```
$ bin/watch-entry --hostname server.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --entryDN uid=user,ou=people,dc=example,dc=com
```

Working with LDAP transactions

The PingDirectory server provides support for batched transactions, which are processed together at commit time.

Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes aren't actually processed until the commit request is received. Therefore, the client can't know whether the changes are successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations that are processed as a single atomic unit when the commit request is received. The write operations include the following:

- `add`
- `delete`
- `modify`
- `modify DN`
- `password modify`

If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It's not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple PingDirectory server backends.

Directory servers can limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that you can use the following controls in conjunction with the transaction specification request control:

- Assertion request control
- manageDsaIT request control
- Pre-read request control
- Post-read request control

The proxied authorization v1 and v2 controls can't be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory server supports the following additional controls in conjunction with operations included in a transaction:

- Account usable request control

Copyright © 2025 Ping Identity Corporation

- Hard delete request control
- Intermediate client request control
- Password policy request control
- Replication repair request control
- Soft delete request control
- Soft-deleted entry access request control
- Subtree delete request control, and undelete request control

Requesting a batched transaction using ldapmodify

About this task

You can run the `ldapmodify` tool's `--useTransaction` option to process multiple operations as part of a single batched transaction.

Steps

1. Create a batch text file with the changes that you want to apply as a single atomic unit.

   Example:

   ```
   dn:uid=user.3,ou=People,dc=example,dc=com
   changetype: delete
   dn:uid=user.1,ou=People,dc=example,dc=com
   changetype: modify
   replace: pager
   pager: +1 383 288 1090
   ```

2. To run the batched transaction, run the `ldapmodify` tool with the `--useTransaction` and `--filename` options.

   Example:

   ```
   $ bin/ldapmodify --useTransaction --filename test.ldif
   ```

   Result:

   ```
   #Successfully created a transaction with transaction ID 400
   #Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
   #DELETE operation successful for DN uid=user.3,ou=People,dc=example,dc=com
   #This operation will be processed as part of transaction 400
   #Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
   #MODIFY operation successful for DN uid=user.1,ou=People,dc=example,dc=com
   #This operation will be processed as part of transaction 400
   #Successfully committed transaction 400
   ```

Copyright © 2025 Ping Identity Corporation

Working with virtual attributes

PingDirectory server supports virtual attributes.

Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the PingDirectory server backend.

Most virtual attributes are operational attributes, providing processing-related information that the server requires. The PingDirectory server virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

Viewing the list of default virtual attributes

Use the `dsconfig` tool to view the list of PingDirectory server virtual attributes.

Some virtual attributes are enabled by default and are useful for most applications.

The default set of virtual attributes is described in the table below. You can enable or disable these attributes using the `dsconfig` tool.

Virtual Attributes

Virtual Attributes	Description
`ds-entry-checksum`	Generates a simple `checksum` of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.
`ds-instance-name`	Generates the name of the PingDirectory server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.
`ds-pwp-state-json`	Generates an operational attribute whose values is a JSON object with information about a user's current password policy state.
`entryDN`	Generates an `entryDN` operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.
`hasSubordinates`	Creates an operational attribute that has a value of `TRUE` if the entry has subordinate entries.
`isDirectMemberOf`	Generates an `isDirectMemberOf` operational attribute that contains the DNs of the groups in which the user is a member. `isDirectMemberOf` includes only static groups in which the user is explicitly named as a member. Compare to `isMemberOf`.

Copyright © 2025 Ping Identity Corporation

Virtual Attributes	Description
`isMemberOf`	Generates an `isMemberOf` operational attribute that contains the DNs of the groups in which the user is a member. `isMemberOf` includes all of the following: • Static groups in which the user is explicitly named as a member • Dynamic groups in which the user is a member because of the criteria for that group • Static groups in which the user is a member because they are a member of a nested group that is listed as a member of the static group Compare to `isDirectMemberOf`.
`numSubordinates`	Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested. **Note** This operational attribute only returns the number of immediate children of the node.
`subschemaSubentry`	A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree. • `ldapSyntaxes` - set of attribute syntaxes • `matchingRules` - set of matching rules • `matchingRuleUse` - set of matching rule uses • `attributeTypes` - set of attribute types • `objectClasses` - set of object classes • `nameForms` - set of name forms • `dITContentRules` - set of DIT content rules • `dITStructureRules` - set of DIT structure rules
`User Defined Virtual Attribute`	Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.
`Virtual Static Member`	Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the `Virtual Static Member` attribute as it is an advanced property and modifying it can lead to undesirable side effects.

Copyright © 2025 Ping Identity Corporation

Virtual Attributes	Description
`Virtual Static Uniquemember`	Generates a `uniqueMember` attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the `Virtual Static Uniquemember` attribute because it is an advanced property, and modifying it can lead to undesirable side effects.

Viewing the list of default virtual attributes using dsconfig non-interactive mode

Steps

- To list the virtual attributes, use `dsconfig`.

```
$ bin/dsconfig list-virtual-attributes
```

Viewing virtual attribute properties

View the basic properties of each virtual attribute using the `dsconfig` tool.

About this task

For a complete list of properties, see General Consent Service configuration. The following table shows some basic properties.

Property	Description
`description`	A description of the virtual attribute.
`enabled`	Specifies whether the virtual attribute is enabled for use.
`base-DN`	Specifies the base DNs for the branches containing entries that are eligible to use this virtual attribute. If no values are given, the server generates virtual attributes anywhere in the server.
`group-DN`	Specifies the DNs of the groups whose members can use this virtual attribute. If no values are given, the group membership is not taken into account when generating the virtual attribute. If one or more group DNs are specified, then only members of those groups are allowed to have the virtual attribute.

Copyright © 2025 Ping Identity Corporation

Property	Description
`filter`	Specifies the filters that the server applies to entries to determine if they require virtual attributes If no values are given, then any entry is eligible to have a virtual attribute value generated.

Steps

- To view the properties of a virtual attribute, use `dsconfig`.

  Example:

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

Enabling a virtual attribute

You can enable a virtual attribute using the `dsconfig` tool.

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the `Standard object menu`.

Enabling a virtual attribute using `dsconfig` interactive mode

Steps

1. To enable a virtual attribute, use `dsconfig`.
   1. Specify the connection port, bind DN, password, and host information.
   2. Enter the LDAP connection parameter for your PingDirectory server:
      - For LDAP, enter `1`.
      - For SSL, enter `2`.
      - For StartTLS, enter `3`.

      Example:

```
bin/dsconfig
```

2. On the PingDirectory server main menu, enter `o` to change the object menu, and then enter the number corresponding to `Standard`.
3. On the PingDirectory server main menu, enter the number corresponding to virtual attributes.
4. On the `Virtual Attribute management` menu, enter the number to view and edit an existing virtual attribute.
5. From the list of existing virtual attributes on the system, select the virtual attribute.

   For this example, enter the number corresponding to the `numSubordinates` virtual attribute.

Copyright © 2025 Ping Identity Corporation

6. On the `numSubordinates Virtual Attribute Properties` menu, enter the number to enable the virtual attribute.
7. On the `Enabled Property` menu for the `numSubordinates` virtual attribute, enter the number to change the value to `TRUE`.
8. On the `numSubordinates Virtual Attribute Properties` menu, enter `f` to apply the changes.
9. Verify that the virtual attribute is enabled.

   Example:

   > **Note**
   >
   > This example assumes you have configured the group entries.

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
   ```

   Result:

   The system returns the following.

   ```
   dn: ou=People,dc=example,dc=com
   numSubordinates: 1000
   ```

Enabling a virtual attribute using `dsconfig` non-interactive mode

Steps

- To enable a virtual attribute, such as `numSubordinates`, use `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-virtual-attribute-prop \
    --name numSubordinates --set enabled:true
  ```

Creating user-defined virtual attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute.

There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, or you will see an error message when you configure it.

You can define your virtual attributes using the `dsconfig` tool from the `Standard object menu`. Only the value property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following.

.

Copyright © 2025 Ping Identity Corporation

Property	Description
`enabled`	Indicates whether the virtual attribute should be used.
`attribute-type`	The attribute type for the virtual attribute that is generated.

`base-dn`
`group-dn`
`filter`
	Can be used to select which entries are eligible to contain the virtual attribute.

`client-connection-policy`	Can be used to select which entries are eligible to contain the virtual attribute.
`conflict-behavior`	Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry. The server can either return only the real values, only the virtual values, or merge both real and virtual values.
`require-explicit-request-by-name`	Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
`multiple-virtual-attribute-evaluation-order-index` `multiple-virtual-attribute-merge-behavior`	Used to control the behavior of the server if multiple virtual attributes can be used to contribute values to the same attribute.

Creating a user-defined virtual attribute in interactive mode

About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter `"(employeeType=employee)"`.

Steps

1. To configure the user-defined virtual attribute:
    1. Run `dsconfig`.
    2. Specify the connection port, bind DN, password, and host information.
    3. Type the LDAP connection parameter for your PingDirectory server:
        - For LDAP, enter `1`.
        - For SSL, enter `2`.
        - For StartTLS, enter `3`.
2. To change the object menu, in the PingDirectory server main menu, type `o`, and then type the number to select `Standard`.

Copyright © 2025 Ping Identity Corporation

3. In the PingDirectory server main menu, type the number corresponding to virtual attributes.
4. To create a new virtual attribute, in the `Virtual Attribute management` menu, type the number.
5. Use an existing virtual attribute as a template for your new attribute, or create a new attribute from scratch.

   In this example, type `n` to create a new Virtual Attribute from scratch.
6. In the `Virtual Attribute Type` menu, enter a number corresponding to the type of virtual attribute that you want to create.

   In this example, type the number corresponding to User Defined Virtual Attribute.
7. Enter a name for the new virtual attribute.

   In this example, enter `Employee Password Policy Assignment`.
8. In the `Enabled Property` menu, enter the number to set the property to `TRUE` (enable).
9. In the `Attribute-Type Property` menu, type the `attribute-type` property for the new virtual attribute.

   You can enter the OID number or attribute name. The `attribute-type` property must conform to your schema. For this example, type `ds-pwp-password-policy-dn`.
10. Enter the value for the virtual attribute, and then press Enter or Return to continue.

    In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type Enter or Return to continue.
11. In the `User Defined Virtual Attributes` menu, enter a description for the virtual attribute.

    Though optional, this step is useful if you plan to create multiple virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, type `Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee)`.
12. In the `User Defined Virtual Attribute` menu, type the number corresponding to the filter.
13. In the `Filter Property` menu, enter the option to add one or more filter properties, type the filter, and then press Enter to continue.

    In this example, type `(employeeType=employee)`. Press the number to use the filter value entered.
14. In the `User Defined Virtual Attribute` menu, type `f` to finish creating the virtual attribute.
15. Verify that the attribute was created successfully.
    1. Add the `employeeType=employee` attribute to an entry, such as `uid=user.0`, using **`ldapmodify`**.
    2. Add the `employeeType=contractor` attribute to another entry, such as `uid=user.1`.
16. To search for the user with the `employeeType=employee` attribute, such as `uid=user.0`, use **`ldapsearch`**.

    Example:

    ```
    $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
      ds-pwp-password-policy-dn
    ```

    Result:

Copyright © 2025 Ping Identity Corporation

The `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn=Password Policies,cn=config
```

17. Run `ldapsearch` again using the filter `(uid=user.1)`.

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
  ds-pwp-password-policy-dn
```

Result:

The `ds-pwp-password-policy-dn` attribute is not present in the entry because the entry has the attribute `employeeType=contractor`.

```
dn: uid=user.1,ou=People,dc=example,dc=com
```

Creating a user-defined virtual attribute using `dsconfig` in non-interactive mode

About this task

You can create a virtual attribute in non-interactive command-line mode using `dsconfig`.

Steps

- To set up the Employee Password Policy Assignment virtual attribute introduced in the previous section, run the following command.

Example:

```
$ bin/dsconfig create-virtual-attribute \
  --name "Employee Password Policy Assignment" \
  --type user-defined \
  --set enabled:true \
  --set attribute-type:ds-pwp-password-policy-dn \
  --set "filter:(employeeType=employee)" \
  --set "value:cn=Employee Password Policy,cn=Password Policies,cn=config"
```

Creating mirror virtual attributes

PingDirectory server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry.

For example, consider a directory information tree (DIT) where users have a `manager` attribute with a value of the DN of the employee as follows.

Copyright © 2025 Ping Identity Corporation

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

Creating a mirror virtual attribute using dsconfig in non-interactive mode

Create a mirror virtual attribute using `dsconfig` in non-interactive command-line mode.

About this task

The following example sets up the `managerName` virtual attribute introduced in the previous section:

Steps

1. Update the schema to define the `managerName` attribute.

   You can optionally add the attribute to an object class.

   1. In a text editor, create a file with the following schema definition for the attribute.

      ```
      dn: cn=schema
      objectClass: top
      objectClass: ldapSubentry
      objectClass: subschema attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.4 NAME 'managerName'
        EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
      1.3.6.1.4.1.1466.115.121.1.44{256}
        X-ORIGIN 'PingDirectory Server Example' )
      ```

   2. Save the file as `98-myschema.ldif` in the `<server-root>/config/schema` folder.

2. Restart the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

```
$ bin/stop-server --restart
```

3. To create the virtual attribute, use `dsconfig`.

```
$ bin/dsconfig create-virtual-attribute \
  --name "managerName" \
  --type mirror \
  --set "description:managerName from manager cn" \
  --set enabled:true \
  --set attribute-type:managerName \
  --set source-attribute:cn \
  --set source-entry-dn-attribute:manager
```

4. To verify the mirror virtual attribute, search for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

Result:

Your search results in the following.

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

Editing a virtual attribute

You can edit virtual attributes with the `dsconfig` tool.

Make sure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute.

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the `Standard object menu`.

Editing a virtual attribute using dsconfig in non-interactive mode

Steps

- To change a property value, use `dsconfig`.

Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
  --set "value:111"
```

Copyright © 2025 Ping Identity Corporation

Deleting a virtual attribute

Delete virtual attributes using the `dsconfig` tool.

About this task

If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu from the `Standard object menu`.

Steps

- To delete the `dept-number` virtual attribute, use `dsconfig`.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

Working with composed attributes

This section provides information on composed attributes, which dynamically generate attribute values to complement virtual attributes.

The PingDirectory server's support for virtual attributes is a useful facility that dynamically generates values in entries for a wide range of use cases. These values are used to generate key operational attributes such as:

- `entryDN`
- `subschemaSubentry`
- `isMemberOf`
- `numSubordinates`
- `hasSubordinates`
- `ds-entry-checksum`

The values of other attributes in the same or different entries can be mirrored, and values can be constructed from other attributes in the same entry. Items such as password policies and privileges can be dynamically generated, and you can create custom virtual attribute providers with the Server SDK using a wide variety of logic.

Virtual attributes should not be used for all use cases. Composed attributes, which complement virtual attributes, are more suited for scenarios that virtual attributes do not support.

Virtual attribute limitations

This section describes the limitations of virtual attributes, such as performance, indexing, and consistency limitations.

Copyright © 2025 Ping Identity Corporation

Performance limitations

The performance impact of virtual attribute generation is limited by computing these values only if they are returned to the client. However, performance can still be impacted because of other factors. Virtual attributes might be included or excluded based on a range of criteria and the evaluation of this criteria (for example, based on group membership) can impact performance.

Indexing limitations

You cannot index the values of a virtual attribute because the values can change from one invocation to the next.

Some virtual attributes implement support for an index-like functionality by offering logic that can quickly identify entries with specified virtual attribute values. These include the following:

- When mirroring values from another attribute in the same entry, and when that source attribute type is indexed, the mirror virtual attribute provider can use an internal search to identify matching entries.
- The `entryDN` virtual attribute provider retrieves the entry with the specified distinguished name (DN).
- The `isMemberOf` virtual attribute provider uses the server's group manager to identify the members of a targeted group.

> **Note**
>
> This is not an option for all types of virtual attributes.

Index-like functionality is not available for the following virtual attribute types:

- User-defined virtual attributes that have a static value
- Constructed virtual attributes whose values are composed from multiple other attributes in the same entry
- Mirror virtual attributes whose values come from other entries
- Any custom virtual attribute types implemented using the Server SDK

If you want to have a mix of standard and virtual values for the same attribute type, whether in the same entry or in different entries, there is not a good solution. If you define an index for that attribute type, it only includes entries with standard values and entries with virtual values are overlooked. If there is no index but the virtual attribute provider supports some search functionality, only entries with virtual values are matched and entries with only standard values are excluded.

Unexpected behavior for write operations

A significant issue with virtual attributes is that they can result in unexpected behaviors when targeted by write operations.

These unexpected behaviors include the following:

- Attempting to delete a virtual value fails with a `no such attribute` result.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to add a value to an entry that only has virtual values causes the virtual values to disappear.
- If the virtual attribute provider is configured with a `conflict-behavior of real-overrides-virtual`, then attempting to remove all real values of an entry causes the virtual values to appear.

Copyright © 2025 Ping Identity Corporation

- If the virtual attribute provider is configured with a `conflict-behavior of virtual-overrides-real`, then attempting to add new values or replace the set of existing values yields a success result, but the operation has no visible effect on the entry.
- If the virtual attribute provider is configured with a `conflict-behavior of merge-real-and-virtual`, then attempting to replace the set of values for an entry yields a success result, but only the real values are replaced and the virtual values remain.

There is currently no method to prevent attempts to write to attributes with virtual values. The `NO-USER-MODIFICATION` constraint in attribute type definitions is honored, but this constraint only applies to operational attribute types. This is not an acceptable limitation in many cases. Access control restrictions could work for many clients, but do not have any effect for requesters with the `bypass-acl` privilege.

Overview of composed attributes

Composed attributes are generated when an entry is written.

This includes entries that are created by add operations and LDIF imports. These entries can be created, updated, or removed when processing `modify` and `modifyDN` operations. The server might optionally permit or reject attempts to alter the generated values.

Composed values are based on a combination of static text and the contents of the entry in which the value is being generated. You cannot construct values using content from other entries in the server because the necessary content might not be available at the time the value is being generated. An example of this is if the referenced entry does not yet exist. It would also be difficult to ensure that the value is kept up to date whenever the referenced entry changes or is removed. Values are generated using the same logic that is available for constructed virtual attributes and constructed attribute mapping functionality in the Synchronization Server.

The composed attribute functionality is implemented using a plugin. The plugin is invoked during the pre-operation phases for `add`, `modify`, and `modifyDN` operations and also operates during LDIF import.

The server provides an administrative task that can be used to iterate through all entries in a backend and generate values. This is useful when a new composed attribute plugin instance is created after the backend has already been populated and you do not want to export the data to LDIF and re-import.

The server does not provide any first-class extensibility mechanisms for composed attributes. Unlike virtual attributes, which can be created through the Server SDK, composed attribute support is limited to what the server can provide. You can implement your own plugins to generate your own data.

Composed attribute plugin configuration properties

The composed attribute plugin provides the following configuration properties.

Configuration properties

`plugin-type`

The plugin type values for which the server is registered.

Copyright © 2025 Ping Identity Corporation

This is a mandatory multi-valued property with a default that includes all of the `ldifimport`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn` values. In general, you should not override this default set, but this might be useful in some rare corner cases. The available options include:

`ldifimport`

Indicates that values should be generated for the target attribute in any appropriate entries created during LDIF import processing.

`preoperationadd`

Indicates that values should be generated for the target attribute in any appropriate entries created by add operations.

`preoperationmodify`

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify operations.

`preoperationmodifydn`

Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify distinguished name (DN) operations.

`attribute-type`

The name or OID of the attribute type for which values are generated.

This attribute type must be defined in the schema. This is a mandatory, single-valued property with no default. To have multiple composed attribute types, configure a separate instance of the plugin for each attribute type. To compose multiple values for the same attribute type from different sets of source attributes, use a single instance of the plugin with multiple value patterns.

`value-pattern`

The value pattern that specifies the logic that should be used when constructing values.

This pattern must be compatible with the format expected by the `com.unboundid.directory.server.sync.mapping.ConstructedValue` class. This is a mandatory, multi-valued property in which the order of the values is preserved. If this is configured with multiple values, then the behavior the plugin should exhibit is controlled by the `multiple-value-pattern-behavior` property.

> **Note**
>
> A value pattern is only used for an entry if that entry contains all of the attributes referenced in the value pattern.
> Virtual attributes are not considered when generating values.

`multiple-value-pattern-behavior`

The behavior that the server should exhibit if multiple value-pattern values are configured.

This is a single-valued property with a default value of `use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The primary reason that a rejection might occur is as a result of multivalued source attributes, but it could also occur if an unexpected error occurs while trying to generate values.

The available options include:

`use-first-non-rejected-value-pattern-with-non-empty-values-but-might-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If all value patterns yield empty results, for example, if the entry is missing at least one source attribute for each of the value patterns, then no composed value is generated. If no value pattern yields a non-empty result but at least one is rejected, then the operation fails, or the entry is rejected if performing an LDIF import.

`use-first-non-rejected-value-pattern-with-non-empty-values-and-never-reject`

Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result.

If none of the value patterns yield non-empty results, regardless of whether any of them is rejected, then no composed value is generated.

`use-first-rejection-or-first-value-pattern-with-non-empty-values`

Indicates that the server should only use values generated from the first value pattern that yields non-empty results, but if a rejection is encountered before a non-empty result is obtained, then the operation or LDIF entry is rejected.

If none of the value patterns is not rejected and yields a non-empty result, then no composed value is generated.

`use-all-non-rejected-value-patterns-with-non-empty-values-but-might-reject`

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results but none were rejected, then no composed value is generated. If none of the value patterns yielded non-empty results and at least one was rejected, then the operation fails or the LDIF entry is rejected.

`use-all-non-rejected-value-patterns-with-non-empty-values-and-never-reject`

Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry.

As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns is used. If none of the value patterns yielded non-empty results, regardless of whether any of them was rejected, then no composed value is generated.

Copyright © 2025 Ping Identity Corporation

use-first-rejection-or-all-value-patterns-with-non-empty-values

Indicates that the server should use all of the values generated by all of the value patterns as long as none of them is rejected.

If any value pattern is rejected, then the operation fails or the LDIF entry is rejected. If none of the value patterns is rejected but none of them generates any values, then no composed values are generated.

multi-valued-attribute-behavior

The behavior that the server should exhibit if any of the attributes used in the value pattern have multiple values.

> **Note**
>
> No more than one source attribute should have multiple values. If multiple source attributes have multiple values, and if this property is configured to try to use all of them, then the attempt to generate composed values for the entry might fail.

This is a single-value property with a default value of `use-all-values-if-possible-but-reject-if-not`. Available options include:

use-first-value

Indicates that the server should only use the first value for each source attribute referenced in the value pattern.

With this value, entries should never be rejected for having multivalued attributes.

reject-entries-with-any-multivalued-source-attribute

Indicates that the server should reject any entry that has more than one value for any of the source attributes.

use-all-values-if-possible-but-reject-if-not

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, the entry is rejected.

use-all-values-if-possible-but-only-first-value-if-not

Indicates that the server should use all values for the source attributes as long as at most one of them has multiple values.

If multiple source attributes have multiple values, then only the first value from each source attribute is used so that the entry is not rejected.

target-attribute-exists-during-initial-population-behavior

The behavior that the server should exhibit for add operations and LDIF imports for entries that already contain one or more values for the target attribute.

This is a single-valued property with a default of `preserve-existing-values`. The available options include:

Copyright © 2025 Ping Identity Corporation

`preserve-existing-values`

Indicates that the server should preserve existing values in entries that are added or imported and should only construct values for entries that do not already contain the target attribute.

`overwrite-existing-values`

Indicates that the server should only use generated values for the target attribute and that any values provided during an add or LDIF import is discarded.

`merge-existing-and-composed-values`

Indicates that the server should preserve any existing values for the target attribute and should construct any additional values.

> **Note**
>
> This option can only be used if the target attribute type allows multiple values.

`reject-existing-values-in-add-but-preserve-in-ldif-import`

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import.

> **Note**
>
> The server does not reject entries that already contain the target attribute when performing an LDIF import since this would interfere with the ability to export data to LDIF from a server that contains composed values and then re-import the LDIF file.

`reject-existing-values-in-add-but-overwrite-in-ldif-import`

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should replace any existing values in an LDIF import with the values which would be composed for that entry.

`reject-existing-values-in-add-but-merge-in-ldif-import`

Indicates that the server should reject any add operation that attempts to provide any values for the target attribute but should preserve any existing values when performing an LDIF import and add any additional values that should be composed for the entry.

`update-source-attribute-behavior`

The behavior that the server should exhibit for entries that are updated by `modify` or `modifyDN` operations that alter values for one of the attributes used in the value pattern.

This is a single-valued property with a default of `replace-composed-values`. The available options include:

`replace-composed-values`

Indicates that the server should only update values for the target attribute that match those that would have been generated by the plugin.

Copyright © 2025 Ping Identity Corporation

Values that would not have been generated by the plugin are preserved.

`replace-all-values`

Indicates that the server should always replace the target attribute with new composed values even if the existing values were not generated by the plugin.

`preserve-existing-values`

Indicates that the server should always preserve the existing values for the target attribute even if they were generated by the plugin.

`source-attribute-removal-behavior`

The behavior that the server should exhibit when an entry is updated in a manner that removes one or more source attributes needed to compose values for the target attribute.

This is a single-valued property with a default of `preserve-non-composed-values`. The available options include:

`preserve-non-composed-values`

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

If the target attribute is required by any of the object classes in the entry and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

`preserve-all-values`

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

`remove-all-values-but-preserve-all-if-required`

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of `preserve-all-values` if the target attribute type is required by any of the entry's object classes.

`remove-all-values-but-preserve-non-composed-values-if-required`

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of `preserve-non-composed-values` if the target attribute type is required by any of the entry's object classes.

`update-target-attribute-behavior`

The behavior that the server should exhibit when a client attempts to alter the target attribute with a `modify` or `modifyDN` operation.

This is a single-valued property with a default of `always-allow`. The available options include:

Copyright © 2025 Ping Identity Corporation

`always-allow`

Indicates that the server always permits clients to alter the value of the target attribute regardless of whether these values were generated.

`allow-only-for-non-composed-values`

Indicates that the server only permits clients to alter values for the target attribute that were not generated by the plugin.

Attempts to alter composed values are rejected.

`never-allow`

Indicates that the server should reject any attempt to alter the target attribute regardless of the values it might have.

`include-base-dn`

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

`exclude-base-dn`

A base DN that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

`include-filter`

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

`exclude-filter`

A search filter that might be used to restrict the set of entries for which values are composed.

The following section provides a detailed description of the include and exclude criteria configuration options.

`updated-entry-newly-matches-criteria-behavior`

The behavior that the server should exhibit if an entry that previously did not satisfy either the base DN or filter criteria, but is updated so that it does match any configured base DN or filter criteria.

This is a single-valued property with a default value of `preserve-existing-values-and-compose-new-values`. The available options include:

`preserve-existing-values-without-composing-new-values`

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then no composed values are generated for the entry.

Copyright © 2025 Ping Identity Corporation

`preserve-existing-values-or-compose-new-values`

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and no additional composed values are added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

`preserve-existing-values-and-compose-new-values`

Indicates that if the entry already had one or more values for the target attribute, those values are preserved and any additional values that would be composed for that entry is also added.

If the entry did not contain the target attribute, then composed values are generated for the entry.

`compose-new-values-without-preserving-existing-values`

Indicates that if the entry already had one more composed values for the target attribute, then those values are removed and replaced with the composed values that would be generated for it

If the entry did not contain the target attribute, then composed values are generated for it. If no composed values would be generated for the entry, for example, if it was missing at least one source attribute for each value pattern, then the entry does not include the target attribute, regardless of whether it contained existing values for the attribute.

`updated-entry-no-longer-matches-criteria-behavior`

The behavior that the server should exhibit if an entry previously satisfied the configured base DN and filter criteria but has been updated so that it no longer matches that criteria.

This is a single-valued property with a default of `preserve-all-values`. The available options include:

`preserve-all-values`

Indicates that the server preserves any values that exist for the target attribute regardless of whether they would have been composed by any of the value patterns.

`preserve-non-composed-values`

Indicates that the server attempts to remove any values for the target attribute that would have been generated for that entry by the associated value patterns but preserves any other values that might exist for the target attribute.

However, if the target attribute is required by any of the object classes in the entry, and if that entry only contains composed values for the target attribute, then the composed values are preserved to avoid violating the schema.

`remove-all-values-but-preserve-all-if-required`

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of `preserve-all-values` if the target attribute type is required by any of the entry's object classes.

Copyright © 2025 Ping Identity Corporation

`remove-all-values-but-preserve-non-composed-values-if-required`

Indicates that the server attempts to remove all values for the target attribute from the entry, regardless of whether they would have been composed but falls back to a behavior of `preserve-non-composed-values` if the target attribute type is required by any of the entry's object classes.

Include and exclude criteria configuration

Attribute values are composed by default for every entry in any public backend that contains all of the source attributes used in the appropriate value patterns. To restrict composed values to a specific set of entries, use the `include-base-dn`, `exclude-base-dn`, `include-filter`, and `exclude-filter` properties.

If the `include-base-dn` property is provided, then values are composed for entries at or below one of those base DNs. If the `exclude-base-dn` property is provided, then values are not composed for any entries at or below one of those base DNs. If both properties are provided and a given entry follows both an include and an exclude base DN, then the exclude base DN takes precedence and values are not generated for that entry. If neither property is specified, then the naming contexts of all public backends are used as the default set of include base DNs.

If the `include-filter` property is provided, then values are composed for entries that match at least one of those filters. If the `exclude-filter` property is provided, then values are not composed for any entries that match at least one of those filters. If both properties are provided and a given entry matches both include and exclude filters, then the exclude filter takes precedence and values are not generated for that entry. If neither property is specified, then the server behaves as if an include filter of "&" had been specified.

> **Note**
>
> No virtual attributes are considered when evaluating this filter although composed values might be taken into consideration. For more information about the order in which composed attribute definitions are evaluated, see Composed attribute dependency considerations.

Populate composed attribute values task

When a composed attribute plugin is created in the server, it takes effect immediately and starts creating values for any appropriate `add`, `modify`, and `modifyDN` operations.

Existing entries are not automatically populated with generated values. To populate existing entries with generated values, export the data to LDIF and then re-import it. This requires temporarily taking each instance out of service, since importing into a single instance has no effect on the data in other instances. The LDIF import option is only feasible when you are starting from scratch, not when you have existing data. To address this need, a "populate composed attribute values" task is provided. The populate composed attribute values task iterates through all entries in one or more backends and generates values as appropriate for any entries.

This task provides several number of configuration attributes, including the following:

`ds-task-populate-composed-attribute-plugin-config`

An optional, multi-valued attribute that can be used to specify the names or distinguished names (DNs) of the composed attribute plugin configuration entries for which values should be generated.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If this attribute is omitted, then values are generated for all defined and enabled composed attribute plugin instances.

`ds-task-populate-composed-attribute-backend-id`

An optional, multi-valued attribute that can be used to specify the backend IDs of the backends in which values should be generated.

> **Note**
>
> If this attribute is omitted, then an appropriate set of backends is determined based on the include and exclude base DNs for the selected plugins.

`ds-task-populate-composed-attribute-max-rate-per-second`

An optional, single-valued integer attribute that can be used to specify the maximum number of entries to be updated per second.

> **Note**
>
> If this attribute is omitted, then no rate limit is imposed.

The task uses the same logic that the plugin uses for entries imported from LDIF when deciding what values to include in the entry, but it uses internal modify operations to make any updates to the entry. These changes are replicated to other servers in the topology, so the task only needs to be invoked on a single instance. However, you should only run it after the composed attribute plugins have been configured on all instances in the topology because this ensures that no entries, including those added or updated while the task is running, are overlooked.

To invoke the task and monitor its progress, use the `populate-composed-attribute-values` command-line tool. This processing is not expected to be needed on a regular basis, so it is not offered as a recurring task.

Composed attribute dependency considerations

Composed attributes must not have dependencies on virtual attributes.

The server does not use virtual attribute values when generating values from a value pattern, nor does it use virtual attribute values when determining if an entry matches an include or exclude filter.

In general, there is no need to have one composed attribute depend on another. If one composed attribute is constructed from other attributes in the entry, then a composed attribute that needs to use another composed attribute as its source can include the value pattern for the initial composed attribute as part of its own value pattern. However, this might not be sufficient if clients can override the composed values.

If there is a reason that one composed attribute needs to depend on another, then ensure that the following requirements are satisfied:

- Any composed attribute plugins that have dependencies should be configured so that they are invoked in the appropriate order.

Copyright © 2025 Ping Identity Corporation

> **Tip**
>
> To configure the order in which composed attribute plugins are invoked, use `plugin-order-ldif-import`.

- Run the populate composed attribute values task separately for each of the attributes to be generated.
- The first run should be to generate values for any composed attributes that are not dependent on any other composed attributes.
- The second run should generate values for any composed attributes that were created during the first run. If multiple levels of nesting are required, you must perform additional runs of the task.
- Enable the `plugin-order-pre-operation-add`, `plugin-order-pre-operation-modify`, and `plugin-order-pre-operation-modify-dn` properties in the plugin root configuration.

Schema validation considerations

The server only generates composed attributes for entries in which that attribute is allowed to be present.

For user attributes, the target attribute type must be permitted by at least one of the object classes associated with the entry. If an entry does not have any object class that permits the target attribute, then an attempt to generate composed values for the entry fails with an `objectClassViolation (65)` result. This restriction does not exist for operational attributes.

The server allows composed attributes to satisfy mandatory attribute requirements. If the target attribute is declared as a `MUST` type for any of the entry's object classes, then a client should be able to add an entry that does not include values for that attribute type as long as the server composes a value for that attribute.

The server enforces attribute syntax restrictions for composed attributes. If a composed attribute violates the syntax for the associated attribute type, then the operation resulting in that composed attribute value is rejected with an `INVALID_ATTRIBUTE_SYNTAX` result. This can be overridden on a per-attribute-type basis using the `permit-syntax-violations-for-attribute` property in the global configuration.

> **Note**
>
> If this option is used to permit values that violate the associated syntax, then matching operations involving malformed values might not behave in a predictable manner.

The server should also enforce the `SINGLE-VALUE` constraint for the target attribute type. If an attribute type is defined with this constraint, you cannot configure the composed attribute plugin to generate multiple values for that attribute, and any operation that results in multiple values for the target attribute is rejected.

Composed attributes cannot set values for operational attributes that are defined with the `NO-USER-MODIFICATION` constraint.

Replication considerations

The composed attribute configuration should be identical for all servers in the replication topology. When a composed attribute plugin is configured for one instance, the same definition should be added to all other instances in the topology.

Copyright © 2025 Ping Identity Corporation

Composed attribute values should only be generated for the server that processes the request from the client. When that operation is replicated to other servers, the composed attribute changes should be included as part of that operation.

Replicated changes involving composed attributes should not be restricted in a way that prevents external clients from writing to those values. This includes composed values for operational attribute types with the `NO-USER-MODIFICATION` constraint as well as for cases in which the plugin forbids clients from modifying values.

> **Note**
>
> The plugin rejects any `modifyDN` operation that alters source attributes in a way that results in composed attribute changes.

Synchronization server considerations

Changes involving composed attributes should be synchronized from a PingDirectory server instance to another endpoint type without issues. Changes that create or update composed attributes should be written to the LDAP changelog, just like changes to regular attributes.

Synchronization to PingDirectory server configured with one or more composed attribute plugin instances might be more problematic. It might not be possible to synchronize a composed attribute type if the plugin that generates values for that attribute is configured to prohibit external clients from altering values of that attribute.

If PingDirectory server is used as a sync destination in an environment in which some attribute values might need to be composed, then you should compose those values in the Synchronization Server using a constructed attribute mapping rather than attempt to generate them in the PingDirectory server with the composed attribute plugin.

PingDirectoryProxy server considerations

Using the PingDirectoryProxy server should not require any special consideration in an environment involving composed attributes. This should be true for both simple and entry-balanced proxy configurations.

Troubleshooting considerations

For operations that are rejected for reasons related to composed attribute processing, the diagnostic message is returned to the client and included in the access log.

Examples of rejected operations that result in a diagnostic message include:

- If an `add`, `modify`, or `modifyDN` operation is rejected because the composed value violated the syntax for the target attribute type.
- If an attempt was made to alter a composed attribute value in a way that is not permitted by the plugin.

The composed attribute plugin also contains detailed debug logging support. If you encounter unexpected behavior when using the composed attribute plugin, you should enable debugging for the plugin to provide information to help diagnose the problem.

Copyright © 2025 Ping Identity Corporation

Security considerations

The primary security consideration for composed attributes is that they can expose the values of other attributes.

For example, if the `cn` attribute is composed from the values of the `givenName` and `sn` attributes, then a user with permission to read the `cn` attribute could determine the values of the `givenName` and `sn` attributes even if they do not have permission to read these attributes directly.

This is not typically a significant concern, and you can address it by ensuring that the user's access-control configuration restricts access to source attributes used in a composed attribute value pattern and imposes similar restrictions to the composed attribute.

Limitations of composed attributes relative to virtual attributes

Composed attribute support provides an alternative to a specific set of use cases that might also be addressed by virtual attribute support. The composed attribute solution might improve performance, searchability, and write behavior, but it also has limitations relative to the virtual attribute subsystem.

Limitations of composed attributes relative to virtual attributes include:

- When creating a composed attribute plugin in the server, you must use manual action to populate composed values in existing entries. When enabling a virtual attribute, the attribute is immediately available to clients.
- When removing a virtual attribute from the server, values that would have been generated for the attribute are no longer present. When removing or disabling a composed attribute plugin, previously generated composed values remain.
- Virtual attributes can be configured so that the values are only generated under certain conditions, such as only for certain clients, and to enable different values being generated for different clients. Composed attributes are the same for all clients although access controls can be used to restrict which clients have access to them.
- Virtual attributes do not require any additional storage or memory usage. Composed attributes exist in the database, so they require additional disk space and memory for caching.
- The composed attribute plugin can only generate values from a combination of static text and values from other attributes in the same entry. Virtual attributes can use a much wider range of logic when generating values, including custom logic implemented using the Server SDK.

Encrypting sensitive data

This section covers how to configure the PingDirectory server to protect sensitive information in the server.

Some of the ways to protect sensitive data covered in this section are enabling on-disk encryption for data in backends, the changelog, and the replication databases. You can protect sensitive attributes by limiting the ways that clients can interact with them.

For more information, see the following topics:

- About encrypting and protecting sensitive data
- About backing up and restoring the encryption settings definitions

Copyright © 2025 Ping Identity Corporation

- Configuring sensitive attributes
- Configuring global sensitive attributes
- Excluding a global sensitive attribute on a client connection policy

About encrypting and protecting sensitive data

The PingDirectory server provides an encryption settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data:

- in backends
- in the changelog
- in the replication databases

You can protect sensitive attributes by limiting the ways that clients can interact with them.

About the encryption settings database

The encryption settings database is a repository that holds information for encrypting and decrypting data.

The database contains encryption settings definitions that specify information about the cipher transformation and encapsulate the key used for encryption and decryption. Before enabling data encryption, you must create an encryption settings definition. An encryption settings definition specifies the cipher transformation to use to encrypt the data and encapsulates the encryption key.

You can use the `encryption-settings` tool to manage the encryption settings database, including:

- Creating, deleting, exporting, and importing encryption settings definitions
- Listing the available definitions
- Indicating which definition to use for subsequent encryption operations
- Managing data encryption restrictions to impose on the server
- Freezing and unfreezing the encryption settings database
- Supplying the passphrase needed for the Wait for Passphrase cipher stream provider

For more about the `encryption-settings` tool, see Using the encryption-settings tool.

Implementing encryption settings definitions

Although the encryption settings database can have multiple encryption settings definitions, you must designate only one of them as the preferred definition. The preferred encryption settings definition is used for all subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten, such as a result of a `modify` or `modifyDN` operation, or if the data is exported to LDIF and re-imported.

Copyright © 2025 Ping Identity Corporation

If you introduce a new preferred encryption settings definition, then any existing encrypted data continues to use the previous definition until it is rewritten. If you do change the preferred encryption settings definition for the server, keep the previous definitions in the database until you have verified that no remaining data uses the older keys.

Supported encryption ciphers and transformations

Learn how to implement encryption ciphers, cipher algorithms, and cipher stream providers in the PingDirectory server.

Cipher algorithms

The PingDirectory server supports encryption cipher suites that are compliant with the Java Virtual Machine (JVM) on which the server is running. When configuring encryption, you must specify the cipher using a key length in bits and either a cipher algorithm name, such as AES, or a full cipher transformation that explicitly specifies the mode and padding to use for the encryption, such as AES/CBC/ PKCS5Padding. If only a cipher algorithm is given, then the default mode and padding for that algorithm are automatically selected.

The following cipher algorithms and key lengths have been tested using the Oracle JVM.

Cipher algorithms and key length

Cipher Algorithm	Key Length (bits)
AES	128
Blowfish	128
DES	64
DESede	192
RC4	128

> **Tip**
>
> Although the server supports all of the cipher algorithms listed in the table, using any algorithm other than AES is discouraged. The DES and RC4 algorithms have known vulnerabilities, and there are no meaningful advantages in using Blowfish or DESede instead of AES.

By default, some JVM implementations come with limited encryption strength, which might restrict the usable key lengths. For example, the Oracle JVM does not allow AES with 192-bit or 256-bit keys unless you download and install the unlimited encryption strength policy files.

Cipher modes indicate how the cipher algorithm should be recurrently applied to portions of the data to produce the final result. Supported cipher transformation modes include:

CBC

The Cipher Block Chaining mode uses an initialization vector to introduce randomness into the encryption process. This ensures that encrypted outputs are always unique even when the input data is identical.

Copyright © 2025 Ping Identity Corporation

GCM

The Galois/Counter mode provides better data integrity protection to ensure that ciphertexts are not altered. Like the CBC mode, GCM uses an initialization vector to introduce randomness into the output.

ECB

The Electronic Codebook mode encrypts each block of data separately without using any randomness. Because of the lack of randomness, this mode is susceptible to plain-text attacks.

Padding is important when using a block cipher because these ciphers can only encrypt a fixed amount of data at a given time. If the amount of data to be encrypted is not a multiple of the block size, then extra bytes must be added to the plain text before encrypting it. It must also be possible to remove these extra bytes when decrypting. Supported padding algorithms in a cipher transformation include:

PKCS5Padding

This is a standard padding algorithm described in the PKCS #7 specification in RFC 5652. You should use this padding algorithm when using a block cipher like AES with the CBC or ECB modes. Optionally, you can also use this algorithm when using the AES block cipher with the GCM mode.

NoPadding

This algorithm indicates that no padding is needed and should be used with stream ciphers rather than block ciphers.

> **Note**
>
> AES can act as a stream cipher when using the GCM mode.

For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the Java Cryptography Architecture Reference Guide and Java Cryptography Architecture Standard Algorithm Name Documentation documentation.

Cipher stream providers

By default, setup generates a strong, random passphrase and writes it to a file. The server then uses a file-based cipher stream provider to read the passphrase and generate a key for encrypting the contents of the encryption settings database. However, the server supports additional cipher stream providers that use alternative means for unlocking the encryption settings database. Options include:

- Require a passphrase to be interactively provided when the server is started or any time an external process needs access to the encryption settings database.
- Use a key stored in the Amazon Key Management Service (KMS).
- Use a key stored in a HashiCorp Vault instance.
- Use a key generated from a passphrase stored in the Amazon Secrets Manager service.
- Use a key generated from a passphrase stored in the Azure Key Vault service.
- Use a key generated from a passphrase stored in a CyberArk Conjur instance.
- Use a key generated from a certificate stored in a PKCS #11 token.

Copyright © 2025 Ping Identity Corporation

For more information, see Configuring cipher stream providers.

Using the encryption-settings tool

The `encryption-settings` tool provides a mechanism for interacting with the server's encryption settings database.

About this task

Use the `encryption-settings` tool to:

- List the available encryption settings definitions.
- Create new encryption settings definitions.
- Delete existing encryption settings definitions.
- Indicate which encryption settings definition is the preferred definition.
- Export encryption settings definitions to a file for backup purposes and to allow them to be imported for use in other PingDirectory server instances.
- Enable and disable data encryption restrictions for the server and list active restrictions.
- Freeze or unfreeze the encryption settings database.
- Supply the passphrase for the Wait for Passphrase cipher stream provider to unlock the encryption settings database.

Steps

- To display the set of available encryption settings definitions, use the `encryption-settings` tool with the `list` subcommand.

  This subcommand does not take any arguments.

  Example:

  ```
  $ bin/encryption-settings list
  ```

  Result:

  For each definition, the result includes:

  - The unique identifier for the definition
  - Whether the definition is the preferred definition
  - The cipher transformation and key length that are used for encryption

Copyright © 2025 Ping Identity Corporation

```
Encryption Settings Definition ID: 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
Cipher Transformation: DESede
Key Length (bits): 192

Encryption Settings Definition ID: F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

Creating encryption settings definitions

The `encryption-settings` tool with the `create` subcommand provides a mechanism for creating a new encryption settings definition.

Steps

- To create an encryption settings definition, use the `encryption-settings` tool with the `create` subcommand.

  This subcommand takes the following arguments.

Argument	Description
`--cipher-algorithm <algorithm>` (required)	Specifies the base cipher algorithm to use. Make sure the *<algorithm>* input is the name of the algorithm, such as AES.
`--cipher-transformation <transformation>` (optional)	Specifies the full cipher transformation to use including the cipher mode and padding algorithms, such as AES, CBC, and PKCS5Padding. If you do not provide this argument, a default transformation is used for the specified cipher algorithm.
`--key-length-bits <length>` (required)	Specifies the length of the encryption key in bits, such as 128.
`--set-preferred`	Indicates that the new encryption-settings definition is made the preferred definition and used for subsequent encryption operations in the server. By default, the first definition you create in the encryption settings database is the preferred definition.
`--key-factory-iteration-count <count>`	Specifies the PBKDF2 iteration count to be used when deriving the encryption key for the resulting definition.

Copyright © 2025 Ping Identity Corporation

Argument	Description
`--prompt-for-passphrase`	Indicates that the tool should prompt the user for a passphrase to use in generating the encryption settings definition.
`--passphrase-file <path>`	Specifies the file path containing the passphrase to be used in generating the encryption settings definition.
`--description <description>`	Provides a readable string describing the purpose of the encryption settings definition.

Each encryption settings definition is backed by a passphrase that generates an associated encryption key. You can specify the passphrase when creating the definition by typing it into an interactive prompt or providing it in a file. If you do not specify a passphrase, then the `encryption-settings` tool will generate a strong random passphrase.

The created encryption settings definition has an identifier that the server uses to indicate the definition used in encrypting a given block of data. That way, the correct definition can be used to decrypt that data. This identifier is generated from several elements, including:

- The passphrase backing the definition
- The iteration count used to derive the encryption key from the passphrase
- The derived key length
- The cipher algorithm and cipher transformation used to perform the encryption

If you create an encryption settings definition with the same passphrase, iteration count, key length, cipher algorithm, and cipher transformation across multiple servers, then each of the servers will have an identical encryption settings definition. To create a definition without specifying a passphrase, use the `encryption-settings export` command to export that definition from its native server instance. Then, use the `encryption-settings import` command to import the definition into other instances of the topology.

> **Note**
>
> Although the `--key-factory-iteration-count` argument is optional, you should provide this argument whenever generating a new encryption settings definition because the default iteration count is lower than the minimum count of 600,000 recommended by OWASP.

Example:

```
$ bin/encryption-settings create --cipher-algorithm AES \
--cipher-transformation AES/GCM/NoPadding \
--key-factory-iteration-count 600000 \
--key-length-bits 256 \
--set-preferred \
--description "Example encryption settings definition with a randomly generated key"
```

Result:

Copyright © 2025 Ping Identity Corporation

```
Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Changing the preferred encryption settings definition

The `encryption-settings` tool with the `set-preferred` subcommand provides a mechanism for changing the preferred encryption settings definition.

About this task

To change a definition to a preferred definition:

Steps

- To change a definition, use the `encryption-settings` tool with the `set-preferred` subcommand to change a definition to a preferred definition.

  This subcommand takes the following argument.

  The `set-preferred` subcommand accepted argument

Argument	Description
`--id <id>` (required)	Specifies the ID to export for the encryption settings definition.

  Example:

  ```
  $ bin/encryption-settings set-preferred --id 4D86C7922F71BB57B8B5695D2993059A26B8FC01
  ```

  Result:

  ```
  Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01 was
  successfully set as the preferred definition for subsequent encryption operations
  ```

Deleting an encryption settings definition

To free space in the encryption settings database, you can use the `encryption-settings` tool to delete encryption settings definitions.

About this task

You should not remove an encryption settings definition that the server is currently using because it will no longer be possible to access any data encrypted by the removed definition. In some cases, removing a definition used to encrypt live data in the database (which can include local DB backends, the replication database, or the LDAP changelog) prevents the server from starting or accessing content in the backend.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Do not remove encryption settings definitions unless there is reason to believe they are compromised. If you believe a key has been compromised, see Handling compromised encryption settings definitions for details on safely removing that key.

To delete an encryption settings definition:

Steps

- **Use the `encryption-settings` command with the `delete` subcommand.**

  > **Important**
  >
  > Make sure to include the `--id` argument to specify the definition.

Argument	Description
`--id <id>` (required)	**Specifies the ID of the encryption settings definition to delete.**

  Example:

  ```
  $ bin/encryption-settings delete --id F635E109A8549651025D01D9A6A90F7C9017C66D
  ```

  Result:

  ```
  Successfully deleted encryption settings definition
  F635E109A8549651025D01D9A6A90F7C9017C66D
  ```

Configuring data encryption restrictions

The PingDirectory server supports several data encryption restrictions that make it harder for unauthorized individuals to access data in an unencrypted form.

About this task

> **Note**
>
> By default, none of the available data encryption restrictions are active in the server.

Steps

- **To configure data encryption restrictions, use the `encryption-settings set-data-encryption-restrictions` command with one of the following arguments.**

Copyright © 2025 Ping Identity Corporation

Arguments	Description
`--add-restriction <restriction-name>`	Activates the specified encryption restriction in the server. You can provide this argument multiple times with a single command to add multiple restrictions.
`--remove-restriction <restriction-name>`	Removes the specified encryption restriction from the server. You can provide this argument multiple times with a single command to remove multiple restrictions.
`--remove-all-restrictions`	Removes any data encryption restrictions that are currently in place.
`--add-all-restrictions`	Activates all supported data encryption restrictions that are not already active.

Example:

```
$ bin/encryption-settings set-data-encryption-restrictions \
    --add-all-restrictions
```

After the successful completion of the previous command, you receive a message like the following:

```
Successfully updated the set of active data encryption restrictions.

The updated set of active data encryption restrictions is:
* prevent-disabling-data-encryption.
* prevent-changing-cipher-stream-provider.
* prevent-encryption-settings-export.
* prevent-unencrypted-ldif-export.
* prevent-passphrase-encrypted-ldif-export.
* prevent-unencrypted-backup.
* prevent-passphrase-encrypted-backup.
* prevent-decrypt-file.
```

- To determine which data encryption restrictions are active in the server, use the `encryption-settings get-data-encryption-restrictions` command.

> **Note**
>
> If you are defining data encryption restrictions in the server, freeze the encryption settings database so that these restrictions cannot be modified by anyone without the appropriate passphrase. For more information, see Freezing the encryption settings database.

Freezing the encryption settings database

You can freeze the encryption settings database with a specified passphrase. While it is frozen, the database operates in read-only mode.

Copyright © 2025 Ping Identity Corporation

About this task

If the encryption settings database is frozen, the server can use the database for data encryption processing but will not allow any of the following:

- Creating new encryption settings definitions
- Importing encryption settings definitions from an exported set
- Removing encryption settings definitions
- Specifying which definition is preferred for new encryption operations
- Adding or removing data encryption restrictions

To make changes to a frozen database, you must unfreeze it by providing the passphrase originally used to freeze it.

Steps

- To freeze the encryption settings database, use the `encryption-settings freeze` command.

  This command supports the `--passphrase-file <path>` argument, which specifies the path to a file containing the passphrase to use for freezing the encryption settings database. If the argument is not provided, the `encryption-settings freeze` command prompts the user for the passphrase.

  Example:

  ```
  $ bin/encryption-settings freeze
  Enter the passphrase to use to freeze the encryption settings database:
  Confirm the freeze passphrase:
  Successfully froze the encryption settings database.
  ```

- To unfreeze the encryption settings database, use the `encryption-settings unfreeze` command and provide the passphrase originally used to freeze the database.

  This command supports the `--passphrase-file <path>` argument, which specifies the path to a file containing the passphrase to use for unfreezing the encryption settings database. If this argument is not provided, the `encryption-settings unfreeze` command prompts the user for the passphrase.

  Example:

  ```
  $ bin/encryption-settings unfreeze
  Enter the passphrase used to freeze the encryption settings database:
  Successfully unfroze the encryption settings database.
  ```

- To determine whether the encryption settings database is currently frozen, use the `encryption-settings is-frozen` command.

  This command does not require any arguments.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/encryption-settings is-frozen
The encryption settings database was frozen at Mon Mar 06 22:42:10 UTC 2023.
```

Encrypting and decrypting files

You can use the `encrypt-file` tool to encrypt and decrypt files with an encryption settings definition or with a supplied passphrase.

About this task

When a file is encrypted with an encryption settings definition, the server can automatically determine that the file is encrypted, retrieve the associated definition from the encryption settings database, and use it to access the file's contents.

Encrypting a file with an encryption settings definition is useful for files containing sensitive content needed for processing. Examples include:

- PIN files for certificate keys and trust stores
- The `tools.properties` file that contains default arguments for command-line tools
- Bind password files for command-line tools
- Files used for file-based passphrase providers

> **Note**
>
> The server does not support encrypting the configuration or schema files. It also does not support encrypting files needed by the configured cipher stream provider to access the encryption settings database.

To encrypt a file with the server's preferred encryption settings definition:

Steps

- Use the `encrypt-file` tool.

  Example:

  ```
  $ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted
  ```

  The `encrypt-file` tool can also decrypt the results of encrypted output files generated by the server, including encrypted backups, LDIF exports, and log files. However, this decryption cannot be performed if the `prevent-decrypt-file` data encryption restriction is active.

  Useful arguments to use with the `encrypt-file` tool include.

Copyright © 2025 Ping Identity Corporation

Arguments	Description
`--input-file <path>`	Specifies the path to the file containing the plain-text data to be encrypted. If you do not provide this argument, then the data will be read from standard input.
`--output-file <path>`	Specifies the path to the file to which the encrypted data should be written.
`--decrypt`	Indicates that the data in the input file should be decrypted rather than encrypted. Use of this argument is not allowed if the `prevent-decrypt-file` data encryption restriction is enabled.
`--encryption-settings-id <id>`	Specifies the ID associated with the encryption settings definition to be used in encrypting the input file. By default, the server uses the preferred encryption settings definition.
`--prompt-for-passphrase`	Indicates that the tool should prompt the user for a passphrase to use to encrypt the file, rather than encrypting the file with an encryption settings definition. The server cannot automatically decrypt passphrase-encrypted files.
`--passphrase-file <path>`	Specifies the path to the file containing the passphrase to use to encrypt the file.
`--compress-output`	Indicates that the server should gzip-compress the output. When encrypting data, the output is compressed before it is encrypted. When decrypting data, the data is compressed after it is decrypted.
`--decompress-input`	Indicates that the input file is gzip-compressed. When decrypting data, the data is decompressed after it is decrypted.

Use the `encrypt-file --help` command to see a complete set of arguments supported by the `encrypt-file` tool.

About backing up and restoring the encryption settings definitions

The PingDirectory server provides two different mechanisms for backing up and restoring encryption settings definitions.

To back up and restore encryption settings definitions, you can either:

- Export one or more encryption settings definitions using the `encryption-settings export` command. This command also generates a passphrase-protected file containing the encryption settings definitions in a portable format. This is the recommended approach.

Copyright © 2025 Ping Identity Corporation

- Back up and restore the entire encryption settings database using the `backup` and `restore` tools.

The `encryption-settings export` command is recommended for the following reasons:

- With the `backup` command, the resulting backup only contains the `encryption-settings-db` file. The backup does not automatically contain any metadata files needed by the configured cipher stream provider to access the encryption settings database. The output generated by the `backup` command indicates which additional files are needed to enable that access.

  > **Note**
  >
  > These metadata files must be present before restoring the encryption settings database.

- With the `backup` command, the resulting backup depends on the cipher stream provider enabled when the encryption settings database was last written. This means that the cipher stream provider must already be configured and active in the server configuration before restoring the encryption settings database.

- Because the backup generated by the `backup` command depends on the existing configuration of the cipher stream provider, that cipher stream provider might not be useable if the system configuration changes. For example, if the Amazon Key Management Service cipher stream provider was used at the time the backup was generated with an encryption key that is no longer available, then it's not possible to restore the backup.

> **Important**
>
> The encryption settings definitions must be exported or backed up regularly, especially after creating a new definition, importing one or more definitions, or changing the preferred encryption settings definition.
> If an encryption settings definition is lost, then any data encrypted with that definition becomes inaccessible. In some cases, a lost definition renders the server inoperable.

Exporting encryption settings definitions

Use the `encryption-settings` tool with the `export` subcommand to export encryption settings definitions.

About this task

The `encryption-settings export` command creates a portable, passphrase-protected export of one or more encryption settings definitions. You can use encryption settings exports in the following ways:

- As the preferred method for backing up encryption settings definitions. The export format is portable, does not depend on the cipher stream provider configuration, and can be used across server versions.

- As a way to transfer encryption settings definitions between servers.

- As a way to set up new server instances with an appropriate set of definitions. When executing `setup`, you can use the `--encryptDataWithSettingsImportedFromFile` and `--encryptionSettingsExportPassphraseFile` options to enable encryption with definitions from an export file.

Steps

- To export the encryption settings definitions to a file, use the `encryption-settings` tool with the `export` subcommand.

  The subcommand can take the following arguments.

Copyright © 2025 Ping Identity Corporation

Arguments	Description
`--id <id>`	Specifies the ID to export for the encryption settings definition. You can specify this argument multiple times. If it's omitted, all definitions are exported.
`--output-file <path>` (required)	Specifies the path to the output file to write the encryption settings definition to.
`--pin-file <path>`	Specifies the path to a passphrase file containing the password for encrypting the contents of the exported definition. If this argument isn't provided, then the PIN is interactively requested.

Example:

The following example shows the specific path to an output file for the exported encryption settings definition:

```
$ bin/encryption-settings export --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
Successfully exported encrpytion settings data to file /tmp/exported-key
```

The successful export returns the following:

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

Importing encryption settings definitions

About this task

To import an encryption-settings definition that has been previously exported, use the `encryption-settings` tool with the `import` subcommand. The subcommand takes the following arguments:

`--input-file {path}`

Specifies the path to the file containing the exported encryption settings definition. This argument is required.

`--pin-file {path}`

Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument isn't provided, then the PIN is interactively requested from the server.

Copyright © 2025 Ping Identity Corporation

`--set-preferred`

Specifies that the newly-imported encryption settings definition should be made for the preferred definition for subsequent encryption settings.

Steps

- Use the `encryption-settings` tool with the `import` subcommand to import the definition to a file.

  Example:

  ```
  $ bin/encryption-settings import --input-file /tmp/exported-key --set-preferred
  Enter the PIN used to encrypt the definition:
  ```

  Result:

  ```
  Successfully imported encryption settings definition
  F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
  ```

Enabling data encryption in the server

Using data encryption ensures that all future operations written to the local backends, LDAP changelog, and replication database are protected from unauthenticated sources.

About this task

Enabling data encryption after setting up the server can result in unencrypted data being stored in local DB backends, the LDAP changelog, and the replication database. You should export all local DB backends to LDIF and re-import the data after enabling encryption to ensure that all data is properly encrypted. This will also ensure that all indexes are encrypted.

To enable data encryption:

Steps

- Use the `dsconfig` tool with the `set-global-configuration-prop` subcommand and set one of the following properties.

Global property	Configuration description
`encrypt-data`	Indicates whether data encryption is enabled in the server: ◦ If set to `true`, then subsequent writes to the local DB backends, the replication database or the LDAP changelog will be encrypted. ◦ If set to `false`, then subsequent writes will be stored in unencrypted form.

Copyright © 2025 Ping Identity Corporation

Global property	Configuration description
`encryption-settings-cipher-stream-provider`	Indicates which cipher stream provider should be used to protect the contents of the encryption settings database. By default, an instance of the file-based cipher stream provider is used to encrypt the database with a key generated by a passphrase read from a specified file.
`encrypt-backups-by-default`	Indicates whether the server should encrypt backups by default: ◦ If set to `true`, a specified **`backup-encryption-settings-definition-id`** value is used to generate the encryption key for the backup. ◦ If a value is not specified, the server attempts to use the preferred encryption settings definition to generate the encryption key. ◦ If the server is not configured with any encryption settings definitions, it uses an internal key shared across instances in the topology. ◦ You can override the property's value with the **`backup`** tool and either the `--encrypt` or `--doNotEncrypt` option.
`backup-encryption-settings-definition-id`	Specifies the unique identifier of the encryption settings definition to use in generating the encryption key: ◦ If this property is given a value, then a definition with that ID must exist in the server's encryption settings database. ◦ If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used. ◦ If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. ◦ You can override the property's value with the **`backup`** tool. Using the `--promptForEncryptionPassphrase` or `--encryptionPassphraseFile` option will generate the encryption key from the provided passphrase. The `--encryptionSettingsDefinitionID` option will generate the key from a specified encryption settings definition.

Copyright © 2025 Ping Identity Corporation

Global property	Configuration description
`encrypt-ldif-exports-by-default`	Indicates whether the server should encrypt LDIF exports by default: ◦ If set to `true`, and an `ldif-export-encryption-settings-definition-id` value is specified, then that encryption settings definition is used to generate the encryption key for the export. ◦ If a value is not specified, the server first tries to use the preferred encryption settings definition to generate the encryption key. ◦ If the server is not configured with any encryption settings definitions, it uses an internal key shared among instances in the topology. ◦ You can override the property's value with the **`export-ldif`** tool and either the `--encryptLDIF` or `--doNotEcryptLDIF` option.
`automatically-compress-encrypted-ldif-exports`	Indicates whether to automatically compress LDIF exports that are encrypted. If set to `true`, any LDIF export that is encrypted, either with the `--encryptLDIF` option or with the **`encrypt-ldif-exports-by-default`** configuration property, is gzip-compressed.

Example:

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

Using data encryption in a replicated environment

Use data encryption for on-disk storage for data within the server.

Whenever clients access stored data in the server, it's presented in unencrypted form although the communication with those clients can itself be encrypted using SSL or StartTLS. Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server can apply data encryption in a independent manner and have different sets of encryption settings definitions. It's possible to have a replication topology containing some servers that have data encryption enabled and others with it disabled.

When initializing the backend of one server from another server with data encryption enabled, the server being initialized must have access to all encryption settings definitions that might have been used for data contained in that backend.

To do this, perform an export of the encryption settings database on the source server using **`bin/encryption-settings export`** and import it on the target server using **`bin/encryption-settings import`**.

Copyright © 2025 Ping Identity Corporation

Handling compromised encryption settings definitions

When an encryption settings definition is compromised, all data encrypted with that definition is vulnerable and you must stop using the definition immediately.

About this task

If an encryption settings definition is compromised, stop using that definition immediately. You must re-encrypt any data encrypted with the compromised definition using a new definition or purge that data from the server. To minimize the risk of data exposure, act quickly on all servers using this definition and act on one server at a time to avoid environment-wide downtime.

If you have a compromised encryption settings definition:

Steps

1. Create a new encryption settings definition and make it the preferred definition for new write operations.
2. Ensure that client traffic is routed away from the compromised server instance.

   If the PingDirectory server is accessed through a PingDirectoryProxy server, then you can set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to `unavailable`.
3. To ensure that external clients are not allowed to perform writes in the PingDirectory server, set the `writability-mode` global configuration property to `internal-only`.
4. Look at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.

   This signals that all outstanding local changes are replicated to other servers.
5. Stop the PingDirectory server instance.
6. Delete the replication server database by removing all files in the `<server-root>/changeLogDb` directory.

   If all local changes have been replicated to other servers, this deletion does not result in any data loss in the replication environment.
7. Export the contents of all local DB and changelog backends to LDIF.

   > **Note**
   >
   > If you are using the AES256 scheme to store passwords in a reversibly encrypted form, and if any of those passwords are encrypted with the compromised encryption settings definition, you should use the **`export-reversible-passwords`** tool rather than the **`export-ldif`** tool to perform the LDIF export of the local DB backends. You can use the **`export-reversible-passwords`** tool to generate an LDIF file in which all reversibly encrypted passwords are exported in a decrypted form so that when they are re-imported, they are re-encrypted.
8. Re-import the data from LDIF.

   The data is now encrypted using the new preferred encryption settings definition.
9. Export the compromised encryption settings definition from the encryption settings database.

Copyright © 2025 Ping Identity Corporation

As a precaution, this backs up the definition in case some remaining data was encrypted with that definition's key.

10. To prevent the PingDirectory server from using the compromised definition, delete the definition from the encryption settings database.
11. Start the PingDirectory server instance.
12. Allow replication to update the server with any changes processed offline.
13. To re-allow externally-performed write operations, change the value of the global `writability-mode` configuration property to `enable`.
14. To allow client traffic to re-route to that server instance, reconfigure the environment.

    For example, if you changed the value of the `health-check-state` property in step 2, change it back to `dynamically-determined`.

Configuring sensitive attributes

Use and configure sensitive attribute definitions to customize the level of client data access and encryption protection needed.

For a PingDirectory server instance, data encryption only applies to the on-disk storage. Although it doesn't automatically protect information accessed or replicated between servers, the server offers mechanisms to provide that protection, such as SSL, StartTLS, and SASL.

All client communication using either SSL or StartTLS encryption and all replication traffic using SSL encryption helps ensure that the data is protected from unauthorized individuals who might eavesdrop on network communication. You can enable this communication security independently of data encryption.

> **Note**
>
> If data encryption is enabled, you should use secure communication to protect network access to that data.

Protecting client data access isn't as simple as enabling secure communication. In some cases, you might want to allow insecure access to some data. In other cases, you might need to have additional levels of protection in place to ensure that some attributes are more carefully protected. To achieve varying levels of protection, use sensitive attribute definitions.

The following table explains the sensitive attribute definitions and their configuration properties.

Sensitive attribute	Configuration details
`attribute-type`	Specifies the set of attribute types whose values might be considered sensitive. You must provide at least one attribute type and define all specified attribute types in the server schema.

Copyright © 2025 Ping Identity Corporation

Sensitive attribute	Configuration details
`include-default-sensitive-operational-attributes`	Indicates whether the set of sensitive attributes that might contain sensitive information should automatically be updated to include any operational attributes maintained by the PingDirectory server itself. This includes the `ds-sync-hist` operation attribute, which is used for data required for replication conflict resolution and can contain values from other attributes in the entry.
`allow-in-filter`	Indicates whether sensitive attributes can be used in filters. This applies not only to the filter used in search requests, but also to filters that can be used in other places, such as the assertion and join request controls. The value of this property must be one of the following: • `Allow` : allows sensitive attributes to be used in filters over both secure and insecure connections. • `Reject` : rejects any request that includes a filter targeting one or more sensitive attributes over both secure and insecure connections. • `Secure-only` : allows sensitive attributesto be used in filters over secure connections but rejects any such requests over insecure connections.
`allow-in-add`	Indicates whether sensitive attributes can be included in entries created by `ldapadd` operations. The value of this property must be one of the following: • `Allow` : allows sensitive attributes included in add requests over both secure and insecure connections. • `Reject` : rejects any add request containing sensitive attributes over both secure and insecure connections. • `Secure-only` : allows sensitive attributes included in add requests received over secure connections but rejects any such requests over insecure connections.

Copyright © 2025 Ping Identity Corporation

Sensitive attribute	Configuration details
`allow-in-compare`	Indicates whether sensitive attributes can be targeted by the assertion used in a compare operation. The value of this property must be one of the following: • `Allow` : allows sensitive attributes to be targeted by requests over both secure and insecure connections. • `Reject` : rejects compare requests targeting a sensitive attribute over both secure and insecure connections. • `Secure-only` : allows compare requests targeting sensitive attributes over secure connections but rejects compare requests over insecure connections.
`allow-in-modify`	Indicates whether sensitive attributes can be updated using modify operations. The value of this property must be one of following: • `Allow` : allows sensitive attributeto be modified by requests over both secure and insecure connections. • `Reject` : rejects any modify request updating a sensitive attribute over both secure and insecure connections. • `Secure-only` : allows only modify requests updating sensitive attributes over secure connections but rejects modify requests over insecure connections.

Note

By default, `allow-in-returned-entries` , `allow-in-filter` , `allow-in-add` , `allow-in-compare` , and `allow-in-modify` properties have values of `secure-only` only. This prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

Sensitive attributes and client connection policies

If a client connection policy references a sensitive attribute definition, any restrictions imposed by that definition are enforced for clients associated with this client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, the server uses the most restrictive combination of all of those sets.

Sensitive attributes and other security mechanisms

The sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and can only be used to enforce additional restrictions on clients.

Copyright © 2025 Ping Identity Corporation

Never use sensitive attribute definitions to grant a client additional access to information that it didn't have already through other means. For example, if the `employeeSSN` attribute is declared a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute is only returned to those clients that have both permissions granted by the access control rules defined in the server and are communicating with the server over a secure connection.

The `employeeSSN` attribute is stripped out of entries returned to clients normally authorized to see it if they are using insecure connections. It is also stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

Creating a sensitive attribute

Creating sensitive attributes involves creating and associating definitions to set configuration properties and policies according to your business needs.

About this task

To create a sensitive attribute:

Steps

1. Create one or more sensitive attribute definitions using `dsconfig create-sensitive-attribute`.

   Example:

   For example, to create a sensitive attribute definition that only allows access to the `employeeSSN` attribute by clients using secure connections, make the following configuration changes.

   ```
   $ bin/dsconfig create-sensitive-attribute \
     --attribute-name "Employee Social Security Numbers" \
     --set attribute-type:employeeSSN \
     --set include-default-sensitive-operational-attributes:true \
     --set allow-in-returned-entries:secure-only \
     --set allow-in-filter:secure-only \
     --set allow-in-add:secure-only \
     --set allow-in-compare:secure-only \
     --set allow-in-modify:secure-only
   ```

2. Associate the sensitive attribute definitions with the client connection policies that you want to enforce using `dsconfig set-client-connection-policy-prop`.

   Example:

   ```
   $ bin/dsconfig set-client-connection-policy-prop --policy-name default \
     --set "sensitive-attribute:Employee Social Security Numbers"
   ```

Configuring global sensitive attributes

The PingDirectory server supports the ability to define sensitive attributes as a global configuration option so that they're automatically used across all client connection policies.

Copyright © 2025 Ping Identity Corporation

About this task

Administrators can assign one or more sensitive attribute definitions to a client connection policy.

> **Note**
>
> When working in an environment with multiple client connection policies, it can be easy to add a sensitive attribute definition to one policy but overlook it in another.

Steps

- To add a global sensitive attribute across all client connection policies, run the `dsconfig` tool.

  Example:

  The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-attribute:employeeSSN"
```

Excluding a global sensitive attribute on a client connection policy

Administrators can exclude a global sensitive attribute on a client connection policy when it's not needed for client connection requests.

About this task

Administrators can set a global sensitive attribute across all client connection policies. However, there can be cases when a specific PingDirectory server must exclude the sensitive attribute because it's not needed for client connection requests.

For example, in most environments, it's good to declare the `userPassword` attribute to be a sensitive attribute that prevents external clients reading it. This solution is more secure than protecting the `password` attribute using the server's default global access control instruction (ACI), which only exists for backwards compatibility purposes. If the PingDirectory server is installed, then it does need to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the server. The PingDirectory server provides an `exclude-global-sensitive-attribute` property for this purpose.

Steps

1. To remove the global ACI that limits access to the `userPassword` or `authPassword` attribute, run the `dsconfig` tool.

   > **Note**
   >
   > The global ACI is present for backwards compatibility.

   Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="userPassword || authPassword")
  (version 3.0; acl "Prevent clients from retrieving passwords from the server";
  deny (read,search,compare) userdn="ldap:///anyone";)'
```

Copyright © 2025 Ping Identity Corporation

2. To add the `userPassword` attribute as a global sensitive attribute, run the `dsconfig` tool and add the built-in `"sensitive-attribute:Sensitive Password Attributes"` definition to the global configuration.

   This applies to all client connection policies.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --add "sensitive-attribute:Sensitive Password Attributes"
   ```

3. If the server is designated to synchronize passwords with a Sync Server, configure a client connection policy for the Sync User to exclude the global sensitive attribute.

   Example:

   The following example shows how to create a new policy if the Data Sync Server binds with the default distinguished name (DN) of `cn=Sync User,cn=Root DNs,cn=config`.

   ```
   $ bin/dsconfig create-connection-criteria \
     --criteria-name "Requests by Sync Users" \
     --type simple \
     --set user-auth-type:internal \
     --set user-auth-type:sasl \
     --set user-auth-type:simple \
     --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

   $ bin/dsconfig create-client-connection-policy \
     --policy-name "Data Sync Server Connection Policy" \
     --set enabled:true \
     --set evaluation-order-index:9998 \
     --set "connection-criteria:Requests by Sync Users" \
     --set "exclude-global-sensitive-attribute:Sensitive Password Attributes"
   ```

Working with the LDAP changelog

The PingDirectory server provides a client-accessible Lightweight Directory Access Protocol (LDAP) changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

Overview of the LDAP changelog

The PingDirectory server provides a client-accessible LDAP changelog, based on the Changelog Internet Draft Specification, for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format.

The LDAP changelog is used by external software to maintain application compatibility between client services. For example, you can install the PingDirectory server that monitors the LDAP changelog for any updates that occur on a source PingDirectory server and synchronizes these changes to a target directory information tree (DIT) or database server.

The PingDirectory server provides an additional feature in that the LDAP changelog supports virtual attributes.

Copyright © 2025 Ping Identity Corporation

Note

The LDAP changelog should not be confused with the Replication changelog. The main distinction is as follows:

- The LDAP changelog (the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication changelog backend (the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

Key changelog features

As of 3.2, the PingDirectory server supports two new changelog backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries.

External client applications can change the contents of attributes seen in the targeted entry based on the access control rules applied to the associated base DN.

Attribute	Description
`apply-access-controls-to-changelog-entry-contents`	**Indicates whether the contents of changelog entry attributes, such as `changes`, `deletedEntryAttrs`, `ds-changelog-entry-key-attr-values`, `ds-changelog-before-values`, and `ds-changelog-after-values`, are subject to access control and sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations are suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry are also suppressed. This property only applies to standard LDAP searches of the `cn=changelog` branch.**

Copyright © 2025 Ping Identity Corporation

`report-excluded-changelog-attributes`	Indicates whether to include additional information about any attributes that might have been removed because of access control filtering. This property only applies to content removed as a result of processing performed by the `apply-access-controls-to-changelog-entry-contents` property. Possible values are: ***none*** Indicates that changelog entries should not include any information about attributes that have been removed. **`attribute-counts`** Indicates that changelog entries should include a count of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, the number of the excluded user attributes are reported in the `ds-changelog-num-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes are reported in the `ds-changelog-num-excluded-operational-attributes` attribute of the changelog entry. Both the `ds-changelog-num-excluded-user-attributes` and `ds-changelog-num-excluded-operational-attributes` are operational and must be explicitly requested by clients or all operational attributes requested using `+` to be returned. **`attribute-names`** Indicates that changelog entries should include the names of user and operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes are reported in the `ds-changelog-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes are reported in the `ds-change-log-excluded-operational-attribute` attribute of the changelog entry. Both the `ds- changelog-excluded-user-attribute` and `ds-changelog-excluded-operational-attribute` attributes are operational and must be explicitly requested by clients or all operational attributes requested using `+` to be returned.

Enabling access control filtering in the LDAP changelog

Use the `dsconfig` tool to enable the properties to the changelog backend to set up access control to the LDAP changelog.

About this task

Only admin users with the `bypass-acl` privilege can read the changelog.

Steps

1. To allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend, enable the `apply-access-control-to-changelog-entry-contents` property.

   Access control filtering is applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the changelog backend is servicing requests from a PingDirectory server that has the `filter-changes-by-user` Sync Pipe property set.

   Example:

   ```
   $ bin/dsconfig set-backend-prop --backend-name "changelog" \
     --set "apply-access-controls-to-changelog-entry-contents:true"
   ```

2. To include a count of users that have been removed through access control filtering, set the `report-excluded-changelog-attributes` property.

   The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and in the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

   Example:

   ```
   $ bin/dsconfig set-backend-prop --backend-name "changelog" \
    --set "report-excluded-changelog-attributes:attribute-counts"
   ```

Useful changelog features

The PingDirectory server provides two changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

changelog-max-before-after-values

Setting this property to a non-zero value causes all of the old values and all of the new values, up to the specified maximum, for each changed attribute to be stored in the changelog entry. The values are stored in the `ds-change-log-before-values` and `ds-changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

> **Note**
>
> The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before and after values are stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute with the following format.:

Copyright © 2025 Ping Identity Corporation

```
attr=attributeName,beforeCount=100,afterCount=101
```

`attributeName` is the name of the attribute, and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. This attribute indicates that you must reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert is generated.

> **Note**
>
> If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values are not stored.

changelog-include-key-attribute

This property is used for correlation attributes that need to be synchronized across servers, such as `uid`. It causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the changelog entry. This applies for all change types. On a `DELETE` operation, the values are from the entry before they were deleted.

The key values are recorded on every change and override the settings configured in `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute`.

Example of the changelog features

After the `changelog-max-before-after-values` property is set, the before and after values of any change attribute are recorded in the LDAP changelog.

For example, consider a simple entry with two multi-valued mail attributes.

```
dn: uid=test,dc=example,dc=com
objectclass: inetorgperson
cn: test user
sn: user
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
```

Then, apply the following changes to the entry.

```
dn: uid=test,dc=example,dc=com
changetype: modify
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
```

Copyright © 2025 Ping Identity Corporation

The resulting changelog would record the following attribute values.

```
dn: changeNumber=1,cn=changelog
objectClass: top
objectClass: changeLogEntry
targetDN: uid=test,dc=example,dc=com
changeType: modify
changes::

changenumber: 1
```

Run the `bin/base64 decode -d` command line tool to view the decoded value for the `changes`, `ds-changelog-before-values`, and `ds-changelog-after-values` attributes.

After base64 decoding, the `changes` attribute displays the following.

```
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
-
```

After base64 decoding, the `ds-changelog-before-values` attribute displays the following.

```
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
```

Copyright © 2025 Ping Identity Corporation

After base64 decoding, the `ds-changelog-after-values` attribute displays the following.

```
description: newDescription
mail: test@gmail.com
mail: test@hotmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
```

Viewing the LDAP changelog properties

To view the LDAP changelog properties, run the `dsconfig` `get-backend-prop` command and specify the changelog backend.

Viewing the LDAP changelog properties using `dsconfig` non-interactive mode

Steps

- To view the changelog properties on the PingDirectory server, use `dsconfig`.

> **Tip**
>
> To view "advanced" properties that are normally hidden, add the `--advanced` option when running the command. For a specific description of each property, see the PingDirectory server Configuration Reference.

Example:

```
$ bin/dsconfig get-backend-prop --backend-name changelog
```

Result:

Copyright © 2025 Ping Identity Corporation

```
Property                                  : Value(s)

```

Enabling the LDAP changelog

Enable the LDAP changelog to maintain application compatibility between client services.

The LDAP changelog is disabled by default on the PingDirectory server. If you are using the `dsconfig` tool in interactive mode, the changelog appears in the backend configuration as a Standard object menu item.

> **Note**
>
> Enable the feature using the **`dsconfig`** tool only if required because it can affect LDAP update performance.

Enabling the LDAP changelog using `dsconfig` non-interactive mode

Steps

- Use `dsconfig` to enable the changelog property on the PingDirectory server.

  Example:

```
$ bin/dsconfig set-backend-prop \
  --backend-name changelog --set enabled:true
```

Copyright © 2025 Ping Identity Corporation

Enabling the LDAP changelog using interactive mode

Steps

1. Use `dsconfig` to enable the changelog on each server in the network.
2. Authenticate to the server by entering the host name, LDAP connection, port, bindDN, and bind password.
3. In the `PingDirectory server main menu`, enter `o` to change from the Basic object level to the Standard object level.
4. Enter the option to select the `Standard object` level.
5. In the `PingDirectory server main menu`, enter the number corresponding to `backend`.
6. In the `Backend Management menu`, enter the option to view and edit an existing backend.

   Result:

   The system displays a list of the accessible backends. For example, you see options for the `changelog` and `userRoot` backends.
7. Enter the option to work with the changelog backend.
8. In the `Changelog Backend properties menu`, enter the number corresponding to the Enabled property.
9. In the `Enabled Property menu`, enter the number to change the `Enabled` property to `TRUE`.
10. In the `Backend Properties menu`, enter `f` to apply the change.

    If you set up the server in a server group, enter `g` to update all of the servers in the group. Otherwise, repeat steps 1-10 on the other servers.
11. Verify that changes made to the data are recorded in the changelog.

Changing the LDAP changelog database location

If you have disk space issues, you can change the on-disk location of the LDAP changelog database.

The changelog backend supports a `db-directory` property that specifies the absolute or relative path (relative to the local server root) to the file system directory that is used to hold the Oracle Berkeley DB Java Edition database files containing the data for this backend.

If you change the changelog database location, you must stop and restart the PingDirectory server for the change to take effect. If the changelog backend is already enabled, then the database files must be manually moved or copied to the new location while the server is stopped.

Changing the LDAP changelog location using dsconfig non-interactive mode

Steps

1. Use `dsconfig` to change the database location for the LDAP changelog, which by default is at `<server-root>/db`.

   Example:

   The following command sets the LDAP changelog backend to `<server-root>/db2`.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "db-directory:db2" --set "enabled:true"
```

> **Note**
>
> Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

The database files are stored under `<server-root>/db2/changelog`. The files for this backend are stored in a sub-directory named after the `backend-id` property.

2. Stop and restart the server.

   Because the LDAP changelog backend was previous disabled, you do not need to manually relocate any existing database files.

   Example:

```
$ bin/stop-server
$ bin/start-server
```

Resetting the LDAP changelog location using dsconfig non-interactive mode

Steps

1. If you have changed the LDAP changelog location, to reset it to its original location, use `dsconfig`.

   Example:

   The following command resets the LDAP changelog backend to `<server-root>/db` location.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --reset "db-directory"
```

> **Note**
>
> Remember to include the LDAP connection parameters such as host name, port, bindDN, and bindPassword.

2. If the LDAP changelog backend at the previous location is enabled:

   1. Stop the server.
   2. Copy the database files to the new LDAP changelog location.
   3. Restart the server.

> **Note**
>
> The server attempts to use whatever it finds in the configured location when it starts. If there is nothing there, it creates an empty database.

Copyright © 2025 Ping Identity Corporation

Viewing the LDAP changelog parameters in the Root DSE

The Root DSE is a special entry that holds operational information about the server.

About this task

The entry provides information about the LDAP controls, extended operations, and Simple Authentication and Security Layer (SASL) mechanisms available in the server as well as the state of the data within the changelog. For changelog parameters, the attributes of interest include:

`firstChangeNumber`

Change number for the first (oldest) change record contained in the LDAP changelog.

`lastChangeNumber`

Change number for the last (most recent) change record contained in the LDAP changelog.

`lastPurgedChangeNumber`

Change number for the last change that was purged from the LDAP changelog. It can be 0 if no changes have yet been purged.

`firstReplicaChange`

Information about the first (oldest) change record for a change received from the specified replica. This is a multi-valued attribute and should include a value for each server in the replication topology.

`lastReplicaChange`

Information about the last (most recent) change record for a change received from the specified replica.

The `firstReplicaChange` and `lastReplicaChange` attributes use the following syntax.

```
serverID:CSN:changeNumber
```

Where:

`serverID`

Specifies the unique identifier for the server updating the change log.

`CSN`

Specifies the Change Sequence Number, which is the time when the update was made to the given replica.

`changeNumber`

Specifies the order of the change that is logged to the LDAP changelog.

The `firstReplicaChange` and `lastReplicaChange` attributes can be used to correlate information in the local LDAP changelog with data in the LDAP changelog of other servers in the replication topology. The order of the individual changes in the LDAP changelog can vary between servers based on the order in which they were received from a replica.

Copyright © 2025 Ping Identity Corporation

Steps

- Use `ldapsearch` to view the Root DSE.

  Example:

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

Viewing the LDAP changelog, change sequence numbers, and monitoring information

View changelog entries using `ldapsearch`.

All records in the changelog are immediate children of the `cn=changelog` entry and are named with the `changeNumber` attribute. Changes are represented in the form documented in the `draft-good-ldap-changelog` specification with the `targetDN` attribute providing the distinguished name (DN) of the updated entry, the `changeType` attribute providing the type of operation (`add`, `delete`, `modify`, or `modDN`), and the changes attribute providing a base64-encoded representation of the attributes included in the entry (for `add` operations) or the changes made (for `modify` operations) in LDIF form. View the changes by decoding the encoded value using the `base64 decode` utility. The UnboundID LDAP SDK for Java also provides support for parsing changelog entries.

Viewing the LDAP changelog using ldapsearch

Steps

1. By default, only users with the `bypass-acl` or `bypass-read-acl` privilege can access changelog entries. To grant control permission to allow other users to see changelog entries, use a global ACI like the following:

   Example:

```
$ bin/dsconfig set-access-control-handler-prop
--add 'global-aci:(targetattr="*||+")(target="ldap:///cn=changelog")(version 3.0;
acl "Access to the changelog backend for the admin account";
allow (read,search,compare) userdn="ldap:///uid=admin,dc=example,dc=com";)'
```

2. Use `ldapsearch` to view the changelog.

   Example:

```
$ bin/ldapsearch --hostname ds.example.com --port 636 --useSSL
--bindDN "uid=admin,dc=example,dc=com" --bindPasswordFile admin-password.txt
--baseDN cn=changelog --dontWrap "(objectclass=*)"
```

   Result:

Copyright © 2025 Ping Identity Corporation

```

changenumber: 2
```

Viewing the LDAP change sequence numbers

About this task

The changelog displays the server state information, which is important for failover between servers during synchronization operations. The server state information is exchanged between the servers in the network (LDAP servers and replication servers) as part of the protocol start message. It also helps the client application determine which server is most up-to-date.

Steps

- Make sure the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

  Example:

  ```
  $ bin/ldapsearch --hostname ds.example.com --port 636 --useSSL
  --bindDN "uid=admin,dc=example,dc=com" --bindPasswordFile admin-password.txt
  --baseDN cn=changelog --dontWrap "(objectclass=*)" "+"
  ```

  Result:

Copyright © 2025 Ping Identity Corporation

```
dn: cn=changelog

dn: changeNumber=1,cn=changelog
entry-size-bytes: 182
targetUniqueId: 68147342-1f61-3465-8489-3de58c532130

replicaIdentifier: 12336
```

Viewing LDAP changelog monitoring information

About this task

The changelog contains a monitor entry accessed over LDAP, JConsole, the administrative console, or SNMP. Make sure the account you're using to request the monitor information has the necessary access rights to the data under `cn=monitor`. You might need to add a global ACI to grant the appropriate users permission to access monitor data.

Steps

- Use `ldapsearch` to view the changelog monitor entry.

  Example:

  ```
  $ bin/ldapsearch --hostname ds.example.com --port 636 --useSSL
  --bindDN "uid=admin,dc=example,dc=com" --bindPasswordFile admin-password.txt
  --baseDN cn=changelog,cn=monitor "(objectclass=*)"
  ```

  Result:

  ```
  dn: cn=changelog,cn=monitor
  objectClass: top
  objectClass: ds-monitor-entry
  objectClass: extensibleObject
  cn: changelog
  changelog: cn=changelog
  firstchangenumber: 1
  lastchangenumber: 8
  lastpurgedchangenumber: 0
  firstReplicaChange: 16225:0000011D0205237F3F6100000001:5

Indexing the LDAP changelog

The PingDirectory server supports attribute indexing in the Changelog Backend to allow Get Changelog Batch requests to filter results that include only changes involving specific attributes.

Normally, the PingDirectory server that receives a request must iterate over the whole range of changelog entries and then match entries based on search criteria for inclusion in the batch. The majority of this processing also involves determining whether or not the changelog entry includes changes to a particular attribute or set of attributes. Using changelog indexing, client applications can dramatically speed up throughput when targeting the specific attributes.

You can configure attribute indexing using the `index-include-attribute` and `index-exclude-attribute` properties on the Changelog Backend. The properties can accept the specific attribute name or special LDAP values `*` to specify all user attributes or `+` to specify all operational attributes.

To determine if the PingDirectory server supports this feature, view the Root DSE for the following entry.

```
supportedFeatures: 1.3.6.1.4.1.30221.2.12.3
```

Indexing a changelog attribute

Steps

1. Use `dsconfig` to set attribute indexing on an attribute in the changelog backend.

   Example:

   Index different attributes by adding specific properties. In the following example, the command enables the Changelog Backend and sets the backend to include all user attributes (`*`) for `ADD` or `MODIFY` operations using the `changelog-include-attribute` property. The `changelog-deleted-entry-include-attribute` property is set to all attributes (`*`) to specify a set of attribute types that should be included in a changelog entry for `DELETE` operations. Attributes specified in this list are recorded in the `deletedEntryAttrs` attribute on the changelog entry when an entry is deleted. The attributes `displayName` and `employeeNumber` are indexed using the `index-include-attribute` property.

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --set "enabled:true" \
     --set "changelog-include-attribute:*" \
     --set "changelog-deleted-entry-include-attribute:*" \
     --set "index-include-attribute:displayName" \
     --set "index-include-attribute:employeeNumber"
   ```

2. To add another attribute to index, use the `dsconfig --add` option, which adds the attribute to an existing configuration setting.

   Example:

   ```
   $ bin/dsconfig set-backend-prop --backend-name changelog \
     --add "index-include-attribute:cn"
   ```

Copyright © 2025 Ping Identity Corporation

Excluding attributes from indexing

Steps

- Use `dsconfig` to set attribute indexing on all user attributes in the changelog backend.

  Example:

  The following command includes all user attributes except the description and location attributes.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
  --set "index-include-attribute:*" \
  --set "index-exclude-attribute:description \
  --set "index-exclude-attribute:location
```

Tracking virtual attribute changes in the LDAP changelog

While the LDAP Changelog primarily tracks changes to real attributes, it can also provide information about virtual attributes included in created, updated, or deleted entries.

About this task

The `include-virtual-attributes` property controls the virtual attribute information to include in changelog entries, and this property might include any or all of the following values:

`add-attributes`

Indicates that changelog entries for `add` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was created.

`deleted-entry-attributes`

Indicates that changelog entries for `delete` operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was deleted.

`before-and-after-values`

Indicates that changelog entries for `modify` and `modify DN` operations should include `ds-changelog-before-virtual-values` and `ds-changelog-after-virtual-values` attributes that contain the values of virtual attributes that have been updated.

`key-attribute-values`

Indicates that changelog entries should include a `ds-changelog-entry-key-virtual-values` attribute that holds the values for any virtual attributes included in the set of key attributes, as defined by the `changelog-include-key-attribute` property.

The `add-attributes` and `before-and-after-values` values are selected by default.

To enable virtual attribute change tracking in the LDAP Changelog:

Copyright © 2025 Ping Identity Corporation

Steps

- Use `dsconfig`.

Example:

> **Note**
>
> The following command enables the LDAP changelog and sets `include-virtual-attributes` to `add-attributes`, which indicates that virtual attributes be included in the set of attributes listed for an add operation. The `delete-entry-attributes` value indicates that virtual attributes should be included in the set of deleted entry attributes listed for a delete operation. The `before-and-after-values` value indicates that virtual attributes should be included in the set of before and after values for attributes targeted by the changes. The `key-attribute-values` value indicates that virtual attributes should be included in the set of entry key attribute values.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "enabled:true" \
  --set "include-virtual-attributes:add-attributes" \
  --set "include-virtual-attributes:deleted-entry-attributes" \
  --set "include-virtual-attributes: before-and-after-values" \
  --set "include-virtual-attributes: key-attribute-values"
```

Managing the schema

This section is a summary of the supported schema components on the PingDirectory server and procedures to extend the schema with new element definitions.

About the schema

A schema is the set of PingDirectory server rules that define the structures, contents, and constraints of a directory information tree (DIT).

The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its PingDirectory server objects.

The PingDirectory server includes a default set of read-only schema files that define the core properties for the server. The administrative console provides a Schema Editor to view existing schema definitions and add new custom schema elements to your DIT.

> **Note**
>
> Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file results in an `Unwilling to Perform` result.

Copyright © 2025 Ping Identity Corporation

About the schema editor

The administrative console provides a user-friendly graphical editor with tabs to manage any existing schema components related to the directory information tree (DIT).

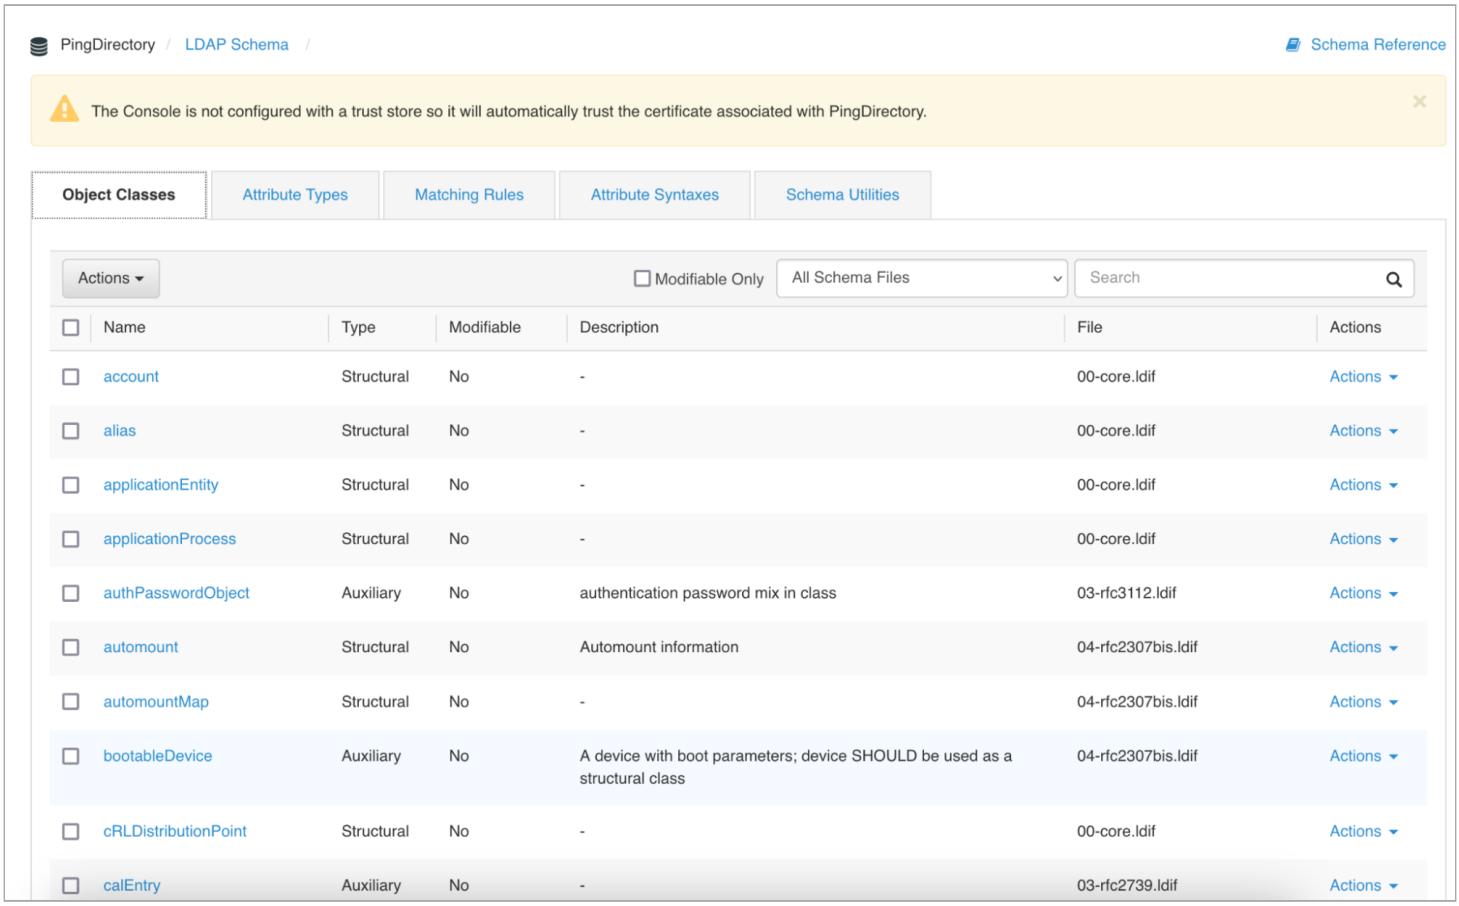
The list of existing schema components that can be managed includes:

- Object classes
- Attributes
- Matching rules
- Attribute syntaxes
- Schema utilities

The following list describes the tabs of the Schema Editor page:

- The Object Classes and Attribute Types tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.
- The Matching Rules and Attribute Syntaxes tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements.
- The Schema Utilities tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules.
- The Utilities tab supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.

Copyright © 2025 Ping Identity Corporation



Example schema editor page

The schema editor provides two views for each definition:

- The Properties View that breaks down the schema definition by its properties and shows any inheritance relationships among the attributes.
- The LDIF View that shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

Default PingDirectory server schema files

The PingDirectory server stores its schema as a set of LDIF files for the server instance in the `<server-root>/config/schema` directory. The PingDirectory server reads the schema files in alphanumeric order at startup in the following order:

1. The `00-core.ldif` file
2. The `01-pwpolicy.ldif` file
3. Remaining files

You should name custom schema files so that they are loaded in last. For example, custom schema elements could be saved in a file labeled `99-user.ldif` that loads after the default schema files are read at startup.

Copyright © 2025 Ping Identity Corporation

The PingDirectory server then uses the schema definitions to determine any violations that might occur during `add`, `modify`, or `import` requests. Clients applications check the schema (matching rule definitions) to determine the assertion value algorithm used in comparison or search operations.

The default set of schema files are present at installation and should not be modified. Modifying the default schema files could result in an inoperable server.

The schema files have the following descriptions.

Default Schema Files

Schema Files	Description
`00-core.ldif`	Governs the PingDirectory server's core functions
`01-pwpolicy.ldif`	Governs password policies
`02-config.ldif`	Governs the PingDirectory server's configuration
`03-changelog.ldif`	Governs the PingDirectory server's change log
`03-rfc2713.ldif`	Governs Java objects
`03-rfc2714.ldif`	Governs Common Object Request Broker Architecture (CORBA) object references
`03-rfc2739.ldif`	Governs calendar attributes for vCard
`03-rfc2926.ldif`	Governs Server Location Protocol (SLP) mappings to and from LDAP schemas
`03-rfc2985.ldif`	Governs PKCS #9 public-key cryptography
`03-rfc3112.ldif`	Governs LDAP authentication passwords
`03-rfc3712.ldif`	Governs printer services
`03-uddiv3.ldif`	Governs web services registries of Service Oriented Architecture (SOA) components
`04-rfc2307bis.ldif`	Governs mapping entities from TCP/IP and UNIX into X.500 entries

Extending the PingDirectory server schema

The PingDirectory server stores its schema as LDIF files in the `<server-root>/config/schema` directory.

At startup, the PingDirectory server reads the schema files in alphanumeric order starting with `00-core.ldif` and ending with any custom schema definition files, such as `99-user.ldif`, if present.

You can extend the schema to include additional customizations necessary for your PingDirectory server data using one of the following methods:

- Using the Schema Editor

Copyright © 2025 Ping Identity Corporation

This method is the easiest and quickest way to set up a schema definition and have it validated for the correct ASN.1 formatting. The Editor lets you define your schema properties, load your custom file, or perform a cut-and-paste operation on a new schema element. If any errors exist in the file, the Schema Editor generates an error message if the schema definitions do not pass compliance.

- Using a custom schema file

  You can create a custom schema file with your new definitions using a text editor, save it as `99-user.ldif`, and then import the file using the Schema Editor or the `ldapmodify` tool. You must name the custom LDIF file with a high two-digit number prefix, so that the PingDirectory server reads the file after the core schema files are read at startup. For example, you can name the file `99-myschema.ldif`.

  > **Note**
  >
  > For more information on the requirements for naming each file, see the next section, General tips on extending the schema.

- Using the command line

  If you have a small number of additions, you can extend the schema over LDAP and from the command line using the `ldapmodify` tool. The PingDirectory server writes the new schema changes to a file such as `99-user.ldif` in the `<server-root>/config/schema` directory. However, this method can be cumbersome because schema definitions require strict adherence to text spacing and white space characters.

General tips on extending the schema

Consider the following points when extending the schema:

- Never modify the default schema files because doing so could damage the PingDirectory server's processing capabilities.
- Define all attributes before they can be used in an object class. If you are using the Schema Editor to add new schema elements, use the `Quick Add Attributes` option when defining new object classes.
- Define the parent object class before creating object classes that inherit from the parent.
- You must name custom schema files according to the following syntax:

  1. Begin with exactly two digits.
  2. Follow the two digits with a non-digit character.
  3. Follow the non-digit character with a zero or more characters.
  4. End in `.ldif`.

  > **Note**
  >
  > The two digits don't need to be followed by a dash ("-").
  > Any files that do not meet this criteria are ignored and either a `NOTICE` or `SEVERE_WARNING` message is logged.

  Any file in the `<server-root>/config/schema` directory with a name that starts with "." or ends with a tilde ('~'), `.swp`, or `.tmp` generates a `NOTICE` message indicating that temporary files will be ignored. Any other file that does not meet the naming criteria generates a `SEVERE_WARNING` message indicating that it will be ignored.

Copyright © 2025 Ping Identity Corporation

- Define custom attributes and object classes in one file. Typically, this file is the `99-user.ldif`. You can specify a different file name that the PingDirectory server writes to using the `X-SCHEMA-FILE` element and the file name in the definition, as in the following example.

```
add: attributeTypes attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.1
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '99-custom.ldif' )
```

- In the white space characters in the schema definitions, `WSP` means zero or more space characters, and `SP` means one or more space characters. The LDIF specification states that LDIF parsers should ignore exactly one space at the beginning of each continuation line because continuation lines must begin with a space character.

  If you define a new schema definition with each keyword on a separate continuation line, you should add two spaces before an element keyword to guarantee correct formatting. For example, the following attribute definition has two spaces before the keywords `NAME`, `SUP`, and `X-ORIGIN`.

```
attributeTypes: ( 2.5.4.32 NAME 'owner' SUP distinguishedName X-ORIGIN 'RFC 4519' )
```

- In a replicated topology, any new schema additions are replicated to other replication servers to their respective Schema backend. The additions are written to the file specified by the `X-SCHEMA-FILE` extension or written to `99-user.ldif` if no file is specified.

About managing attribute types

An attribute type determines the important properties related to an attribute, such as specifying the matching and syntax rules used in value comparisons. An attribute description consists of an attribute type and a set of zero or more options.

Options are short, case-insensitive text strings that differentiate between attribute descriptions. For example, the LDAPv3 specification defines only one type of option, the tagging option, that can be used to tag language options, such as `cn;lang-de;lang-sp` or binary data, such as `userCertificate;binary`. You can also extend the schema by adding your own attribute definitions.

Attributes have the following properties:

- Attributes can be user attributes that hold information for client applications, or operational attributes used for administrative or server-related purposes.

  > **Tip**
  >
  > To specify the purpose of the attribute, use the `USAGE` element.

- Attributes are multi-valued by default. Multi-valued means that attributes can contain more than one value within an entry.

Copyright © 2025 Ping Identity Corporation

> **Tip**
>
> If the attribute should contain at most one value within an entry, include the `SINGLE-VALUE` element.

- Attributes can inherit properties from a parent attribute as long as they both have the same `USAGE`, and the child attribute has the same `SYNTAX`, or its `SYNTAX` allows values that are a subset of the values allowed by the `SYNTAX` of the parent attribute. For example, the surname (`sn`) attribute is a child of the name attribute.

Attribute type definitions

New attribute types don't require server code extensions if the provided matching rules and attribute syntaxes are used in the definitions.

Administrators can create new attributes using the Schema Editor, which stores the definition in a file in the `<server-root>/config/schema` directory. For more information, see Extending the PingDirectory server schema.

The formal specification for attribute types is provided in RFC 4512, section 4.1.2 as follows.

```
AttributeTypeDescription = "(" wsp; Left parentheses followed by a white space
numericoid                       ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]         ; Short name descriptor as alias for the OID
[ sp "DESC" sp qdstring ]        ; Optional descriptive string
[ sp "OBSOLETE" ]                ; Determines if the element is active
[ sp "SUP" sp oid ]              ; Specifies the supertype
[ sp "EQUALITY" sp oid ]         ; Specifies the equality matching rule
[ sp "ORDERING" sp oid ]         ; Specifies ordering matching rule
[ sp "SUBSTR" sp oid ]           ; Specifies substrings matching rule
[ sp "SYNTAX" sp oidlen ]        ; Numeric attribute syntax with minimum upper bound
                                 ;  length expressed in {num}
[ sp "SINGLE-VALUE" ]            ; Specifies if the attribute is single valued in
                                 ;  the entry
[ sp "COLLECTIVE" ]              ; Specifies if it is a collective attribute
[ sp "NO-USER-MODIFICATION" ]    ; Not modifiable by external clients
[ sp "USAGE" sp usage ]          ; Application usage
extensions wsp ")"               ; Extensions followed by a white space and ")"

usage = "userApplications" /     ; Stores user data
  "directoryOperation" /         ; Stores internal server data
  "distributedOperation" /       ; Stores operational data that must be synchronized
                                 ; across servers
  "dSAOperation"                 ; Stores operational data specific to a server and
                                 ; should not be synchronized across servers
```

The following extensions are specific to the PingDirectory server and are not defined in RFC 4512.

Copyright © 2025 Ping Identity Corporation

```
extensions = /
"X-ORIGIN" /             ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-APPROX" /             ; Specifies the approximate matching rule
"X-ALLOWED-VALUE" /      ; Explicitly specifies the set of allowed values
"X-VALUE-REGEX" /        ; Specifies the set of regular expressions to compare against
                         ;  attribute values to determine acceptance
"X-MIN-VALUE-LENGTH" /   ; Specifies the minimum character length for attribute values
"X-MAX-VALUE-LENGTH" /   ; Specifies the maximum character length for attribute values
"X-MIN-INT-VALUE" /      ; Specifies the minimum integer value for the attribute
"X-MAX-INT-VALUE" /      ; Specifies the maximum integer value for the attribute
"X-MIN-VALUE-COUNT" /    ; Specifies the minimum number of allowable values for the
                         ;  attribute
"X-MAX-VALUE-COUNT" /    ; Specifies the maximum number of allowable values for the
                         ;  attribute
"X-READ-ONLY"            ; True or False. Specifies if the file that contains the
                         ;  schema element is marked as read-only in the server
                         ;  configuration.
```

Basic properties of attributes

The following table details the standard elements in schema definition.

Basic Properties of Attributes

Attributes	Description
`Name`	The globally unique name
`Description`	An optional definition that describes the attribute and its contents The LDIF equivalent is `DESC`.
`OID`	The object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
`Syntax`	The attribute syntax used For example, the `userPassword` attribute uses the User Password Syntax whereas the `authPassword` attribute uses the Authentication Password Syntax.
`Parent`	The schema definition's parent or supertype, if any The analogous LDIF equivalent is `SUP`.
`Multivalued`	Specifies if the attribute can appear more than once in its containing object class
`Required By Class`	Specifies any object classes that require the attribute
`Allowed By Class`	Specifies any object classes that can optionally use the attribute

Copyright © 2025 Ping Identity Corporation

Attributes	Description
`Value Restrictions`	Specifies any restriction on the value of the attribute

The Additional Properties table details auxiliary information associated with the attribute.

Attributes	Description
`Aliases`	Any shortform alias names, if any You can have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the `NAME` element. For example, `NAME`, `sn`, `surname`.
`Origin`	The origin of the schema definition Typically, it could refer to a specific RFC or company.
`Stored in File`	Specifies the schema file that stores the definition in the `<server-root>/config/schema` folder
`Usage`	The intended use of the attribute The choices are: • `userApplications` • `directoryOperation` • `distributedOperation` • `dSAOperation`
`User-Modifiable`	Specifies if the attribute can be modified by an authorized user
`Obsolete`	Specifies if the schema definition is obsolete or not
`Matching Rules`	Specifies the associated matching rules for the attribute

Viewing attributes

The Schema Editor displays all of the attribute types on your PingDirectory server instance.

It shows the basic properties that are required elements in addition to the extra properties that are allowed within the attribute definition.

Viewing attribute types using the Schema Editor

Before you begin

Ensure that the PingDirectory server instance is running.

About this task

To view attribute types using the Schema Editor:

Copyright © 2025 Ping Identity Corporation

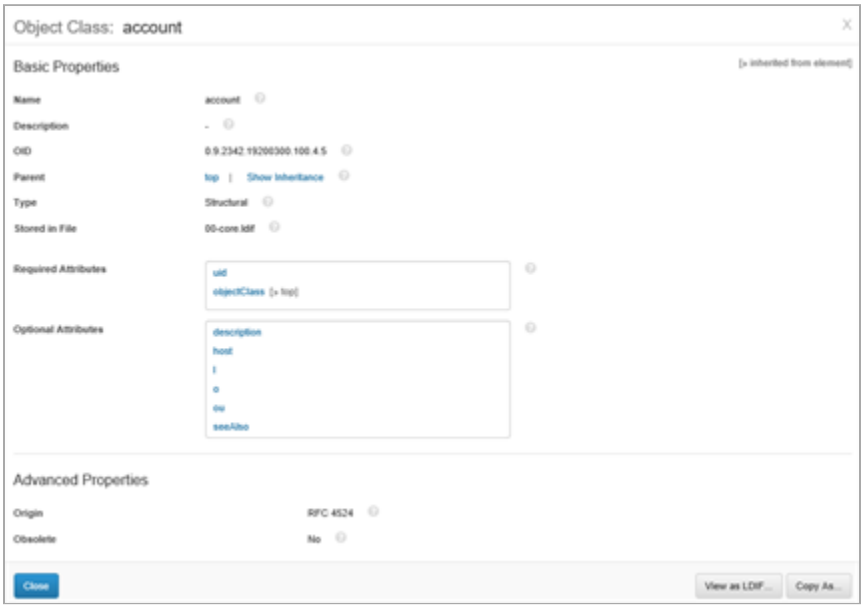
Steps

1. Start the administrative console.
2. In the main menu, select Schema.
3. In the Schema Editor, click the Attribute Types tab.
4. Click a specific attribute to view its definition.

   In the Object Class window, view the attribute properties.

   Example:

   To follow this example, click the `account` attribute.



5. To see the equivalent attribute definition in ASN.1 format, click the View as LDIF button.

Viewing attribute types over LDAP

Steps

- To view an operational attribute, run `ldapsearch`.

  Example:

  This example uses `ldapsearch` to view the multi-valued operational attribute `attributeTypes`, which publishes the definitions on the PingDirectory server.

> **Note**
>
> The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" attributeTypes
```

Copyright © 2025 Ping Identity Corporation

Viewing a specific attribute type over LDAP

Steps

- To search for a specific attribute, run `ldapsearch` with the `--dontWrap` option and use the `grep` command.

  Example:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base --dontWrap "(objectclass=*)" \
  attributeTypes | grep 'personalTitle'
```

Creating a new attribute over LDAP

The following sections demonstrate how to add a schema element over LDAP.

You can create your own schema file or type the schema from the command line.

> **Note**
>
> Make sure you're aware of text spacing and ASN.1 formatting.

Adding a new attribute to the schema over LDAP

Steps

1. In a text editor, create an LDIF file with the new attribute definition.

   Example:

   In this example, the LDIF file is named `myschema.ldif`.

```
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ALLOWED-VALUES ( 'Y' 'N' 'y' 'n' )
  X-ORIGIN 'PingDirectory Server Example' )
```

2. To add the attribute, run `ldapmodify`.

   Example:

```
$ bin/ldapmodify --filename myschema.ldif
```

3. To verify the addition, display the attribute using `ldapsearch`.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  --dontwrap "(objectclass=*)" attributeTypes | grep 'contractorStatus'
```

4. To view the custom schema file, go to `<server-root>/config/schema/99-user.ldif`.

   Result:

   For this example, you see the following details:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( contractorStatus-OID
  NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'PingDirectory Server Example' )
```

Adding constraints to attribute types

About this task

The PingDirectory server provides attribute type extensions that constrain the values for the associated attribute using the `DirectoryString` attribute syntax.

To constrain the values for an attribute:

Steps

- Use the `DirectoryString` attribute syntax.

  Example:

  The following example schema definition includes two `attributeType` definitions for `myAttr1` and `myAttr2`:

  - The first definition constrains the values for the attribute `myAttr1` to `'foo'`, `'bar'`, and `'baz'`.
  - The second definition constrains the minimum allowable length for `myAttr2` to `1` and the maximum allowable length to `5`.

Copyright © 2025 Ping Identity Corporation

```
attributeTypes: (1.2.3.4
  NAME 'myAttr1'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-ALLOWED-VALUES ( 'foo' 'bar' 'baz' ))
attributeTypes: ( 1.2.3.5
  NAME 'myAttr2'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  X-MIN-VALUE-LENGTH '1'
  X-MAX-VALUE-LENGTH '5' )
```

Managing object classes

Object classes are sets of related information objects that form entries in a directory information tree (DIT).

The PingDirectory server uses the schema to do the following:

- Define the entries.
- Specify the position of the entries in a DIT.
- Control the operations of the server.

You can also extend the schema by adding your own schema definitions.

Object classes have the following general properties:

- Object classes must have a globally unique name or identifier.
- Object classes specify the required and allowed attributes in an entry.
- Object classes can inherit the properties and the set of allowed attributes from its parent object classes, which might also be part of a hierarchical chain derived from the top abstract object class.
- Object classes that are defined in the PingDirectory server can be searched using the `objectClasses` operational attribute.

> **Note**
>
> The PingDirectory server also has a special entry called the subschema subentry, which provides information about the available schema elements on the server.

Object classes types

Based on RFC 4512, object classes can be a combination of three different types:

Abstract object classes

Used as the base object class from which structural or auxiliary classes inherit its properties.

This inheritance is a one-way relationship because abstract object classes cannot be derived from structural or auxiliary classes. The most common abstract object class is `top`, which defines the highest level object class in a hierarchical chain of object classes.

Copyright © 2025 Ping Identity Corporation

Structural object classes

Define the basic attributes in an entry and define where an entry can be placed in a directory information tree (DIT).

All entries in a DIT belong to one structural object class. Structural object classes can inherit properties from other structural object classes and from abstract object classes to form a chain of inherited classes. For example, the `inetOrgPerson` structural object class inherits properties from the `organizationalPerson` structural class, which inherits from another object class, person.

Auxiliary object classes

Used together with structural object classes to define additional sets of attributes required in an entry.

The auxiliary object class cannot form an entry alone but must be present with a structural object class. Auxiliary object classes cannot derive from structural object classes or vice-versa. They can inherit properties from other auxiliary classes and from abstract classes.

Object class definition

You can specify new object classes with existing schema components that don't require additional server code extensions for their implementation. To create new object classes, use the Schema Editor, which manages schema in the `<server-root>/config/schema` directory. For more information, see Extending the PingDirectory server schema.

RFC 4512, section 4.1.1, defines the following object class definition.

```
ObjectClassDescription = "(" wsp; Left parenthesis followed by a white space
numericoid                      ; Required numeric object identifier
[ sp "NAME" sp qdescrs ]        ; Short name descriptor as alias for the OID
[ sp "DESC" sp qdstring ]       ; Optional descriptive string
[ sp "OBSOLETE" ]               ; Determines if the element is inactive
[ sp "SUP" sp oid ]             ; Specifies the direct superior object class
[ sp kind ]                     ; abstract, structural (default), auxiliary
[ sp "MUST" sp oids ]           ; Required attribute types
[ sp "MAY" sp oids ]            ; Allowed attribute type
extensions wsp ")"              ; Extensions followed by a white space and ")"

usage = "userApplications" /    ; Stores user data
  "directoryOperation" /        ; Stores internal server data
  "distributedOperation" /      ; Stores operational data that must be synchronized
                                ;   across servers
  "dSAOperation"                ; Stores operational data specific to a server and
                                ;   should not be synchronized across servers
```

The following extensions are specific to PingDirectory server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /            ; Specifies where the object class is defined
"X-SCHEMA-FILE" /       ; Specifies which schema file contains the definition
"X-READ-ONLY"           ; True or False. Specifies if the file that contains
                        ;   the schema element is marked as read-only
                        ;   in the server configuration.
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Although RFC 4512 allows multiple superior object classes, PingDirectory server allows at most one superior object class, which is defined by the `SUP` element in the definition.

Basic object class properties

The Basic Properties table displays the standard elements in schema definition.

Attributes	Description
`Name`	The globally unique name.
`Description`	An optional definition that describes the object class and its contents. The analogous LDIF equivalent is `DESC`.
`OID`	The object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
`Parent`	The schema definition's hierarchical parent or superior object class, if any. An object class can have one parent.
`Type`	The type of schema definition, which can be abstract, structural, or auxiliary. The analogous LDIF equivalent is `ABSTRACT`, `STRUCTURAL`, or `AUX`.
`Required Attributes`	Specifies required attributes with the object class. The analogous LDIF equivalent is `MUST`. **Tip** The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the Properties View for that particular attribute.
`Optional Attributes`	Specifies optional attributes that can be used with the object class. The analogous LDIF equivalent is `MAY`. **Tip** The Schema Editor marks any inherited attributes from another object class. Double-click an attribute value to take you to the properties view for that particular attribute.

The Additional Properties table provides auxiliary information associated with the object class.

Attributes	Description
`Aliases`	Specifies short-form alias names, if any. You could have any number of short-form names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the `NAME` element although most object classes do not have aliases.
`Origin`	The origin of the schema definition. Typically, it could refer to a specific RFC or company.

Copyright © 2025 Ping Identity Corporation

Attributes	Description
`Obsolete`	Specifies if the schema definition is obsolete or not.
`Stored in File`	Specifies the schema file that stores the definition in the `<server-root>/config/schema` folder.

Viewing object classes

About this task

To view the object classes on your PingDirectory server, use any of the following:

- The Administrative Console Schema Editor
- LDAP with the `ldapsearch` tool
- A third-party tool

> **Note**
>
> The Schema Editor displays all of the object classes on the PingDirectory server instance. It shows the basic properties that are required elements and the extra properties that are allowed within the object class.

To view object classes over LDAP:

Steps

- To view an operational attribute, run `ldapsearch`.

  Example:

  This example uses `ldapsearch` to view the multi-valued operational attribute `objectClasses`, which publishes the object class definitions on the PingDirectory server.

  > **Note**
  >
  > The attribute is stored in the subschema subentry.

  ```
  $ bin/ldapsearch --baseDN cn=schema --searchScope base \
  --dontWrap "(objectclass=*)" objectClasses
  ```

  Result:

  ```
  dn: cn=schema
  objectClasses: ( 2.5.6.0 NAME 'top' ABSTRACT MUST objectClass X-ORIGIN 'RFC 4512' )
  objectClasses: ( 2.5.6.1 NAME 'alias' SUP top STRUCTURAL MUST aliasedObjectName
    X-ORIGIN 'RFC 4512' )
  objectClasses: ( 2.5.6.2 NAME 'country' SUP top STRUCTURAL MUST c
    MAY ( searchGuide $ description ) X-ORIGIN 'RFC 4519' )
  ...(more output)...
  ```

Managing an object class over LDAP

Manage an object class schema element over LDAP by adding a new attribute element to an existing object class. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting.

Before you begin

Define the attribute you want to add to the custom schema file.

About this task

The following example procedure adds a predefined attribute, `contractorAddress`, to the custom schema file, then adds it to the `contractor` object class.

Steps

1. Create and save an LDIF file with the content in the following example.

   Example:

   In this example, the file is named `contractorAddress-attr.ldif`.

   ```
   dn: cn=schema
   changetype: modify

   add: attributeTypes attributeTypes: ( contractor-OID NAME 'contractorAddress'
     SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
     SINGLE-VALUE
     USAGE userApplications
     X-ORIGIN 'user defined'
     X-SCHEMA-FILE '98-custom-schema.ldif' )
     X-ORIGINS 'user defined'
     X-SCHEMA-FILE '98-custom-schema.ldif' )
   ```

2. To add the attribute you defined, run `ldapmodify`.

   Example:

   In this example, the `contractorAddress` attribute is being added.

   ```
   $ bin/ldapmodify --filename contractorAddress-attr.ldif
   ```

3. To modify the contractor object class to allow this attribute, create an LDIF file.

   When doing this, you are re-adding the updated `objectClass`. The PingDirectory server handles the proper replacement of the existing object class with the new one.

   > **Note**
   >
   > Ensure that the lines are not wrapped, the `objectClasses` line should be one continuous line.

Copyright © 2025 Ping Identity Corporation

Example:

In this example, the file is named `contractor-oc.ldif`.

```
dn:cn=schema
changetype: modify
add: objectClasses
objectClasses: ( contractor-OID NAME 'contractor'
  DESC 'Contractor status information
  SUP top
  AUXILIARY MAY ( contractorStatus $ contractorAgency $ contractorAddress )
  X-ORIGIN 'Directory Server Example'
  X-SCHEMA-FILE '98-custom-schema.ldif' )
```

4. To update the `objectClass`, run `ldapmodify`.

   Example:

   ```
   $ bin/ldapmodify --filename contractor-oc.ldif
   ```

   Result:

   These schema changes are replicated to all servers in the replication topology.

5. To verify the change, view the `config/schema/98-custom-schema.ldif` file on the other servers in the replication topology to ensure that the changes are present.

6. (Optional) To add an index for this attribute, run `dsconfig` with the `create-local-db-index` option.

   > **Note**
   >
   > You must do this on each server in your topology unless you have server configuration groups set up. For more information, see Configuring server groups.

   Example:

   ```
   $ bin/dsconfig create-local-db-index --backend-name userRoot \
     --index-name contractorAddress --set index-type:equality
   ```

7. Rebuild the index online.

   > **Note**
   >
   > This doesn't affect other indexes or entries because there is no existing data for this attribute on any entry.

   Example:

   ```
   $ bin/rebuild-index --baseDN dc=example,dc=com --index contractorAddress
   ```

Creating a new object class using the schema editor

Before you begin

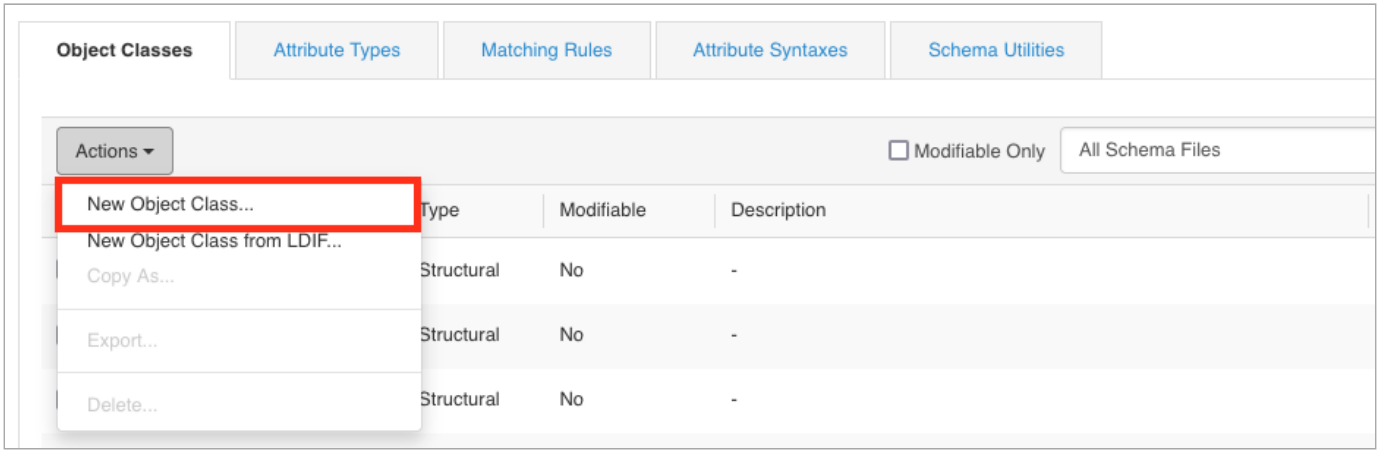
Make sure that any attributes that are part of the new object class are defined before creating the object class.

About this task

Creating a new object class is similar to creating a new attribute. To create a new object class:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, select LDAP Schema.
3. Click the Object Classes tab, and then in the Actions list, select New Object Class.



4. Enter the properties for the new object class.
5. In the Attributes box, filter the types of attributes required for the new object class. Click the right arrow to move it into the Required or the Optional box.

> **Note**
>
> All custom attributes appear at the bottom of the list in the **Attributes** box.

Extending the schema using a custom schema file

To add new attributes and object classes to your PingDirectory server schema, create a custom schema file.

Steps

1. Create an LDIF file with the new attribute extensions using a text editor.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
attributeTypes: ( contractorStatus-OID NAME 'contractorStatus'
  EQUALITY booleanMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'Directory Server Example' )
attributeTypes: ( contractorAgency-OID NAME 'contractorAgency'
  EQUALITY caseIgnoreMatch
  SUBSTR caseIgnoreSubstringsMatch
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.44{256}
  SINGLE-VALUE
  USAGE userApplications
  X-ORIGIN 'PingDirectory Server Example' )
```

2. In the LDIF file you created in step 1, add a new object class definition after the attribute types.

   Example:

   This example creates an auxiliary object class, `contractor`, that alone cannot be used as an entry.

   The object class is used to add supplemental information to the `inetOrgPerson` structural object class. The attributes are all optional for the new object class.

   ```
   objectClasses: ( contractor-OID
     NAME 'contractor'
     DESC 'Contractor status information'
     SUP top
     AUXILIARY
     MAY ( contractorStatus $ contractorAgency )
     X-ORIGIN 'PingDirectory Server Example' )
   ```

3. Save the file and place it in the `<server-root>/config/schema` directory.

   In this example, the file is saved as `99-auxobjclass.ldif`.

4. Load the schema extensions into the PingDirectory server. You have four options:

   Choose from:

   - Create a task that loads the new extensions into the schema.

     The following example creates a task with the ID `add-schema-99-auxobjclass` and adds it using `ldapmodify`.

Copyright © 2025 Ping Identity Corporation

```
dn: ds-task-id=add-schema-99-auxobjclass,cn=Scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-add-schema-file
ds-task-id: add-schema-99-auxobjclass
ds-task-class-name: com.unboundid.directory.server.tasks.AddSchemaFileTask
ds-task-schema-file-name: 99-auxobjclass.ldif
```

Note

When using this method, you don't need to restart the server.

- **Import the schema file using the Administrative Console Schema Editor.**

Note

When using this method, you don't need to restart the server.

- **Place the `99-auxobjclass.ldif` file in the `<server-root>/config/schema` directory. Restart PingDirectory server.**

Note

The schema file is read at startup.

- **Add the schema file using `load-ldap-schema-file`.**

```
$ bin/load-ldap-schema-file --schemaFile config/schema 99-auxobjclass.ldif
```

Note

When using this method, you don't need to restart the server.

5. **Add the new object class and attribute to an existing user entry.**

Example:

```
$ bin/ldapmodify
dn: uid=user.9,ou=People,dc=example,dc=com
changetype: modify
add: objectClass
objectClass: contractor
-
add: contractorStatus
contractorStatus: TRUE
```

6. **To verify the addition, run `ldapsearch` to display the attribute.**

Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.9)" contractorStatus
```

Result:

```
dn: uid=user.9,ou=People,dc=example,dc=com
contractorStatus: TRUE
```

About managing matching rules

Matching rules determine how clients and servers compare attribute values during LDAP requests or operations.

Matching rules are also used in evaluating search filter elements, including distinguished names (DNs) and attributes. They are defined for each attribute based on the following properties:

- `EQUALITY`: two attributes are equal based on case, exact match, and so forth
- `SUBSTR`: assertion value is a substring of an attribute
- `ORDERING`: greater than or equal, less than or equal, and so forth

> **Note**
>
> PingDirectory server supports an `APPROXIMATE` matching rule that compares similar attributes based on fuzzy logic. Attributes that are similar or sound alike are matched. For example, `petersen` would match `peterson`.

Matching rule definition

New matching rules require additional server code extensions to be implemented on the PingDirectory server.

If you need new matching rules, contact a Ping Identity support representative for assistance.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.3.

```
MatchingRuleDescription = "(" wsp    ; Left parentheses followed by a white space
numericoid                           ; Required numeric object identifier identifying
                                     ;   this matching rule
[ sp "NAME" sp qdescrs                ; Short name descriptor
[ sp "DESC" sp qdstring              ; Description
[ sp "OBSOLETE" ]                    ; Specifies if the rule is inactive
sp "SYNTAX" sp numericoid            ; Assertion syntax
extensions wsp ")"                        ; Extensions followed by a white space and ")"
```

Default matching rules

PingDirectory server provides a large set of matching rules that support a variety of applications.

Copyright © 2025 Ping Identity Corporation

The default matching rules available for the PingDirectory server are listed in the table below for each matching rule type:

- Equality matches
- Substring matches
- Ordering matches
- Approximate matches

Default Matching Rules

Matching Rule/OID	Attribute Syntax/OID	Description
`uuidMatch/ 1.3.6.1.1.16.2`	`UUID/ 1.3.6.1.1.16.1`	Compares an asserted UUID with a stored UUID attribute value for equality RFC 4530
`uuidOrderingMatch/ 1.3.6.1.1.16.3`	`UUID/ 1.3.6.1.1.16.1`	Compares the collation order of an asserted UUID with a stored UUID attribute value for ordering RFC 4530
`caseExactIA5Match/ 1.3.6.1.4.1.1466.109.114.1`	`IA5 String/ 1.3.6.1.4.1.1466.115.121.1.26`	Compares an asserted value with an attribute value of International Alphabet 5 (IA5) syntax RFC 4517
`caseIgnoreIA5Match/ 1.3.6.1.4.1.1466.109.114.2`	`IA5 String/ 1.3.6.1.4.1.1466.115.121.1.26`	Compares an asserted value with an attribute value of IA5 syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
`caseIgnoreIA5SubstringsMatch/ 1.3.6.1.4.1.1466.109.114.3`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring with an attribute value of IA5 string syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
`authPasswordExactMatch/ 1.3.6.1.4.1.4203.1.2.2`	`Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2`	Authentication password exact matching rule
`authPasswordMatch/ 1.3.6.1.4.1.4203.1.2.3`	`Authentication Password Syntax/ 1.3.6.1.4.1.4203.1.1.2`	Authentication password matching rule

Copyright © 2025 Ping Identity Corporation

Matching Rule/OID	Attribute Syntax/OID	Description
`ds-mr-double-metaphone-approx/ 1.3.6.1.4.1.30221.1.4.1`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Syntax based on the phonetic Double Metaphone algorithm for approximate matching
`ds-mr-user-password-exact/ 1.3.6.1.4.1.30221.1.4.2`	`User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1`	User password exact matching rule
`ds-mr-user-password-equality/ 1.3.6.1.4.1.30221.1.4.3`	`User Password Syntax/ 1.3.6.1.4.1.30221.1.3.1`	User password equality matching rule
`historicalCsnOrderingMatch/ 1.3.6.1.4.1.30221.1.4.4`	`1.3.6.1.4.1.30221.1.3.5`	Compares the collation order of a historical change sequence number with a historical Change Sequence Number (CSN) attribute value
`caseExactIA5SubstringsMatch/ 1.3.6.1.4.1.30221.1.4.902`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring with an attribute value of IA5 string syntax RFC 4517
`compactTimestampMatch/ 1.3.6.1.4.1.30221.2.4.1`	`Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1`	Compact Timestamp matching rule
`compactTimestampOrderingMatch/ 1.3.6.1.4.1.30221.2.4.2`	`Compact Timestamp/ 1.3.6.1.4.1.30221.2.3.1`	Compares the collation order of a compact timestamp number with an attribute value of Compact Timestamp syntax
`objectIdentifierMatch/ 2.5.13.0`	`OID/ 1.3.6.1.4.1.1466.115.121.1.38`	Compares an asserted value with an attribute value of OID syntax RFC 4517
`distinguishedNameMatch/ 2.5.13.1`	`DN/ 1.3.6.1.4.1.1466.115.121.1.12`	Compares an asserted value with an attribute value of distinguished name (DN) syntax Spaces around commas and semicolons are ignored. Spaces around plus and equal signs around relative distinguished name (RDN) components are ignored. RFC 4517.
`caseIgnoreMatch/ 2.5.13.2`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares an asserted value with an attribute value Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517

Copyright © 2025 Ping Identity Corporation

Matching Rule/OID	Attribute Syntax/OID	Description
`caseIgnoreOrderingMatch/ 2.5.13.3`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares the collation order of the asserted string with an attribute value of Directory String syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
`caseIgnoreSubstringsMatch/ 2.5.13.4`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring value with an attribute value of Directory String syntax Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
`caseExactMatch/ 2.5.13.5`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares an asserted value with an attribute value of Directory String syntax RFC 4517
`caseExactOrderingMatch/ 2.5.13.6`	`Directory String 1.3.6.1.4.1.1466.115.121.1.15`	Compares the collation order of the asserted string with an attribute value of Directory String syntax RFC 3698
`caseExactSubstringsMatch/ 2.5.13.7`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring with an attribute value of Directory String syntax RFC 3698
`numericStringMatch/ 2.5.13.8`	`Numeric String/ 1.3.6.1.4.1.1466.115.121.1.36`	Compares an asserted value with an attribute value of Numeric String syntax. Spaces are ignored when performing these comparisons RFC 4517.
`numericStringOrderingMatch/ 2.5.13.9`	`Numeric String/ 1.3.6.1.4.1.1466.115.121.1.36`	Compares the collation order of the asserted string with an attribute value of Numeric String syntax Spaces are ignored when performing these comparisons. RFC 4517

Copyright © 2025 Ping Identity Corporation

Matching Rule/OID	Attribute Syntax/OID	Description
`numericStringSubstringsMatch/ 2.5.13.10`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring with an attribute value of Numeric String syntax Spaces are ignored when performing these comparisons. RFC 4517
`caseIgnoreListMatch/ 2.5.13.11`	`Postal Address/ 1.3.6.1.4.1.1466.115.121.1.41`	Compares an asserted value with an attribute value, which is a sequence of Directory Strings Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517
`caseIgnoreListSubstringsMatch/ 2.5.13.12`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares the asserted substring with an attribute value, which is a sequence of Directory Strings Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 3698
`booleanMatch/ 2.5.13.13`	`Boolean/ 1.3.6.1.4.1.1466.115.121.1.7`	Compares an asserted boolean value with an attribute value of BOOLEAN syntax Returns true if the values are both `TRUE` or both `FALSE`. RFC 3698
`integerMatch/ 2.5.13.14`	`Integer/ 1.3.6.1.4.1.1466.115.121.1.27`	Compares an asserted value with an attribute value of INTEGER syntax RFC 4517
`integerOrderingMatch/ 2.5.13.15`	`Integer/ 1.3.6.1.4.1.1466.115.121.1.27`	Compares the collation order of the asserted integer with an attribute value of Integer syntax Returns true if the attribute value is less than the asserted value. RFC 3698
`bitStringMatch/ 2.5.13.16`	`Bit String/ 1.3.6.1.4.1.1466.115.121.1.6`	Compares an asserted Bit String value with an attribute value of Bit String syntax RFC 4517

Copyright © 2025 Ping Identity Corporation

Matching Rule/OID	Attribute Syntax/OID	Description
`octetStringMatch/ 2.5.13.17`	`Octet String/ 1.3.6.1.4.1.1466.115.121.1.40`	Compares an asserted value with an attribute value of octet string syntax using a byte-for-byte comparison RFC 4517
`octetStringOrderingMatch/ 2.5.13.18`	`Octet String/ 1.3.6.1.4.1.1466.115.121.1.40`	Compares the collation order of the asserted octet string with an attribute value of Octet String syntax Zero precedes a one bit. Shorter strings precede longer strings. RFC 3698
`octetStringSubstringsMatch/ 2.5.13.19`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted substring with an attribute value of octet string syntax using a byte-for-byte comparison RFC 4517
`telephoneNumberMatch/ 2.5.13.20`	`Telephone Number/ 1.3.6.1.4.1.1466.115.121.1.50`	Compares an asserted value with an attribute value of Telephone Number syntax RFC 4517
`telephoneNumberSubstringsMatch/ 2.5.13.21`	`Substring Assertion/ 1.3.6.1.4.1.1466.115.121.1.58`	Compares an asserted value with the substrings of an attribute value of Telephone Number String syntax RFC 4517
`presentationAddressMatch/ 2.5.13.22`	`Presentation Address/ 1.3.6.1.4.1.1466.115.121.1.43`	Compares an asserted value with an attribute value of Presentation Address syntax RFC 4517
`uniqueMemberMatch/ 2.5.13.23`	`Name and Optional UID/ 1.3.6.1.4.1.1466.115.121.1.34`	Compares an asserted value with an attribute value of Unique Member syntax RFC 4517
`protocolInformationMatch/ 2.5.13.24`	`Protocol Information/ 1.3.6.1.4.1.1466.115.121.1.42`	Compares an asserted value with an attribute value of Protocol Information syntax RFC 4517
`generalizedTimeMatch/ 2.5.13.27`	`Generalized Time/ 1.3.6.1.4.1.1466.115.121.1.24`	Compares an asserted value with an attribute value of Generalized Time syntax RFC 4517

Copyright © 2025 Ping Identity Corporation

Matching Rule/OID	Attribute Syntax/OID	Description
`generalizedTimeOrderingMatch/ 2.5.13.28`	`Generalized Time 1.3.6.1.4.1.1466.115.121.1.24`	Compares the collation order of the asserted string with an attribute value of Generalized Time String syntax and case is ignored RFC 4517
`integerFirstComponentMatch/ 2.5.13.29`	`Integer/ 1.3.6.1.4.1.1466.115.121.1.27`	Equality matching rules for subschema attributes between an Integer syntax and the value syntax RFC 4517
`objectIdentifierFirstComponentMatch/ 2.5.13.30`	`OID/ 1.3.6.1.4.1.1466.115.121.1.38`	Equality matching rules for subschema attributes between an OID syntax and the value syntax RFC 4517
`directoryStringFirstComponentMatch/ 2.5.13.31`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares an asserted Directory String value with an attribute value of type `SEQUENCE` whose first component is mandatory and of type Directory String Returns true if the attribute value has a first component whose value matches the asserted Directory String using the rules of `caseIgnoreMatch`. RFC 3698.
`wordMatch/ 2.5.13.32`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares an asserted word with any word in the attribute value for equality RFC 3698
`keywordMatch/ 2.5.13.33`	`Directory String/ 1.3.6.1.4.1.1466.115.121.1.15`	Compares an asserted value with any keyword in the attribute value for equality RFC 3698

Basic matching rule properties

The following table describes the standard elements in a matching rule schema definition.

Attributes	Description
`Name`	Specifies the descriptive and unique name of the element

Copyright © 2025 Ping Identity Corporation

Attributes	Description
`Description`	Specifies an optional definition that describes the matching rule The analogous LDIF equivalent is `DESC`.
`OID`	Specifies the globally unique object identifier assigned to the schema definition You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.
`Type`	Specifies the type of matching rule: • `Equality` • `Ordering` • `Substring` • `Approximate`
`Syntax`	Specifies the matching rule syntax
`Used by Attributes`	Specifies any attributes that use the corresponding matching rule

Viewing matching rules

To view the matching rules on your PingDirectory server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

About this task

To view matching rules over LDAP:

Steps

- To view the `matchingRules` attribute, run `ldapsearch`.

  Example:

  The following example uses `ldapsearch` to view a multi-valued operational attribute, `matchingRules`, which publishes the definitions on the PingDirectory server.

  > **Note**
  >
  > The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" matchingRules
```

Copyright © 2025 Ping Identity Corporation

About managing attribute syntaxes

The attribute type definition has a `SYNTAX` element, or attribute syntax, that specifies how the data values for the attribute are represented.

The syntax can be used to define a large range of data types necessary for client applications. An attribute syntax uses the Abstract Syntax Notation One (ASN.1) format for its definitions.

Attribute syntax definition

New attribute syntaxes require additional code to be implemented on the PingDirectory server.

If you need new syntax definitions, contact Ping Identity support for assistance.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.5.

```
SyntaxDescription = "(" wsp
numericoid                    ; Object identifier
[ sp "DESC" sp qdstring ] ; Description
extensions wsp ")"            ; Extensions followed by a white space and ")"
```

Default attribute syntaxes

PingDirectory server supports a large set of Attribute Syntax rules for applications.

The default Attribute Syntax rules available for the server are listed in the following table.

LDAP Syntax	OID	Description
`UUID`	`1.3.6.1.1.16.1`	128-bit (16 octets) Universally Unique Identifier (UUID) used for Uniform Resource Names as defined in RFC 4122 For example, `a4028c1a-f36e-11da-ba1a-04112154bd1e`
`Attribute Type Description`	`1.3.6.1.4.1.1466.115.121.1.3`	Syntax for the `AttributeTypeDescription` rule based on RFC 4517
`Binary`	`1.3.6.1.4.1.1466.115.121.1.5`	Strings based on Basic Encoding Rules (BER) or Distinguished Encoding rules (DER) For example, an X.509 digital certificate or LDAP messages are BER encoded
`Bit String`	`1.3.6.1.4.1.1466.115.121.1.6`	Sequence of binary digits based on RFC 4517 For example, `'0010111'B`
`Boolean`	`1.3.6.1.4.1.1466.115.121.1.7`	`TRUE` or `FALSE`

Copyright © 2025 Ping Identity Corporation

LDAP Syntax	OID	Description
`Certificate`	`1.3.6.1.4.1.1466.115.121.1.8`	BER/DER-encoded octet strings based on an X.509 public key certificate as defined in RFC 4523
`Certificate List`	`1.3.6.1.4.1.1466.115.121.1.9`	BER/DER-encoded octet string based on an X.509 certificate revocation list as defined in RFC 4523
`Certificate Pair`	`1.3.6.1.4.1.1466.115.121.1.10`	BER/DER-encoded octet string based on an X.509 public key certificate pair as defined in RFC 4523
`Country String`	`1.3.6.1.4.1.1466.115.121.1.11`	Two character country code specified in ISO 3166 For example, `US`, `CA`, and so forth **Note** The current implementation for Country String: • Only verifies that values are two printable characters, where the set of printable characters is defined in RFC 2252. • Does not check that the value is a valid ISO 3166 country code.
`DN`	`1.3.6.1.4.1.1466.115.121.1.12`	Distinguished name of an entry as defined in RFC 4514
`Delivery Method`	`1.3.6.1.4.1.1466.115.121.1.14`	Sequence of services in preference order by which an entity receives messages as defined in RFC 4517 For example, `videotext $ telephone`
`Directory String`	`1.3.6.1.4.1.1466.115.121.1.15`	String of one or more characters from the Universal Character Set (UCS) using UCS Transformation Format 8 (UTF-8) encoding of the string
`DIT Content Rule Description`	`1.3.6.1.4.1.1466.115.121.1.16`	`DITContentRuleDescription` as defined in RFC 4517
`DIT Structure Rule Description`	`1.3.6.1.4.1.1466.115.121.1.17`	`DITStructureRuleDesciption` as defined in RFC 4517
`Enhanced Guide`	`1.3.6.1.4.1.1466.115.121.1.21`	Combination of attribute types and filter operators to be used to construct search filters as defined in RFC 4517 For example, `person#(sn$EQ)#oneLevel`
`Facsimile Telephone Number`	`1.3.6.1.4.1.1466.115.121.1.22`	Fax telephone number on the public switched telephone network as defined in RFC 4517
`Fax`	`1.3.6.1.4.1.1466.115.121.1.23`	Image generated using Group 3 fax process as defined in RFC 4517

Copyright © 2025 Ping Identity Corporation

LDAP Syntax	OID	Description
`Generalized Time`	`1.3.6.1.4.1.1466.115.121.1.24`	String representing data and time as defined in RFC 4517 `YYYYMMDDHHMMSS[.|,fraction][(+|-HHMM)|Z]` For example, `201103061032`, `201103061032-0500`, or `201103061032Z` (`Z` indicates Coordinated Universal Time)
`Guide`	`1.3.6.1.4.1.1466.115.121.1.25`	Attribute types and filter operators as defined in RFC 4517
`IA5 String`	`1.3.6.1.4.1.1466.115.121.1.26`	String of zero or more characters from the International Alphabet 5 (IA5) character set as defined in RFC 4517
`Integer`	`1.3.6.1.4.1.1466.115.121.1.27`	String representations of integer values For example, the character string `1234` represents the number 1234 as defined in RFC 4517
`JPEG`	`1.3.6.1.4.1.1466.115.121.1.28`	Image in JPEG File Interchange Format (JFIF) as defined in RFC 4517
`Matching Rule Description`	`1.3.6.1.4.1.1466.115.121.1.30`	`MatchingRuleDescription` as defined in RFC 4512
`Matching Rule Use Description`	`1.3.6.1.4.1.1466.115.121.1.31`	Attribute types to which a matching rule is applied in an `extensibleMatch` search filter RFC 4511
`Name and Optional UID`	`1.3.6.1.4.1.1466.115.121.1.34`	Distinguished name and an optional unique identifier that differentiates identical distinguished names (DNs) as defined in RFC 4517 For example, `uid=jsmith,ou=People,dc=example,dc=com#'0111'B`
`Name Form Description`	`1.3.6.1.4.1.1466.115.121.1.35`	`NameFormDescription` as defined in RFC 4512
`Numeric String`	`1.3.6.1.4.1.1466.115.121.1.36`	Sequence of one or more numerals and spaces as defined in RFC 4517 For example, `14 848 929 102`
`Object Class Description`	`1.3.6.1.4.1.1466.115.121.1.37`	`ObjectClassDescription` as defined in RFC 4512
`OID`	`1.3.6.1.4.1.1466.115.121.1.38`	Object identifier as defined in RFC 4512
`Other Mailbox`	`1.3.6.1.4.1.1466.115.121.1.39`	Specifies an electronic mailbox as defined in RFC 4517 For example, `otherMailbox = google $ user@gmail.com`

Copyright © 2025 Ping Identity Corporation

LDAP Syntax	OID	Description
`Octet String`	`1.3.6.1.4.1.1466.115.121.1.40`	Sequence of zero or more octets (8-bit bytes) as defined in RFC 4517
`Postal Address`	`1.3.6.1.4.1.1466.115.121.1.41`	Strings of characters that form a multi-line address in a physical mail system. Each component is separated by a `$` For example, `1234 Main St.$Austin, TX 78744$USA`
`Protocol Information`	`1.3.6.1.4.1.1466.115.121.1.42`	Undefined
`Presentation Address`	`1.3.6.1.4.1.1466.115.121.1.43`	String encoded OSI presentation address as defined in RFC 1278 For example, `TELEX+00728722+RFC-1006+03+10.0.0.6`
`Printable String`	`1.3.6.1.4.1.1466.115.121.1.44`	String of one or more printable ASCII alphabetic, numeric, and punctuation characters as defined in RFC 4517
`RFC3672 Subtree Specification`	`1.3.6.1.4.1.1466.115.121.1.45`	Syntax based on subtree specification as defined as RFC 3672
`Supported Algorithm`	`1.3.6.1.4.1.1466.115.121.1.49`	Octet string based on the LDAP-encoding for a supported algorithm value that results from the BER encoding of a `SupportedAlgorithm` ASN.1 value
`Telephone Number`	`1.3.6.1.4.1.1466.115.121.1.50`	String of printable international telephone number representations in E.123 format as defined in RFC 4517 For example, `+1 512 904 5525`
`Teletex Terminal Identifier`	`1.3.6.1.4.1.1466.115.121.1.51`	Identifier and telex terminal as defined in RFC 4517
`Telex Number`	`1.3.6.1.4.1.1466.115.121.1.52`	String representing the telex number, country code, and answerback code as defined in RFC 4517 For example, `812374, ch, ehhg`
`UTC Time`	`1.3.6.1.4.1.1466.115.121.1.53`	Character string representing the data and time in UTC Time format as defined as RFC 4517: `YYMMDDHHMM[SS][(+|-HHMM)|Z]`, where `Z` is the coordinated universal time. For example, `0903051035Z, 0903051035-0500`
`LDAP Syntax Description`	`1.3.6.1.4.1.1466.115.121.1.54`	`SyntaxDescription` as defined in RFC 4512
`Substring Assertion`	`1.3.6.1.4.1.1466.115.121.1.58`	Syntax for assertion values in an extensible match as defined in RFC 4517

Copyright © 2025 Ping Identity Corporation

LDAP Syntax	OID	Description
`Authentication Password Syntax`	`1.3.6.1.4.1.4203.1.1.2`	Encoded password storage syntax as defined in RFC 3112 For example, the syntax specifies the storage scheme in brackets: `<storage-scheme>$<auth component>$<auth value>` For example, `SSHA$xdEZWRqgyJk=$egDEFDXvdeeEnXUEIDPnd39dkpe=`
`User Password Syntax`	`1.3.6.1.4.1.30221.1.3.1`	Encoded password storage syntax as defined in RFC 2307 For example, the syntax specifies the storage scheme in brackets: `{SSHA}` `XaljOF0ii3fOwCrU1klgBpWFayqSYs+5W1pMnw==`
`Relative Subtree Specification`	`1.3.6.1.4.1.30221.1.3.2`	Similar to the RFC 3672 subtree specification except it uses an LDAP search filter as the specification filter
`Absolute Subtree Specification`	`1.3.6.1.4.1.30221.1.3.3`	Syntax for a subset of entries in a subtree based on RFC 3672
`Sun-defined Access Control Information`	`1.3.6.1.4.1.30221.1.3.4`	Syntax for access control instructions used in Sun Directory Servers
`Compact Timestamp`	`1.3.6.1.4.1.30221.2.3.1`	Syntax based on Compact Timestamp ISO 8601 format For example, `20110306T102532`

Basic attribute syntax properties

The following table provides a description of the standard elements in an attribute syntax.

Attributes	Description
`Name`	Specifies the descriptive and unique name of the element
`Description`	Indicates an optional definition that describes the attribute syntax The analogous LDIF equivalent is `DESC`.
`OID`	Specifies the globally unique object identifier assigned to the schema definition
`Used by Attributes`	Indicates any attributes that use the corresponding attribute syntax

Viewing attribute syntaxes

To view the attribute syntaxes on your PingDirectory server, use the Schema Editor, LDAP with `ldapsearch`, or a third-party tool.

Copyright © 2025 Ping Identity Corporation

About this task

To view attribute syntaxes over LDAP:

Steps

- To view the PingDirectory server's published list of attribute syntaxes, run `ldapsearch` using the `ldapSyntaxes` attribute.

  Example:

  The following example uses `ldapsearch` to view the PingDirectory server's published list of attribute syntaxes using the multi-valued operational attribute, `ldapSyntaxes`, which publishes the definitions on the server.

  > **Note**
  > The attribute is stored in the subschema subentry.

  ```
  $ bin/ldapsearch --baseDN cn=schema \
    --searchScope base "(objectclass=*)" ldapSyntaxes
  ```

Using the schema editor utilities

The schema editor provides a Schema Utilities tab where you can import new schema elements from a file and check schema compliance.

About this task

If you are importing a schema file, the system automatically checks for compliance before the import. If the definition doesn't meet schema compliance, the system displays an error message. However, you should check if your file is compliant with your schema before importing it.

To check schema compliance using the schema editor:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click LDAP Schema.
3. In the schema editor, click the Schema Utilities tab.
4. Add your schema definition using one of two methods:

   Choose from:

   - To have the system check an LDIF file, click Import Schema Elements and select a file to upload.
   - Copy and paste a new schema definition into the field.
5. Click Validate Entries.

   Result:

Copyright © 2025 Ping Identity Corporation

If there is a problem with your definition, you see an error message.

Modifying a schema definition

About this task

You can only edit schema definitions in the PingDirectory server that are read-write. The schema elements indicated by the Modifiable column in the schema editor's tables can be modified.

To modify a schema definition:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click Schema.
3. Click the Object Classes tab.
4. Select the object class that you want to modify, and then click Actions → Edit.

5. Make your changes and click OK.

Deleting a schema definition

About this task

You can only delete schema definitions in the PingDirectory server that are read-write. In general, you can only remove schema definitions in the Custom folder of the schema editor. Ensure that the schema element you are deleting is not currently in use.

To delete a schema definition:

Steps

1. Start the administrative console.
2. In the top-level navigation menu, click Schema.
3. Click the Object Classes tab.
4. Select the object class that you want to remove, and then in the Actions list, select Delete.

Copyright © 2025 Ping Identity Corporation

Result:

The Confirmation dialog box opens.

5. To delete the schema element, click Yes.

Managing schema checking

The PingDirectory server provides full support for parsing all schema elements and provides access to all of its components.

By default, the PingDirectory server enables schema checking for all operations, especially when importing data to the server or when modifying entries using the `ldapmodify` tool. Any schema violations generate an error message to standard output.

Viewing the schema checking properties

Steps

- To view the schema checking property, run `dsconfig` with the `get-global-configuration-prop` option.

  Example:

  ```
  $ bin/dsconfig get-global-configuration-prop \
    --property check-schema
  ```

Disabling schema checking

Although you can use the `dsconfig` tool to disable the schema checking, it's not recommended.

About this task

This feature only applies to public backends. Schema checking is enforced on private backends, such as changes to the configuration, schema, task, and others. An admin action alert is generated if you attempt to disable schema checking using `dsconfig` in interactive or non-interactive mode. The alert provides alternatives to disabling schema checking.

Steps

1. To disable the `check-schema` property, run `dsconfig` with the `set-global-configuration-prop` option.

   Example:

   ```
   $ bin/dsconfig --no-prompt set-global-configuration-prop \
     --set check-schema:false
   ```

   Result:

   The system generates an admin action alert that provides alternate options to disabling schema checking.

Copyright © 2025 Ping Identity Corporation

```
One or more configuration property changes require administrative action or
confirmation/notification.

Those properties include:

  *   check-schema: Schema checking should only be disabled as a last resort
      since disabling schema checking harms performance and can lead to
      unexpected behavior in the server as well as the applications that
      access it. There are less severe options for addressing schema issues:

  1.  Update the data to conform to the server schema.

  2.  Modify the server schema to conform to the data. Contact support before
      modifying the server's default schema.

  3.  Change the single-structural-objectclass-behavior property to allow
      entries to have no structural object class or multiple structural object
      classes.

  4.  Change the invalid-attribute-syntax-behavior property to allow attribute
      values to violate their attribute syntax.

  5.  Change the allow-zero-length-values property of the Directory String
      Attribute Syntax configuration to allow attributes with this syntax to
      have a zero length value.

Continue?  Choose 'no' to return to the previous step (yes / no) [yes]:
```

2. To continue the process of disabling the schema checking instead of following one of the alternate options, press Enter.

Managing matching rule uses

Matching rule use definitions map certain attribute types with a matching rule definition for extensible match filters.

Extensible match filters allow clients to search using distinguished name (DN) components, such as (`ou:dn:=engineering`), or using an OID number, such as (`cn:1.2.3.4:=Sam Carter`). The matching rule use attribute publishes those attribute types and matching rule combinations, which can be used in extensible match assertions.

Typically, you define a matching rule use that isn't normally specified in the attribute type definition. You can create new matching rule uses from the existing schema definitions by adding a custom schema file in the `<server-root>/config/schema` directory.

Matching rule use definitions

Matching rule uses can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.4.

Copyright © 2025 Ping Identity Corporation

```
MatchingRuleUseDescription = "(" wsp
numericoid                  ; Object identifier
[ sp "NAME" sp qdescrs ]    ; Short name descriptor
[ sp "DESC" sp qdstring ]   ; Description
[ sp "OBSOLETE" ]           ; Specifies if the rule use is inactive
sp "APPLIES" sp oid         ; Attribute types
extensions wsp ")"          ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory server and aren't defined in RFC 4512.

```
extensions = /
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in the
                         ;   server configuration.
```

Viewing matching rule uses

About this task

A matching rule use lists the attribute types that are suitable for use with an `extensibleMatch` search filter.

Steps

- To view the PingDirectory server's published list of matching rule uses that use the operational attribute `matchingRuleUse`, run `ldapsearch`.

  > **Note**
  >
  > The multi-valued operational attribute `matchingRuleUse` publishes the definitions on the PingDirectory server, if any. The attribute is stored in the subschema subentry.

  Example:

  ```
  $ bin/ldapsearch --baseDN cn=schema --searchScope base \
    "(objectclass=*)" matchingRuleUse
  ```

Managing DIT content rules

Directory information tree (DIT) content rules provide a way to precisely define what attributes might be present in an entry based on its structural object class without specifically creating a new object class definition.

The DIT content rules can define the following:

- Mandatory and optional attributes that entries contain
- The set of auxiliary object classes that entries can be part of
- Any optional attributes from the structural and auxiliary object classes that are prohibited from being present in the entries

Copyright © 2025 Ping Identity Corporation

DIT content rule definitions

DIT content rules can be specified with existing schema components and don't require additional code for implementation.

On the PingDirectory server, only one DIT content rule can be defined for an entry in the structural object class.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.6.

```
DITContentRuleDescription = "(" wsp
numericoid                  ; Object identifier of the structural object class the rule applies to
[ sp "NAME" sp qdescrs ]    ; Short name descriptor
[ sp "DESC" sp qdstring ]   ; Description
[ sp "OBSOLETE" ]           ; Specifies if the rule is inactive
[ sp "AUX" sp oids ]        ; List of allowed auxiliary object classes
[ sp "MUST" sp oids ]       ; List of required attributes
[ sp "MAY" sp oids ]        ; List of allowed attributes in the entry
[ sp "NOT" sp oids ]        ; List of prohibited attributes in the entry
extensions wsp ")"          ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /              ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /         ; Specifies which schema file contains the definition
"X-READ-ONLY"             ; True or False. Specifies if the file that contains
                          ;   the schema element is marked as read-only in
                          ;   the server configuration.
```

Viewing DIT content rules

Steps

- To view the `dITContentRules` attribute, run `ldapsearch`.

> **Note**
>
> `dITContentRules` is a multi-valued operational attribute that publishes the definitions on the PingDirectory server, if any. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITContentRules
```

Managing name forms

Name forms define how entries can be named based on their structural object class.

Copyright © 2025 Ping Identity Corporation

Specifically, name forms specify the structural object class you are naming as well as the mutually-exclusive set of required and allowed attributes to form the relative distinguished names (RDNs) of the entries. Each structural object class can be associated with at most one name form definition.

Name form definitions

Name forms can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.7.2.

```
NameFormDescription = "(" wsp
numericoid                  ; object identifier
[ sp "NAME" sp qdescrs ]    ; short name descriptor
[ sp "DESC" sp qdstring ]   ; description
[ sp "OBSOLETE" ]           ; not active
sp "OC" sp oid              ; structural object class
sp "MUST" SP oids           ; attribute types
[ sp "MAY" sp oids ]        ; attribute types
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory server and aren't defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /             ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in
                         ;   the server configuration.
```

Viewing name forms

Steps

- To view the `nameForms` attribute, run `ldapsearch`.

> **Note**
>
> `nameForms` is a multi-valued operational attribute that publishes the definitions on the PingDirectory server. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
"(objectclass=*)" nameForms
```

Managing DIT structure rules

Directory information tree (DIT) structure rules define which entries might be superior or subordinate to other entries in the DIT.

Copyright © 2025 Ping Identity Corporation

Together with name forms, DIT structure rules determine how relative distinguished names (RDNs) are added together to make up distinguished names (DNs). Because DITs don't have a global standard and are specific to a company's implementation, each DIT structure rule associates a name form with an object class and specifies each structure rule with an integer rule identifier, instead of an OID number. The identifier defines its relationship, either superior or subordinate, to another object class. If no superior rules are specified, the DIT structure rule applies to the root of the subtree.

DIT structure rule definition

DIT structure rules can be specified with existing schema components and don't require additional code for implementation.

The following formal specification for attribute types is provided in RFC 4512, section 4.1.7.1.

```
DITStructureRuleDescription = "(" wsp
ruleid                      ; object identifier
[ sp "NAME" sp qdescrs ]    ; short name descriptor
[ sp "DESC" sp qdstring ]   ; description
[ sp "OBSOLETE" ]           ; specifies if the rule is inactive
sp "FORM" sp oid            ; OID or name form with which the rule is associated
[ sp "SUP" ruleids ]        ; Superior rule IDs
extensions wsp ")"          ; extensions followed by a white space and ")"
```

The following extensions are specific to PingDirectory Server and are not defined in RFC 4512.

```
extensions = /
"X-ORIGIN" /             ; Specifies where the rule is defined
"X-SCHEMA-FILE" /        ; Specifies which schema file contains the definition
"X-READ-ONLY"            ; True or False. Specifies if the file that contains
                         ;   the schema element is marked as read-only in
                         ;   the server configuration.
```

Viewing DIT structure rules

Steps

- To view the `dITStructureRules` attribute, run `ldapsearch`.

> **Note**
>
> `dITStructureRules` is a multi-valued operational attribute that publishes the definitions on the PingDirectory server. The attribute is stored in the subschema subentry.

Example:

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
  "(objectclass=*)" dITStructureRules
```

About managing JSON attribute values

The PingDirectory server supports a JSON object attribute syntax that can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object.

Copyright © 2025 Ping Identity Corporation

The following is an example schema definition.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( jsonAttr1-OID NAME 'jsonAttr1' DESC 'test json attribute support' EQUALITY
jsonObjectExactMatch SYNTAX 1.3.6.1.4.1.30221.2.3.4 USAGE userApplications )
objectClasses: ( jsonObjectClass-OID NAME 'jsonObjectClass' AUXILIARY MAY jsonAttr1 )
```

Note

You should always specify the `EQUALITY` matching rule as `jsonObjectExactMatch` in the schema definition. Using the `jsonObjectFilterExtensibleMatch` isn't valid in this case.

The `jsonObjectExactMatch` and `jsonObjectFilterExtensibleMatch` matching rules are provided to filter equality matching rule JSON object syntax. The following three additional matching rules are used in conjunction with `jsonObjectExactMatch` and provide support for customizing the way that the server treats case sensitivity in JSON field names and in string values:

- `jsonObjectCaseSensitiveNamesCaseSensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseInsensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseSensitiveValues`

The `jsonObjectExactMatch` equality matching rule is used in evaluating equality filters in `search` operations, and for matching performed against JSON object attributes for `add`, `compare`, and `modify` operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly, although fields can appear in different orders. The values of each field must have the same data types. The order of elements in arrays is considered significant. Substring or approximate matching isn't supported.

The `jsonObjectFilterExtensibleMatch` matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation for the LDAP SDK for Java. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.

The following are example searches using the `jsonObjectFilterExtensibleMatch` rule with available filter types:

`"equals"` *filter type*

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" : "equals", "field" : ["stuff", "onetype", "name"],
"value" : "John Doe" })'
```

Copyright © 2025 Ping Identity Corporation

"containsField" *filter type*

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" : "containsField", "field" : "age", "expectedType" :
"number" })'
```

"greaterThan" *filter type*

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com  -D "cn=Directory Manager" -w password
'(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" : "greaterThan", "field" : "age", "value" : 26,
"allowEquals" : true})'
```

Configuring JSON attribute constraints

The PingDirectory server can define several constraints for the fields included in JSON objects stored in values of a specified attribute type.

Defining constraints on JSON object fields allows administrators to set requirements on what values a JSON field can take to ensure consistency across entries.

Constraints that can be placed on a JSON field include:

- Requiring values of the field to have a specified data type.
- Indicating whether the field is required or optional.
- Indicating whether the field can have multiple values in an array. If a field is permitted to have array values, restrictions can also be placed on the number of elements that can be present in the array.
- Indicating whether the field can have a value that is the null primitive as an alternative to values of the indicated data type.
- Restricting values of string fields to a predefined set of values that match a given regular expression or to a length specified by the user.
- Restricting values of numeric fields with upper and lower bounds.

> **Note**
>
> Only new entries are subject to the new constraints. Existing data that doesn't match newly-defined JSON constraints can still be decoded and managed by the server. Attempts to alter existing entries with non-compliant JSON objects might require fixing those objects to conform to the new constraints.

The global configuration properties that define schema constraints for JSON objects are `create-json-attribute-constraints` and `create-json-field-constraints` in `dsconfig`. In `dsconfig` interactive, under advanced settings, the menu options are `JSON Attribute Constraints` and `JSON Field Constraints`.

Configuration properties for each include:

Copyright © 2025 Ping Identity Corporation

`attribute-type`

The name or object identifier of the attribute type with which the definition is associated. This attribute type must have the JSON object syntax. `attribute-type` is the naming attribute for the configuration entry.

`allow-unnamed-fields`

A Boolean value that indicates whether JSON objects, used as the values of attributes of the associated type, can include fields that are not referenced in the `attribute-value-constraints` object. The default value is `true`.

If `allow-unnamed-fields` is `true` JSON objects can have fields that are not referenced, and no constraints are imposed on those fields. If `allow-unnamed-fields` is `false`, JSON objects can only have the defined fields.

> **Note**
>
> Unless a schema definition is configured with `allow-unnamed-fields` set to `false`, only information about fields whose values should be indexed or tokenized is required. To ensure that clients cannot store invalid values, you should define any other expected fields. .

As with the standard LDAP schema, JSON schema constraints are enforced for any changes made after the constraints are defined. If there are already JSON values in the data before a JSON schema is defined for that attribute type, or before changes are made, values that already exist might violate those constraints. JSON schema constraints are also enforced for data provided in an LDIF import, and entries containing JSON objects that violate these constraints are rejected.

JSON Field Constraints

Property	Description
`field`	Specifies the path to the target field as a string with periods to separate levels of hierarchy. If any field name in the hierarchy includes a period, then that period must be escaped with a backslash.

Copyright © 2025 Ping Identity Corporation

Property	Description
`value-type`	Specifies the expected data type for the target field. The available values are: ***any*** The target field can have any value. ***boolean*** The target field must have a value of `true` or `false`. ***integer*** The target field must have a number that can be exactly represented as an integer. ***null*** The target field must have a value of `null`. ***number*** The target field must have a value that represents a valid JSON number. ***object*** The target field must have a value that represents a valid JSON object. The `allowed-fields` array can contain additional elements that define constraints for the fields. ***string*** The target field must have a value that represents a valid JSON string.
`is-required`	Specifies whether the target field is required to be present. If the target field is present, its value must be either `true` or `false`. If it is absent, a default of `false` is assumed.
`is-array`	Indicates whether the target field can be an array. If the value can be an array, all of the elements of the array must be of the type specified in the `value-type` field. The field constraint can be present with a value of one of the single strings listed below. If the constraint is absent, a value of `prohibited` is assumed. Values are: ***required*** The target field must be an array with zero or more values of the specified type and must not be a single value of the specified type. ***optional*** The target field can be an array with zero or more values of the specified type, or it can be a single value of the specified type. ***prohibited*** The target field must not be an array and can only be a single value of the specified type.

Copyright © 2025 Ping Identity Corporation

Property	Description
`allow-null-value`	Specifies whether the target field can have a value of `null` as an alternative to the specified `value-type`. If the field constraint is present, `allows-null-value`'s value must be either `true` or `false`. If the constraint is absent, a default of `false` is assumed. `allow-null-value` has no effect if the `value-type` is `null`.
`allow-empty-object`	Specifies whether empty objects are permitted if the value of the target field is a JSON object or an array of JSON objects. If the field constraint is present, the value must be either `true`, where the object can have zero or more fields, or `false`, where the object can have one or more fields. If the constraint is absent, a default of `false` is assumed.
`index-values`	Specifies whether values of the target field should be indexed in backends. If the field constraint is present, the value must be either `true` (the field should be indexed) or `false` (the field should not be indexed). If the constraint is absent, a default of `false` is assumed. If `true`, the `value-type` must be `boolean`, `integer`, `null`, or `string`.
`index-entry-limit`	Specifies the maximum number of entries in which a particular value can appear before the entry ID list for that value is no longer maintained. If the field constraint is present, the value must be an integer greater than or equal to 1. If the constraint is absent, the server uses the default index entry limit for the associated backend. This is only applicable if `index-values` is `true`.
`prime-index`	Specifies whether backends should prime the contents of the JSON index database into memory when they are opened. This is ignored if the backend's `prime-all-indexes` property has a value of `true`.
`cache-mode`	Specifies the cache mode to use for the contents of the JSON index database. If the value is not specified, the backend's default cache mode is used. If a cache mode of `cache-keys-only` is configured, priming only loads the internal nodes into memory for the index. If `no-caching` is configured, no priming is performed for the index.
`tokenize-values`	Specifies whether values of the target field should be tokenized in backends. If the field constraint is present, the value is either `true` (field values should be tokenized) or `false` (field values should not be tokenized). If the constraint is absent, a value of `false` is assumed. If `true`, the `value-type` must be `string`.
`allowed-values`	Specifies an explicit set of values allowed in the target field . If the field constraint is present, the value must be an array of strings. Any attempt to use a value not in this array for the associated field is rejected. `allowed-values` can only be used with a `value-type` of `string`. If the constraint is absent, any value can be used as long as it satisfies all other defined constraints.

Copyright © 2025 Ping Identity Corporation

Property	Description
`allowed-value-regular-expression`	Specifies a regular expression that the target field must match If the field constraint is present, the value must be a single string or an array of strings representing valid regular expressions (which might require escaping to represent in JSON). Any attempt to use a value that does not match one of the provided regular expressions is rejected. `allowed-value-regular-expression` can only be used with a `value-type` of `string`. If the constraint is absent, values are not required to match any regular expression.
`minimum-numeric-value`	Specifies the lower bound for values of the target field If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is less than this number is rejected. `minimum-numeric-value` can only be used with a `value-type` of `integer` or `number`. If the constraint is absent, no minimum numeric value applies.
`maximum-numeric-value`	Specifies the upper bound for values of the target field If the field constraint is present, the value must be a single number and can be an integer. Any attempt to use a value that is greater than this number is rejected. `maximum-numeric-value` can only be used with a `value-type` of `integer` or `number`. If the constraint is absent, no maximum numeric value applies.
`minimum-value-length`	Specifies the minimum number of characters allowed for values of the target field If the field constraint is present, the value must be an integer. Any attempt to use a value with fewer characters than this number is rejected. `minimum-value-length` can only be used with a `value-type` of `string`. If the constraint is absent, no minimum length applies.
`maximum-value-length`	Specifies the maximum number of characters allowed for values of the target field If the field constraint is present, the value must be an integer. Any attempt to use a value with more characters than this number is rejected. `maximum-value-length` can only be used with a `value-type` of `string`. If the constraint is absent, no maximum length applies.
`minimum-value-count`	Specifies the minimum number of elements that must be present in an array If the field constraint is present, the value must be an integer. Any attempt to use an array with fewer elements is rejected. `minimum-value-count` can only be used with an `is-array` value of `required` or `optional`. If the constraint is absent, no minimum array value count applies.
`maximum-value-count`	Specifies the maximum number of elements that must be present in an array If the field constraint is present, the value must be an integer. Any attempt to use an array with more elements is rejected. `maximum-value-count` can only be used with an `is-array` value of `required` or `optional`. If the constraint is absent, no maximum array value count applies.

Copyright © 2025 Ping Identity Corporation

When writing JSON objects in a local database backend, field names and JSON primitive values of `null`, `true`, and `false` are always tokenized. Integers are either tokenized or compacted using their two's complement representation. Other numbers are stored using string representations. Array and object sizes are compacted, and their contents are compacted based on their data types.

String values are tokenized and match a recognizable format, including:

- Dates and times in common generalized time and ISO 8601 formats
- UUIDs in which the alphabetic characters are either all uppercase or all lowercase
- Strings of at least 12 bytes that are a valid base64 encoding
- Strings of at least 6 bytes that are a valid hexadecimal encoding, in which the alphabetic characters are either all uppercase or all lowercase

Adding constraints to JSON attributes

About this task

To create and configure JSON attribute constraints:

Steps

- Run `dsconfig` with the `create-json-attribute-constraints` option.

  Example:

  In this example, a JSON attribute constraint is defined on the `appjson` attribute type. This constrains values of the `appjson` attribute to be JSON objects. Because `allow-unnamed-fields` is set to false, those JSON objects can only have fields for which there is a corresponding JSON field constraints definition.

  > **Note**
  >
  > `appjson` is meant to be replaced by the name of the user's desired attribute type, as defined in the directory schema. For more information, see About managing JSON attribute values.

  ```
  $ bin/dsconfig create-json-attribute-constraints \
    --attribute-type appjson \
    --set enabled:true \
    --set allow-unnamed-fields:false
  ```

  Example:

  In this example, a JSON field constraint object is defined for the `email.verified` field. The `email.verified` field must be present and must take a boolean value.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.verified \
  --set value-type:boolean \
  --set is-required:true \
  --set index-values:false \
  --set tokenize-values:false \
  --set allow-null-value:true
```

Example:

In this example, a JSON field constraint object is defined for the `email.type` field. The `email.type` field must be present and must take a value of `home`, `work`, or `other`.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.type \
  --set value-type:string \
  --set is-required:true \
  --set index-values:false \
  --set tokenize-values:true \
  --set allowed-value:home \
  --set allowed-value:other \
  --set allowed-value:work \
  --set allow-null-value:false
```

Example:

In this example, a JSON field constraint is defined for the `email.value` field. The `email.value` field must be present and must take a string value that matches the specified regular expression.

```
$ bin/dsconfig create-json-field-constraints \
  --attribute-type appjson \
  --json-field email.value \
  --set value-type:string \
  --set is-required:true \
  --set index-values:true \
  --set tokenize-values:false \
  --set prime-index:true \
  --set allow-null-value:true \
  --set maximum-value-length:256 \
  --set minimum-value-length:1 \
  --set allowed-value-regular-expression:[-_\+\.\w\d]+@\w+\.\w{2,5}
```

Managing password policies

The PingDirectory server provides a flexible password policy system to assign, manage, or remove password policies for root and non-root users.

Copyright © 2025 Ping Identity Corporation

The password policy contains configurable properties for password expiration, failed sign-on attempts, account lockout, and other aspects of password and account maintenance on the PingDirectory server. The server also provides a global configuration option and a per-user privilege feature that disables parts of the password policy evaluation for production environments that don't require a password policy.

Viewing password policies

Password policies enforce rules that ensure that access to data is not compromised through negligent password practices.

The PingDirectory server provides mechanisms to create and maintain password policies that determine:

- Whether passwords should expire
- Whether users are allowed to modify their own passwords
- Whether too many failed authentication attempts should result in an account lockout

Many other options are available to fully configure a password policy for your PingData Platform system.

The PingDirectory server provides three out-of-the-box password policies that you can apply to your entries or as templates for configuring customized policies:

Default password policy

The default password policy is automatically applied to all users although it is possible to use an alternate password policy on a per-user basis.

Root password policy

The root password policy is enforced for the default root user, which uses a stronger password storage scheme (PBKDF2 instead of the salted 256-bit SHA-2 scheme) and requires that a root user provide their current password to select a new password.

Secure password policy

The secure password policy provides a more secure option than the default policy that makes use of several features, including password expiration, account lockout, last sign-on time and last sign-on IP address tracking, password history, and several password validators.

> **Caution**
>
> Using the Secure password policy as-is might notably increase write load in the server by requiring updates to password policy state attributes in user entries and by requiring users to change passwords more frequently. In environments where write throughput is a concern (including environments spread across multiple data centers requiring replication over a WAN), it might be useful to consider whether the policy should be updated to reduce the number of required entry updates.

Viewing password policies

About this task

To view the list of password policies configured on the PingDirectory server:

Copyright © 2025 Ping Identity Corporation

Steps

- Do one of the following:

  Choose from:

  - Run the `dsconfig` tool in either interactive or non-interactive mode.
  - Use the Administrative Console.

    Example:

    The following example demonstrates the process for obtaining a list of defined password policies in non-interactive mode.

    ```
    $ bin/dsconfig list-password-policies
    ```

    Result:

    ```
    Password Policy         : Type    : password-attribute : default-password-storage-scheme
    ------------------------:---------:--------------------:------------------------------
    Default Password Policy : generic : userPassword       : Salted SHA-256
    Root Password Policy    : generic : userPassword       : PBKDF2
    Secure Password Policy  : generic : userPassword       : PBKDF2
    ```

Viewing a specific password policy

About this task

To view a specific password policy:

Steps

- Do one of the following:

  Choose from:

  - Run the `dsconfig` tool.
  - Use the Administrative Console.

    Example:

    This example uses `dsconfig` to view the default password policy that applies to all uses for which no specific policy is configured.

    ```
    $ bin/dsconfig get-password-policy-prop \
      --policy-name "Default Password Policy"
    ```

    Result:

Copyright © 2025 Ping Identity Corporation

```

```

About the password policy properties

The PingDirectory server provides several configurable properties that you can use to control password policy behavior.

> **Note**
>
> To view a description of each of the password policy properties, see the Ping Identity Directory Server Configuration Reference that is bundled with the PingDirectory server.

Some of the most notable properties include:

`allow-user-password-changes`

Specifies whether users can change their own passwords. If a user attempts to change their own password, then the server consults this property for the user's password policy and ensures that the access control handler allows the user to modify the configured password attribute.

Copyright © 2025 Ping Identity Corporation

`default-password-storage-scheme`

Specifies the names of the password storage schemes that are used to encode clear-text passwords for this password policy.

`enable-debug`

When enabled, is used to debug password policy interaction. This property should be used in addition to the server's debug framework with a relevant debug target.

`force-change-on-add`

Specifies whether users are required to change their passwords upon first authenticating to the PingDirectory server after their account is created.

`force-change-on-reset`

Specifies whether users are required to change their passwords after they're reset by an administrator. An administrator is a user who has the `password-reset` privilege and the appropriate access control instruction to allow modification of other users' passwords.

`idle-lockout-interval`

Specifies the maximum length of time that an account can remain idle (the associated user does not authenticate to the server) before that user is locked out. For accounts that don't have a last sign-on time value, the password changed time or the account creation time is used. If that information is not available, then the user isn't allowed to authenticate.

> **Note**
>
> The server should be allowed to run for a period of time with last sign-on time tracking enabled, such as values for both `last-login-time-attribute` and `last-login-time-format` properties to ensure that users have a last sign-on time before enabling idle account lockout.

`lockout-duration`

Specifies the length of time that an account is locked after too many authentication failures. The value of this attribute is an integer followed by a unit of seconds, minutes, hours, days, or weeks. A value of `0` seconds indicates that the account must remain locked until an administrator resets the password.

`lockout-failure-count`

Specifies the maximum number of times that a user can attempt to bind with the wrong password before that user's account becomes locked either temporarily (in which case the account is automatically unlocked after a configurable length of time) or permanently (in which case an administrator must reset the user's password before the account is used again). For example, if the value is set to `3`, the user is locked out after three failed attempts, even if a fourth attempt is made with the correct password.

`max-password-age`

Specifies the maximum length of time that a user can continue to use the same password before they must choose a new one. The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w). You can specify a minimum length of time before the user can change the password.

Copyright © 2025 Ping Identity Corporation

`password-change-requires-current-password`

Specifies whether users must include their current password when changing their password. This applies for both password changes made with the password modify extended operation as well as simple modify operations targeting the password attribute. In the latter case, if the current password is required then the password modification must remove the current value and add the desired new value (providing both the current and new passwords in the clear rather than using encoded representations).

`password-expiration-warning-interval`

Specifies the length of time before a user's password expires that they receive notification about the upcoming expiration (either through the password policy or password expiring response controls). The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w).

`password-retirement-behavior`

Specifies the behavior of a password that is allowed a retirement period before becoming invalid. You can use this setting by application service accounts that require a transition period while updating passwords. This is disabled by default.

`password-validator`

Specifies the names of the password validators that are used with the associated password storage scheme. The password validators are invoked when a user attempts to provide a new password to determine whether the new password is acceptable.

`require-secure-authentication`

Indicates whether users with the associated password policy are required to authenticate in a secure manner. This can mean either using a secure communication channel between the client and the server, or using a Simple Authentication and Security Layer (SASL) mechanism that doesn't expose the credentials.

`require-secure-password-changes`

Indicates whether users with the associated password policy are required to change their password in a secure manner that does not expose the credentials.

> **Note**
>
> As an alternative to account lockout, you can set a **`failed-bind-response-delay`** configuration property on the LDAP connection handler to instruct the server to introduce a delay (such as one second) into the process of returning a response to an unsuccessful bind operation.
> Delaying the response to a failed bind only affects the connection on which the bind was attempted, and still limits the rate at which a malicious client can try to guess a user's password. However, it won't affect other attempts to authenticate as that user on other connections, so the legitimate user can still authenticate with the correct password.

Access log

You can configure the server to maintain a recent sign-on history for both successful and failed sign-on attempts.

Copyright © 2025 Ping Identity Corporation

You can maintain this history by count or duration, and you can configure the history separately for successful and failed sign-on attempts. Each record in the sign-on history contains the following:

- The time of the sign-on attempt
- The client IP address
- The authentication method
- The reason for failure for failed attempts

You can collapse information about multiple similar attempts on the same date to avoid flooding the history for accounts that bind frequently. Records have an additional attempt count that tracks the number of attempts with the same client IP address, authentications method, and failure reason on the same date. You can configure the server to maintain each attempt separately, or to only update the history at most once per day.

Recent sign-on history is disabled by default. You can enable and configure the recent sign-on history in password policy. You can retrieve sign-on history with the `get recent login history` control, available in the LDAP SDK or with the `ldapsearch` and `ldapmodfy` commands. The recent sign-on history is also available in the `ds-pwp-state-json` JSON attribute, the password policy state extended operation, and the `manage-account` command-line tool.

You can enable and configure the recent sign-on history with the following password policy configuration properties:

`maximum-recent-login-history-successful-authentication-count`

The maximum number of records that the server maintains about recent successful authentications.

`maximum-recent-login-history-successful-authentication-duration`

The maximum length of time for which the server maintains information about recent successful authentications.

`maximum-recent-login-history-failed-authentication-count`

The maximum number of records that the server maintains about recent failed authentication attempts.

`maximum-recent-login-history-failed-authentication-duration`

The maximum length of time for which the server maintains information about recent failed authentication attempts.

`recent-login-history-similar-attempt-behavior`

The behavior that the server exhibits for cases in which a user makes multiple authentication attempts on the same date in which all of the fields in the record other than the timestamp (`client-ip-address` , `authentication-method` , and potentially `failure-reason`) match.

Possible values for this property include the following:

`collapse-similar-attempts-on-the-same-date`

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields, and it uses the `additional-attempt-count` field to keep track of the number of additional attempts that were collapsed into the same record. The timestamp field for that record reflects the most recent attempt on that date.

This is the default behavior.

Copyright © 2025 Ping Identity Corporation

`maintain-every-attempt`

Indicates that the server maintains a separate record for every attempt, regardless of how similar it is to a previous attempt although duplicate attempts within the same millisecond might not be preserved.

For more information, see Replication considerations.

`update-at-most-once-per-day`

Indicates that the server only maintains one record for any given date with the same values for all non-timestamp fields. This can help reduce the number of writes needed to maintain a recent sign-on history, but the value of the timestamp field might not accurately reflect the timestamp of the most recent attempt.

None of these properties are defined by default. If at least one of these properties is defined, the server maintains a recent sign-on history within the specified constraints.

If both the `maximum-recent-login-history-successful-authentication-count` and `maximum-recent-login-history-successful-authentication-duration` properties are defined, the server uses the more-restrictive value that applies to a given user. This is also true for the `maximum-recent-login-history-failed-authentication-count` and `maximum-recent-login-history-failed-authentication-duration` properties. For example, if you configure the password policy to maintain a successful count of 10 and a successful duration of 30 days, then a user who successfully authenticates on more than 10 dates in a 30-day period would be capped at 10 records. A user who authenticates less frequently would only have records for however many attempts they made within those 30 days.

The server can collapse multiple authentication attempts from the same date into a single record if other fields in the record (`client-ip-address`, `authentication-method`, and potentially `failure-reason`) match. This caps the number of records that are maintained if you want to maintain records by duration rather than count. Because multiple records can be generated for the same user on the same date, if something is different (such as a different IP address or authentication method), there is technically no limit to the number of records that can be generated when using only a duration-based cap. To mitigate this, you can specify a maximum count to place an upper bound on what information the server maintains for a given user.

The password policy state for a given user is only updated when that user attempts to authenticate to the server. A user might have records in their entry for authentication attempts that occurred outside of the maximum duration if they have not made any authentication attempt within that duration.

If you configure the server to maintain recent sign-on history for successful authentication attempts, then it keeps a record of the most recent attempt even if the attempt occurs outside of the maximum duration.

> **Note**
>
> If the `recent-login-history-similar-attempt-behavior` is set to `update-at-most-once-per-day`, it keeps an attempt from the same date as the most recent attempt.

If you configure the server to maintain a history of failed attempts, then it provides information about the most recent failed attempt even if it is older than the maximum duration.

If you configure the password policy to maintain a recent sign-on history, the `ds-pwp-state-json` virtual attribute includes a `recent-login-history` field whose value is a JSON object with the same representation used in the `get recent login history` response control. It can also include the following additional fields that provide information about related configuration in the password policy:

- `maximum-recent-login-history-successful-authentication-count`

Copyright © 2025 Ping Identity Corporation

- `maximum-recent-login-history-successful-authentication-duration-seconds`
- `maximum-recent-login-history-failed-authentication-count`
- `maximum-recent-login-history-failed-authentication-duration-seconds`

The password policy state extended operation provides support for two additional operations:

- An operation you can use to retrieve the recent sign-on history. The value returned in this operation is a JSON object in the same format as used in the `get recent login history` response control and the `ds-pwp-state-json` virtual attribute.
- An operation that you can use to clear the `get recent login history` for a user.

Replication considerations

Each sign-on attempt is maintained as a separate attribute value to avoid the potential for data loss as a result of replication propagation delay.

If a record of all sign-on attempts was maintained within a single JSON object, the object written on one server would not reflect concurrent attempts made on other servers, and replication would only use what it perceives to be the most recent value rather than attempting to merge the values.

It is possible that information about one or more attempts made around the same time could be lost. This includes the following cases:

- If the server is not configured to collapse information about multiple similar attempts, then it will not record information about multiple similar attempts made within the same millisecond because that would result in duplicate attribute values.
- If the server is configured to collapse information about multiple similar attempts, then concurrent modifications (especially on different servers) might cause the `additional-attempt-count` value to be incremented to the same value on each of those servers.

> **Note**
>
> If the concurrent attempts occur within the same millisecond, then only one of them is preserved and any others are lost. If the attempts do not occur within the same millisecond, then you can infer the correct value during internal processing, but there might still be corner cases in which the server loses information about one or more attempts.

Get Recent Login History control

You can use a pair of request and response controls to obtain the recent sign-on history.

The request control, which has an OID of 1.3.6.1.4.1.30221.2.5.61 and no value, can be included in a bind request to indicate that the server should return the recent sign-on history in the bind response. This is provided in the response control, which has an OID of 1.3.6.1.4.1.30221.2.5.62 and a value containing only the string representation of a JSON object with the recent sign-on history.

The JSON object will have one or both of two top-level fields:

Copyright © 2025 Ping Identity Corporation

successful-attempts

This field is present if the server is configured to maintain a history of successful attempts, and its value is an array of JSON objects with information about those successful attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `additional-attempt-count`

failed-attempts

This field is present if you configure the server to maintain a history of failed attempts, and its value is an array of JSON objects with information about these failed attempts.

In particular, each of those objects contains the following fields, as used in the `ds-pwp-recent-login-history-json` attribute:

- `timestamp`
- `client-ip-address`
- `authentication-method`
- `failure-reason`
- `additional-attempt-count`

The response control is only returned if the server is configured to maintain a recent sign-on history. When provided, the elements of the arrays are arranged in chronological order from most-recent to least-recent.

The UnboundID LDAP SDK for Java provides support for these controls, including enhanced support for retrieving information from the response control value. By ensuring that the request control does not have a value and that the response control value is a simple string, this information is readily accessible to applications using other APIs.

Modifying an existing password policy

Modify an existing password policy to meet your company's requirements.

About this task

> **Tip**
>
> Keep your password policies synchronized across all PingDirectory servers and PingDirectoryProxy server instances.

To modify the configuration for any defined password policy:

Copyright © 2025 Ping Identity Corporation

Steps

- Choose one of the following methods:

  Choose from:

  - Run the `dsconfig` tool in interactive or non-interactive mode.
  - Use the administrative console.

  Example:

  The following example sets some of the properties presented in the previous section for the default password policy using `dsconfig`.

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "max-password-age:90 days" \
  --set "password-expiration-warning-interval:14 days" \
  --set "lockout-failure-count:3" \
  --set "password-history-count:6"
```

Creating new password policies

You can create new password policies that meet your organization's requirements.

You can create any number of password policies in the PingDirectory server using either the `dsconfig` tool (in interactive or non-interactive mode) or the Administrative Console.

> **Tip**
>
> You can find best practices for creating password policies in Password policy tips to improve performance.

Creating a new password policy

Steps

- To create a new password policy:

  Choose from:

  - Run `dsconfig` in interactive or non-interactive mode.
  - Use the administrative console.

  Example:

  This example demonstrates creating a new policy using `dsconfig` in non-interactive mode.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-password-policy \
  --policy-name "Demo Password Policy" \
  --set "password-attribute:userpassword" \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set "force-change-on-add:true" \
  --set "force-change-on-reset:true" \
  --set "password-expiration-warning-interval:2 weeks" \
  --set "max-password-age:90 days" \
  --set "lockout-duration:24 hours" \
  --set "lockout-failure-count:3" \
  --set "password-change-requires-current-password:true"
```

Assigning a password policy to an individual account

About this task

Rather than a user automatically inheriting the default password policy, you can assign a user to a particular password policy by including the `ds-pwp-password-policy-dn` operational attribute in that user's entry with a value equal to the distinguished name (DN) of the desired password policy for that user. This operational attribute is explicitly included in a user's entry, or generated by a virtual attribute, which makes it easy to apply a custom password policy to a set of users based on a flexible set of criteria.

Steps

1. Create an LDIF file that adds the `ds-pwp-password-policy-dn` attribute with the password policy DN you want to assign to that user.

   Example:

   This example creates the file `assign.ldif` with the following contents.

   ```
   dn: uid=user.1,ou=People,dc=example,dc=com
   changetype: modify
   add: ds-pwp-password-policy-dn
   ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password Policies,cn=config
   ```

2. To apply the modification to the user's entry, run `ldapmodify`.

   Example:

   For this example, the file used is `assign.ldif`.

   ```
   $ bin/ldapmodify --filename assign.ldif
   ```

Assigning a password policy using a virtual attribute

About this task

You can automatically assign a custom password policy for a set of users using a virtual attribute. You can configure the virtual attribute so that it uses a range of criteria for selecting the entries for which the virtual attribute should appear.

Copyright © 2025 Ping Identity Corporation

Steps

1. Create an LDIF file, which you can use to add a group to the server.

   Example:

   ```
   dn: ou=Groups,dc=example,dc=com
   objectClass: organizationalunit
   objectClass: top
   ou: Groups

   dn: cn=Engineering Managers,ou=groups,dc=example,dc=com
   objectClass: groupOfUniqueNames
   objectClass: top
   cn: Engineering Managers
   uniqueMember: uid=user.0,ou=People,dc=example,dc=com
   ```

2. To add the entries to the server, run the `ldapmodify` tool.

   Example:

   ```
   $ bin/ldapmodify --defaultAdd --filename groups.ldif
   ```

3. To create a virtual attribute, run `dsconfig`.

   Example:

   This virtual attribute adds the `ds-pwp-password-policy-dn` attribute with a value of `cn=Demo Password Policy,cn=Password Policies,cn=config` to the entries for all users that are members of the `cn=Engineering Managers,ou=Groups,dc=example,dc=com` group.

   ```
   $ bin/dsconfig create-virtual-attribute \
     --name "Eng Mgrs Password Policy" \
     --type user-defined \
     --set "description:Eng Mgrs Grp PWPolicy" \
     --set enabled:true \
     --set attribute-type:ds-pwp-password-policy-dn \
     --set "value:cn=Demo Password Policy,cn=Password Policies,cn=config" \
     --set "group-dn:cn=Engineering Managers,ou=Groups,dc=example,dc=com"
   ```

4. To verify that a user in the group contains the assigned password policy distinguished name (DN), run the `ldapsearch` tool.

   Example:

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
   ds-pwp-password-policy-dn
   ```

   Result:

Copyright © 2025 Ping Identity Corporation

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password Policies,cn=config
```

Deleting a password policy

You can delete a password policy with the `dsconfig` tool running in interactive or non-interactive mode.

About this task

> **Note**
>
> You can also use the administrative console to delete a password policy.

Steps

- To delete a password policy, run the `dsconfig` command with the `delete-password-policy` subcommand.

  Example:

```
$ bin/dsconfig delete-password-policy \
  --policy-name "Demo Password Policy"
```

Modifying a user's password

There are two primary ways to change user passwords in the PingDirectory server:

- Perform a modify operation which replaces the value of the password attribute (often `userPassword`).

  > **Note**
  >
  > In some configurations, when a user attempts to change their own password, it might be necessary to perform the modification by removing the password value and adding the desired new value to demonstrate that the user knows the current password value.

- Use the password modify extended operation to change the password.

  > **Note**
  >
  > If a user is changing their own password, it might be necessary to provide the current password value. If the new password is acceptable to all configured password validators, the server provides a new password, or it can automatically generate a new password for the user.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Regardless of the mechanism used to change the password, all password values should be provided in cleartext rather than pre-encoded, and the user must have sufficient access control rights to update the password attribute in the target user's entry.
> When one user attempts to change the password for another user, the requester must have the `password-reset` privilege.

Validating a password

About this task

A new password is valid if it:

- Meets the server's password requirements
- Is assigned a password policy
- Passes user authentication

The server can display requirements for a password change to users. You can use the `get-password-quality-requirements` extended operation to retrieve information about the requirements, which you can forward to an end user before an attempted password change. You can also use these requirements to enable client-side validation so that any password problems can be identified before it is sent to the server. The password validation details request control can be included in an `add` or `modify` request, or a `password modify` extended request, to identify which validation requirements were not met by the password provided in the request.

You can configure password validators with user-friendly messages that describe the password requirements, and error messages that display if a proposed password does not satisfy those requirements. The server will automatically generate these messages if they are not provided in the configuration.

Password properties include the following:

`bind-password-validator`

Specifies which validators to invoke on bind.

`password-validator`

Specifies which validators to invoke during a password change.

`minimum-bind-password-validation-frequency`

Specifies how frequently the server should validate a user's password during bind. Although you can specify that the password should be validated during each bind, it's probably sufficient to only do so periodically (for example, once a week or once a month).

`bind-password-validation-failure-action`

Specifies the action the server should take if a user's password fails validation. By default, the account is placed in a "must change password" state where the user is allowed to bind, but any other operations the user attempts fail until the user changes their password. Alternatively, the account can be locked so that the password needs to be reset by an administrator, or the server can generate an account status notification to recommend that the user choose a new password.

Copyright © 2025 Ping Identity Corporation

Steps

1. Create a password validator.

> **Note**
>
> Password validator properties include `validator-requirement-description` and `validator-failure` messages.

Example:

The following is a simple password validator configuration that requires passwords to contain a minimum of five characters and lists custom validator messages.

```
$ dsconfig create-password-validator \
  --validator-name "Minimum 5 Characters Password Validator" \
  --type length-based --set enabled:true \
  --set "validator-requirement-description:The password must contain
         at least 5 characters." \
  --set "validator-failure-message:The password did not contain
         at least 5 characters." \
  --set min-password-length:5
```

2. To make the newly created password validator take effect, assign it to a password policy.

Example:

```
$ dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Minimum 5 Characters Password Validator"
```

3. To validate the password, authenticate as a user.

> **Note**
>
> When a user authenticates, password validation processing is performed so that the server has access to the user's clear-text password.

Retiring a password

About this task

An account password can be retired and rotated out of service instead of being invalidated. Retiring a password enables a new password to be assigned to an account while keeping the original password valid for a period of time to enable a transition. This is useful for application service accounts that require uninterrupted authentication with the server.

Steps

- To enable password retirement, set the `password-retirement-behavior` and `maximum-retired-password-age` properties in the password policy configuration.
- To manually retire an account password or purge a password that has been retired, run the `ldapmodify` and `ldappasswordmodify` tools with subcommands `-- retireCurrentPassword` and `--purgeCurrentPassword`.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> To use these commands on an account, enable the **`password-retirement-behavior`** subcommand on the password policy that governs the account.

Changing a user's password using the Modify operation

Steps

- Use `ldapmodify` to change a user's password by replacing the `userPassword` attribute.

  Example:

```
$ bin/ldapmodify
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
replace: userPassword
userPassword: newpw
```

Changing a user's password using the Password Modify extended operation

About this task

To request that the Password Modify extended operation be used to modify a user's password:

Steps

- Run the `ldappasswordmodify` tool.

  Example:

```
$ bin/ldappasswordmodify --authzID dn:uid=jdoe,ou=People,dc=example,dc=com \
  --newPassword newpw
```

Using an automatically-generated password

Steps

- To automatically generate a new password for a user, run the `ldappasswordmodify` tool.

  Example:

```
$ bin/ldappasswordmodify --authzID "u:user.1"
```

  Result:

```
The LDAP password modify operation was successful
Generated Password: fbi27oqy
```

Copyright © 2025 Ping Identity Corporation

Enabling YubiKey authentication

Users can authenticate with YubiKey devices, which generate secure one-time passcodes (OTPs) with the `UNBOUNDID-YUBIKEY-OTP SASL` mechanism.

A YubiKey device generates a different password for every authentication attempt, and that OTP is sent to a validation service to ensure that it is genuine and has not been used in an earlier authentication attempt.

> **Note**
>
> It is possible to use the OTP as the only proof of identity, but you should combine it with a static password as a form of two-factor authentication.

YubiKey authentication requires:

- Server configuration and the addition of this capability to a user entry
- Configuration of a client ID and API key to use when communicating with the validation service

> **Note**
>
> The API key is a shared secret between the YubiKey validation service and the client that is interacting with it and is used when generating digital signatures so that both the server and the YubiKey validation service can ensure that the peer server is genuine.

All server and user entry configuration details are available in the Security Guide.

Enabling social sign-on

You can enable authentication involving credentials that do not reside in, or cannot be forwarded to or validated by, the PingDirectory server (such as social sign-on through Facebook, Google, or Twitter) with the `UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL` mechanism.

The bind request does not include any credentials, and authentication with this mechanism does not actually change the state of the underlying client connection. The server behaves as if the bind request included the retain identity request control, whether or not that control was included.

Bind requests using this mechanism can include any request controls that are permitted with other bind requests. If the externally-processed authentication is successful, the client can include the `get password policy state issues request contro` l in the bind request to obtain information about any password policy state issues that might cause the PingDirectory server authentication attempt to fail. You can include the password policy request control to obtain certain password policy state warnings and errors or to look for the password expired or password expiring controls in the bind response.

Managing user accounts

Manage user accounts with the `manage-account` tool.

About this task

The PingDirectory server provides a user management utility, the `manage-account` tool, that provides a means to quickly view and manipulate several password and account policy properties for a user or group of users.

Copyright © 2025 Ping Identity Corporation

The server also hosts the Self Service Account Manager project at https://github.com/pingidentity/ssam, which is a customizable web application that allows users to perform their own account registration, profile updates, and password changes.

> **Note**
>
> The project is for testing and development purposes and is not a supported PingDirectory server application.

Steps

- Unlock a user account with the `manage-account` tool.
- To enable a disabled account, contact the administrator for assistance.

> **Note**
>
> Password resets are not used.

Returning the password policy state information

Steps

- To get information about the account's password policy, run the `manage-account` tool.

Example:

```
$ bin/manage-account get-all \
  --targetDN uid=user.1,ou=People,dc=example,dc=com
```

Result:

```
Password Policy DN: cn=Demo Password Policy,cn=Password Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration: 1209600
Seconds Until Password Expiration Warning: 0
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count: 3
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

Copyright © 2025 Ping Identity Corporation

Determining whether an account is disabled

Steps

- To determine whether a user's account has been disabled, run the `manage-account` tool with the `get-account-is-disabled` subcommand.

  Example:

  ```
  $ bin/manage-account get-account-is-disabled \
    --targetDN uid=user.1,ou=People,dc=example,dc=com
  ```

  Result:

  If the account has been disabled, you receive the following message. `Account Is Disabled: true`

Disabling an account

Steps

- To disable a user's account, run the `manage-account` tool.

  Example:

  ```
  $ bin/manage-account set-account-is-disabled \
    --operationValue true --targetDN uid=user.1,ou=People,dc=example,dc=com
  ```

  Result:

  You receive the following message. `Account Is Disabled: true`

Enabling a disabled account

Steps

- To enable a user's account, run the `manage-account` tool with the `clear-account-is-disabled` subcommand.

  Example:

  ```
  $ bin/manage-account clear-account-is-disabled \
    --targetDN uid=user.1,ou=People,dc=example,dc=com
  ```

  Result:

  You receive the following message. `Account Is Disabled: false`

Assigning the manage-account access privileges to non-root users

Assign access rights to the non-root admin user.

About this task

Non-root users, such as `uid=admin`, with admin right privileges require access control permission to interact with certain password policy operational attributes when using the `manage-account` tool.

Copyright © 2025 Ping Identity Corporation

For example, the presence of the `ds-pwp-account-disabled` operational attribute in an entry determines that the entry is disabled. If the non-root admin user does not have the access privilege to read or interact with the `ds-pwp-account-disabled` operational attribute, the **`manage-account`** tool might report that the account is active. An account is considered active if the `ds-pwp-account-disabled` operational attribute does not exist in the entry or if the admin user does not have permission to see it.

Steps

1. Create a non-root user admin account, such as `uid=admin,dc=example,dc=com`.
    1. Grant the `password-reset` privilege to the account.

    For more information, see steps 1 and 6 in the Setting up a single administrator account section in Configuring Administrators.

2. To view the account status for an account, run the **`manage-account`** tool.

    Example:

    ```
    $ bin/manage-account get-all \
      --targetDN uid=user.0,ou=People,dc=example,dc=com
    ```

    Result:

    The system displays the following information for the account.

    ```
    Password Policy DN:  cn=Default Password Policy,cn=Password Policies,cn=config
    Account Is Disabled:  false
    Account Expiration Time:
    Seconds Until Account Expiration:
    Password Changed Time:  19700101000000.000Z
    Password Expiration Warned Time:
    Seconds Until Password Expiration:
    Seconds Until Password Expiration Warning:
    Authentication Failure Times:
    Seconds Until Authentication Failure Unlock:
    Remaining Authentication Failure Count:
    Last Login Time:
    Seconds Until Idle Account Lockout:
    Password Is Reset:  false
    Seconds Until Password Reset Lockout:
    Grace Login Use Times:
    Remaining Grace Login Count:  0
    Password Changed by Required Time:
    Seconds Until Required Change Time:
    Password History:
    ```

3. Grant access control privileges to an account.

    Example:

    The following allows access to manage accounts to a helpdesk user. Depending on the configuration requirements, this user might also need the `permit-get-password-policy-state-issues` and `password-reset` privileges.

Copyright © 2025 Ping Identity Corporation

```
dn: dc=example,dc=com
 changetype: modify
 add: aci
 aci: (targetattr="userPassword||ds-pwp-last-login-time||ds-pwp-password-changed-by-required-time||
ds-pwp-reset-time||ds-pwp-warned-time||
 ds-pwp-account-disabled||ds-pwp-account-expiration-time||ds-pwp-password-policy-dn||ds-pwp-auth-
failure||ds-pwp-last-login-ip-address||
 ds-pwp-retired-password||ds-pwp-account-activation-time||pwdReset||pwdChangedTime||
pwdAccountLockedTime")
 (version 3.0; acl "Grant full access to PWP related attributes to helpdesk"; allow (all)
userdn="ldap:///uid=helpdesk,dc=example,dc=com";)
```

4. To disable an account, run the `manage-account` tool.

   Example:

   The following command sets the `account-is-disabled` property to true for the `uid=user.0,dc=example,dc=com`.

   ```
   $ bin/manage-account set-account-is-disabled \
     --targetDN uid=user.0,ou=People,dc=example,dc=com \
     --operationValue true
   ```

   Result:

   You receive the following message. `Account Is Disabled: true`

5. To view the presence of the `ds-pwp-account-disabled` operational attribute in the entry, run the `ldapsearch` tool.

   Example:

   ```
   $ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" "+"
   ```

   Result:

   The system displays the following information.

   ```
   dn: uid=user.0,ou=People,dc=example,dc=com
   ds-pwp-account-disabled: true
   ```

Bypassing password policy evaluation

You can bypass password policy evaluations when performing operations on accounts other than your own.

About this task

The PingDirectory server supports the use of a `bypass-pw-policy` privilege, which can skip password policy evaluation for operations on a per-user basis. If a user has this privilege, then they are allowed to perform operations on user entries that would normally be rejected by the password policy associated with the target entry.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `bypass-pw-policy` privilege does not have any effect for bind operations.

Any user with this privilege will be permitted to perform operations against other users that would otherwise be rejected under the constraints associated with that user's password policy, such as:

- Setting a pre-encoded password
- Setting a new password that wouldn't be accepted by one or more password validators
- Setting a new password that already exists in a user's password history

> **Note**
>
> These restrictions can also be circumvented on a per-operation basis using the password update behavior control. If you have a set of users that should be subject to lesser or differing constraints than another set of users, you can create a new password policy with the desired constraints, if any, and assign it to the appropriate users. Learn more about assigning password policies to users.

Steps

- To add the `bypass-pw-policy` privilege to a user entry, run the `ldapmodify` tool with the `bypass-pw-policy` subcommand.

  Example:

```
$ bin/ldapmodify
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: bypass-pw-policy
```

Managing password validators

A password validator is a password policy component you can use to determine if a new password is acceptable.

A password policy can be configured with any number of password validators. If a password policy is configured with multiple password validators, then they all must consider a proposed new password acceptable before it is allowed.

Password validators

The PingDirectory server offers several types of password validators.

You can use the Server SDK to create custom password validators with the constraints necessary for your environment.

Copyright © 2025 Ping Identity Corporation

Password Validators

Password Validators	Description
Attribute Value	Ensures that the proposed password does not match the value of another attribute in the user's entry. You can configure the validator to look in all attributes or in a subset of attributes. It can perform forward and reverse mapping and reject values that are substrings of another attribute.
Character Set	Ensures that the proposed password contains a sufficient number of characters from one or more user-defined character sets. For example, the validator can ensure that passwords must have at least one lowercase letter, one uppercase letter, one digit, and one symbol.
Commonly-Used Passwords Dictionary	Ensures that the proposed password is not one of 10,000 commonly used passwords. These are words that are common for attackers to use when trying to access user accounts. The Commonly-Used Passwords validator is invoked by the Secure Password Policy by default. The word list is located in `<server-root>/config/commonly-used-passwords.txt`. While it can be used to create a custom validator, it should not be modified.
Dictionary	Ensures that the proposed password is not present in a specified dictionary file, optionally also testing the password with all characters in reverse order. A large dictionary file is provided with the server, but the administrator can supply an alternate dictionary. In this case, the dictionary must be a plain-text file with one word per line.
Haystack Password Validator	Ensures that the proposed password is secure based on a combination of its length and the types of characters that it contains. For example, a longer password containing only lowercase letters might be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols. This is based on the Gibson Research Corporation Password Haystacks concept.
Length-Based Password Validator	Ensures that the number of characters in the proposed new password is within an acceptable range. Both a maximum and minimum number of characters can be specified.
Pwned Passwords Password Validator	Can be used to prevent users from choosing passwords that are known to have been compromised. By default, it checks with the free Pwned Passwords service, which includes a database of hundreds of millions of compromised passwords although it can be used with any other service that uses a compatible API.
Regular Expression Validator	Ensures that a proposed password either matches or does not match a given regular expression.

Copyright © 2025 Ping Identity Corporation

Password Validators	Description
Repeated Characters	Ensures that a proposed password does not contain a substring in which the same character is repeated more than a specified number of times (for example, "aaaaa" or "aaabbb"). You can configure the validator to operate in a case-sensitive or case-insensitive manner, and you can also define custom sets of equivalent characters, such as defining all digits as equivalent so the proposed password could not contain more than a specified number of consecutive digits.
Similarity-Based Password Validator	Ensures that the proposed new password is not too similar to the current password, using the Levenstein Distance algorithm, which calculates the number of characters that need to be inserted, removed, or replaced to transform one string into another. **Note** For this password validator to be effective, you must have access to the user's current password. If this password validator is enabled, the `password-change-requires-current-password` attribute in the password policy configuration must also be set to true.
Unique Characters	Ensures that the proposed password contains at least a specified minimum number of unique characters, optionally using case-insensitive validation.

Configuring password validators

You can use the `dsconfig` configuration tool or the administrative console to configure or modify any password validators.

After you define your password validators, you can add them to an existing password policy. The following example procedures show the `dsconfig` non-interactive commands necessary to carry out such tasks. If you use `dsconfig` in interactive command-line mode, you can access the `Password Validator menu` in the `Basic Objects menu`. For more details on the password validator properties, see the PingDirectory server Configuration Reference.

Viewing the list of defined password validators

Steps

- To view the set of password validators defined in the server, run the `dsconfig` tool.

Configuring the Attribute Value Password Validator

Steps

1. To edit the existing default configuration for the Attribute Value Password Validator, run the `dsconfig` tool.

   Example:

   In this example, the configuration change configures the validator to only examine a specified set of attributes.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Attribute Value" \
  --set match-attribute:cn \
  --set match-attribute:sn \
  --set match-attribute:telephonenumber \
  --set match-attribute:uid
```

2. Update an existing password policy to use the Attribute Value Password Validator.

   Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Attribute Value"
```

3. Test the Attribute Value Password Validator by submitting a password that is identical to one of the configured attributes (`cn`, `sn`, `telephonenumber`, `uid`).

   Example:

```
$ bin/ldappasswordmodify --authzID "uid=user.0,ou=People,dc=example,dc=com" \
  --newPassword user.0
```

   Result:

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks defined in the
server: The provided password was found in another attribute in the user entry
```

Configuring the Character Set Password Validator

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

   Example:

   This example changes the requirement for special characters by making them optional in a password and adds a requirement to include at least two digits in the password. In this example, all newly created passwords must have at least one lowercase letter, one uppercase letter, two digits, and optionally any special characters listed.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Character Set" \
  --remove character-set:1:0123456789 \
  --remove "character-set:1:~\!@#\$\%^&*()-_=+[]{}\|;:,.<>/?" \
  --add character-set:2:0123456789 \
  --add "character-set:0:~\!@#\$\%^&*()-_=+[]{}\|;:,.<>/?" \
  --set allow-unclassified-characters:false
```

2. Update an existing password policy to use the Character Set Password Validator.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Character Set"
```

3. Test the Character Set Password Validator by submitting a password that meets the requirements (one lowercase letter, one uppercase letter, two digits).

   Example:

   This example should reject the given password because it does not pass the Character Set Password Validator.

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abab1
   ```

Configuring the Length-Based Password Validator

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

   Example:

   In this example, the required minimum number of characters in a password is set to five.

   ```
   $ bin/dsconfig create-password-validator \
     --validator-name "Length-Based Password Validator" \
     --set max-password-length:5 --set min-password-length:5
   ```

2. Update an existing password policy to use the Length-Based Password Validator.

   Example:

   ```
   $ bin/dsconfig set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Length-Based Password Policy"
   ```

3. Test the Length-Based Password Validator by submitting a password that has fewer than the minimum number of required characters.

   Example:

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abcd
   ```

   Result:

Copyright © 2025 Ping Identity Corporation

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks defined in
the server: The provided password is shorter than the minimum required length of
5 characters
```

Configuring the Pwned Passwords Password Validator

The server is preconfigured with an instance of the Pwned Passwords Password Validator.

About this task

Use the `dsconfig` tool to configure the Pwned Passwords Password Validator.

Steps

1. Run the `dsconfig` tool to update an existing password policy to use the Pwned Passwords Password Validator, replacing *[PASSWORD_POLICY_NAME]* with the name of your password policy.

   ```
   dsconfig set-password-policy-prop \
            --policy-name "[PASSWORD_POLICY_NAME]" \
            --add "password-validator:Pwned Passwords"
   ```

2. Test the validator by submitting a password that is known to be compromised; for example, `password`.

Configuring the Regular Expression Password Validator

About this task

Use the `dsconfig` tool to configure the Regular Expression Password Validator.

Steps

1. Use `dsconfig` to create a regular expression password validator.

   Example:

   The following password validator checks that the password contains at least one number, one lowercase letter, and one uppercase letter with no restrictions on password length. If the password matches the regular expression, then it is accepted. When using the following command, remember to include the LDAP/LDAPS connection parameters (host name and port), bind DN, and bind password.

   ```
   $ bin/dsconfig create-password-validator \
     --validator-name "Regular Expression" \
     --type regular-expression --set enabled:true \
     --set "match-pattern:^\\w*(?=\\w*\\d)(?=\\w*[a-z])(?=\\w*[A-Z])\\w*\$" \
     --set match-behavior:require-match
   ```

2. Update an existing password policy to use the regular expression password validator.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "password-validator:Regular Expression"
```

3. Test the regular expression password validator by submitting a password that meets the requirements.

> **Note**
>
> To meet the password requirements, make sure your password contains one number, one lowercase letter, and one uppercase letter.

Example:

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaA1
```

Result:

```
The LDAP password modify operation was successful
```

4. Test a password that does not meet the password requirements.

Example:

The following password should fail because no uppercase letter is present.

```
$ bin/ldappasswordmodify \
  --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaa1
```

Result:

```
Error Message: The provided new password failed the validation checks
defined in the server: The provided password is not acceptable because it does
not match regular expression pattern '^\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-Z])\w*$'
```

Configuring the Repeated Character Password Validator

You can configure the Repeated Character Password Validator with the `dsconfig` command. This validator ensures that user passwords don't contain character fragments, such as strings of repeated characters like "aaaaaa" or "aaabbb."

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

Choose from:

- Set the maximum consecutive length of any character.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> For the following example, the maximum consecutive length of any character is set to 3. The validator rejects any passwords with 4 or more consecutive characters, such as "baaaa1" or "4eeeeb", etc.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set max-consecutive-length:3
```

- **Configure the validator to reject any character from a pre-defined character set that appears more than the specified number of times in a row (2).**

> **Note**
>
> You can specify more than one character set. For example, the following validator defines two characters sets: `abc` and `123`. It rejects any passwords with more than two consecutive characters from a character set, such as "aaa", "bbb", "ccc", "abc", or "123". However, a password, such as "12a3", is acceptable.

```
$ bin/dsconfig set-password-validator-prop \
  --validator-name "Repeated Characters" \
  --set character-set:123 --set character-set:abc
```

2. **Update an existing password policy to use the Repeated Character Password Validator.**

   Example:

   ```
   $ bin/dsconfig --no-prompt set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Repeated Characters"
   ```

3. **To test the Repeated Character Validator, submit a password that has more than the maximum allowable length of consecutive characters.**

   Example:

   For this example, the faulty password submitted is `baaa1`.

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" \
     --newPassword baaa1
   ```

   Result:

   ```
   The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password contained too many instances of the same character appearing consecutively. The maximum number of times the same character may appear consecutively in a password is 2
   ```

Copyright © 2025 Ping Identity Corporation

Configuring the Similarity-Based Password Validator

Use the `dsconfig` tool to configure the Similarity-Based Password Validator.

Steps

1. To edit the existing default configuration, run the **`dsconfig`** tool.

   Example:

   In this example, we set the minimum number of differences to 2.

   ```
   $ bin/dsconfig set-password-validator-prop \
     --validator-name "Similarity-Based Password Validator" \
     --set min-password-difference:2
   ```

2. Update an existing password policy to use the Similarity-Based Password Validator.

   > **Note**
   >
   > The `password-change-requires-current-password` property must be set to `true` so that the password policy will ensure that the user's current password is available when that user is choosing a new password.

   Example:

   ```
   $ bin/dsconfig set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Similarity-Based Password Validator" \
     --set password-change-requires-current-password:true
   ```

3. Test the Similarity-Based Password Validator by submitting a password that has fewer than the minimum number of changes, such as 2.

   > **Note**
   >
   > The **`ldappasswordmodify`** command requires the `--currentPassword` option when testing the Similarity-Based Password Validator.

   Example:

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" \
     --currentPassword abcde --newPassword abcdd
   ```

   Result:

   ```
   The LDAP password modify operation failed with result code 49.
   ```

Configuring the Unique Characters Password Validator

Use the `dsconfig` tool to configure, update, and test the Unique Characters Password Validator.

Copyright © 2025 Ping Identity Corporation

Steps

1. To edit the existing default configuration, run the `dsconfig` tool.

   Example:

   In this example, we set the minimum number of unique characters that a password is allowed to contain to 3.

   ```
   $ bin/dsconfig set-password-validator-prop \
     --validator-name "Unique Characters" --set min-unique-characters:3
   ```

2. Update an existing password policy to use the Unique Characters Password Validator.

   Example:

   ```
   $ bin/dsconfig set-password-policy-prop \
     --policy-name "Default Password Policy" \
     --set "password-validator:Unique Characters"
   ```

3. Test the Unique Characters Password Validator by submitting a password that has fewer than the minimum number of unique characters, such as 3.

   Example:

   ```
   $ bin/ldappasswordmodify \
     --authzID "uid=user.0,ou=People,dc=example,dc=com" \
     --newPassword aaaaa
   ```

   Result:

   ```
   The LDAP password modify operation failed with result code 53 Error Message: The provided new password failed the validation checks defined in the server: The provided password does not contain enough unique characters. The minimum number of unique characters that may appear in a user password is 3
   ```

Managing replication

The PingDirectory server provides a robust replication system to ensure high availability and fast failover in production environments.

Every server in the topology can handle write requests, with the replication component performing immediate synchronization with other members. The replicated server environment ensures that Lightweight Directory Access Protocol (LDAP) clients can seamlessly fail over to another server instance.

Overview of replication

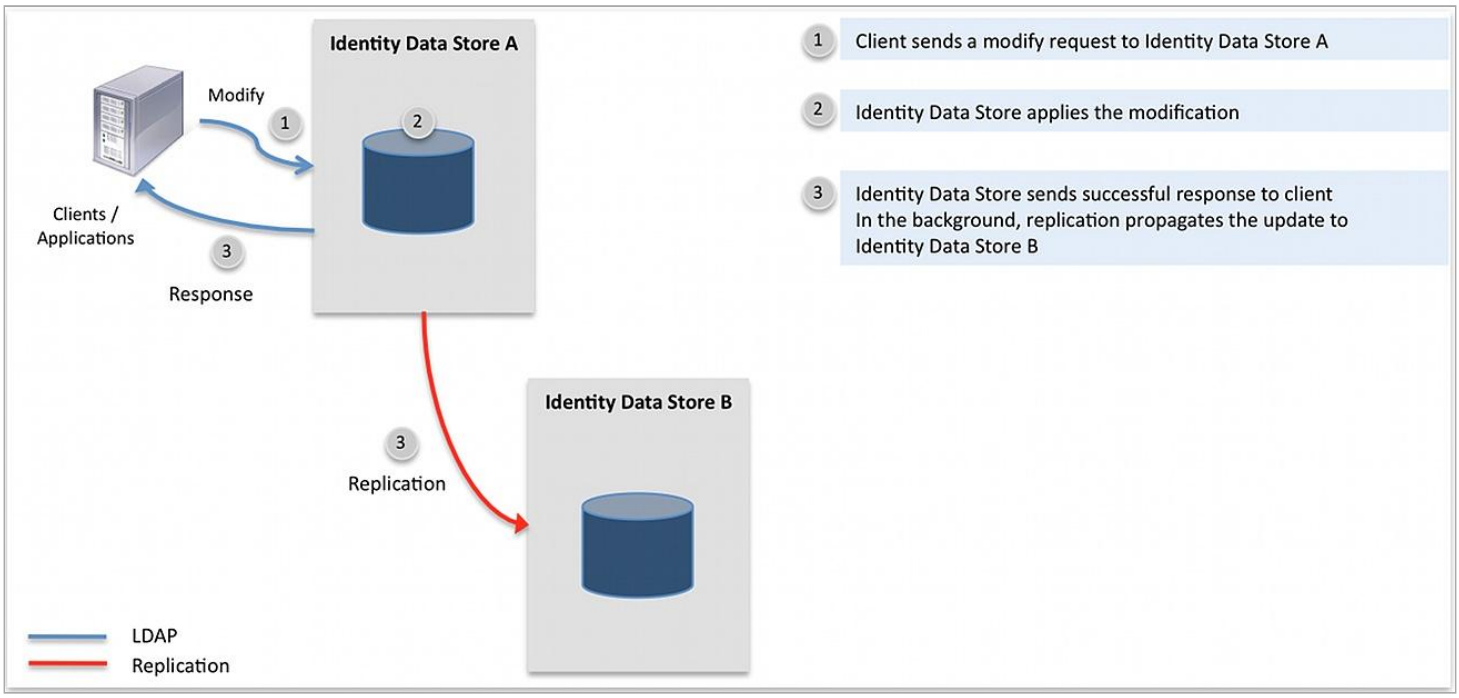
Replication is a data synchronization mechanism that ensures that updates made to a database are automatically duplicated to other servers.

Copyright © 2025 Ping Identity Corporation

Replication improves data availability when unforeseen or planned outages occur and improves search performance by allowing client requests to be distributed across multiple servers.

By default, all PingDirectory server instances participating in replication are writable so that LDAP clients can perform updates at any of these server instances. These updates are automatically propagated to the other servers in the background in the same order as the updates were entered. The replication process flow is designed to immediately propagate changes to the other replicas in the topology with little or no latency.

The following figure demonstrates the basic flow of replication.



The benefits of replication can be summarized as follows:

High-Availability

Because the data is fully replicated on all other servers in the topology, replication allows participating servers to process all types of client requests. This mitigates any availability issues when a particular server is down because of a planned maintenance or unplanned outage. Servers that are temporarily unavailable receive updates when they become available again.

Improved Search Performance

Search requests can be directed to any PingDirectory server participating in replication, which improves search performance over systems that only access single servers.

> **Note**
>
> Replication does not improve write throughput because updates need to be applied at all servers.

WAN Friendly Data Synchronization

The built-in compression feature in the replication protocol allows efficient propagation of updates over WAN links.

Copyright © 2025 Ping Identity Corporation

Replication versus synchronization

Replication and synchronization are distinct functions from one another and are not interchangeable.

Replication is not a general purpose synchronization function because it creates replicas with exact copies of the replicated data. By contrast, synchronization can:

- Transform data between two different directory information tree (DIT) structures
- Map attribute types
- Synchronize subsets of branches and specific object classes

> **Note**
>
> For data migration, use synchronization instead of replication unless you are adding cloud directories to an existing PingDirectory cluster.

The differences between replication and synchronization are as follows:

Replication doesn't support differing DIT structures

The distinguished name (DN) of replicated entries must be the same on all servers. In some situations, you might want to replicate entries with the help of DN mapping that are under different base DNs, but represent the same data, for example `uid=john.doe,ou=people,o=corp` on one server could represent the same user as `uid=john.doe,ou=people,dc=example,dc=com`.

This is not supported by replication. Synchronization fully supports this feature.

Replication doesn't support differing FIPS-compliance modes

Replication can't occur between server instances running in FIPS-compliant mode and server instances running in non-FIPS-compliant mode. Learn more about the Differences between FIPS 140-2-compliant and non-FIPS-compliant modes.

Replication can't map attribute types or transform attribute values

Some situations might require you to map attribute types or transform attribute values when synchronizing data from one server to another. Replication doesn't support attribute type mappings or attribute value transformations.

Replication doesn't support fractional replication

Replication can't be configured to replicate a subset of the attribute types from the replicated data set. Synchronization fully supports this feature.

Replication doesn't support sparse replication

Replication can't be configured to replicate only entries with a particular object class. Synchronization fully supports this feature.

Copyright © 2025 Ping Identity Corporation

Replication requires full control of replicated data

> When two servers participate in replication, both servers implicitly trust each other using public key cryptography and apply all received updates by replication, which is considered an internal operation. While trust between servers is established between two endpoint servers, synchronization doesn't require full control of the data. Disparate server system endpoints can be synchronized, such as a PingDirectory server and a relational database management system (RDBMS) database endpoint with each fully in control of its own data.

If replication doesn't meet your data synchronization requirements, consider using PingDataSync server instead, which provides the versatility and robust performance required for most production environments.

Replication terminology

The following terms have specific definitions as they apply to replication.

Replication Terminology

Term	Description
Assured Replication	Data is guaranteed to replicate before the response is returned to the client. This is useful for applications that require immediate access to replicated data or require data consistency over response time.
Change Number	A 64-bit number used to consistently order replication updates across the entire topology. It is composed of 3 fields: • The timestamp of the update in milliseconds since 00:00:00 UTC, January 1, 1970 • The replica ID • The sequence number
Conflict	Client updates made at different replicas affecting the same entry might be found in conflict when the updates are replayed at another replica. The Change Number of each update allows most of these conflicts to be resolved automatically. Certain updates, such as adding an entry with different attribute values at two servers simultaneously, result in conflicts that are flagged for manual resolution.
Eventual Consistency	When not using assured replication, recent updates from LDAP clients are not immediately present at all servers. Out-of-sync data will eventually be synchronized and will be consistent on all servers. The network latency typically controls how long a given update takes to replicate.
Global Administrator	The administrative user with full rights to manage the replication topology. The user is created at the time of replication enablement between two non-replicating servers and thereafter copied to newly-enabled servers. The replication command-line utility expects the user name of the Global Administrator (by default, admin). The user is stored in `cn=Topology Admin Users,cn=Topology,cn=config`.

Copyright © 2025 Ping Identity Corporation

Term	Description
Historical Data	Historical Data are records of attribute value changes as a result of an LDAP Modify operation. Historical data are stored in the `ds-sync-hist` attribute of the target entry. This information allows replication to resolve conflicts from simultaneous LDAP Modify operations automatically.
Location	The collection of servers that can have similar performance characteristics when accessed from this PingDirectory server or reside in the same data center or city. A separate location setting can be defined for each data center, such as Austin, London, Chicago, and so forth. Location settings are used in the selection of the WAN Gateway server.
Modify Conflict	A conflict between two LDAP Modify operations. Modify conflicts are automatically resolved.
Naming Conflict	Any conflict other than Modify Conflicts. Naming conflicts typically include an operation that changes the DN of the target entry, creates an entry, or deletes an entry at one replica.
Replica	The component in the PingDirectory server that handles interaction with a single replication domain. For example, the `dc=example,dc=com` replication domain within the `userRoot` backend is a replica.
Replica ID	The unique identifier of a replica. Replica ID is automatically set in the corresponding Replication Domain configuration entry at each participating server. The replica ID identifies the source of each update in the replication topology.
Replica State	A list of the most recent change numbers of replication updates that have been applied to a replica. Each replica in the state can have a maximum of one change number. The Replication Server component uses the replica state to determine which updates the Replica has not yet received.
Replication	An automated background process that pushes PingDirectory server data changes to all other replicas.

Copyright © 2025 Ping Identity Corporation

Term	Description
Replication Changelog	A backend maintained independently by each replication server that records updates from each replica. This backend is distinct from the LDAP Changelog, and the two should not be confused. The main distinction is as follows: • The LDAP Changelog is the external changelog that clients can access. It is located at `<server-root>/db/changelog`. • The Replication Changelog Backend is the changelog that replication servers use. It is located at `<server-root>/changelogDB`, and is not accessible by clients or server extensions.
Replication Domain	The data configured for replication as defined by the base DN. Updates to entries at and below the base DN will be replicated.
Replication Replay	When a replica locally applies the update received via a replication server.
Replication Server	A component within the PingDirectory server process that is responsible for propagating server data changes to and from replicas. Each PingDirectory server instance participating in replication is also running a replication server.
Replication Server ID	The unique identifier of a replication server. The replication server ID is set automatically in its configuration object at each server in the replication topology. This identifier is used in the connection management code of the replication servers.
Replication Server State	A list of the most recent change numbers of replication updates that have been processed by a replication server. Each replica in the topology can have a maximum of one change number. The Replication Server State is used to determine which updates need to be sent to other replication servers. Similarly, the replica can use the Replication Server State to identify the set of updates to send to the replication server.
Sequence Number	A field in the change number that indicates the sequence of the client updates at a particular replica. The sequence number increases incrementally for every update at the replica. The initial value of the sequence number is 1. The number is stored as a 32-bit integer, but only positive values are used. The sequence number can roll over.
WAN Gateway	The designated replication server that assumes the WAN Gateway role within a collection of servers that are defined with identical location settings. Replication update messages between servers at different locations are routed through WAN gateways. The WAN Gateway role is assigned automatically by the protocol based on the server's WAN Gateway Priority setting. If the WAN Gateway server is down for any reason, the server with the next highest WAN Gateway Priority will dynamically assume the WAN Gateway role.

Copyright © 2025 Ping Identity Corporation

Term	Description
WAN Gateway Priority	The configuration setting that determines which replication server assumes the WAN Gateway role. The replication server with the highest WAN Gateway Priority in a location assumes the role of the WAN Gateway. Servers can have a WAN Gateway Priority value from 1 to 10, with 1 being the highest priority. A server with a WAN Gateway priority value of 0 will never be a gateway.

Replication architecture

This section introduces the major elements of replication in PingDirectory server.

Eventual consistency

Replication is based on an eventual-consistency model where the updates propagated through a connected network of servers will eventually be consistent on all servers over a short period of time.

In a typical update operation, a client application updates an entry or group of entries on a PingDirectory server with an `ADD`, `DELETE`, `MODIFY`, or `MODIFY DN` operation. After processing the operation, the PingDirectory server returns an LDAP response while simultaneously propagating the update to the other servers in the replicated topology. This simultaneous processing model allows the client to continue submitting update requests without waiting for a replication completion response from the server.

To support this processing model, replication never locks the targeted entries at the other PingDirectory server instances before an update can be made locally. This means that the replicated servers might have an inconsistent view of the targeted entry for a short period of time, but will catch up as the propagated changes are applied.

The eventual-consistency model also allows clients to complete update operations faster because clients can propagate a change without having to wait for replication. The rate of update operations remains the same no matter how many PingDirectory servers participate in replication.

Alternatively, you can configure assured replication for specific write requests to require local or global consistency, across data center locations, before a response is returned to the client. For more information, see Configuring assured replication.

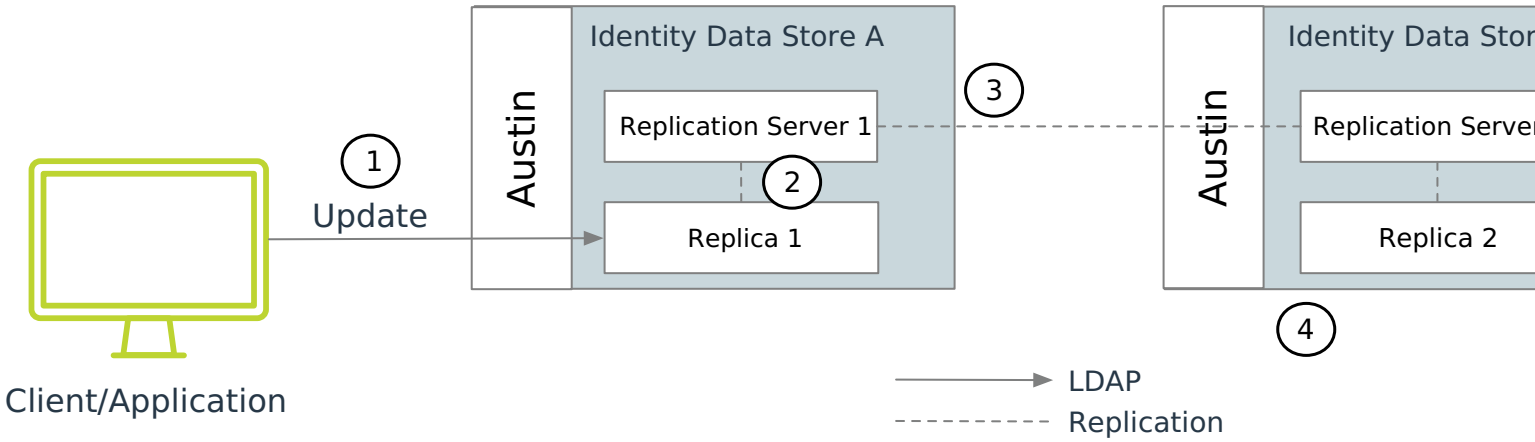
Replicas and replication servers

Each PingDirectory server has an embedded replication server that is responsible for transmitting updates to other replication servers. Each replicating base distinguished name (DN), such as `cn=schema, dc=example,dc=com`, has a separate component called a replica. Each replica connects to the embedded replication server running within the PingDirectory server Java virtual machine (JVM) process.

When a client application updates an entry on the PingDirectory server, the replica sends an update message to its embedded replication server. The replication server applies the change to the `replicationChangelog` backend repository and then sends an update message to the connected replication server on another PingDirectory server. The replication server on other PingDirectory servers then passes the change to the appropriate replica, which in turn applies the change to its backend after performing conflict resolution.

The following figure shows the standard setup.

Copyright © 2025 Ping Identity Corporation



Replicas and Replication Servers

1. The client or application sends a modification request to Identity Store A. The identity store applies the change.
2. The Replica backend in Identity Store A sends an update message to the Replication Server in Identity Store A.
3. The Replication Server in Identity Store A pushes the update to the Replication Server in Identity Store B.
4. The Replication Server in Identity Store B applies the update the to the Replica backend in Identity Store B.

Authentication and authorization

The PingDirectory server uses a simple authentication model to authorize replication servers.

After it is authenticated, the remote PingDirectory server is fully authorized to exchange replication messages with the local PingDirectory server. There is no other access control in place.

Authentication in the replication protocol is based on public key cryptography using TLS client certificate authentication. The certificate used for authentication is stored in the `ads-truststore` backend of the PingDirectory server.

During replication setup, the command-line utility distributes public keys to all PingDirectory servers to establish trust between the servers and to enable TLS client authentication.

Logging

The access log messages in the PingDirectory server indicate if the update was received by replication and includes the corresponding change number. This allows the administrator to track which server the update originated from.

Replication deployment planning

Consider the following factors before deploying replication in a production environment:

Minimizing Replication Conflicts

If two different clients attempt to create an entry with the same distinguished name (DN) at the same time against different servers, it's possible that both client requests will succeed. This triggers the server to send a conflict alert. You can minimize these conflicts by understanding the client traffic pattern beforehand. PingDirectory's Assured Replication feature and the PingDirectoryProxy server can both assist in minimizing conflicts.

For more information, see Configuring assured replication and PingDirectoryProxy.

Copyright © 2025 Ping Identity Corporation

Replication Purge Delay

Adjust the default one-day replication purge delay to accommodate automatic catchup of changes when a server is offline for an extended period of time. The replication changes database, stored in `<server-root>/changelogDb`, grows larger with longer replication purge delays.

Define a minimum value for the replication purge delay. Make sure the value is consistent across all servers.

For more information, see Modifying the replication purge delay.

Domains

All servers in a replication topology must have the same domains.

> **Note**
>
> Because the PingDirectory replication topology assumes that all domains are on all servers, it is not suitable for environments with an inconsistent presence of domains across the server topology.

Location

If your deployment incorporates multiple data regions, you should configure the PingDirectory servers with location information.

To set locations, use the `dsconfig create-location` and `dsconfig set-global-configuration-prop` commands.

The PingDirectory server cannot determine LAN boundaries automatically, so incorrect location settings can result in undesired WAN communication. By default, replication compresses all traffic between PingDirectory servers in different locations.

Set up the locations before enabling replication. The `dsreplication enable` command prompts for location information if you have forgotten to define the property.

User-defined LDAP

PingDirectory servers participating in replication must have a uniform user-defined schema.

The `dsreplication` command-line utility sets up replication for the schema backend the first time replication is enabled to ensure that future schema changes are propagated to all PingDirectory servers.

Disk space

Replication increases the disk space required for the PingDirectory server.

The Replication Changelog backend keeps changes from all PingDirectory servers for 24 hours by default. After this time period, also known as the purge delay, the backend is trimmed automatically.

In addition, within the `userRoot` and other local DN backends, attribute-level changes are recorded for a short period of time in the `ds-sync-hist` attribute of the entry targeted by an LDAP Modify operation. This attribute is used to resolve all conflicts resulting from LDAP Modify operations automatically.

The disk space impact of replication is dependent on the rate and size of changes in the replication topology and the Replication Changelog purge delay.

Copyright © 2025 Ping Identity Corporation

Memory

Replicated PingDirectory server instances require slightly more memory than a standalone server.

All of the items discussed in Disk space have an impact on the amount of memory the PingDirectory server is using. The additional replication overhead is typically less than 5%.

Time synchronization

Even though replication has a built-in mechanism to compensate for the potential clock skew between hosts, you should keep system clocks in sync within the deployment.

Communication ports

The replication server component in each PingDirectory server listens on a TCP/IP port for replication communication.

This replication server port, typically 8989, must be accessible from all PingDirectory servers participating in replication. The server-to-server communication channel is kept alive using a heartbeat, which occurs every 10 seconds. This traffic prevents firewalls from closing connections prematurely.

The replication command-line utility (`dsreplication`) requires access to all PingDirectory servers participating in replication. This includes the LDAP or LDAPS port of the servers.

> **Tip**
>
> When configuring firewalls, keep these communication requirements in mind.

Hardware load balancers

Replication allows write operations to be directed to any PingDirectory server in the topology. Distributing write operations in a round-robin fashion could introduce conflicts. In particular, distributing a series of LDAP `add`, `delete`, and `modify DN` operations targeting the same distinguished name (DN) in quick succession can cause conflicts that require manual intervention.

The Assured Replication feature can help prevent conflicts created by the same client application. For more information, see Configuring assured replication.

Consider using server affinity with the load balancer that either associates a client IP address or a client connection with a single PingDirectory server instance at a time.

For load balancing LDAP traffic, consider using the PingDirectoryProxy server. The Server Affinity feature in PingDirectoryProxy server enables replication-friendly load balancing. For more information, see Configuring server affinity.

PingDirectoryProxy

To facilitate replication-friendly load balancing, consider using PingDirectoryProxy in every replication deployment.

The PingDirectoryProxy server can automatically adapt to conditions in the backend PingDirectory server using health checks and route traffic accordingly.

For example, the PingDirectoryProxy server can re-route traffic from PingDirectory servers with a large backlog of replication updates.

Displaying the server information for a replication deployment

Steps

- To display the server information for a replication deployment, run the `dsreplication status` command with the `--displayServerTable` option.

```
$ bin/dsreplication status --displayServerTable
```

Result:

```
          --- Replication Status for dc=example,dc=com: ---
Server                          : Location : Priority (1) : Status
--------------------------------:----------:--------------:----------
austin-01.example.com:8989      : US       : 1 (*)        : Available
austin-02.example.com:8989      : US       : 2            : Available
london-01.example.com:8989      : UK       : 5            : Available
london-02.example.com:8989      : UK       : 5 (\*)        : Available
sydney-01.example.com:8989      : AU       : 5 (\*)        : Available
sydney-02.example.com:8989      : AU       : 5            : Available

[1] WAN Gateway Priority. WAN gateways are marked with a *. To minimize
WAN utilization, the server with the WAN Gateway role is the only server
in a location that exchanges updates with remote locations.

--- Replication Status for dc=example,dc=com: Enabled ---

```

Displaying all status information for a replication deployment

Steps

- To display the status information for a replication deploymnent, run the `dsreplication status` command with the `--showAll` option.

  You can also use the `--showAll` option together with the `--displayServerTable` option to see the server table information for the replication topology.

Enabling replication

Enabling replication between multiple PingDirectory servers ensures that changes within the replicated base distinguished name (DN) are automatically propagated to all other PingDirectory servers in the topology.

Copyright © 2025 Ping Identity Corporation

Configuration changes are not replicated by default but can be through the use of server groups. Each PingDirectory server should be configured according to the deployment design.

Overview

To interface with the replication topology, the PingDirectory server provides a command-line utility, `dsreplication`, that should be used to manage and monitor replication.

The cluster name for an instance should be set to a unique name during install. The cluster-name controls a handle of configuration settings that are used cluster-wide; any changes to the configuration will always get pushed out to other members of the topology. If the cluster-name is set to a unique name for each server, any change to the configuration via the `dsconfig` command or the console needs to be done on every server in the topology. In a devops model, it is recommended that the cluster name be unique so that everything can be managed with server profiles. If you are doing an on-premise install, you might want to use a common cluster-name across the topology. NOTE: You should set a cluster name for the topology if you want cluster-wide settings to propagate across the topology in a single action.

Replication setup involves the following basic steps:

- Set up the servers.

  This is the basic installation step to set up a PingDirectory server instance.

- Import or restore data to one server.

  After setting up the servers, at least one server should have the target data loaded through `import-ldif` or restore.

- Enable replication between the servers.

  Using the `dsreplication` tool, enable replication for each server to be included in the replication topology. The `dsreplication enable` subcommand should be run N - 1 times for a topology of N servers. For more information, see Command-line interface.

- Initialize data from source server to all servers in the topology.

  Run the `dsreplication initialize` subcommand for every target server that needs a copy of the data from the source server.

- Verify the replication topology.

  Check the replication status after configuring the topology using the `dsreplication` status tool.

Command-line interface

Replication topologies are configured and maintained using the `dsreplication` command-line utility, which supports interactive and non-interactive modes. If you are running the server for the first time, use the `dsreplication` tool in interactive mode.

The `dsreplication` tool uses the following format, including some important subcommands listed in About the `dsreplication` command-line utility.

```
dsreplication  \{subcommand}  \{connection parameters}
```

Copyright © 2025 Ping Identity Corporation

The `dsreplication` tool keeps a history of invocations in the `logs/tools/dsreplication.history` file and keeps a log of up to 10 `dsreplication` sessions in the `logs/tools` directory.

What happens when you enable replication

The `dsreplication enable` subcommand is used to set up replication. The `enable` subcommand carries out the following functions:

- If it does not already exist, the global administrator user is created. The global administrator user has all the rights and privileges to update replication-related configuration objects. Most `dsreplication` subcommands require the global administrator.
- The server instances are registered in the `cn=topology,cn=config` tree. The registration includes basic host name, port information, and the public key used during the replication authentication process.

  If both servers are already participating in replication, the `cn=topology,cn=config` is merged to retain the server information from existing topologies.
- The embedded replication server is enabled. Servers already in replication see their replication server configuration updated with the information of the new replication server.
- A replication domain is created for the requested base distinguished names (DNs). If the first base DN is enabled, the replication domains for two additional base DNs are also enabled: `cn=topology,cn=config` and `cn=schema`.
- Initialization for the `cn=schema` base DN is executed. This ensures that a uniform schema is present in the replication topology.
- Initialization must be performed for the enabled base DNs.

> **Important**
>
> The `dsreplication enable` subcommand removes all existing topology administrative users except for the default uid=admin that is provided to enable replication. Administrative users must be re-added after enabling replication.

Initialization

Replica initialization transfers a copy of the backend containing the replication domain to a target server. You should perform this after replication is enabled with the `dsreplication initialize` subcommand. There is no impact on the source server during this process.

> **Note**
>
> When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers.
> This option is used in place of specifying `host 1`, `port 1`. When the `hosts` file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

Copyright © 2025 Ping Identity Corporation

`dsreplication initialize`

The recommended approach for replica initialization. The `dsreplication initialize` subcommand performs the most efficient copy of data needed to initialize one or more replicas on a target server. Existing data on the target server replica is lost and the backend containing the base DN is taken offline on the target server during the initialization.

Binary copy

The database copy method involves copying database backup files from the source PingDirectory server to one or more target servers. The PingDirectory server provides tools necessary for backing up and restoring backends. Using `server-root/bin/backup`, create a backup of the backend containing the replicated base DN. The backup files must then be transferred to the target servers and restored individually with `server-root/bin/restore`. There are additional considerations when using database copy as the means to initialize a target replica:

- If encryption is enabled on the servers, then a database `bin/encryption-settings export` followed by `bin/encryption-settings import` must be performed on the `encryption-settings` backend.
- When using database copy to initialize a server that has been offline longer than the replication purge delay, the database copy of the `replicationChanges`, `schema`, and `adminRoot` backends are required.

Import/export LDIF

The import/export LDIF method is the most flexible approach, as it works well in environments where target replicas are configured differently than the backend containing the data (for example, the target replica has different indexes than the source server). The process involves exporting the backend data as LDIF from the source server and importing the LDIF into the target servers. Replicas can be initialized locally while the server is offline or online through remote access. For more information, see Importing and exporting data.

Replica generation ID

Each replica has a generation ID, which is an integer that summarizes the replica. It provides replication with a quick and simple means of determining if two replicas contain the same data. Two replicas containing the same data have the same generation ID.

When replication is operating correctly, all of the replicas for each replicated base DN have the same generation ID. The generation ID is stored on each replica as the operational attribute `ds-sync-generation-id`, as in the following example.

```
ldapsearch -b 'dc=example,dc=com' -s base '(&)' ds-sync-generation-id
 dn: dc=example,dc=com
 ds-sync-generation-id: 2058329333
```

When the server starts, or when replication is enabled, the generation ID is computed for each affected replica that does not already have a generation ID stored as `ds-sync-generation-id`. The following is used to calculate the generation ID:

- The total number of entries in the replica. This is referred to as the count.
- The first 1000 entries in the replica are converted to normalized LDIF, referred to as the LDIF. Normalized LDIF only includes attributes `objectclass`, `sn`, `cn`, and `ds-entry-unique-id` and uses OIDs in place of attribute names.

Copyright © 2025 Ping Identity Corporation

- The Adler-32 checksum is calculated with the string produced by concatenating the count and the LDIF as input. This Adler-32 checksum is the generation ID.
- The generation ID is stored on the base DN as `ds-sync-generation-id`. This ensures that the ID does not need to be computed the next time the replica is loaded.

Deploying a basic replication topology

Set up a two-server replication topology.

About this task

The example uses the LDAP and replication server ports 1389 and 8989, respectively.

Replica Ports

Host Name	LDAP Port	Replication Port
server1.example.com	1389	8989
server2.example.com	1389	8989

Steps

1. Install the first PingDirectory server with 2000 sample entries.

   Example:

   ```
   $ ./setup --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389 \ --rootUserPassword pass --sampleData
   2000 --no-prompt
   ```

2. Install the second PingDirectory server either on a separate host or the same host as the first, but with a different LDAP port.

   Example:

   ```
   $ ./setup --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389 \ --rootUserPassword pass --no-prompt
   ```

3. To configure a replication topology, from the first server, run the `bin/dsreplication` command in interactive mode.

   Example:

   ```
   $ bin/dsreplication
   ```

4. From the `Replication Main Menu`, select `Manage the topology`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
>>>> Replication Main Menu

What do you want to do?

    1) Display replication status
    2) Manage the topology (add and remove servers)
    3) Initialize replica data over the network
    4) Initialize replica data manually
    5) Replace existing data on all servers

    q) quit

Enter choice: 2
```

5. From the `Manage Replication Topology` menu, select `Enable Replication`.

   Example:

```
>>>> Manage Replication Topology

Select an operation for more information.

    1)  Enable Replication -- add or re-attach a server to the topology
    2)  Disable Replication -- permanently remove a running replica from the topology
    3)  Remove Defunct Server -- permanently remove an unavailable server from the
          topology
    4)  Cleanup Server -- remove replication artifacts from an offline, local server
          (allowing it to be re-added to a topology)

    b)  back
    q)  quit

Enter choice [b]: 1
```

6. From the `Enable Replication` menu, read the setup introduction. To continue the enable process, enter `c`.
7. Enter the LDAP connection parameters for the first of the two server replicas that you are configuring.
   1. Enter the host name or IP address of the server.
   2. Enter the type of LDAP connection to the server.

      Choose from:

      - LDAP
      - LDAP with SSL
      - LDAP with StartTLS

   3. Enter the LDAP listener port for the server.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you are a root user, you see port 389 as the default. Others see port 1389.

4. Authenticate as a root distinguished name (DN), such as `cn=Directory Manager`.

> **Note**
>
> Later in the process, you are prompted to set up a global administrator and password. The global administrator is the user ID that manages the replication topology group.

8. Repeat steps 7a-7d for the second server replica.

9. When the `dsreplication` tool checks for the base DN on both servers, press enter to select the default base DN.

> **Note**
>
> To enable replication, data must be present on at least one of the servers.

Example:

```
Choose one or more available base DNs for which to enable replication:

    1)  dc=example,dc=com

    c)  cancel

Enter one or more choices separated by commas [1]:
```

> **Note**
>
> If you see the following message, in most cases, a base DN was not set up on one of the PingDirectory servers, or the backend is disabled.
>
> ```
> There are no base DNs available to enable replication between the two servers.
> ```

10. When you are prompted to set up entry balancing using the PingDirectoryProxy server, press enter to accept the default value.

> **Note**
>
> For more information, see the PingDirectoryProxy Server Administration Guide.

Example:

```
Do you plan to configure entry balancing using the Directory Proxy Server? (yes / no) [no]:
```

11. Enter the replication port for the first replica.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The default replication port is 8989.
> The port you enter must be free.

12. If you are prompted to enter a location, press enter to accept the default and set up a location for the first server. Enter the name of the server's location.

> **Note**
>
> You are prompted for the location if you did not pre-define a location setting for the server.

Example:

```
The first server has not been configured with a location.
Assigning a location to each server in the replication topology reduces
network traffic in multi-site deployments. Would you like to set the
location in the first server? (yes / no) [yes]

The location of the first server: Austin
```

13. Repeat steps 9-12 for the second PingDirectory server.

> **Note**
>
> If you did not pre-define a location setting for the second server, you are prompted to enter location information for the server.

14. Set up the global administrator user ID and a password for this account.

> **Note**
>
> The default global administrator user ID is `admin`.
> The global administrator user ID manages the PingDirectory servers used in the replication topology.

Example:

```
Specify the user ID of the global administrator account
that will be used to manage the Ping Identity
                 Directory Server
instances to be replicated [admin]:

Password for the global administrator:
Confirm Password:
```

15. Return to the `Replication Main Menu` and enter the number corresponding to initializing data over the network.
16. To initialize data on a single server, from the `Initialize Replica Data over the Network` menu, select `Initialize`, and enter `c` to continue.
17. To specify a server in the replication topology, enter the following information for the first server:
    - Host name or IP address

Copyright © 2025 Ping Identity Corporation

- LDAP connection type
- LDAP port
- Global admin user ID and password

18. Select the source server that is hosting the data to which the target server will be initialized.

    For this example, select the first server, since the sample dataset has been loaded onto this server.

19. Select the base DN to initialize.

> **Note**
>
> In most cases, the base DN for the root suffix is replicated. In this example, `dc=example,dc=com`.

20. Select the second server to have its data initialized, and enter the global admin user ID and password for the target server.

> **Note**
>
> Any data present on the target server is over-written.

21. To confirm that you want to initialize data on the target server, press enter.

    Example:

```
Initializing the contents of a base DN removes all the existing contents of
that base DN. Do you want to remove the contents of the selected base DNs on server
server2.example.com:1389 and replace them with the contents of server
server1.example.com:1389? (yes / no) [yes]:
```

    Result:

    The server displays a `Base DN initialized successfully` message.

22. On the `Initialize Replica Data Over Network` menu, enter `b` to back out one level to the main menu.

23. To view the replication status, on the `Replication Main Menu`, enter the host name or IP address.

    Example:

```
     --- Replication Servers: dc=example,dc=com ---
Server                  : Location : Conflict Entries : Backlog : Recent Change Rate
------------------------:----------:------------------:---------:--------------------
ds1 (example.com:1389)  : austin   : 0                : 0       : 0
ds2 (example.com:1389)  : austin   : 0                : 0       : 0
```

Example deployment with non-interactive dsreplication

The following example creates a 4-server topology spanning two data centers.

In the example, the four servers are already installed and have locations Austin and Budapest defined.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> When enabling or initializing servers, the `--topologyFilePath` option can be used with **`dsreplication`** to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying `host 1`, `port 1`.
> When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the **`manage-topology export`** command.

Deploying with non-interactive dsreplication

Steps

1. To generate the sample data on the first server, use the **`make-ldif`** tool.

   Example:

   ```
   $ bin/make-ldif --templateFile config/MakeLDIF/example-10K.template \
     --ldifFile ldif/10K.ldif
   ```

2. To import the data, select a server from which to import data and to be the source for future initialization to other servers, and then follow the import steps.

   1. Stop the server.
   2. To import the sample LDIF to the server, run **`import-ldif`**.
   3. Start the server.

      Example:

      ```
      $ bin/stop-server
      $ bin/import-ldif --backendID userRoot --ldifFile ldif/10K.ldif
      $ bin/start-server
      ```

3. To enable replication, select a specific server and run **`dsreplication enable`** three times.

   > **Note**
   >
   > For the first invocation, create the replication topology administrator with the name **`admin`**.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 austin02.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 budapest01.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt

$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
    --bindDN1 "cn=Directory Manager" --bindPassword1 password \
    --replicationPort1 8989 --host2 budapest02.example.com --port2 1389 \
    --bindDN2 "cn=Directory Manager" --bindPassword2 password \
    --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
    --adminPassword password --no-prompt
```

4. To initialize the other servers, the `dc=example,dc=com` replicas, from the server you imported the data into with **`import-ldif`**, run **`dsreplication initialize`**.

   Example:

   For this example, initialize **`budapest02`** from **`budapest01`** to minimize the WAN transfers.

```
$ bin/dsreplication initialize --hostSource austin01.example.com --portSource 1389 \
  --hostDestination austin02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-prompt

$ bin/dsreplication initialize --hostSource austin01.example.com --portSource 1389 \
  --hostDestination budapest01.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-prompt

$ bin/dsreplication initialize --hostSource budapest01.example.com --portSource 1389 \
  --hostDestination budapest02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-prompt
```

5. To view the replication state, run **`dsreplication status`**.

   Example:

```
$ bin/dsreplication status --adminPassword password --no-prompt --displayServerTable --showAll
```

Using `dsreplication` with SASL GSSAPI (Kerberos)

Before you begin

This example procedure assumes that you have configured SASL GSSAPI on all servers in the replication topology and that they are working properly.

Copyright © 2025 Ping Identity Corporation

About this task

The PingDirectory server's utilities all support SASL GSSAPI options for systems using Kerberos as its main authentication mechanism. The following procedure shows how to use `dsreplication` with SASL GSSAP to set up a new `replication.admin` identity while enabling replication on a server.

> **Note**
>
> A separate Kerberos identity is required to manage replication. Existing Kerberos credentials can be used to interact with the server when enabling replication and creating the new identity.
> The new identity, such as `replication.admin`, must not exist as the `cn` or `uid` value under any public base distinguished name (DN).

Steps

1. **To set the LDAP Connection Handler to explicitly listen on the server's host name address, run `dsconfig` with the `set-connection-handler-prop` option.**

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "LDAP Connection Handler" \
     --remove listen-address:0.0.0.0 --add listen-address:host.example.com
   ```

2. **To update the identity mapper to have `cn=topology,cn=config` included in the list of base DNs and to add the `cn` attribute to match attributes, run `dsconfig` with the `set-identity-mapper-prop` option.**

   > **Note**
   >
   > You must do this to map the admin account to the Kerberos realm.

   Example:

   ```
   $ bin/dsconfig set-identity-mapper-prop \
     --mapper-name "Regular Expression" \
     --add match-attribute:cn \
     --set "match-base-dn:cn=topology,cn=config" \
     --set match-base-dn:dc=example,dc=com
   ```

3. **To invoke replication enable, authenticate as the existing Kerberos `authid`, and then run `dsreplication enable`.**

   > **Note**
   >
   > No bind DNs and passwords are required to authenticate because you are using SASL binding. However, the new replication admin user requires a password at creation time, and you should use a strong random password. After SASL is working, you no longer have to provide this random password.
   > You must use the ticket cache, so make sure you have properly authenticated as `ds.admin` from your local host and the ticket is not expired in the cache.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ kinit -p ds.admin
$ bin/dsreplication enable \
  --host1 server1.example.com --port1 1389 --replicationPort1 1989 \
  --host2 server2.example.com --port2 2389 --replicationPort2 2989 \
  --baseDN dc=example,dc=com \
  --adminUID replication.admin --adminPassword strongPassword \
  --saslOption1 mech=gssapi --saslOption1 authid=ds.admin@EXAMPLE.COM \
  --saslOption1 useTicketCache=true --saslOption1 requireCache=true \
  --saslOption2 mech=gssapi --saslOption2 authid=ds.admin@EXAMPLE.COM \
  --saslOption2 useTicketCache=true --saslOption2 requireCache=true
```

4. To initialize data on the remote server, run `dsreplication initialize`.

   Example:

```
$ kinit -p replication.admin
$ bin/dsreplication initialize \
  --hostSource server1.example.com --portSource 1389 \
  --hostDestination server2.example.com --portDestination 2389 \
  --baseDN dc=example,dc=com \
  --saslOption mech=GSSAPI \
  --saslOption authID=replication.admin@EXAMPLE.COM  \
  --no-prompt
```

5. To delete the temporary `userPassword` from the `replication.admin` entry, create an LDIF file.

   Example:

   In this example, the file is named `remove-password.ldif` and contains the following.

```
dn: cn=replication.admin,cn=Administrators,cn=topology,cn=config
changetype: modify
delete: userPassword
```

6. To apply the modifications, use the `ldapmodify` tool.

   Example:

```
$ ./ldapmodify --filename remove-password.ldif -o mech=GSSAPI
-o authid=replication.admin@example.com \
  --saslOption useTicketCache=true \
  --hostname host.example.com --port 1389 \
  --noPropertiesFile
```

7. To check the topology's status, run `dsreplication status`.

> **Note**
>
> After the admin account and mappers are created, you can use the `--saslOption useTicketCache=true` and `--saslOption requireCache=true` properties instead of a password for all **`dsreplication`** commands.

Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsreplication status \
  --saslOption mech=gssapi \
  --saslOption authid=replication.admin@EXAMPLE.COM \
  --saslOption useTicketCache=true --saslOption requireCache=true \
  --hostname host.example.com --port 1389 \
  --no-prompt
```

Configuring assured replication

The PingDirectory server's replication mechanism is based on the eventual-consistency model, which is a loosely-connected topology that propagates updates to other servers without waiting for their corresponding replication response messages.

There is a small window of time where updates are not all present on the replicas while the changes are replicating through the system. However, there are deployments that require immediate access to replicated data. In such cases, administrators can configure assured replication, which ensures that replication has completed before the update response is returned to the client.

From the LDAP client's perspective, assured replication has no bearing on the result code of the operation, just on the time in which it takes to receive the response for those requests in which replication assurance is applied. Detailed information regarding assurance processing is available to an LDAP client with awareness of the assured replication control.

The assured replication mechanism uses server location to distinguish between local and remote servers to allow different policies to apply. For example, a common assurance approach is to respond to a client update after all servers in the same location have applied the update and one or more servers in remote locations have received the update. The level of assurance applied to each operation can be explicitly requested by the client, specified by the server configuration using the Replication Assurance Policy, or both.

Assured replication is supported by client requests directly to PingDirectory server, through a PingDirectoryProxy server, or both.

About the Replication Assurance Policy

Assured replication uses a Replication Assurance Policy to define the properties needed to ensure that replication has completed before the update response is returned to the client. Multiple policies can be defined, but only one policy is matched with a client update request. Each policy contains an evaluation order index that, together with an optional request and connection criteria, provides flexibility in matching a policy to request.

The Replication Assurance Policy defines local and remote assurance levels. A level defines how rigorous the policy should be when waiting for propagation of updates while local and remote distinguish servers in the same location versus servers in remote locations. Although optional, you should associate request or connection criteria with a policy to apply replication assurance appropriately.

PingDirectory server contains a default Replication Assurance Policy that is enabled with the local-level processed-all-servers assurance level. In addition to using the Default Replication Assurance Policy, any number of policies can be created and enabled. When a client request is received, the server iterates through the list of enabled policies according to each policy's `evaluation-order-index` property. A smaller `evaluation-order-index` value (such as 1) has precedence over policies with larger `evaluation-order-index` values (such as 2, 3, 4, and so forth). The `evaluation-order-index` values do not need to be contiguous. The first policy that matches a request is associated with the operation.

Copyright © 2025 Ping Identity Corporation

The Replication Assurance Policy, which is defined on the PingDirectory server and not on the PingDirectoryProxy server, has the following properties:

evaluation-order-index

Determines the evaluation order among multiple Replication Assurance Policies that match against an operation. The smaller value has precedence.

local-level

Specifies the assurance level used to replicate to local servers. A local server is defined as a server with the same `location` property value as set in the global configuration. The `local-level` property must be set to an assurance level as strict as the `remote-level` property. For example, if the `remote-level` is set to `processed-all-remote-locations`, then the `local-level` property must be `processed-all-servers`.

None

Replication to any local server is not assured.

received-any-server

At least one available local server must receive a replication update before a response is sent to the client.

processed-all-servers

All available local servers must complete replay of the replication update before the response is sent to the client. If a singular server is enabled, or only one server is available for a particular location, `processed-all-servers` returns a value of `false`.

remote-level

Specifies the assurance level used to replicate to remote servers. A remote server is defined as a server that has a different `location` property value as set in the global configuration.

None

Replication to any remote server is not assured.

received-any-remote-location

At least one server at any available remote location must receive a replication update before a response is sent to the client.

received-all-remote-locations

All available remote servers must receive a replication update before the response is sent to the client.

processed-all-remote-servers

All available servers at all locations must complete replay of the replication update before the response is sent to the client. If a single server is enabled, or only one server is available for a particular location, `processed-all-remote-servers` returns a value of `false`.

Copyright © 2025 Ping Identity Corporation

timeout

Specifies the maximum length of time to wait for the replication assurance requirements to be met before timeout and replying to the client.

connection-criteria

Specifies connection criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

request-criteria

Specifies request criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and a request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

Servers in a replication topology are not required to share a homogeneous set of policies. You can configure the Replication Assurance Policies differently on the replicas in a topology. For example, if you configure server A to match add operations to a `processed-all-servers` assurance level, and server B to match add operations to a local `received-any-server` level, then `add` operations received on server A have the assurance level of `processed-all-servers` and `add` operations received on server B have the assurance level of `received-any-server`.

About assured replication

When implementing assured replication, make note of the following.

Item	Description
Client Controls	The client can include an assured replication request control with each operation. This control allows the client to specify bounds on assurance levels, override the timeout assigned by the matching replication assurance policy for the associated operation, or both. The server always honors these request controls. For more information, see About the Assured Replication Controls.
Directory Proxy Server	Replication assurance policies are not supported on PingDirectoryProxy. Replication client controls are passed through to the underlying PingDirectory server backend.
Schema Backend Replication	The schema backend is not supported by assured replication. Replication assurance policies that include criteria to match this backend are rejected.
Backward Compatibility	Server versions that support assured replication are backwards-compatible with prior versions that do not support assured replication.

Copyright © 2025 Ping Identity Corporation

Item	Description
WAN-Friendly Replication	Assured replication functions independently from WAN-Friendly Replication and the notion of WAN Gateways.
Global Configuration Properties	PingDirectory server provides two configurable global configuration properties that determine the timing of the assurance source and maximum number of replication backup updates recognized as an available source. **`replication-assurance-source-timeout-suspend-duration`** Specifies the amount of time a replication assurance source is suspended from assurance requirements if it experiences an assurance timeout. While suspended, the source is excluded from assurance requirements for all operations originating on this PingDirectory server. This avoids the situation of repeated timeouts caused by degraded or offline servers. The default time is 10 seconds. **`replication-assurance-source-backlog-fast-start-threshold`** Specifies the maximum number of replication backlog updates a replication assurance source can have and be immediately recognized as an available source. If a source connects to this PingDirectory server with more than the configured threshold backlog updates, it is excluded from assurance requirements for all operations originating from the server until it completes at least one assurance successfully, indicated by the server receiving an update acknowledgment message from it within the timeout window. The default maximum number of updates is 1000.

Configuring assured replication

About this task

It is common for all servers to have the same policy. The following example, which demonstrates the configuration of various assured replication policies, assumes that three servers are configured on localhost, on ports 1389, 2389, and 3389.

> **Note**
>
> In this example, each server has a default Replication Assurance Policy with no assurance levels set.

Steps

1. To create request criteria for `add` operations on server 1, run `dsconfig` with the `create-request-criteria` option.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This request criteria is used to match any `add` operation with the Replication Assurance Policy that is configured in the following step.

Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add
```

2. **To make all add operations assured with a level of `processed-all-servers` on server 1, set up the Replication Assurance Policy using `dsconfig` and specify the `Adds` request criteria configured in the previous step.**

> **Note**
>
> The `processed-all-servers` level indicates that all local servers in the topology must complete replay of the replication update before the response is sent to the client.

Example:

```
$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Processed All Locally" \
  --set evaluation-order-index:1 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Adds
```

3. **On server 1, repeat steps 1-2 for `modify` operations.**

> **Note**
>
> The Replication Assurance Policy `Mods Received Any Locally` ensures that at least one available local server must receive a replication modify update before a response is sent to the client.

Example:

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Received Any Locally" \
  --set evaluation-order-index:2 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

4. **To set up the `Adds` and `Mods` request criteria and a Replication Assurance Policy on server 2, repeat steps 1-3.**

Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-request-criteria \
  --criteria-name Adds \
  --type simple \
  --set operation-type:add

$ bin/dsconfig create-request-criteria \
  --criteria-name Mods \
  --type simple \
  --set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Adds Received Any Locally" \
  --set evaluation-order-index:1 \
  --set local-level:received-any-server \
  --set "timeout:500ms" \
  --set request-criteria:Adds

$ bin/dsconfig create-replication-assurance-policy \
  --policy-name "Mods Processed All Locally" \
  --set evaluation-order-index:2 \
  --set local-level:processed-all-servers \
  --set "timeout:500ms" \
  --set request-criteria:Mods
```

Note

Leave server 3 with the default Replication Assurance Policy configured with no assurance levels or criteria. In practice, it is common for all servers to have the same assurance levels or criteria.

5. **To list the policies on server 1 to confirm that they exist, run `dsconfig` with the `list-replication-assurance-policies` option.**

   Example:

   ```
   $ bin/dsconfig list-replication-assurance-policies
   ```

6. **Repeat step 5 for server 2 and server 3.**

   Server 3 should only show the Default Replication Assurance Policy.

7. **To check the Replication Assurance counters on all servers before any `add` or `modify` operation, use `ldapsearch`.**

   Note

   The counters should be set to zero. These counters are on the replica server where the policy is matched and assigned.

   Example:

   For this example, on server 1, run the following command.

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

8. To check the Replication Summary table on all of the servers, use `ldapsearch`.

   Example:

   For this example, on server 1, run the following command.

```
$ bin/ldapsearch --baseDN "cn=Replication Summary dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 0
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

9. To add an entry to server 1 on the PingDirectory server, use `ldapmodify`.

   The counters should match the newly added entry to the `Adds Processed All Locally` policy and complete assured.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapmodify --filename add-user.ldif --defaultAdd

$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 0
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-remote-level-uses: none: 1

$ bin/ldapsearch --baseDN "cn=Replication Summary dc_example_dc_com,cn=monitor" \
  "(objectclass=)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

10. Perform a `modify` of an entry under `dc=example,dc=com` on server 1.

    The counters should match the `modify` operation to the `Mods Processed All Locally` policy and the operations should complete assured.

    Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy: 0
replication-assurance-policy-matches: Mods Received Any Locally: 1
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-local-level-uses: received-any-server: 1
replication-assurance-remote-level-uses: none: 2

$ bin/ldapsearch --baseDN "cn=Replication Summary dc_example_dc_com,cn=monitor" \
  "(objectclass=)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

Result:

You have successfully configured Assured Replication.

About the assured replication controls

The LDAP SDK for Java provides an implementation of an LDAP control that can be included in `add`, `bind`, `modify`, `modifyDN`, and certain extended requests to indicate the optimal level of replication assurance for the associated operation. The OID for this control is 1.3.6.1.4.1.30221.2.5.28 and can have a criticality of either `TRUE` or `FALSE`.

For more information, see the LDAP SDK Javadoc for the `AssuredReplicationRequestControl` class.

Managing the topology

The following sections describe common topology management operations.

When enabling or disabling replication within a topology that contains multiple product versions, you must run the **`dsreplication`** tool from the server root location of a member of the topology that has the oldest product version.

Copyright © 2025 Ping Identity Corporation

Adding a server to the topology

Before you begin

You must:

- Have an existing PingDirectory server topology.
- Ensure that more than 50% of servers in the topology and the new server are online.

About this task

The commands are identical for initial enablement between two servers where one server contains data for the replication domain stored in the `userRoot` backend. If database encryption is being used on the servers in the topology, the server being initialized must have a copy of the `encryption-settings` backend from the source server.

Steps

1. To enable replication for the base distinguished name (DN), or base DNs, run `dsreplication enable` using an existing server as `host1` and the new server as `host2`.

   Example:

   ```
   $ bin/dsreplication enable \
     --host1 austin01.example.com --port1 1389 \
     --bindDN1 "cn=Directory Manager" --bindPassword1 password \
     --replicationPort1 8989 --host2 austin03.example.com --port2 1389 \
     --bindDN2 "cn=Directory Manager" --bindPassword2 password \
     --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
     --adminPassword password --no-prompt
   ```

2. (Optional) To compare the configurations between the two hosts used in the `dsreplication enable` command, run `config-diff`.

   > **Note**
   >
   > Ensure settings are consistent across the topology and are also consistent with the new system.

   Example:

   ```
   $ bin/config-diff --sourceLocal \
     --targetHost austin03.example.com \
     --targetBindDN "cn=directory manager" \
     --targetBindPassword pass --targetPort 1389
   ```

Disabling replication and removing a server from the topology

Before you begin

More than 50% of the servers not being removed from the topology must be online during the process.

About this task

Copyright © 2025 Ping Identity Corporation

When removing a server from the topology, the remaining servers need to be made aware of the change. If additional servers are offline and cannot be online while removing the server, you must distinguish between offline servers that are offline permanently and those that are offline temporarily.

Remove a live server

Removing a live server

Steps

- To remove a server that is online, run the `dsreplication disable` command from any server.

```
$ bin/dsreplication disable --hostname austin03.example.com --port 1389 \
--baseDN dc=example,dc=com --adminUID admin --adminPassword password \
--no-prompt
```

> **Note**
>
> If the server to remove is online, only one invocation of **`dsreplication disable`** is necessary.

Copyright © 2025 Ping Identity Corporation

Remove an offline server

Removing an offline server from the topology
Steps

- To remove a defunct or misbehaving server from the topology while that server is offline, run `remove-defunct-server` from a live server in the topology. Doing this will remove configuration references to the offline server from the topology's perspective. This is useful if the server is broken and cannot start. For example:

```
$ bin/remove-defunct-server --serverInstanceName austin01 \
--bindDN "cn=Directory Manager" --bindPassword password
```

After you have removed the server, you can delete it. However, if you want to keep the server as a standalone server, proceed to Cleaning up an offline defunct server.

Note

The `--ignore-online` option removes an online server cleanly from the topology.

Tip

To speed up the process of removing multiple servers, change the default 10-minute timeout for each server you are taking out of rotation by setting the Java virtual machine (JVM) property `com.unboundid.connectionutils.LdapResponseTimeoutMillis` before you run **`remove-defunct-server`**.

Cleaning up an offline defunct server

About this task

If you have removed a defunct server and want to keep it as a standalone server, then you also need to run the **`remove-defunct-server --performLocalCleanup`** command on the defunct server while it is offline. This will remove all topology configuration references on the offline server, and make it a standalone server. This is useful if a server is temporarily misbehaving, but you want to add it back to the topology at a later time. The **`remove-defunct-server`** command will only accept the `--performLocalCleanup` argument if the server is offline.

Steps

- Run the **`remove-defunct-server`** command on each server that is removed from the topology. For example:

```
$ bin/remove-defunct-server --performLocalCleanup --no-prompt
```

Copyright © 2025 Ping Identity Corporation

> **Warning**
>
> To remove the defunct server, you must include the `--no-prompt` parameter. If you exclude this parameter, the server won't be removed from the topology. Additionally, the server might attempt to contact additional hosts in the topology, which could result in an error. These are known issues that only apply to `--performLocalCleanup` and will be corrected in a future release.

Replacing the data for a replicating domain

About this task

In case the data for the entire replication domain, such as the backend, needs to be replaced, perform the following steps:

Steps

1. With all servers online, run `dsreplication pre-external-initialization` against any server in the topology.

   Example:

   ```
   $ bin/dsreplication pre-external-initialization --hostname austin01.example.com \
      --port 1389 --baseDN dc=example,dc=com --adminUID admin \
      --adminPassword password --no-prompt
   ```

   Result:

   Replication is stopped for the domain. No writes are made by clients to any of the servers.

2. To replace the data for `dc=example,dc=com`, use `import-ldif`.

   1. (Optional) To overwrite the existing data for the domain, use the `--overwriteExistingEntries` option.
   2. (Optional) To ensure that the input LDIF is free of any replication attributes, use the `--excludeReplication` option.

   Example:

   In this example, you perform the `import-ldif` with the server offline using the `--excludeReplication` and `--overwriteExistingEntries` options.

   ```
   $ bin/import-ldif --ldifFile new-data.ldif --backendID userRoot --excludeReplication --
   overwriteExistingEntries
   ```

3. To initialize the other servers in the topology, run `dsreplication initialize` using the server that has the new data as the source host.

   Example:

   ```
   $ bin/dsreplication initialize --hostSource austin01.example.com --portSource 1389 \
      --hostDestination budapest01.example.com --portDestination 1389 \
      --adminUID admin --adminPassword password --baseDN dc=example,dc=com \
      --no-prompt
   ```

4. From any server in the topology, run `dsreplication post-external-initialization` once.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> All servers in the topology must be online.

Example:

```
$ bin/dsreplication post-external-initialization --hostname austin01.example.com \
   --port 1389 --baseDN dc=example,dc=com --adminUID admin \
   --adminPassword password --no-prompt
```

Advanced configuration

The following sections cover advanced configuration procedures for your company's deployment needs.

Changing the replicationChanges DB location

About this task

If on-disk space issues arise, you can change the `replicationChanges` database (DB) location. The replication changelog database can live outside `<server-root>` and be placed in another location on the file system. To do this, specify the absolute path of the replication changelog directory.

Steps

1. To change the database location for the replication changelog, use the `dsconfig` tool.

   > **Note**
   >
   > By default, the database location is at `<server-root>/changelogDb` .

   Example:

   The following command sets the replication Changelog Backend to `<server-root>/data/directory/changelogDb` .

   > **Note**
   >
   > Remember to include the LDAP connection parameters, such as host name, port, bindDN, and bindPassword.

   ```
   $ bin/dsconfig set-replication-server-prop \
     --provider-name "Multimaster Synchronization" \
     --set "replication-db-directory:/data/directory/changelogDb" \
     --bindDN "cn=Directory Manager" --bindPassword secret --no-prompt
   ```

2. Stop the server.

   Example:

   ```
   $ bin/stop-server
   ```

3. Move the DB files.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ mv changelogDb /data/directory
```

4. Restart the server.

   Example:

   ```
   $ bin/start-server
   ```

Modifying the replication purge delay

The replication purge delay specifies the period after which the PingDirectory server purges replication server database changes. Any change that is older than the purge delay is removed from the replication server database regardless of whether the change has been applied.

About this task

Currently, PingDirectory server sets the default purge delay to one day. Administrators can change the default purge delay using the `dsconfig` tool.

> **Note**
>
> To ensure proper replication processing, you must have the same purge delay value set for all replication servers in the topology.

Steps

- To change the purge delay, choose from one of the following options:

  Choose from:

  - Use the `dsconfig` tool.
  - Use the `dsconfig` tool in interactive mode:

    1. Open the Advanced objects menu.
    2. Select Replication Server.
    3. Select the replication synchronization provider.
    4. Select the option to change the replication purge delay.

  The property accepts time units of seconds (s), minutes (m), hours (h), days (d), or weeks (w).

  Example:

  The following command changes the purge delay from the default of one day to two days.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-purge-delay:2 d"
```

Configuring a single listener-address for the replication server

Configure a single listener-address for the replication server to change the default setting of listening on all addresses.

About this task

By default, the replication server binds the listening ports to all available interfaces of the machine. To bind the listener to a specific address, change the address to the host name provided when replication is enabled and set the `listen-on-all-addresses` property to `FALSE`.

The replication server's configuration entry stores a host name for itself so that it can resolve the address and specify it during the socket bind. If the server information is missing from the system, an error message generates with instructions on specific address binding. You can use the **`dsconfig`** tool to change the value of the `listen-on-all-addresses` property from `TRUE` (default) to `FALSE`.

To configure a replication server to listen on a single address:

Steps

1. Create a new PingDirectory server instance and enable replication on port 8989.
2. To see the ports bound for listening on port 8989, run **`netstat`**.

   > **Note**
   >
   > A port of `*.8989` means that it is listening on all addresses.

   Example:

   ```
   $ netstat -an | grep LISTEN | grep 8989
   ```

3. To disable listening on all addresses for the replication server, run the **`dsconfig`** tool.

   Example:

   ```
   $ bin/dsconfig set-replication-server-prop \
     --provider-name "Multimaster Synchronization" \
     --set listen-on-all-addresses:false
   ```

4. To see the ports bound for listening on port 8989, run **`netstat`** again.

   > **Note**
   >
   > A port of `<address>.8989`, such as 10.8.1.211.8989, means that it is listening on the one address.

Monitoring replication

This section covers how to use the PingDirectory server to monitor replication.

The PingDirectory server monitors replication in the following ways:

- Use the `dsreplication` tool with the `status` subcommand to display basic information about the replicated base distinguish names (DNs), the number of entries replicated, as well as the approximate size of replication backlogs at each PingDirectory server.
- Obtain more detailed information about the state of replication through the information exposed in its monitoring framework under `cn=monitor`.
- Use Periodic Stats Logger plugin, which allows collecting replication statistics for profiling server performance. For more information, see Profiling Server Performance Using the Periodic Stats Logger.

Administrators can monitor their replication topologies using several tools and protocols:

- The PingDataMetrics Server
- SNMP
- LDAP
- JMX
- The administrative console. For more information, see Managing Logging and Managing Monitoring.

Monitoring replication using cn=monitor

The `cn=monitor` branch has several entries that store the replication state of a topology.

`cn=monitor` *branch entries and their descriptions*

cn=monitorentries	Description
Direct LDAP Server `<baseDN><host name:port><serverID>`	Defines an LDAP server that directly connects to the replication server you are querying. The information in this entry applies to the replication server local to the `cn=monitor` entry. For more information, see Summary of the Direct LDAP Monitor information.
Indirect LDAP Server `<baseDN><serverID>`	Defines an LDAP server that connects to another replication server in the topology. While this server connects to the same topology, it does not connect to the replication server you are querying. For more information, see Summary of the Indirect LDAP Server Monitor information.

Copyright © 2025 Ping Identity Corporation

cn=monitorentries	Description
Remote Repl Server `<baseDN><host name:port><serverID>`	Defines a remote replication server that connects to the local replication server. Information in this entry is in respect to the Replication Server local to the `cn=monitor` branch. For more information, see Summary of the Remote Replication Server Monitor information.
Replica `<baseDN>`	Stores information for an instance of the replicated naming context, also known as the replica, with respect to the PingDirectory server and its communication with a replication server. The replica information sends and receives changes from the replication servers. For more information, see Summary of the Replica Monitor information.
Replication Server	Shows information specific to the Replication Server running. For more information, see Summary of the Replication Server Monitor information.
Replication Server Database `<baseDN><serverID>`	Shows information for the changelog table of replica (suffix) in the replication server. As the Replication Server receives updates from the PingDirectory server, it records those changes in the changelog table. For more information, see Summary of the Replication Server Database Monitor information.
Replication Server Database Environment	Shows information for the database environment for the replication server backend as well as the total number of records added to and deleted from the database. For more information, see Summary of the Replication Server Database Environment Monitor information.
Replication Summary `<baseDN>`	Shows summary information on the replication topology and the state for a particular base distinguish name (DN). For more information, see Summary of the Replication Summary Monitor information.
replicationChanges Backend	Shows the backend information for all replication changes. For more information, see Summary of the replicationChanges Backend Monitor information.
Replication Protocol Buffer	Shows the state of the buffer (initially 4k) for protocol operations, which is stored in thread local storage. For more information, see Summary of the Replication Protocol Buffer Monitor information.

Replication best practices

This section covers the best practices for replication based on our observations in production environments.

Purging obsolete replicas

About this task

By default, the PingDirectory server retains replicas for every server that has been part of a given topology. Over time, this can lead to an accumulation of obsolete replicas in your topology, which can increase the complexity of replication and negatively impact reliability.

To purge these obsolete replicas by default, you can set the `replication-purge-obsolete-replicas` global configuration property to `true`.

> **Important**
>
> If you set `replication-purge-obsolete-replicas` to `true`, you must make this change on all servers, including new servers as they are added. Failure to do so could cause replicated servers to communicate an inconsistent state across the topology. An inconsistent state can lead to a `replication-missing-changes` alert and a server lockdown because of the missing replication changes.

Steps

- To set `replication-purge-obsolete-replicas` to `true`, run `dsconfig set-global-configuration-prop`, as in the following example:

  Example:

```
bin/dsconfig set-global-configuration-prop \
    --set replication-purge-obsolete-replicas:true
```

About the `dsreplication` command-line utility

The following points involve some security practices that apply to replication. For specific questions, contact your authorized support provider.

Developing Scripts

The `dsreplication` utility maintains the history of executed `dsreplication` commands with the full command-line arguments in the `logs/tools/dsreplication.history` file. Use the recorded commands to develop scripts to set up and configure replication.

Scripts invoking the `dsreplication` utility in non-interactive mode check the return code from the `dsreplication` process. A non-zero return code indicates a failure.

To exclude output messages from the `dsreplication` utility, use the `--quiet` option to suppress them.

By default, the utility fails if one or more warnings are issued during the command execution. To suppress warnings, use the `--ignoreWarnings` option.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> This option is required when using `dsreplication` with non-fully-qualified host names, such as localhost. Otherwise `dsreplication` fails. However, you should avoiding using this flag in production environments.

Concurrent Use

With the exception of using the `dsreplication` utility with the `status` subcommand, the `dsreplication` subcommands cannot execute concurrently. The command-line utility locks the replication topology at one or more servers to prevent accidental configuration changes caused by multiple `dsreplication` subcommands running at the same time. For best practices, avoid making concurrent configuration changes.

Status

Using the `dsreplication` utility with the `status` subcommand requires the Replication Servers to provide monitoring information. This can lead to a delay before the output of `dsreplication status` displays. By default, `dsreplication` displays the status for all replicated domains with the exception of the special domains of the schema and the server registry.

Select a particular base distinguished name (DN) for `dsreplication status` if multiple base DNs are configured for replication.

Avoid invoking `dsreplication status` too often, such as more than once every 15 seconds or from multiple locations at the same time. Some of the information displayed by `dsreplication status` is based on monitor information that does not refresh every time the monitor is queried.

Do not use the `status` subcommand for collecting performance metrics. It is best to use the Periodic Stats Logger plugin for replication-related information.

Topology Tasks

The `dsreplication` tool allows specifying more than one server in a topology to act as the host for other servers for the enable and initialize actions. Use the `--topologyFilePath` option to specify a file with a series of hosts and ports in the topology.

For example, when the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available. This file generates with the `manage-topology export` command.

Replication conflicts

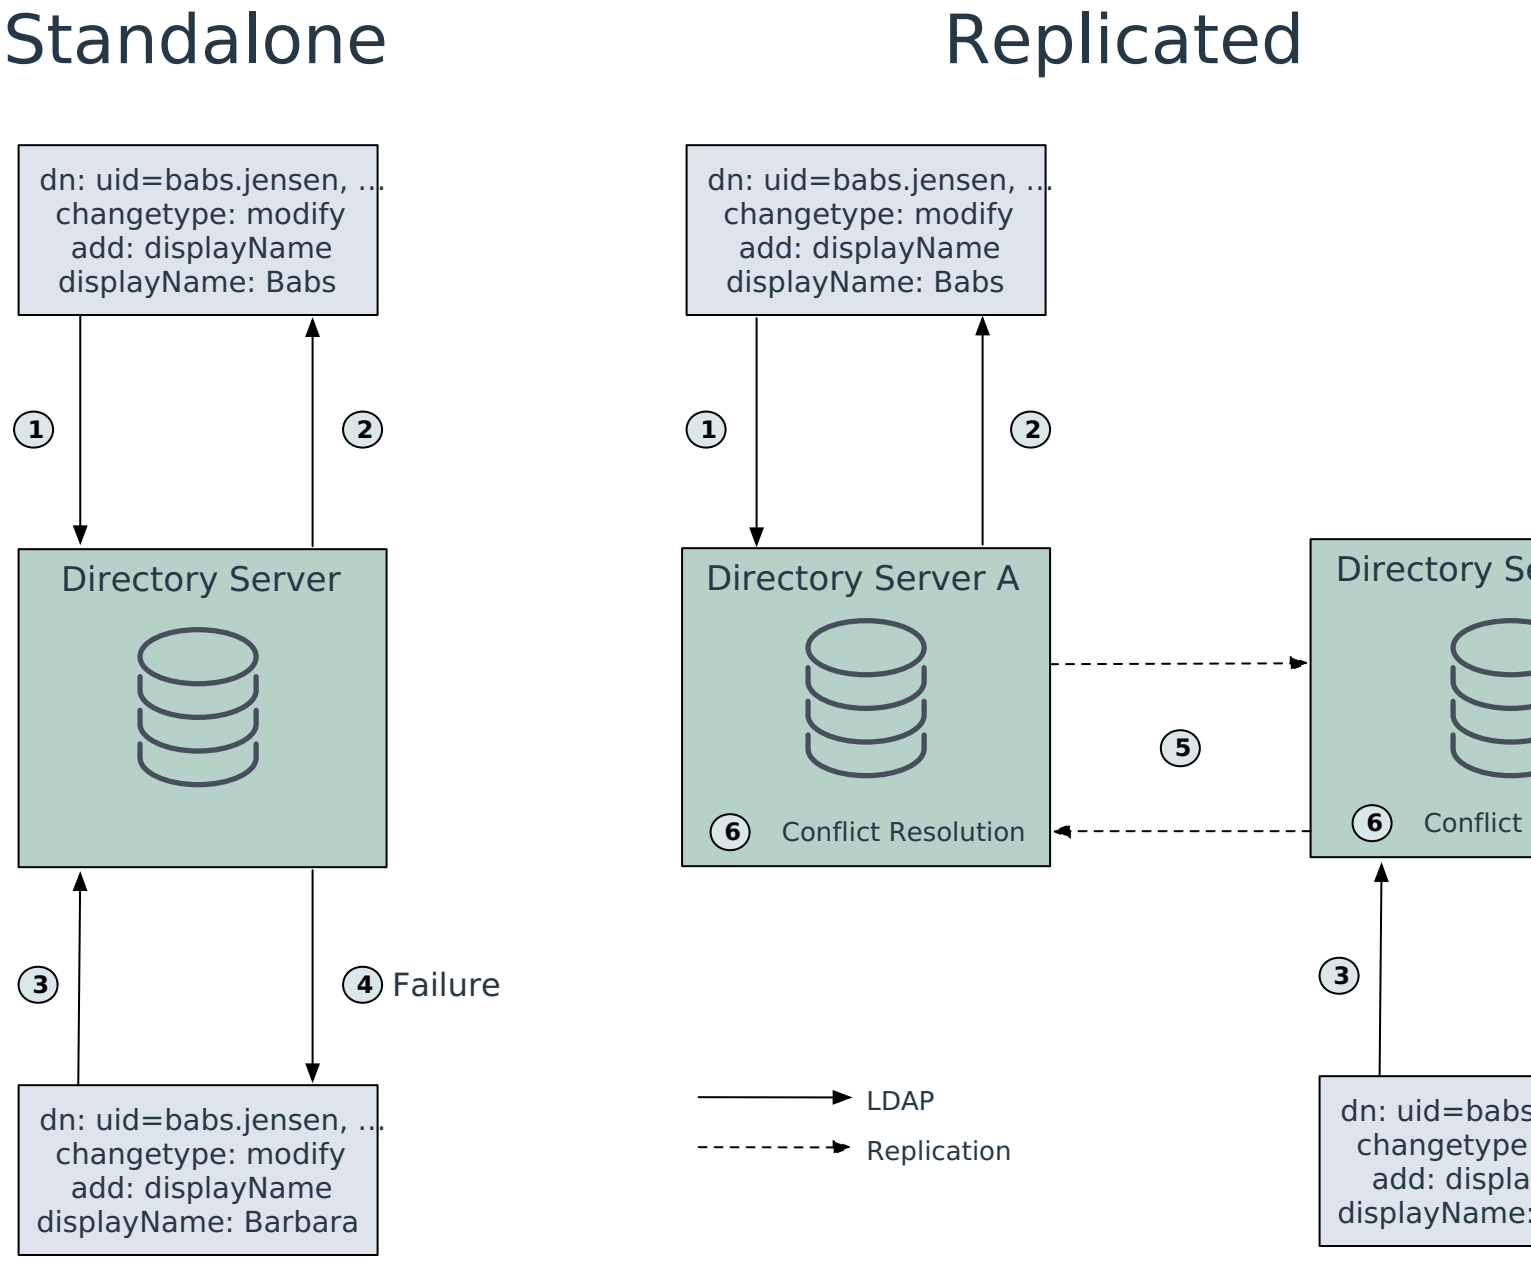
This section provides in-depth information about the mechanisms and possible scenarios behind replication conflicts.

Updates to the PingDirectory server entries in a replication topology can happen independently because replication guarantees only eventual consistency and not strong consistency. The eventual consistency model enables applying conflicting changes at different PingDirectory server instances. In most cases, the PingDirectory server can resolve these conflicts automatically and in a consistent manner: for example, all server instances in a replication topology resolving each and every conflict the same way. However, in some scenarios, manual administrative action is required. For any of these unresolved conflicts, the administrator receives notification through administrative alerts.

Copyright © 2025 Ping Identity Corporation

On a high level, the conflict resolution algorithm tries to resolve conflicts as if the operations causing the conflict in a distributed environment apply to a single PingDirectory server instance. For example, if the same entry is added to two different PingDirectory server instances at about the same time, after these operations are replicated, both servers keep only the first entry added.

The following image highlights the differences between standalone versus replicated environments.



Processing steps

1. Client sends LDAP modify request to directory server and succeeds.
2. Client sends another LDAP modify request that conflicts with the first.
3. In the standalone case, the request is rejected. In the replicated case, the request succeeds.
4. Replication propagates the updates (replicated only).

Copyright © 2025 Ping Identity Corporation

5. Conflict resolution (replicated only): A ignores the update from B, and B sets the attribute value to the value on A.

Types of replication conflicts

There are two types of replication conflicts:

Naming conflicts

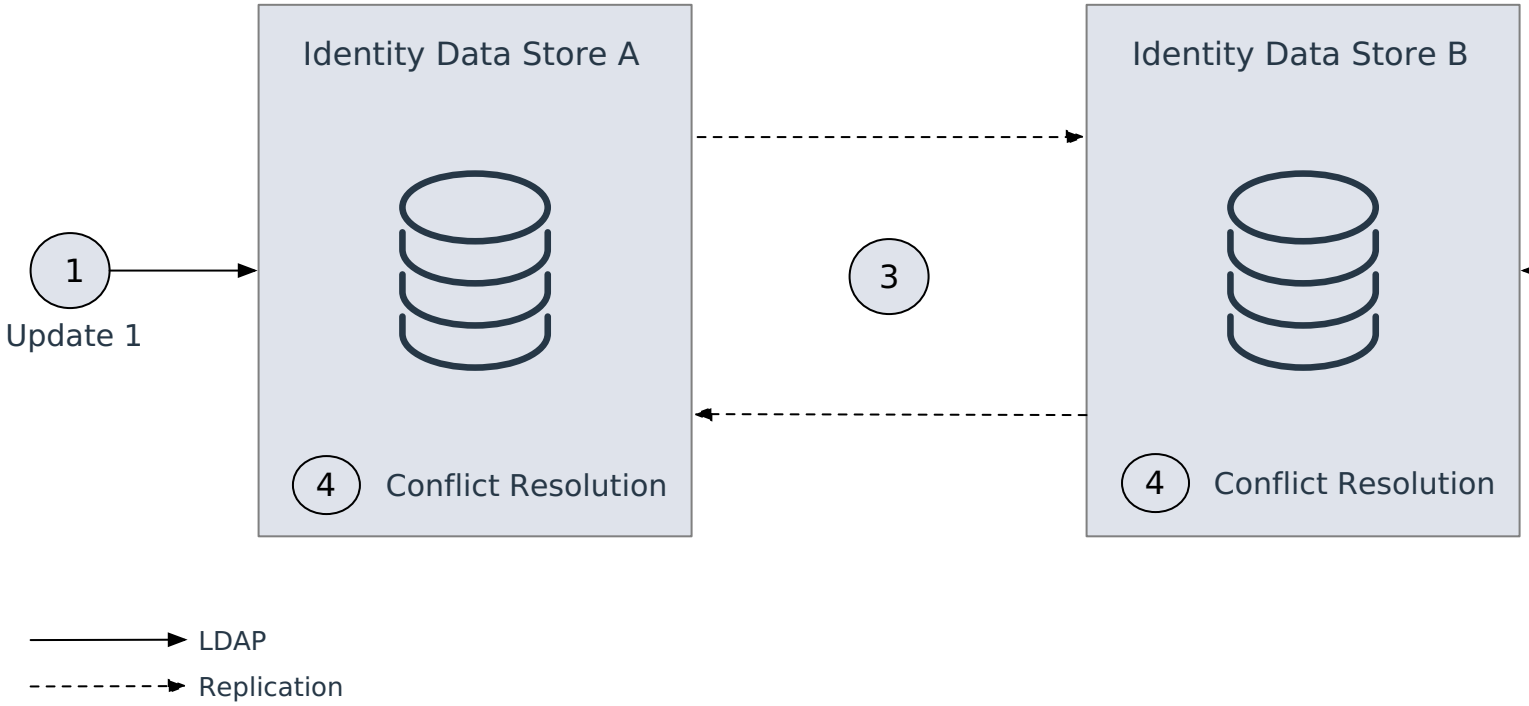
Naming conflicts include operations that cause conflicts with the naming of the distinguish name (DN) of the existing or new entries.

Modification conflicts

Modification conflicts include operations that result in conflicts in the modification of attributes.

Naming conflict scenarios

The following illustration depicts the naming conflict scenario.



Processing steps

1. The Client sends an update (Add, Delete, or Modify DN) request to server A.
2. The Client sends an update (Add, Delete, or Modify DN) request conflicting with the first request to server A.
3. Replication propagates the updates.
4. Conflict resolution takes place.

The following table shows the result of a modification conflict depending on the type of updates that occur. The code does not compare change sequence numbers (CSNs) but applies operations in the order they were received. This might lead to inconsistent replays.

Copyright © 2025 Ping Identity Corporation

For all of the naming conflict scenarios, assume the following:

- Update 1 was applied at PingDirectory server 1.
- Update 2 was applied at PingDirectory server 2.
- Update 1 occurred shortly before Update 2 so that PingDirectory server 2 received Update 1 after Update 2 was applied.

Naming Conflict Scenarios

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at PingDirectory server 2 When Update 1 is received
`Modify`	`Delete`	Yes	`Modify` is discarded.
`Modify`	`Modify DN`	Yes	New entry is located based on the entryUUID and `Modify` is applied to the renamed entry.
`Delete`	`Delete`	Yes	`Delete` operation is ignored.
`Delete`	`Modify DN`	Yes	`Delete` operation is applied to the renamed entry.
`Delete` of A	`Add` of B under A	Yes	Entry B is renamed and Entry A is deleted.
`Modify DN`	`Delete` of the same entry targeted by the `Modify DN`	Yes	`Modify DN` operation is ignored.
`Modify DN` with a new parent	`Delete` of parent	No	The entry targeted in the `Modify DN` operation is marked as a conflict entry.
`Modify DN` with a new parent	`Modify DN` of the parent	Yes	The entry is moved under the new DN of the parent.
`Modify DN` of A with new DN B	`Modify DN` of C with new DN B	No	A and B will be conflict entries.
`Add` A	`Modify DN` of the parent of A	Yes	The entry is added under the new DN of the parent.
`Add` A	`Delete` of the parent of A	No	The added entry is marked as a conflict entry.
`Add` A	`Add` A with same set of attributes	Yes	The entryUUID of the incoming Add operation applied to the existing entry.
`Add` A	`Add` A with different set of attributes (or values)	No	The existing entry is marked as a conflicting entry and the incoming `Add` is executed.

Copyright © 2025 Ping Identity Corporation

Modification conflict scenarios

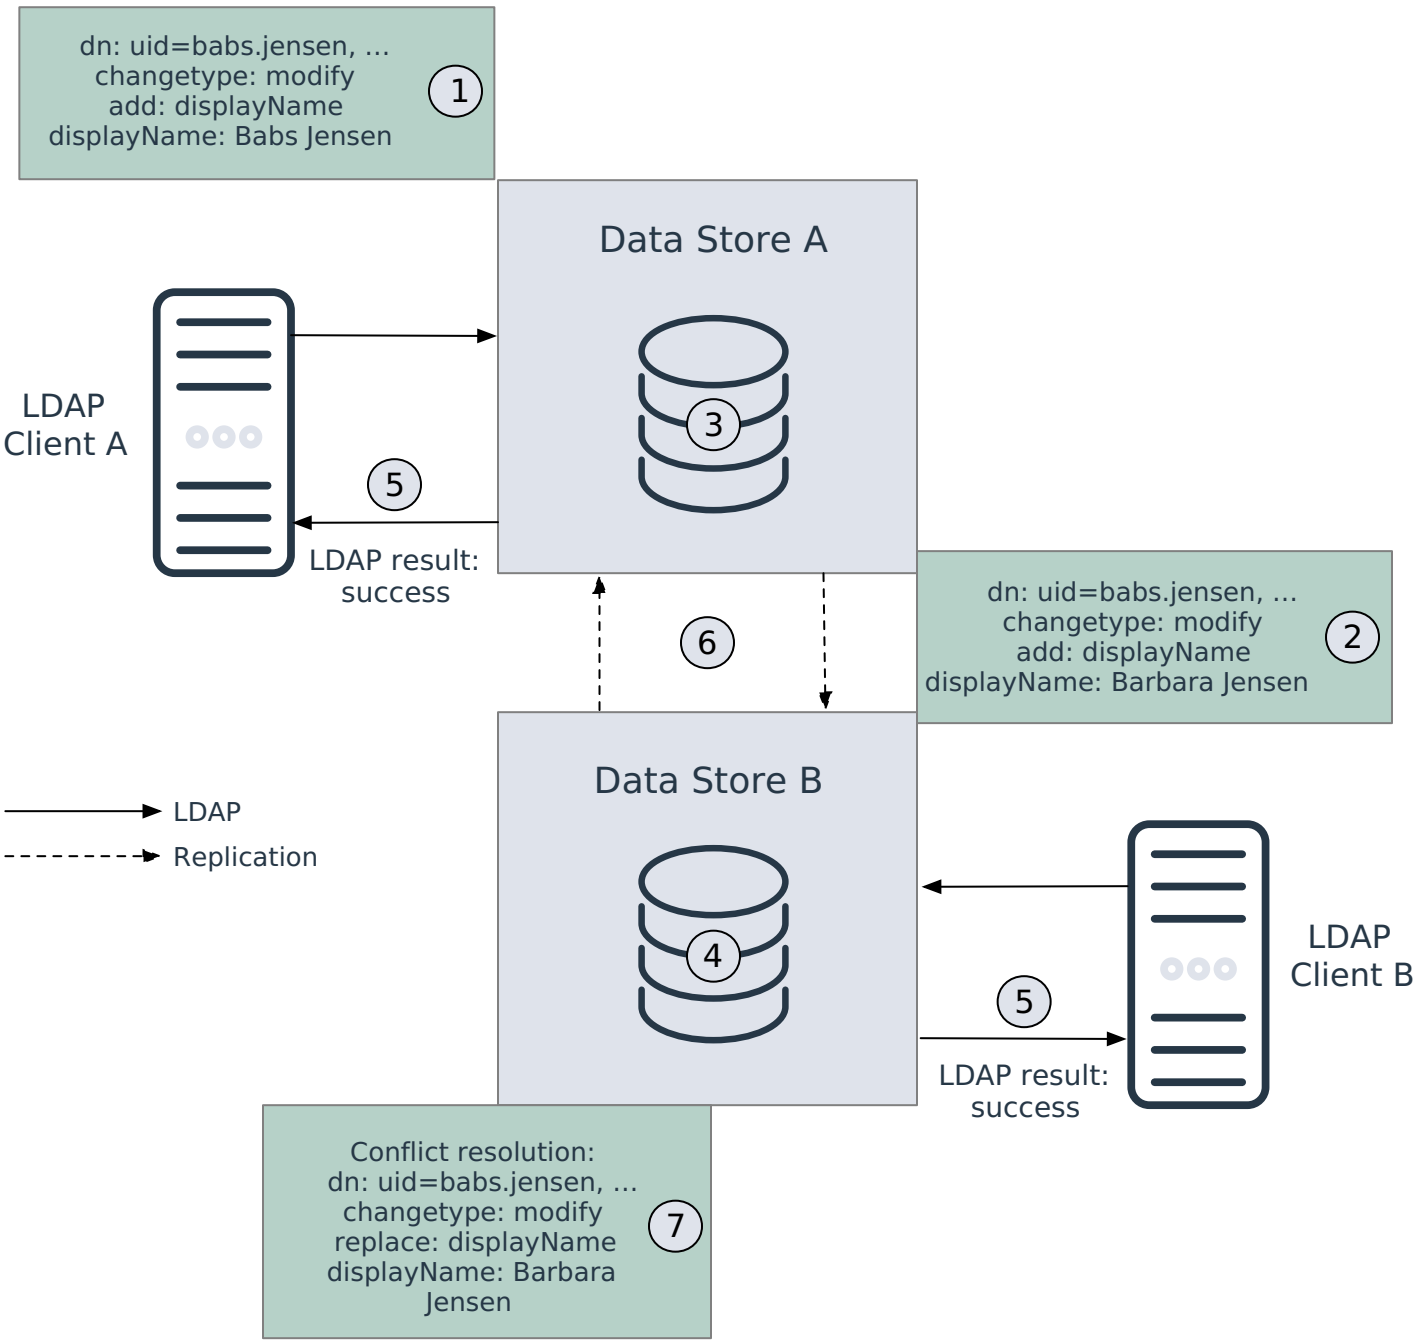
Modification conflicts resolve automatically and no manual action is required. The `LDAPModify` operation allows the following modification types:

- Add of one or more values
- Delete of one or more values or the entire attribute
- Replacement of all values

> **Note**
>
> Replication does not currently support the increment LDAP modification type.

The following illustration presents a modification conflict scenario.

Copyright © 2025 Ping Identity Corporation



Processing steps

1. LDAP client A sends a `modify` request to directory server A.
2. LDAP client B sends a conflicting `modify` request to directory server B.
3. Directory server A applies the modification.
4. Directory server B applies the modification.
5. The LDAP clients receive successful responses.
6. Replication propagates the updates.

Copyright © 2025 Ping Identity Corporation

7. Conflict resolution on directory server A updates the entry to reflect the value on directory server B.

   Conflict resolution on directory server B ignores the update received from directory server A.

The following table shows the result of a modification conflict depending on the type of updates that occur. For all of the operations in the table, assume the following:

- LDAP Modify 1 was applied at PingDirectory server 1.
- LDAP Modify 2 was applied at PingDirectory server 2.
- LDAP Modify 1 occurred shortly before LDAP Modify 2, so that PingDirectory server 2 received LDAP Modify 1 after LDAP Modify 2 was applied.

Modification Conflict Scenarios

Modify 1	Modify 2	Result of Conflict Resolution at PingDirectory server 2 When Modify 1 is received
`Add` of a single-value attribute	`Add` of the same attribute with a different value	Incoming `Modify` is ignored.
`Delete` of a single-valued attribute	Replacement of the value of the same attribute	Incoming `Delete` is ignored.
Replacement of a single-valued attribute	`Delete` of the same attribute	Incoming Replacement is ignored.
`Delete` some values from a multi-valued attribute	`Delete` some values from a multi-valued attribute	Incoming `Delete` is ignored.
`Delete` a multi-valued attribute	`Delete` of the same multi-valued attribute	Incoming `Delete` is ignored.
`Delete` a multi-valued attribute	`Add` the same multi-valued attribute	Incoming `Delete` is ignored.
`Delete` value X from a multi-valued attribute	`Delete` value X from the same multi-valued attribute	Incoming `Delete` is ignored.
`Delete` value X from a multi-valued attribute	`Add` value Y to the same multi-valued attribute	`Delete` of value X is applied.
`Delete` value X from a multi-valued attribute	`Delete` value Y from the same multi-valued attribute	`Delete` of value X is applied.
`Delete` value X from a multi-valued attribute	Replace all values of the same multi-valued attribute	Incoming `Delete` is ignored.
`Add` of values X and Y to a multi-valued attribute	`Delete` value X from the same multi-valued attribute	Only value Y is added.

Copyright © 2025 Ping Identity Corporation

Modify 1	Modify 2	Result of Conflict Resolution at PingDirectory server 2 When Modify 1 is received
`Delete` value X from a multi-valued attribute	`Add` of values X and Y to the same multi-valued attribute	Incoming `Delete` is ignored.

Troubleshooting replication

This section covers information on troubleshooting your replication deployment.

Discovering obsolete replicas

About this task

To avoid entering lockdown mode when upgrading servers in a replicated topology, before upgrading, check the `replicationChanges` database for any obsolete replicas. To perform this check, run the `check-replication-domains` tool, which scans `changelogDb` for all known replication domains and identifies any obsolete replicas still listed as part of a topology.

Steps

1. Run `check-replication-domains --serverRoot <serverRootDirectory>`.

   > **Note**
   >
   > You can use the `--serverRoot` argument to specify the root directory where the server containing the replication data is installed. If you don't supply this argument, `check-replication-domains` uses the default value of the server where you run the tool.

2. Review the output for any replica IDs listed as `Obsolete`.

   Example:

   The following is an example output from the `check-replication-domains` tool:

Copyright © 2025 Ping Identity Corporation

```
Server topo-1
[pinguser@topo-1 ~]$ PingDirectory/bin/check-replication-domains --serverRoot PingDirectory/

SERVER           DOMAIN DN                ID
---------------- ------------------------ ------
topo-1           cn=schema                20693 (local)
topo-1           dc=example,dc=com        23135 (local)
topo-2           cn=schema                8371
topo-2           dc=example,dc=com        19233

Server topo-2
[pinguser@topo-2 ~]$ PingDirectory/bin/check-replication-domains --serverRoot PingDirectory/

SERVER           DOMAIN DN                ID
---------------- ------------------------ ------
<unknown>        dc=example,dc=com        7403  OBSOLETE
topo-1           cn=schema                20693
topo-1           dc=example,dc=com        23135
topo-2           cn=schema                8371 (local)
topo-2           dc=example,dc=com        19233 (local)
```

Next steps

If you identified any obsolete replicas, purge the obsolete replicas.

Recovering a replica with missed changes

If a server has been offline for a period of time longer than the replication purge delay, you must run the `dsreplication initialize` command to bring the replica into sync with the topology.

Any missed changes are detected at the time of server startup. A missed change is a change that the replica detects it needs, but the change is not found within any other replication server's replicationChanges backend stored in the `/changelogDb` server root path.

If missed changes are detected, the server enters lockdown mode, where only privileged clients can make requests. Any other server that is not missing changes can be used as a source for `dsreplication initialize`.

If the server requires a manual backup and restore, perform the following steps, which are equivalent to `dsreplication initialize`.

Performing a manual initialization

About this task

The PingDirectory server provides the tools necessary for backing up and restoring backends, which can be used to manually initialize a replica.

As detailed in the following procedure, you use `<server-root>/bin/backup` to create a backup of the backend containing the replicated base DN. If encryption is enabled for the backend containing the replicated base DN, then you must also make a backup of the `encryption-settings` backend.

When initializing a server that has been offline longer than the `replication-purge-delay`, you must also make backups of the `replicationChanges` and `schema` backends.

Copyright © 2025 Ping Identity Corporation

You then need to transfer all backup files to the target server(s) and restore them individually using `<server-root>/bin/restore`.

> **Note**
>
> To preserve existing encryption settings, `<server-root>/bin/restore` appends to the `encryption-settings` database as opposed to replacing it.

To manually initialize a server when an online initialization isn't possible:

Steps

1. From another server in the replication topology, back up the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends to the `<server-root>/bak` directory.

   > **Tip**
   >
   > If data encryption is enabled, export the `encryption-settings` backend, because you might need to import one or more encryption settings IDs into the new replica.

   Example:

   ```
   $  <source-server-root>/bin/backup --backendID userRoot --backupDirectory \
      bak/userRoot
   $  <source-server-root>/bin/backup --backendID schema --backupDirectory \
      bak/schema
   $  <source-server-root>/bin/backup --backendID changelog --backupDirectory \
      bak/changelog
   $  <source-server-root>/bin/backup --backendID replicationChanges \
      --backupDirectory bak/replicationChanges
   $  <source-server-root>/bin/encryption-settings export --id <id> \
      --output-file bak/exported-key
   ```

2. Copy the `bak` directory to the new replica.

   Example:

   ```
   $ scp -r  <source-server-root>/bak/* \
       <user>@<destination-server>:<destination-server-root>/bak
   ```

3. Stop the server.

4. Restore the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends.

   > **Important**
   >
   > If the `encryption-settings` backend was exported, import it before restoring any of the backends.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$  <destination-server-root>/bin/encryption-settings import --input-file \
   bak/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
$  <destination-server-root>/bin/restore --backupDirectory bak/userRoot
$  <destination-server-root>/bin/restore --backupDirectory bak/schema
$  <destination-server-root>/bin/restore --backupDirectory \
bak/changelog
$  <destination-server-root>/bin/restore --backupDirectory \
   bak/replicationChanges
```

5. Start the server using `bin/start-server`.

Fixing replication conflicts

Replication conflicts occur when an incompatible change to an entry is made on two replicas at the same time. The change processes on one replica and then replicates to the other replica, which causes the conflict. While most conflicts resolve automatically, some require manual action.

To fix replication conflicts, initialize the replica containing the conflicts with the data from another replica that does not have conflicts. If the database is large and the number of conflicts is small, and the command includes the Replication Repair Control specified by OID value `1.3.6.1.4.1.30221.1.5.2`, run `ldapmodify` against the server with the conflict. The Replication Repair Control prevents the change from replicating and enables changing operational attribute values, which are not normally writable.

The following tasks use the Replication Repair Control to fix replication conflicts and apply change only to the server with the conflict. There are two examples provided to fix replication conflicts: one for fixing a modify conflict using the `ldap-diff` tool and the other for fixing a naming conflict.

Fixing a modify conflict

Steps

1. To isolate conflicting entries between two replicas, use the `bin/ldap-diff` tool.

> **Note**
>
> Replace the `sourceHost` value with the server that needs the adjustment.

Example:

The following example uses the tool to search across the entire base distinguish name (DN) for any difference in user attributes and reports the difference in `difference.ldif`.

```
$ bin/ldap-diff \
  --sourceHost austin02.exmple.com --sourcePort 1389 \
  --sourceBindDN "cn=Directory Manager" --sourceBindPassword pass \
  --targetHost austin01.example.com --targetPort 1389 \
  --targetBindDN "cn=Directory Manager" --targetBindPassword \
  --baseDN "dc=example,dc=com" --outputLDIF difference.ldif \
  --searchFilter "(objectclass=*)" --numPasses 3 "*" pass \
  "^userPassword"
```

Copyright © 2025 Ping Identity Corporation

2. To apply changes to the server that contains conflicts, use the `difference.ldif` file in a format compatible with `ldapmodify`.

   > **Important**
   >
   > Run `ldap-diff` command with the `sourceHost` value as the server with conflicts.

   Example:

   The following is an example of the contents of `difference.ldif` file.

   ```
   dn: uid=user.1,ou=people,dc=example,dc=com
                          changetype: modify
                          add: mobile
                          mobile: +1 568 232 6789
                          -
                          delete: mobile
                          mobile: +1 568 591 7372
                          -
   ```

3. To correct the entries on the sole server with conflicts, run `bin/ldapmodify`.

   Example:

   ```
   $ bin/ldapmodify --bindPassword <password> -J "1.3.6.1.4.1.30221.1.5.2" \
     --filename difference.ldif
   ```

Fixing a naming conflict

About this task

In this example, a naming conflict was encountered when the replica attempted to replay an `ADD` of `uid=user.200,ou=people,dc=example,dc=com`. Because of this conflict, the server returns a replication conflict message. See the following example message.

```
[18/Feb/2010:14:53:12 -0600] category=EXTENSIONS severity=SEVERE_ERROR
msgID=1880359005 msg="Administrative alert type=replication-unresolved-conflict
id=bbd2cbaf-90a4-42af-94a8-c1a42df32fc6
class=com.unboundid.directory.server.replication.plugin.ReplicationDomain
msg='An unresolved conflict was detected for DN uid=user.200,ou=People,dc=example,dc=com.
The conflicting entry has been renamed to
entryuuid=69807e3d-ab27-43a3-8759-ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com'"
```

The PingDirectory server prepends the entryUUID to the DN of the conflicting attribute and adds a `ds-sync-conflict-entry` auxiliary object class to the entry to aid in search.

To resolve the conflict:

Steps

1. Search for any entry that has the `ds-sync-conflict-entry` objectclass and returns only the DNs that match the filter.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub \
  "(objectclass=ds-sync-conflict-entry)" "1.1"
```

Result:

The search results display the conflicting entry for uid=user.200.

```
dn: entryuuid=69807e3d-ab27-43a3-8759-ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com

dn: entryuuid=523c430e-a870-4ebe-90f8-9cd811946420+uid=user.200,ou=People,dc=example,dc=com
```

> **Note**
>
> Conflict entries are not returned unless the `objectclass=ds-sync-conflict-entry` is present in the search filter.

2. Compare the conflict entry with the target entry.
3. Apply the difference in two ways:

   Choose from:

   - Use the `ldapmodify` tool with the Replication Repair Control.

     > **Note**
     >
     > You can also delete the conflict entry using this command.

   - Run `bin/ldapmodify` with the Replication Repair Control to make the fix.

     > **Note**
     >
     > When making changes using the Replication Repair Control, the updates are not propagated through replication. Examine each replica individually, and apply the necessary modifications using the request control.

     Example:

     ```
     $ bin/ldapmodify -J "1.3.6.1.4.1.30221.1.5.2" \
       --filename difference.ldif
     ```

Fixing mismatched generation IDs

About this task

If you receive a warning message that multiple generation IDs were detected for a specific suffix, you must re-initialize one or more replicas. If the warning is presented from a server after an initialization, it could be that the `post-external-initialization` command was not run as part of a global change in data.

Try the following fixes as needed.

Copyright © 2025 Ping Identity Corporation

Steps

- To re-initialize replicas as part of a global change in data, run the `post-external-initialization` command.
- To fix mismatchd generation IDs, run the `dsreplication` command.
- To warn when any generation IDs are different across the topology, run the `dsreplication` tool with the `status` command.

Replication reference

This section covers general reference information about replication.

Summary of the dsreplication Subcommands

Use this topic as a reference for `dsreplication` subcommands and functions and their descriptions.

The following table presents a summary of the `dsreplication` subcommands and functions.

> **Tip**
>
> To see the available options for each subcommand, run `bin/dsreplication <subcommand> --help` .

Subcommand	Description
`disable`	Disables replication on the specified server for the provided base distinguish name (DN) and removes references to this server in the other servers with which it is replicating data.
`enable`	Updates the configuration of the servers to replicate the data under the specified base DN. If one of the servers is already replicating the data under the base DN with other servers, executing this subcommand updates the configuration of all the servers. It is sufficient to execute the command line one time for each server you add to the replication topology.
`initialize`	Initializes the data under the specified base DN on the destination server with the contents on the source server.
`initialize-all`	Initializes the data under the specified base DN on all servers in the replication topology with the contents on the specified server.

Copyright © 2025 Ping Identity Corporation

Subcommand	Description
`post-external-initialization`	Used with `pre-external-initialization`, the command resets the generation ID based on the newly-loaded data. Consider the following using this subcommand: • You must call this subcommand after initializing the contents of all the replicated servers using the `import-ldif` tool or `dsreplication initialize`. • Specify the list of base DNs that have been initialized and provide the credentials of any of the servers that are being replicated. For more information, see the usage of the `pre-external-initialization` subcommand. • This subcommand only needs to be run one time on one of the replicas.
`pre-external-initialization`	Clears the existing generation ID and removes all accumulated changes of the replicated suffix from the Replication Changelog Database on every replication server. Consider the following using this subcommand: • Use this subcommand when globally restoring the replicas on all of the servers in a topology. • You must specify the list of base DNs that will be initialized and provide the credentials of any of the servers that are being replicated. • After calling this subcommand, initialize the contents of all the servers in the topology, then call the `post-external-initialization` subcommand. • You only need to run this subcommand one time on one of the replicas.
`status`	Displays the status of replication domains. If no base DNs are specified as parameters, the information for all base DNs displays. Available options with the status subcommand are: • `--showAll` • `--displayServerTable` • `--location`

Summary of the Direct LDAP Monitor information

The following table provides a description of the attributes in the `cn=Direct LDAP Server` monitor entry.

The following is the distinguished name (DN) for the monitor entry.

```
dn: cn=Direct LDAP Server <baseDN> <host name:ldapPort> <serverID>,cn=monitor
```

Copyright © 2025 Ping Identity Corporation

Direct LDAP Monitor Information

Monitor Attribute	Description
`replica-id:<serverID>`	Replica ID number.
`replication-backlog`	Number of changes that the replication server has not seen from the server.
`missing-changes`	Number of missing changes.
`approximate-delay`	Difference between the time of the last change that the replication server has seen from the LDAP server and the most current timestamp on the latest change on the server.
`base-dn`	Base DN
`ssl-encryption`	Flag to indicate if SSL encryption is in use.
`protocol-version`	Displays the replication protocol version.
`generation-id`	Generation ID for the base DN on the PingDirectory server.
`restricted`	Boolean that indicates whether the replication domain is restricted in an Entry Balancing Configuration with the Directory Proxy Server.
`ack-sent`	Number of acknowledgment messages sent to this replica not currently used.
`ack-received`	Number of acknowledgment messages received from this replica not currently used.
`add-sent`	Number of protocol messages with an `LDAPAdd` sent to this replica.
`add-received`	Number of protocol messages with an `LDAPAdd` received from this replica.
`delete-sent`	Number of protocol messages with an `LDAPDelete` sent to this replica.
`delete-received`	Number of protocol messages with an `LDAPDelete` received from this replica.
`done-sent`	Number of done messages sent to this replica. A done message indicates an end of an online initialization session. If the value is non-zero, then this replica has been initialized over the replication protocol.
`done-received`	Number of done messages received from this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has completed the initialization of other replicas over the replication protocol.
`entry-sent`	Number of entry messages sent to this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
`entry-received`	Number of entry messages received from this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`error-sent`	Number of error messages sent to this replica.
`error-received`	Number of error messages received from this replica.
`heartbeat-sent`	Number of heartbeat messages sent to this replica.
`heartbeat-received`	Number of heartbeat messages received from this replica. **Note** The number of messages should always be 0 because the replica never sends a heartbeat message to the server.
`initialize-request-sent`	Number of initialize-request messages sent to this replica. This message is sent when another replica requested initialization of its data using the replication protocol.
`initialize-request-received`	Number of initialize-request messages received from this replica. This message is sent when this replica requested initialization of its data using the replication protocol from another replica.
`initialize-target-sent`	Number of initialize-target messages sent to this replica. This message is sent before another replica has started the initialization of this replica.
`initialize-target-received`	Number of initialize-target messages received from this replica. This message is sent before this replica starts the initialization of one or more replicas.
`ldap-server:<hostname:ldapPort>`	The host name and port of the local replication server.
`modify-sent`	Number of protocol messages with an `LDAPModify` sent to this replica.
`modify-received`	Number of protocol messages with an `LDAPModify` received from this replica.
`modify-dn-sent`	Number of protocol messages with an `LDAPModify` DN sent to this replica.
`modify-dn-received`	Number of protocol messages with an `LDAPModify` DN received from this replica.
`repl-server-start-sent`	Number of replication-server-start messages sent to this replica. The Replication Server responds with this message to the start message received from the replica. **Note** The number of messages should never be more than 1.
`repl-server-start-received`	Number of replication-server-start messages received from this replica. **Note** The number of messages should always be 0.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`reset-generation-id-sent`	Number of reset generation ID messages received from this replica.
`reset-generation-id-received`	Number of reset generation ID messages sent to this replica. **Note** The number of messages should always be 0.
`server-start-sent`	Number of server-start messages sent to this replica. **Note** The number of messages should always be 0.
`server-start-received`	Number of server-start messages received from this replica. Server-start is the first message the replica sends after establishing a replication connection. **Note** The number of messages should never be more than 1.
`window-sent`	Number of window messages sent to this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
`window-received`	Number of window messages received from this replica. Window messages are used for cumulative acknowledgment in the replication protocol.
`window-probe-sent`	Number of window probe messages sent to this replica. **Note** The number of messages should always be 0.
`window-probe-received`	Number of window probe messages received from this replica. The replica sends a window probe message to the server if the send window in the replica is closed and the replica is unable to publish updates to the server.
`update-sent`	Number of changes sent to this server.
`update-received`	Number of changes received from this server.
`internal-connection`	Indicates if the replica is in the same process as the replication server.
`server-state`	Displays the state of the replica. Displays the latest change number that the replica has seen from all the other replicas including itself.
`consumed-update-recent-rate`	Rate that the connected PingDirectory server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`consumed-update-peak-rate`	Highest rate that the connected PingDirectory server has consumed updates sent by this replication server, measured over a 5 second period from the start of the replication server.
`produced-update-recent-rate`	Rate that the connected PingDirectory server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
`produced-update-peak-rate`	Highest rate that the connected PingDirectory server has sent updates to this replication server, measured over a 5 second period from the start of the replication server.
`max-send-window`	Maximum number of changes that can send to the LDAP server before requiring an ACK.
`current-send-window`	Current number of changes remaining to be sent to the LDAP server before requiring an ACK.
`max-rcv-window`	Maximum number of changes that can be received by the LDAP server before sending an ACK.
`current-rcv-window`	Number of changes remaining to be received by the LDAP server before sending an ACK.
`degraded`	Indicates that the generation ID of the replica does not match the generation ID of the server. When loading data into the topology, this is a temporary state. If this is not a temporary state, the replica has not been initialized. **Note** The `degraded` value should be false.

Summary of the Indirect LDAP Server Monitor information

Use this topic as a reference for Indirect LDAP Server Monitor attribute information.

These attributes provide information about a PingDirectory server that is connected to a different replication server in the topology.

The following is the distinguished name (DN) for the Indirect LDAP server monitor entry.

```
dn: cn=Indirect LDAP Server <baseDN> <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Indirect LDAP Server` monitor entry.

Monitor Attribute	Description
`replica-id: <serverID>`	ID number identifying the replica
`base-dn:<baseDN>`	Base DN

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`connected-to: Remote Repl Server <baseDN> <host name:replPort> <repl ID>`	Replication server to which the directory server is connected
`replication-backlog`	Number of changes that the replication server has not seen from the server
`approximate-delay`	Amount of time between the last change seen by this PingDirectory server and the most recent change seen by the remote replication server. **Note** This value is the amount of time between the time stamps, not the amount of time required to synchronize the 2 servers.
`generation-id`	Generation ID for this suffix on this remote replication server
`consumed-update-recent-rate`	Rate that the connected Replication Server is consuming updates sent by this replication server This value is expressed as the number of updates per second and measured over the last 5 seconds.
`consumed-update-peak-rate`	Highest rate that the connected Replication Server has consumed updates sent by this replication server This value is measured over a 5 second period beginning at the start of the replication server.

Summary of the Remote Replication Server Monitor information

Use this topic as a reference for Remote Replication Server Monitor attribute information.

The following is the distinguished name (DN) for the Remote Replication Server monitor entry.

```
dn: cn=Remote Repl Server <baseDN> <host name:replPort> <serverID>,cn=monitor
```

The following table provides a description of the attributes in the `cn=Remote Repl Server` monitor entry.

Monitor Attribute	Description
`replication-server: <host name>:<repl port>`	Host name and replication port number of the Replication Server.
`replication-server-id:<serverID>`	Server ID for the Replication Server.
`available`	Indicates if the remote replication server is available or not. Values: `true` or `false`.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`sending-paused`	Indicates if sending is paused. Values: `true` or `false`.
`receiving-paused`	Indicates if receiving is paused. Values: `true` or `false`.
`wan-gateway-priority`	Specifies the WAN Gateway priority of the remote replication server.
`is-wan-gateway`	Indicates if the remote replication server is a WAN Gateway. Values: true or false.
`wan-gateway-desired`	Indicates if the remote replication server is a desired gateway. Values: `true` or `false`. This entry together with the `is-wan-gateway` property indicates the desired state. **`is-wan-gateway=false, wan-gateway-desire=false`** Indicates another server with a higher gateway priority exists or the gateway priority is set to disabled. **`is-wan-gateway=false, wan-gateway-desire=true`** Indicates that the remote replication server wants to be a WAN gateway. **`is-wan-gateway=true, wan-gateway-desire=false`** Indicates that the remote replication server wants to give up its role as a WAN gateway. **`is-wan-gateway=false, wan-gateway-desire=true`** Indicates the remote replication server wants to remain as a gateway server.
`base-dn`	base DN
`ssl-encryption`	Flag to indicate if SSL encryption is in use.
`protocol-version`	Replication protocol version.
`generation-id`	Generation ID for this suffix on this remote replication server.
`restricted`	Indicates that remote replication server is in an entry-balancing deployment.
`add-sent`	Number of protocol messages with an `ldapadd` sent to the remote replication server.
`add-received`	Number of protocol messages with an `ldapadd` received from the remote replication server.
`delete-sent`	Number of protocol messages with an `ldapdelete` sent to the remote replication server.
`delete-received`	Number of protocol messages with an `ldapdelete` received from the remote replication server.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`done-sent`	Number of done messages sent to the remote replication server. A done message indicates an end of online initialization session.
`done-received`	Number of done messages received from the remote replication server. A done message indicates an end of online initialization session.
`entry-sent`	Number of entry messages sent to the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
`entry-received`	Number of entry messages received from the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
`error-sent`	Number of error messages sent to the remote replication server.
`error-received`	Number of error messages received from the remote replication server.
`heartbeat-sent`	Number of heartbeat messages sent to the remote replication server.
`heartbeat-received`	Number of heartbeat messages received from the remote replication server.
`initialize-request-sent`	Number of initialize-request messages sent to the remote replication server. This message is used during online initialization from one replica to another.
`initialize-request-received`	Number of initialize-request messages received from the remote replication server. This message is used during online initialization from one replica to another.
`initialize-target-sent`	Number of initialize-target messages sent to the remote replication server. This message is used before online initialization from one replica to another.
`initialize-target-received`	Number of initialize-target messages received from the remote replication server. This message is used before online initialization from one replica to another.
`modify-sent`	Number of protocol messages with an `ldapmodify` sent to the remote replication server.
`modify-received`	Number of protocol messages with an `ldapmodify` received from the remote replication server.
`modify-dn-sent`	Number of protocol messages with an `ldapmodify` DN sent to the remote replication server.
`modify-dn-received`	Number of protocol messages with an `ldapmodify` DN received from the remote replication server.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`monitor-sent`	Number of monitor messages sent to the remote replication server. This message is used when communicating with PingDirectory servers running an earlier release.
`monitor-received`	Number of monitor messages received from the remote replication server. This message is primarily used when communicating with a PingDirectory server running an earlier release.
`monitor-request-sent`	Number of monitor requests sent to the remote replication server. The receiving server responds with a monitor message that includes server's information about the state of the topology.
`monitor-request-received`	Number of monitor requests received from the remote replication server. This server responds with a monitor message that includes server's information about the state of the topology.
`monitor-v2-sent`	Number of monitor messages sent to the remote server. **Note** This monitor message is only used with PingDirectory server 3.5 or later.
`monitor-v2-received`	Number of monitor messages received from the remote server. **Note** This monitor message is only used with PingDirectory 3.5 or later.
`pause-sending-updates-sent`	Number of pause-sending-updates messages sent to the remote server. The remote server must stop sending update messages to this server when receiving this message.
`pause-sending-updates-received`	Number of `pause-sending-updates` messages received from the remote server. This server stops sending update messages to the remote server when it receives this message.
`repl-server-start-sent`	Number of `replication-server-start` messages sent to the remote replication server. The Replication Server responds with this message to the `replication-server-start` message received from remote replication servers. **Note** The number of messages should never be more than 1.
`repl-server-start-received`	Number of `replication-server-start` messages received from the remote replication server. **Note** The number of messages should never be more than 1.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`reset-generation-id-sent`	Number of reset generation ID messages received from the remote replication server. This message is sent before and after the data is initialized in the topology.
`reset-generation-id-received`	Number of reset generation ID messages sent to the remote replication server. This message is sent before and after the data is initialized in the topology.
`server-info-sent`	Number of replication server information messages sent to the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
`server-info-received`	Number of replication server information messages received from the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
`set-source-location-sent`	Number of `set-source-locations` messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
`set-source-location-received`	Number of `set-source-locations` messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
`start-sending-updates-sent`	Number of `start-sending-updates` messages sent to the remote replication server. The remote server can only start sending updates to this server after receiving this message.
`start-sending-updates-received`	Number of `start-sending-updates` messages received from the remote server. Sending update messages to the remote server can only start after receiving this message.
`window-sent`	Number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.
`window-received`	Number of window messages received from the remote replication server. Window messages are used for cumulative acknowledgment in the replication protocol.
`messages-sent`	Total number of messages sent.
`messages-received`	Total number of messages received.
`update-sent`	Total number of updates sent.
`update-received`	Total number of updates received.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`server-state`	Displays the server state of the remote replication server. It displays the last change seen on the remote replication server.
`consumed-update-recent-rate`	Rate that the connected PingDirectory server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
`consumed-update-peak-rate`	Highest rate that the connected PingDirectory server has consumed updates sent by this replication server, measured over a 5 second period from the time the replication server was started.
`produced-update-recent-rate`	Rate that the connected PingDirectory server has sent updates to this replication server, expressed as the number of updates per second and measured over the last 5 seconds.
`produced-update-peak-rate`	Highest rate that the connected PingDirectory server has sent updates to this replication server, measured over a 5 second period since the replication server was started.
`max-send-window`	Maximum number of changes that can be sent to the remote replication server before requiring an ACK.
`current-send-window`	Number of changes remaining to be sent to the remote replication server before requiring an ACK.
`max-rcv-window`	Maximum number of changes that can be received from the remote replication server before sending an ACK.
`current-rcv-window`	Number of changes remaining to be received from the remote replication server before sending an ACK.
`degraded`	Indicates that the generation ID of the replica does not match the generation ID of the remote replication server. This is a temporary state when loading data into the topology or the replica has not been initialized. **Note** Normally, the `degraded` value should be `false`.

Summary of the Replica Monitor information

The following table provides a description of the attributes in the `cn=Replica` monitor entry for a specific base DN.

The following is the distinguished name (DN) for the Replica Monitor server monitor entry.

```
dn: cn=Replica <baseDN>,cn=monitor
```

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`base-DN: <baseDN>`	Specified base DN The monitor entries track your company's base DN or `base-DN: <baseDN>`, `dc=example,dc=com`, `cn=schema` `base-DN:` and `cn=topology,cn=config`.
`connected-to: Replication Server <replPort> <serverID>`	Replication port number and server ID of the replication server to which this LDAP Server is connected The first number is the replication server port number and the second number is the `server-id` of the replication server.
`lost-connections`	Number of times the server has lost connection to a replication server
`received-updates`	Number of updates that the server Replica has received from the connected replication server
`sent-updates`	Number of updates sent to the replication server.
`pending-updates`	Number of updates pending to send to the replication server.
`replayed-updates`	Total number of updates from the replication server that have been replayed for this replica.
`replayed-updates-ok`	Number of updates for this replica that have been successfully replayed with no conflicts.
`replayed-update-failed`	Number of updates for this replica that were successfully replayed after automatically resolving a modify conflict.
`resolved-modify-conflicts`	Number of updates for this replica that were successfully resolved after a modify conflict.
`resolved-naming-conflicts`	Number of updates for this replica that were successfully resolved after a naming conflict.
`unresolved-naming-conflicts`	Number of updates for this replica that could not be replayed because of an unresolvable naming conflict.
`replica-id`	Server ID for this replica.
`max-rcv-window`	Maximum number of changes that the server Replica can receive at a time before sending an acknowledgment back to the replication server.
`current-rcv-window`	Current received window size for this replica.
`max-send-window`	Maximum number of changes that the server Replica can send at a time to the replication server before requiring an ACK.
`current-rcv-window`	Number of changes remaining to be received from the replication server before it must send an ACK.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`max-send-window`	Maximum number of changes that the server Replica can send at a time to the replication server before requiring an ACK.
`current-send-window`	Number of changes remaining to be sent to the replication server before requiring an ACK.
`ssl-encryption`	Flag to indicate if SSL encryption is in use.
`generation-id`	Generation ID for this suffix on the server.
`replication-backlog`	Number of changes that are from this replica.

Summary of the Replication Server Monitor information

Use this topic as a reference for the Replication Server Monitor attributes and information.

The following is the distinguish name (DN) for the replication server monitor entry.

```
dn: cn=Replication Server,cn=monitor
```

The following table provides a description of the attributes in the `cn=Replication Server` monitor entry.

Attribute	Description
`replication-server-id`	Server ID for the Replication server ID
`replication-server-port`	Port number on which the replication server listens for communication from other servers
`base-dn:<baseDN>`	Indicates the suffix to which this replication server database applies
Generation IDs by Base DN	List of generation IDs for each base DN on the server
`num-outgoing-replication-server-connections`	Number of outgoing connections from the replication server
`num-incoming-replication-server-connections`	Number of incoming connections into the replication server
`num-incoming-replica-connections`	Number of incoming connections to the replica

Summary of the Replication Server Database Monitor information

The following table provides a description of the attributes in the `cn=Replication Server database` monitor entry.

Copyright © 2025 Ping Identity Corporation

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server database <baseDN> <replServerID>,cn=monitor
```

Replication Server Database Monitor Information

Monitor Attribute	Description
`database-replica-id:<replicaID>`	Specifies the replication server ID.
`base-dn: <baseDN>`	Indicates the suffix to which this replication server database applies.
`first-change`	First change number that is in this replication database table for this suffix from this `server-id`. The following is an example entry. `0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011`
`last-change`	Last change number that is in this replication database table for this suffix from this `server-id`. The following is an example entry. `0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011`
`queue-size`	Number of changes in the replication server queue waiting to be sent to this remote replication server database.
`queue-size-bytes`	Size in bytes of all the messages waiting in the queue.
`records-added`	Displays the number of records changed or added to the directory information tree (DIT).
`records-removed`	Displays the number of records removed from the DIT.

Summary of the Replication Server Database Environment Monitor information

The following table provides a description of the attributes in the `cn=Replication Server Database Environment` monitor entry, which includes the environment variables associated with the Oracle Berkeley Database Java Edition backend.

The following is the distinguished name (DN) for the Replica Server Database Monitor entry.

```
dn: cn=Replication Server Database Environment,cn=monitor
```

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`je-version`	Current version of the Oracle Berkeley Java Edition.
`current-db-cache-size`	Current database (DB) cache size.
`max-db-cache-size`	Maximum DB cache size.
`db-cache-percent-full`	Percentage of the cache used by the server.
`db-directory`	Directory that holds the changelogDb file.
`db-on-disk-size`	Size of the DB on disk.
`cleaner-backlog`	Number of log files that must be cleaned for the cleaner to meet its target utilization.
`random-read-count`	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
`random-write-count`	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
`sequential-read-count`	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
`sequential-write-count`	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
`nodes-evicted`	Accumulated number of nodes evicted.
`active-transaction-count`	Number of currently active transactions.
`num-checkpoints`	Number of checkpoints. A checkpoint is a process that writes to your log files all the internal BTree nodes and structures modified as a part of write operations to your log files to facilitate a quick recovery.
`checkpoint-in-progress: false`	Indicates if a checkpoint is in progress.
`total-checkpoint-duration-millis`	Total time in milliseconds for all checkpoints.
`average-checkpoint-duration-millis`	Average time in milliseconds for all checkpoints.
`last-checkpoint-duration-millis`	Duration in milliseconds of the last checkpoint run.
`last-checkpoint-start-time`	Start time of the last checkpoint.
`last-checkpoint-stop-time`	Stop time of the last checkpoint.
`millis-since-last-checkpoint`	Time in milliseconds since the last checkpoint.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`read-locks-held`	Total read locks currently held.
`write-locks-held`	Total write locks currently held.
`transactions-waiting-on-locks`	Total transactions waiting for locks.
`je-env-stat-AdminBytes`	Number of bytes of JE cache used for log cleaning metadata and other administrative structure.
`je-env-stat-BufferBytes`	Total memory currently consumed by log buffers, in bytes.
`je-env-stat-CacheDataBytes`	Total memory of cache used for data.
`je-env-stat-CacheTotalBytes`	Total amount of JE cache in use, in bytes.
`je-env-stat-CleanerBacklog`	Number of files to be cleaned to reach the target utilization.
`je-env-stat-CursorsBins`	Number of bottom internal nodes (BINs) encountered by the INCompressor that had cursors referring to them when the compressor ran. The compressor thread cleans up the internal BTree as records are deleted to ensure unused nodes are not present.
`je-env-stat-DataBytes`	Amount of JE cache used for holding data, keys and internal Btree nodes, in bytes.
`je-env-stat-DbClosedBins`	Number of bins encountered by the INCompressor that had their database closed between the time they were put on the compressor queue and when the compressor ran.
`je-env-stat-EndOfLog`	Location of the next entry to be written to the log.
`je-env-stat-InCompQueueSize`	Number of entries in the INCompressor queue when the `getStats()` call was made.
`je-env-stat-LastCheckpointEnd`	Location in the log of the last checkpoint end.
`je-env-stat-LastCheckpointId`	ID of the last checkpoint.
`je-env-stat-lastCheckpointStart`	Location in the log of the last checkpoint start.
`je-env-stat-lockBytes`	Number of bytes of Java Edition (JE) cache used for holding locks and transactions.
`je-env-stat-NBINsStripped`	Number of BINS stripped by the evictor.
`je-env-stat-NCacheMiss`	Total number of requests for database objects that were not in memory.
`je-env-stat-NCheckpoints`	Total number of checkpoints run so far.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`je-env-stat-NCleanerDeletions`	Number of cleaner file deletions this session.
`je-env-stat-NCleanerEntriesRead`	Accumulated number of log entries read by the cleaner.
`je-env-stat-NCleanerRuns`	Number of cleaner runs this session.
`je-env-stat-NClusterLNsProcessed`	Accumulated number of leaf nodes (LNs) processed because they qualify for clustering.
`je-env-stat-NDeltaINFlush`	Accumulated number of delta internal nodes (INs) flushed to the log.
`je-env-stat-NEvictPasses`	Number of passes made to the evictor.
`je-env-stat-NFSyncRequests`	Number of fsyncs requested through the group commit manager. `fsync()` synchronizes the file system after a write or a transaction.
`je-env-stat-NFSyncTimeouts`	Number of fsync requests submitted to the group commit manager which timed out.
`je-env-stat-NFSyncs`	Number of fsyncs issued through the group commit manager.
`je-env-stat-NFileOpens`	Number of times a log file has been opened.
`je-env-stat-NFullBINFlush`	Accumulated number of full BINs flushed to the log.
`je-env-stat-NFullINFlush`	Accumulated number of full INs flushed to the log.
`je-env-stat-NINsCleaned`	Accumulated number of INs cleaned.
`je-env-stat-NINsDead`	Accumulated number of INs that were not found in the tree anymore (deleted).
`je-env-stat-NINsMigrated`	Accumulated number of INs migrated.
`je-env-stat-NINsObsolete`	Accumulated number of INs obsolete.
`je-env-stat-NLNQueueHits`	Accumulated number of LNs processed without a tree lookup.
`je-env-stat-NLNsCleaned`	Accumulated number of LNs cleaned.
`je-env-stat-NLNsDead`	Accumulated number of LNs that were not found in the tree anymore (deleted).
`je-env-stat-NLNsLocked`	Accumulated number of LNs encountered that were locked.
`je-env-stat-NLNsMarked`	Accumulated number of LNs that were marked for migration during cleaning.
`je-env-stat-NLNsMigrated`	Accumulated number of LNs migrated.
`je-env-stat-NLNsObsolete`	Accumulated number of LNs obsolete.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`je-env-stat-NLogBuffers`	Number of log buffers currently instantiated.
`je-env-stat-NMarkedLNsProcessed`	Accumulated number of LNs processed because they were previously marked for migration.
`je-env-stat-NNodesExplicitlyEvicted`	Accumulated number of nodes evicted.
`je-env-stat-NNodesScanned`	Accumulated number of nodes scanned to select the eviction set.
`je-env-stat-NNodesSelected`	Accumulated number of nodes selected to evict.
`je-env-stat-NNotResident`	Number of requests for database objects not contained within the in memory data structures.
`je-env-stat-NOpenFiles`	Number of files currently open in the file cache.
`je-env-stat-NPendingLNsLocked`	Accumulated number of pending LNs that could not be locked for migration because of a long duration application lock.
`je-env-stat-NPendingLNsProcessed`	Accumulated number of LNs processed because they were previously locked.
`je-env-stat-NRandomReadBytes`	Number of bytes read which required repositioning the disk head more than 1MB from the previous file position.
`je-env-stat-NRandomReads`	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
`je-env-stat-NRandomWriteBytes`	Number of bytes written which required repositioning the disk head more than 1MB from the previous file position.
`je-env-stat-NRandomWrites`	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
`je-env-stat-NRepeatFaultReads`	Number of reads that had to be repeated when faulting in an object from disk because the read chunk size controlled by `je.log.faultReadSize` is too small.
`je-env-stat-NRepeatIteratorReads`	Number of times we try to read a log entry larger than the read buffer size and can't grow the log buffer to accommodate the large object.
`je-env-stat-NRootNodesEvicted`	Accumulated number of database root nodes evicted.
`je-env-stat-NSequentialReadBytes`	Number of bytes read which did not require repositioning the disk head more than 1MB from the previous file position.
`je-env-stat-NSequentialReads`	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`je-env-stat-NSequentialWriteBytes`	Number of bytes written which did not require repositioning the disk head more than 1MB from the previous file position.
`je-env-stat-NSequentialWrites`	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
`je-env-stat-NSharedCacheEnvironments`	Number of environments using the shared cache.
`je-env-stat-NTempBufferWrites`	Number of writes which had to be completed using the temporary marshalling buffer because the fixed size log buffers specified by `je.log.totalBufferBytes` and `je.log.numBuffers` were not large enough.
`je-env-stat-NToBe-CleanedLNsProcessed`	Accumulated number of LNs processed because they are soon to be cleaned.
`je-env-stat-NonEmptyBins`	Number of non-empty bins.
`je-env-stat-ProcessedBins`	Number of bins that were successfully processed by the INCompressor.
`je-env-stat-RequiredEvictBytes`	Number of bytes that must be evicted to get within the memory budget.
`je-env-stat-SharedCacheTotalBytes`	Total amount of the shared JE cache in use in bytes.
`je-env-stat-SplitBins`	Number of bins encountered by the INCompressor that were split between the time they were put on the compressor queue and when the compressor ran.
`je-env-stat-TotalLogSize`	Approximation of the current total log size in bytes.
`je-env-stat-NOwners`	Total lock owners in the lock table.
`je-env-stat-NReadLocks`	Total read locks currently held.
`je-env-stat-NRequests`	Total number of lock requests to date.
`je-env-stat-NTotalLocks`	Total locks currently in the lock table.
`je-env-stat-NWaiters`	Total transactions waiting for locks.
`je-env-stat-NWaits`	Total number of lock waits to date.
`je-env-stat-NWriteLocks`	Total write locks currently held.
`je-env-stat-LastCheckpointTime`	Time of the last checkpoint.
`je-env-stat-LastTxnId`	Last transaction ID allocated.
`je-env-stat-NAborts`	Number of transactions that have aborted.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`je-env-stat-NActive`	Number of transactions that are currently active.
`je-env-stat-NBegins`	Number of transactions that have begun.
`je-env-stat-NCommits`	Number of transactions that have committed.
`je-env-stat-NXAAborts`	Number of XA transactions that have aborted.
`je-env-stat-NXACommits`	Number of XA transactions that have committed.
`je-env-stat-NXAPrepares`	Number of XA transactions that have been prepared.

Summary of the Replication Summary Monitor information

The following table provides a description of the attributes in the `cn=Replication Summary` monitor entry, `dn: cn=Replication Summary <baseDN>,cn=monitor`.

Monitor Attribute	Description
`base-dn:<baseDN>`	Base DN summary.
`replica: replica-id, ldap-server connected-to, generation-id, replication-backlog, recent-update-rate, peak-update-rate, age-of-oldest- backlog-change`	Summary information for each replica in the topology. This entry appears for each replica in the topology with its own respective properties.
`replication-server: server-id, server, generation-id, status, last-connected, last-failed, failed-attempts, attributes.`	Summary information for each remote replication server only in the topology. This entry appears for each Replication Server in the topology with its own respective `serverID` and `server` properties.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`update-queue: id, max-count, current-count, max-size, current-size, polling-source, polling-source-changed`	Summary information for each update queue on a server: ***id*** The ID of the receiving replica or replication server. ***max-count*** The maximum number of update messages that the sending replication server will keep in memory for the receiving replica or replication server. If the receiver cannot accept messages fast enough for any reason, such as high load and network latency, then this queue fills up.When that happens, the sending replication server reads update messages from the changelog backend and slows down the update processing considerably. ***current-count*** The number of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this counter is decremented. ***max-size*** The maximum total size in bytes of update messages that can be in the queue.This queue is capped by both the `max-count` and the `max-size` setting, whichever is reached first. ***current-size*** The total size of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this value is decremented by the size of the published update message. ***polling-source*** Set to either `memory` or `db`. If set to `memory`, the sending replication server relies only on the in-memory queue to push update messages to the receiving replica or replication server. If set to `db`, update messages are read and sorted from the changelog database, which is significantly slower than publishing updates from the in-memory queue. ***polling-source-changed*** The total number of times the polling-source attribute has changed value either from `db` to `memory` or from `memory` to `db`. **Tip** If this value changes frequently, the queue size setting is too low.

Summary of the replicationChanges Backend Monitor information

The following table provides a description of the attributes in the `cn=replicationChanges Backend` Monitor entry.

The following is the distinguished name (DN) for the replicationChanges Backend Monitor entry.

Copyright © 2025 Ping Identity Corporation

```
dn: cn=replicationChanges Backend,cn=monitor
```

Monitor Attribute	Description
`ds-backend-id`	ID descriptor for the backend. **Note** Typically, this is `replicationChanges`.
`ds-backend-base-dn`	Base DN for the backend. **Note** Typically, this is `replicationChanges`.
`ds-backend-is-private`	Flag to indicate if the backend is private.
`ds-backend-entry-count`	Entry count for the backend.
`ds-base-dn-entry-count`	Entry count for the base DN and the specified base DN.
`ds-backend-writability-mode`	Flag to indicate if the backend is writable or not.

Summary of the Replication Protocol Buffer Monitor information

The following table provides a description of the attributes in the `cn=Replication Protocol Buffer` monitor entry.

The following is the distinguished name (DN) for the Replication Protocol Buffer Monitor entry. The monitors provide information on the state of the buffer for protocol operations, which is kept in the local storage.

```
dn: cn=Replication Protocol Buffer,cn=monitor
```

Replication Protocol Buffer Monitor Information

Monitor Attribute	Description
`saved-buffers`	Number of protocol buffers. **Note** Initial buffer size is 4k.
`reallocations`	Number of times the buffers had to be reallocated because of insufficient size.
`large-buffer-creates`	Number of times a buffer larger than 512k was requested.

Copyright © 2025 Ping Identity Corporation

Monitor Attribute	Description
`large-buffer-evictions`	Number of times a buffer was removed from the thread local storage because it has grown above 512k.

Advanced topics reference

This section provides background reference information for advanced replication topics.

Topics in this section include:

- About the replication protocol
- Change number
- Conflict resolution
- WAN-friendly replication
- WAN Gateway Server
- WAN message routing
- WAN Gateway Server selection
- WAN replication in mixed-version environments
- Recovering a replication changelog
- Performing disaster recovery

About the replication protocol

The topic covers the replication, topology, protocol process, and background information.

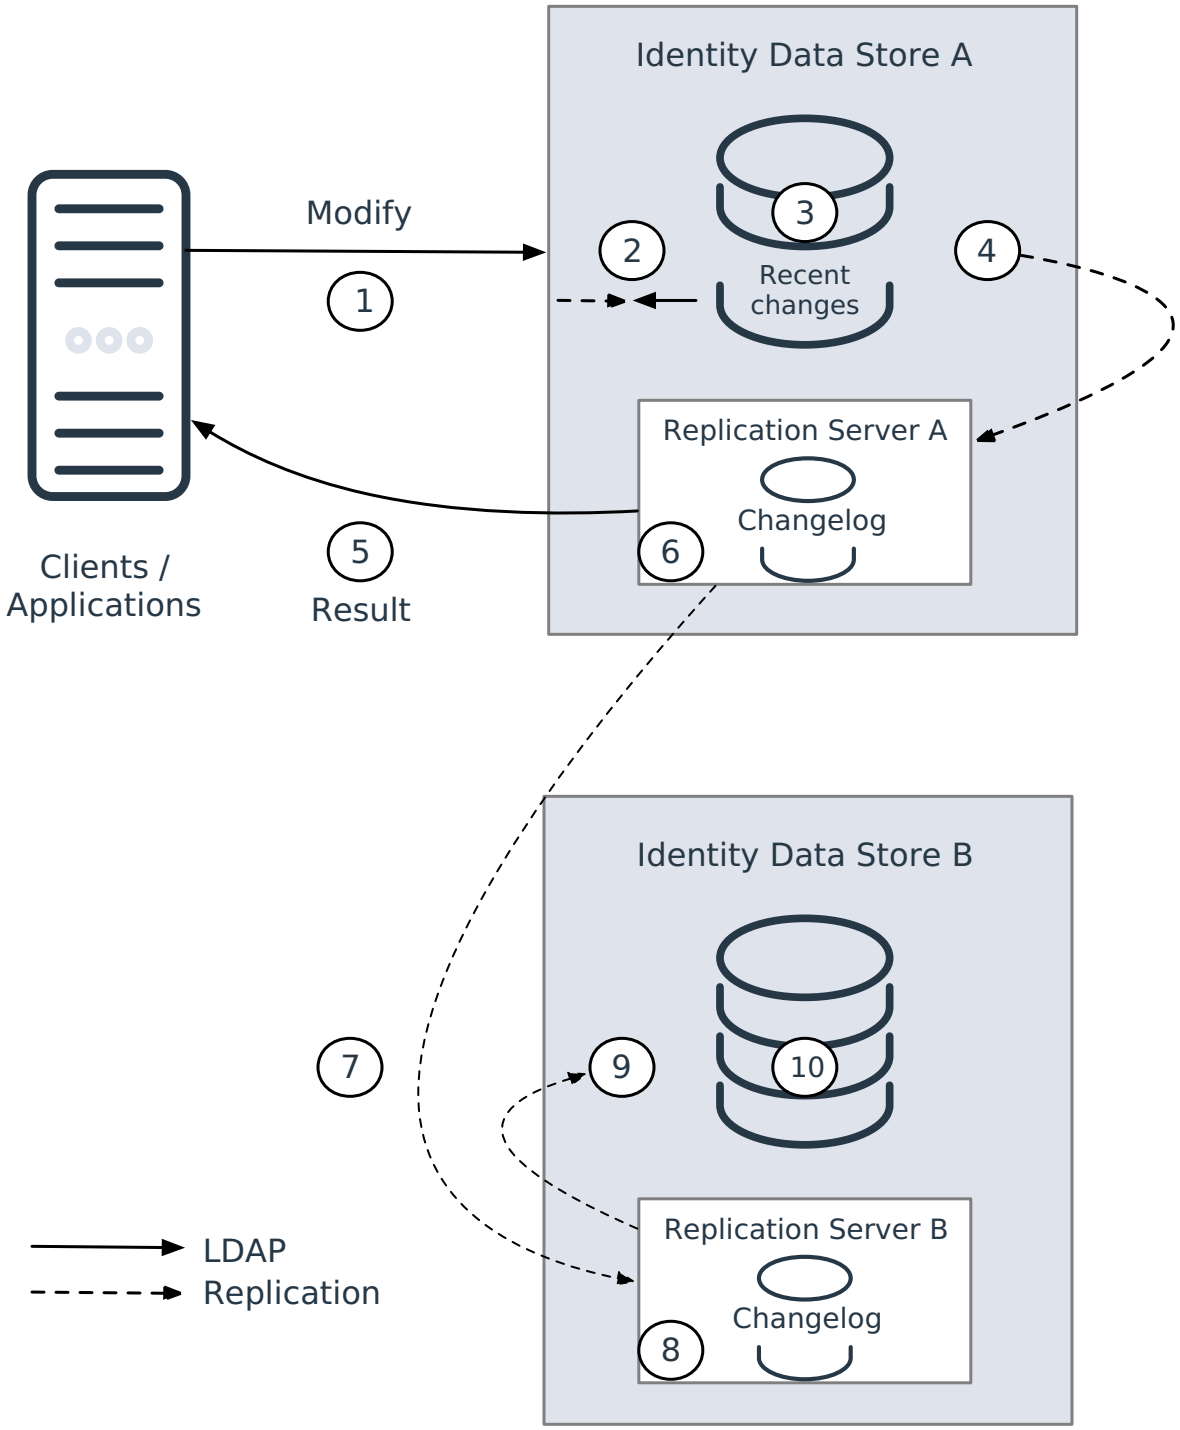
Replication communication uses a proprietary binary protocol that implements on top of the TCP/IP protocol using SSL encryption. Some protocol messages are used for administrative purposes, such as WAN Gateway server negotiation or flow control, some carry updates to replicated data, and others are directed to all servers for monitoring requests.

In a replicated topology, each participating PingDirectory server connects to every other server through the replication server port to monitor health. Servers that share the same location setting are connected to rapidly replicate changes, and the WAN Gateway servers are all interconnected to replicate changes across locations.

The PingDirectory servers keep connections open as long as possible to reduce the communication latency when exchanging messages. Heartbeat messages transmit on a regular basis to detect a network failure or an unresponsive server as early as possible. Heartbeat messages also prevent idle connections from being closed by firewalls.

Copyright © 2025 Ping Identity Corporation

Replication Communication Flow



1. The client sends a `MODIFY` request to PingDirectory server A.

2. PingDirectory server A assigns a unique change number to the operation. Conflict resolution is executed to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry. The change number is assigned before the server backend is updated to preserve the arrival order of client requests. Historical data in the target entry is updated to reflect the change.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Historical data is only updated for `ADD` and `MODIFY` operations.

3. The PingDirectory server applies the modifications in the corresponding backend.
4. If the `MODIFY` operation successfully completes, then the PingDirectory server submits the update to its embedded replication server. The replication server is a component within the PingDirectory server process responsible for propagating updates to and from the replication topology. The PingDirectory server itself only communicates with a single replication server, whereas the replication server component is connected to all other replication servers. If the PingDirectory server process exits unexpectedly and some updates haven't been passed to the replication server, the backend has the ability to recover the last 50,000 recent changes that were processed at this server, guaranteeing that these changes can be replicated when the server starts up. The figure above also shows that replication protocol is used not just between replication servers but also between the PingDirectory server and the replication server.
5. The response is sent to the client. In this example, a successful response is assumed.
6. The replication server records the update in its own Changelog backend, such as backend ID of `replicationChanges` and on disk with the path to `changelogDb` under the server root. The Replication Changelog backend keeps track of updates at each and every PingDirectory server in the replication topology. When a server joins the replication topology after being disconnected for some reason, updates from the Replication Changelog backend are re-sent to this server. Old records from the Replication Changelog backend are purged, which, by default, removes records older than 24 hours. If the backend doesn't contain all of the records that another PingDirectory server needed when rejoining the replication topology, then the replicated data set in the PingDirectory server must be re-initialized. In this case, the server enters lockdown mode and sends an administrative alert.
7. The replication server submits the update to the replication server component in PingDirectory server B. If there were more PingDirectory servers in this example, the replication server would submit the update to all the other replication servers in the same location.
8. Just like in Step 6, the replication server component receiving an update inserts the change into its Replication Changelog backend.
9. The update forwards to the Replica in PingDirectory server B. Conflict resolution executes to see if the `MODIFY` request is in conflict with the existing attribute types or values in the existing entry.
10. The PingDirectory server applies the modification in the corresponding backend. The Recent Changes database doesn't update because only updates that originate at this server record in the Recent Changes database.

Change number

This topic provides the change number purpose, functions, and components.

As described in About the replication protocol, the PingDirectory server assigns a unique change number to each update operation, specifically `ADD`, `DELETE`, `MODIFY`, or `MODIFY DN` operations, to track each request received from a client. The change number is attached to each update propagated through replication and allows each PingDirectory server to order updates exactly the same way.

The change number is composed of the following fields:

Copyright © 2025 Ping Identity Corporation

`Timestamp`

Identifies when the update was made. The timestamp is time-zone-independent and recorded with millisecond resolution.

`Server ID`

Uniquely identifies the PingDirectory server where the update was made.

`Sequence number`

Defines the order of the updates received from external clients at a particular server..

> **Tip**
>
> The replication protocol sets a virtual clock that eliminates the need for synchronized time on servers. For troubleshooting purposes, you should keep the system clocks synchronized.

Conflict resolution

This topic covers background information, the conflict resolution process flow, and explanation of conflict resolution.

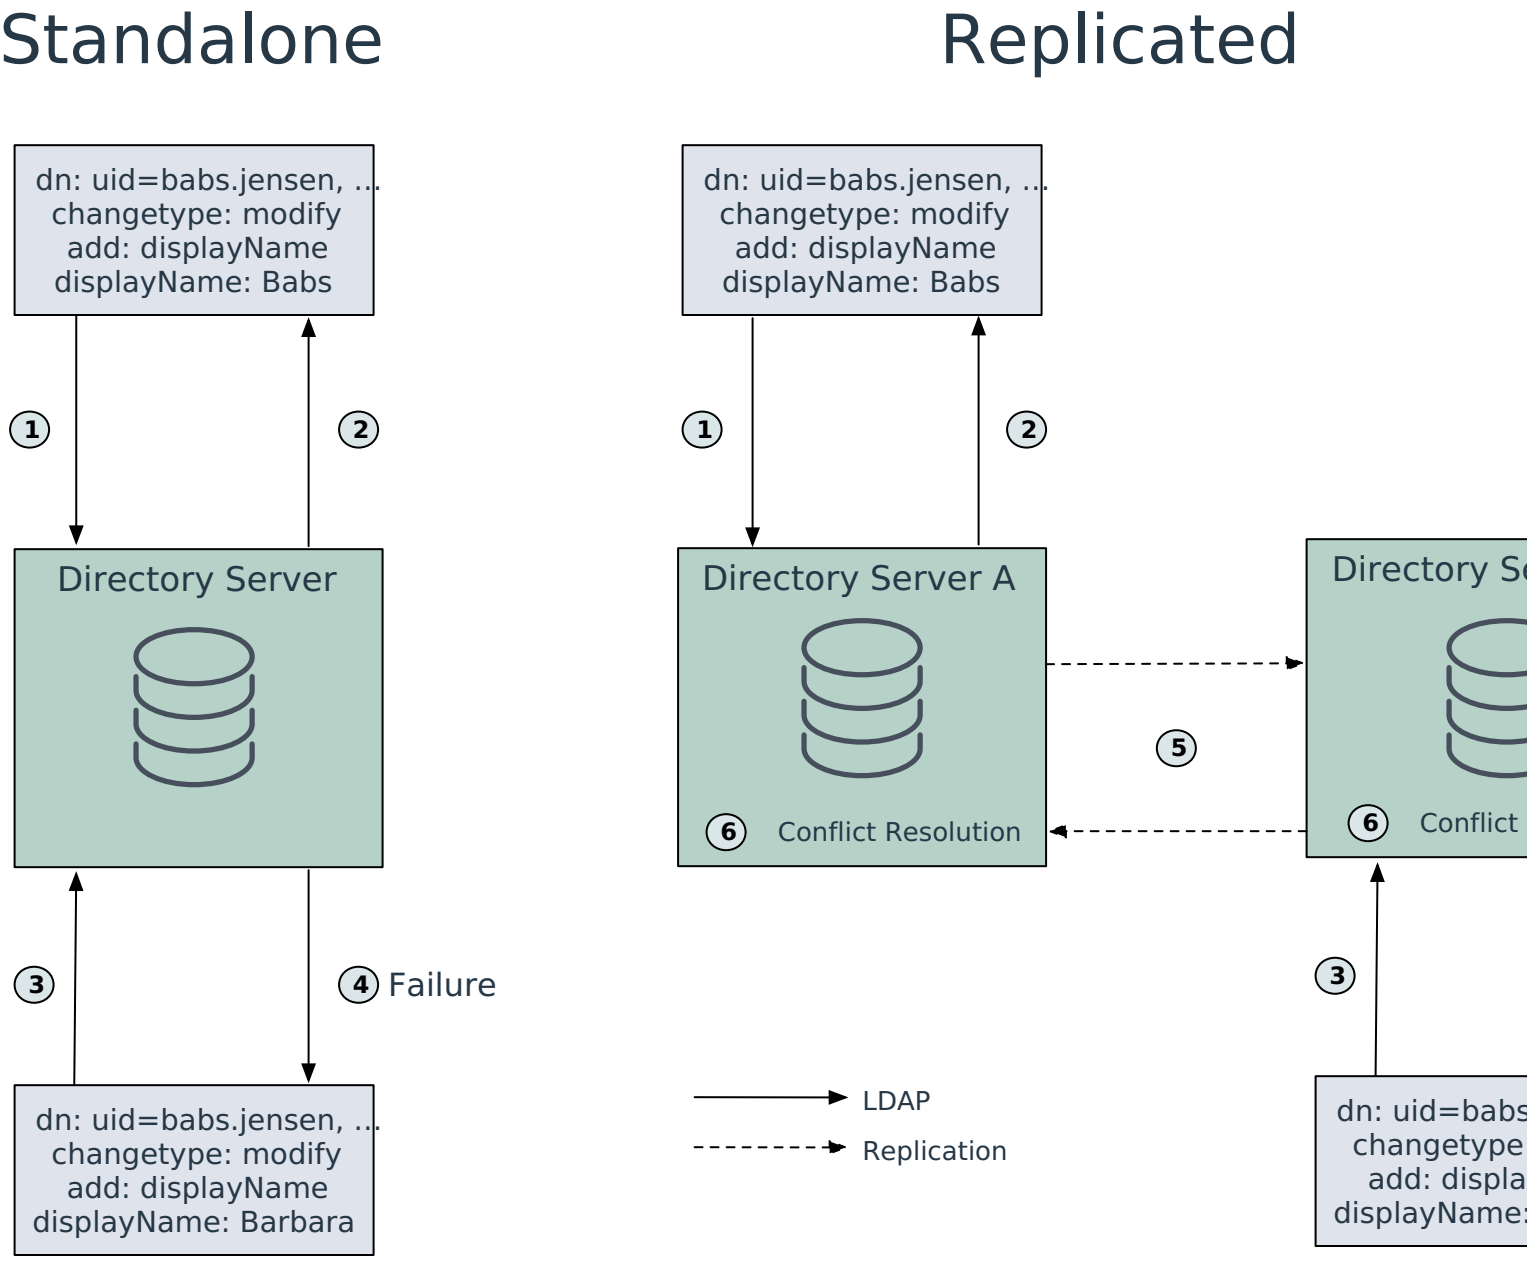
Replication employs an eventual-consistency model which can introduce a window where conflicting updates targeting the same entry might be applied at two different PingDirectory servers. In general, if the update that arrived later fails, two updates to the same server are in conflict. Conflict resolution, when possible, corrects conflicts introduced by clients automatically. There are some exceptions, however, when manual administrative action is required. For example, adding an entry in one replica and simultaneously deleting the parent of this entry on another replica introduces a conflict that requires manual action. In a carefully implemented deployment, the risk of introducing conflicts that require manual action can be significantly reduced or even eliminated.

The conflict resolution algorithm in PingDirectory server uses a mechanism that orders all updates in the replication topology. The server assigns a unique change number to each update. The change number is attached to each update propagated through replication and allows each server to order updates exactly the same way. See the following diagram for an example.

Conflict resolution process flow

The following diagram depicts adding a single-valued attribute with different values to an entry concurrently at two PingDirectory servers resulting in a conflict as well as the conflict resolution in the standalone environment versus the replicated environment.

Copyright © 2025 Ping Identity Corporation



Processing steps

1. **The client sends a modify request to the Identity Datastore and succeeds.**
2. **The client sends another modify request that conflicts with the first.**
3. **In the standlaone environment, the request is rejected. In the replicated environment, the request succeeds.**
4. **In the replicated environment only: Replication propagates the updates.**
5. **In the replicated environment only: Conflict resolution concludes with A ignores the update from B, B sets the attribute value to the value on A.**

Copyright © 2025 Ping Identity Corporation

From the diagram example, you can make the following observations:

- The second operation fails if a client attempted to add the same attribute to the same entry at the same PingDirectory server.
- In a replicated environment, the conflict is not immediately seen if these updates are applied concurrently at two different PingDirectory servers.
- The conflict is handled only after replication propagates the updates.
- The PingDirectory servers resolve the conflict independently of the other server. On one server, the entry updates to reflect the correct value. On the other server, the value stays the same. As a result, each server independently resolves the conflict the same way based on the ordering of the updates.

WAN-friendly replication

Minimize latency with the PingDirectory server if you are using a WAN for your client applications.

Many multinational corporations that have data centers in different countries must minimize latency over WAN to ensure acceptable performance for their client applications.

To minimize WAN latency, the PingDirectory server assigns one of following two roles to the replication servers:

- The role of standard replication transmitting updates to the other co-located replication servers.
- The role of a WAN-dedicated replication server designed to send updates to other WAN-designated replication servers in other locations.

This two-role system minimizes WAN traffic by pushing all replication updates onto the connected replication servers that are designated as WAN Gateway Servers. Only the designated WAN Gateway Servers can transmit the update messages to other connected WAN Gateway servers at other locations.

WAN Gateway Server

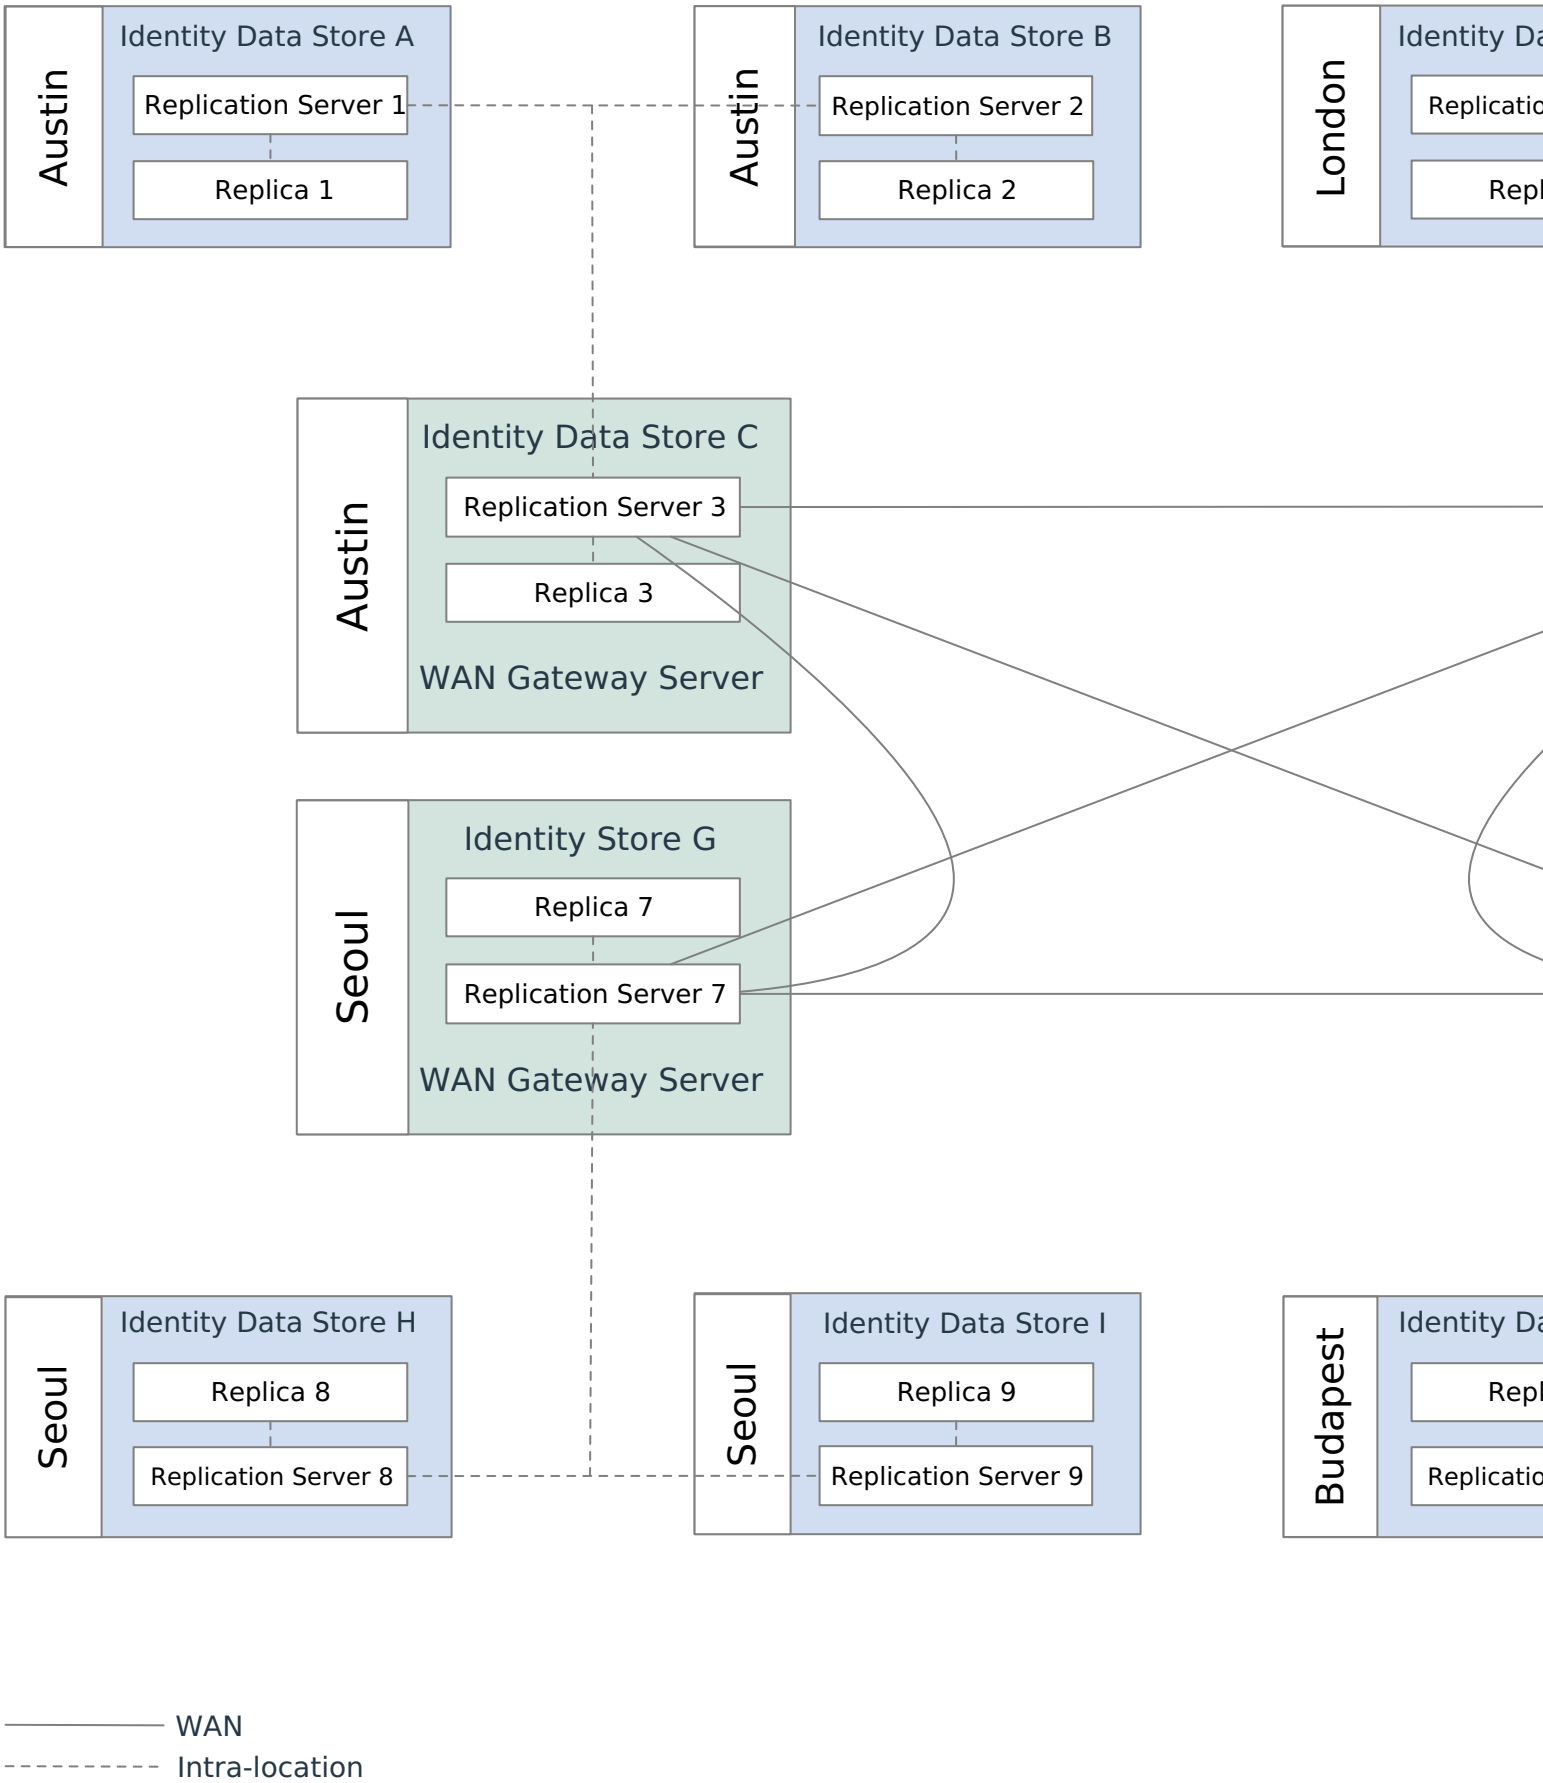
The PingDirectory server's replication mechanism relies on the server's location information to reduce protocol traffic on WAN links.

During protocol negotiation, the replication server with the highest WAN Gateway priority (priority 1 indicates the highest priority) automatically assumes the role as the WAN Gateway Server for that particular location. The Gateway Server's main function is to route update messages from other non-gateway servers at the same location to remote WAN Gateway servers at other locations. At the destination point, the replication server with the WAN Gateway role receives update messages from other WAN gateway servers at other locations and pushes them out to all replication servers at the current location.

This setup ensures that all WAN communication flows through the WAN Gateway Servers.

The following diagram shows a basic connection configuration for updates. All of the replication servers are fully connected to each other for monitoring or server negotiation purposes.

Copyright © 2025 Ping Identity Corporation



Copyright © 2025 Ping Identity Corporation

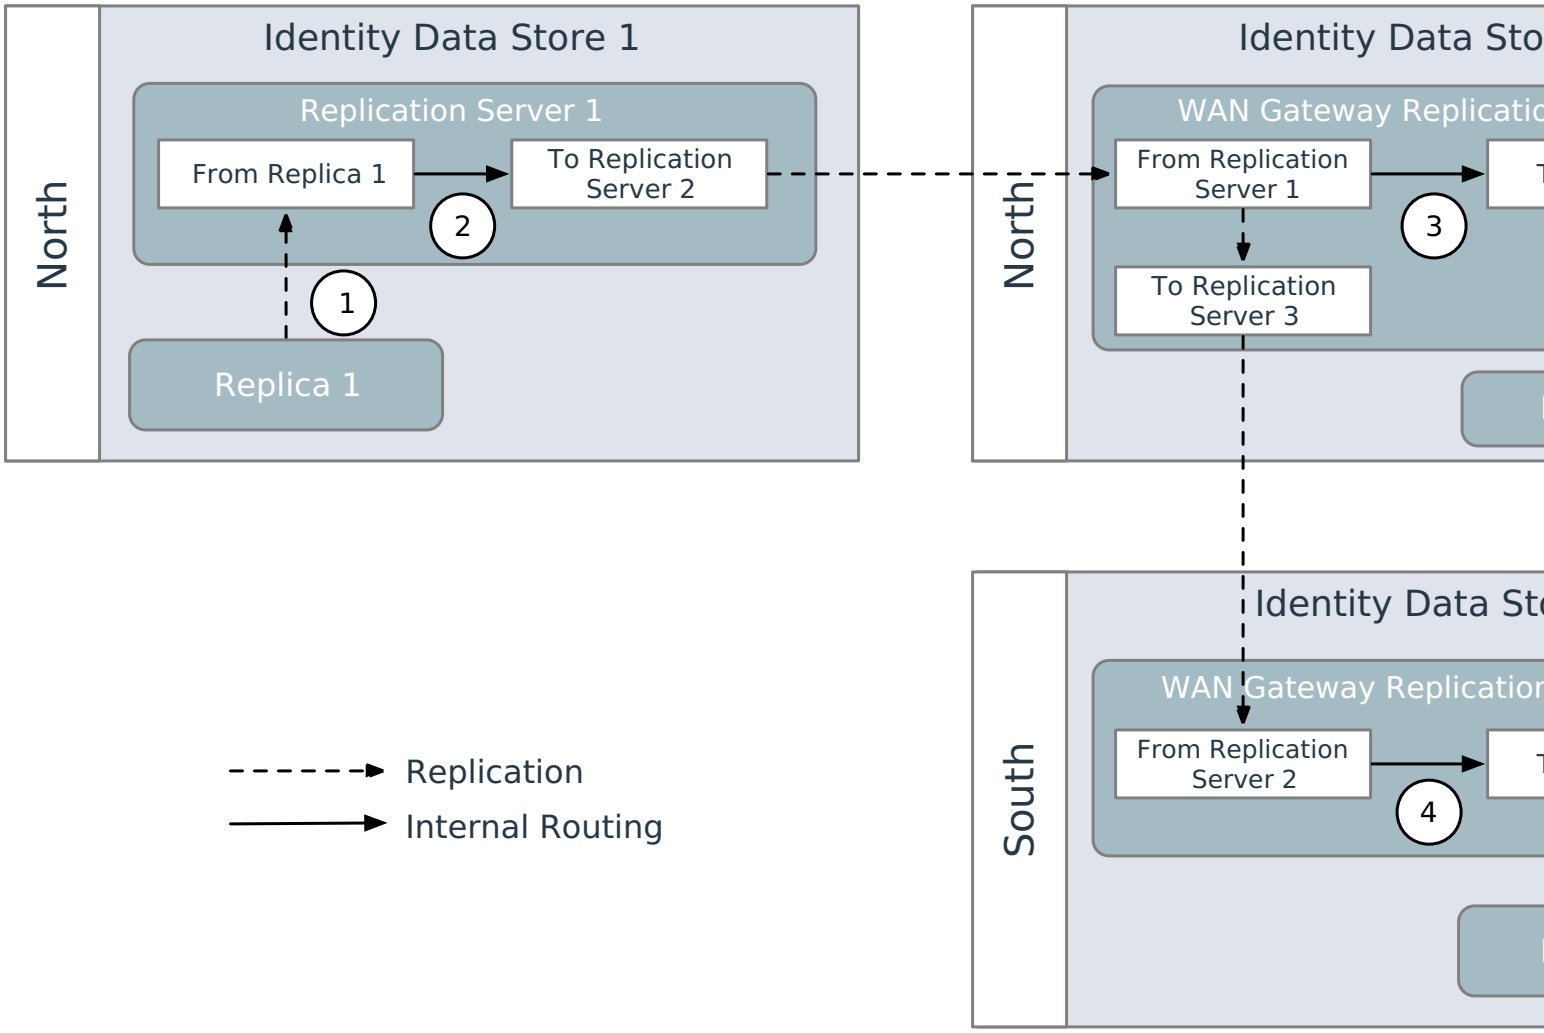
If the WAN Gateway Server is temporarily unavailable because of planned or unplanned downtime, the system dynamically re-routes updates to a newly-designated WAN Gateway Server in the same location. The replication server with the next highest WAN Gateway priority number automatically assumes the WAN Gateway role. For deployments with entry-balancing Directory Proxy Servers, there is one WAN Gateway Server per data set.

> **Note**
>
> By default, all servers are enabled to serve as WAN Gateways and all are set to priority 5, which makes them all equal. After replication has been enabled, you can change the WAN Gateway priority using `dsconfig`.

WAN message routing

Non-gateway replication servers forward update messages from replicas to co-located replication servers only. It is the responsibility of the WAN gateway server to forward these messages to WAN gateway servers at other locations.

The following figure illustrates how an update message is routed from a non-gateway server to a remote location.



Processing steps

1. Update received at Identity Datastore 1 at the north location is sent to the embedded Replication Server.

Copyright © 2025 Ping Identity Corporation

2. Replication Server 1 routes message to the WAN Gateway only.
3. The WAN Gateway at the North location (Identity Data Store 2) routes message to Replica 2 and to the WAN Gateway at the south location.
4. Replication Server 3, which is the WAN Gateway at the south location, routes the message to Replica 3.

WAN Gateway Server selection

The WAN Gateway role is dynamically assigned to the most suitable server in a particular location.

In most cases, the replication server with the higher WAN Gateway priority (priority 1 is the highest priority) assumes this role.

A replication server does not attempt to become a WAN Gateway if any of the following conditions exists:

- The WAN Gateway priority is set to 0.
- The replication server is backlogged at server startup.
- The current WAN Gateway has higher priority.
- The WAN Gateway has not been elected yet, but higher priority replication servers are present in the location.

The currently active WAN Gateway server gives up the gateway role in the following cases:

- The server has started the shutdown process.
- The server is preparing for a scheduled maintenance cycle.
- The server learns about a higher priority replication server in its location.

Replication servers send WAN Gateway information to other servers at regular intervals using the replication protocol. This allows the replication servers to take the appropriate action, such as to become a WAN Gateway, if necessary, without any manual administrative action.

WAN replication in mixed-version environments

This topic covers the WAN Gateway role, replication actions, and updates in PingDirectory server mixed version environments.

Consider the following when using the WAN Gateway role in mixed-version environments:

- WAN Gateway Role assignment is only available on PingDirectory servers version 3.5 and later.
- Legacy servers earlier than 3.5, are never selected as WAN Gateways.
- Updates from legacy replication servers forward to all replication servers and do not funnel to a single WAN Gateway, which increases WAN during replication.
- Updates from remote WAN Gateways forward to the legacy replication servers, which increases WAN traffic during replication.

Recovering a replication changelog

If the replication changelog, `<server-root>/changelogDb`, is compromised because of a disk or NAS failure, you can recover a replication changelog.

About this task

To recover a replication changelog:

Steps

1. Stop the server.
2. Backup `replicationChanges` from a remote server using the following command.

```
$ bin/backup --backupDirectory /app/backups/replicationChanges \
  --backendID replicationChanges
```

3. Copy the `replicationChanges` backup from the remote server and restore it on the local host using the following command.

```
$ bin/restore --backupDirectory /app/tmp/replicationChanges
```

4. Start the server.

Performing disaster recovery

If data is compromised across all systems and a restore is necessary, you can perform disaster recovery.

About this task

> **Note**
>
> Consider the following for disaster recovery:
>
> - With the default configuration, the server automatically exports all data nightly using the **`Export All Non-Administrative Backends`** recurring task. Up to 7 days of exports are maintained. You should archive these exports on another system.
> - The Data Recovery Log logs all changes in a reversible format to `logs/data-recovery/data-recovery`.
> - The **`bin/extract-data-recovery-log-changes`** tool provides the ability to redo or undo any changes from the `logs/data-recovery/data-recovery` logs.
>
> The combination of these allows you to either rebuild the data set to any point in time or to revert specific changes on a live data set, such as if an errant application mistakenly wipes out some data.

For more information about LDIF exports, see LDIF export as a recurring task.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> These steps assume that no server performs read or write operations during this process.

To complete a restore of your systems and perform a disaster recovery:

Steps

1. Stop all servers.
2. Go to one of the servers and remove it from the topology:

   Example:

   ```
   bin/remove-defunct-server --performLocalCleanup --no-prompt
   ```

3. Locate the backup or exported LDIF file that represents the last working copy of the database.
4. Restore the backup or import the LDIF file on a single server. If importing an LDIF file, use the `--excludeReplication` option with the `bin/import-ldif` command.
5. Start the restored server. The server can now receive client requests.
6. Clean up replication artifacts from the next server before starting it up:

   Example:

   ```
   bin/remove-defunct-server --performLocalCleanup --no-prompt
   ```

7. Start the server in lockdown mode with the following command:

   Example:

   ```
   bin/start-server --skipPrime --lockdownMode
   ```

8. Enable replication from the first server to the second server.

   Example:

   ```
   bin/dsreplication enable
   ```

9. Initialize the second server from the first with the following command:

   Example:

   ```
   bin/dsreplication initialize
   ```

10. Restart the second server or use the `bin/leave-lockdown-mode` command to exit lockdown mode.

    The second server can now receive client requests.

11. Repeat steps 5 through 10 for any other servers.

Managing logging

The PingDirectory server supports a rich set of log publishers to monitor access, debug, and error messages that occur during normal server processing.

Administrators can view the standard set of default log files and configure custom log publishers with pre-defined filtering with its own log rotation and retention policies.

Default PingDirectory server logs

The PingDirectory server provides a standard set of default log files to monitor the server activity.

PingDirectory server logs

View this set of logs in the `PingDirectory/logs` directory. The following default log files are available on the PingDirectory server and are defined in the following table.

Log File	Description
`access`	File-based Access Log that records operations processed by the PingDirectory server. Access log records can be used to provide information about problems during operation processing, such as unindexed searches, failed requests, and so forth, and provide information about the time required to process each operation.
`change-notifications.log`	Records changes to data anywhere in the server, which match one or more configured change subscriptions.
`config-audit.log`	Records information about changes made to the PingDirectory server configuration in a format that can be replayed using the `dsconfig` tool.
`errors`	File-based Error Log. Provides information about warnings, errors, and significant events that occur during server processing.
`expensive-ops`	Expensive Operations Log. Disabled by default. Provides only those operations that took longer than 1000 milliseconds to complete.
`failed-ops`	Failed Operations Log. Provides information on all operations that failed in single-line log format.
`replication`	Records any replication errors and publishes them to the file system.
`searches-returning-no-entries`	Searches Returning No Entries Log. Disabled by default. Provides information only on operations that did not return any entries.
`server.out`	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information is written to `server.out`.

Copyright © 2025 Ping Identity Corporation

Log File	Description
`server.pid`	Stores the server's process ID.
`server.status`	Stores the timestamp, a status code, and an optional message providing additional information on the server status.
`setup.log`	Records messages that occur during the initial configuration of a PingDirectory server with the `setup` tool.
`tools`	Directory that holds logs for long running utilities `import-ldif`, `export-ldif`, `backup`, `restore`, and `verify-index`. Current and previous copies of the log are present in the PingDirectory server.
`update.log`	Records messages that occur during a PingDirectory server update.

Types of log publishers

The PingDirectory server provides several classes of log publishers for parsing, aggregating, and filtering information events that occur during normal processing in the server.

There are three primary types of log publishers:

- Access log publishers
- Debug log publishers
- Error log publishers

Each type has multiple subtypes of log files based on the log server type.

Access log publishers

Access log publishers provide the requests received and the responses returned by the PingDirectory server. This information can be used to understand the operations performed by clients and to debug problems with the client applications. It can also be used for collecting usage information for performance and capacity planning purposes.

For information on tools that can analyze the access log to provide summaries of LDAP activity and performance, see Monitoring PingDirectory metrics with Splunk and the `summarize-access-log` tool description in Available command-line tools.

Copyright © 2025 Ping Identity Corporation

Access log type	Description
File-based audit log	Special type of access logger that provides detailed information about changes processed within the server. Disabled by default. ***Data Recovery Log*** Publishes information about each write operation processed in the server in a manner that allows those changes to be reverted or replayed (in conjunction with the `extract-data-recovery-log-changes` tool) if data recovery is needed. You can find this log publisher in the `<pd_install>/logs/data-recovery/data-recovery` directory.
JDBC-based access log	Stores access log information using a Java Database Connectivity (JDBC) database connection. Disabled by default.

Copyright © 2025 Ping Identity Corporation

Access log type	Description
File-based access logs	Provides a character-based stream used by TextWriter publishers as a target for outputting log records. There are several types of file-based access loggers: ***Admin Alert Access Log*** Generates administrative alerts for any operations that match the criteria for this access logger. Disabled by default. ***File-based Access Log*** Publishes access log messages to the file system. Enabled by default. You can find this log publisher in the `<pd_install>/logs/access` directory. ***Syslog-based Access Log*** Publishes access log messages to a syslogd port. Disabled by default. ***Expensive-Operations Access Log*** Publishes only those access log messages of operations that take longer than 1000 milliseconds. Disabled by default. You can find this log publisher in the `<pd_install>/logs/expensive-ops` directory. ***Failed-Operations Access Log*** Publishes only those access log messages of operations that failed for any reason. Enabled by default. You can find this log publisher in the `<pd_install>/logs/failed-ops` directory. ***Successful Searches with No Entries Returned Log*** Publishes only those access log messages of search operations that failed to return any entries. Disabled by default. ***JSON Access Logger*** Publishes JSON-formatted access log messages to the file system. You can find this log publisher in the `<pd_install>/logs/access.json` directory. ***Console JSON Access Logger*** Publishes JSON-formatted access log messages to the Java virtual machine (JVM)'s standard output or standard error stream. **Note** This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error. ***Third-Party Access Log Publisher*** Publishes access log messages using a custom log publisher created using the Server SDK. ***Third-Party File-Based Access Log Publisher*** Publishes access log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.

Copyright © 2025 Ping Identity Corporation

Access log type	Description
HTTP operation log publishers	*Common Log File HTTP Operation Log Publisher* Publishes information about HTTP requests in the W3C common log format. *HTTP Detailed Access* Publishes detailed information about HTTP requests processed by the server. You can find this log publisher in the `<pd_install>/logs/http-detailed-access` directory.

Debug log publishers

Debug log publishers provide information about warnings, errors, or significant events that occur within the server.

Debug log type	Description
Debug loggers	*Debug ACI Logger* Stores debug information on access control instruction (ACI) evaluation for any request operations against the server. You can find this log publisher in the `<pd_install>/logs/debug-aci` directory. *Server SDK Extension Debug Logger* Provides simplified access to debug messages generated by Server SDK extension. You can find this log publisher in the `<pd_install>/logs/server-sdk-extension-debug` directory.

Error log publishers

The Error log reports errors, warnings, and informational messages about events that occur during the course of the server's operation.

Copyright © 2025 Ping Identity Corporation

Error log type	
File-based error logs	There are several types of File-based error logs: ***Error log*** Publishes error messages to the file system. Enabled by default. You can find this log publisher in the `<pd_install>/logs/errors` directory. ***Replication log*** Publishes replication error messages to the file system. Enabled by default. You can find this log publisher in the `<pd_install>/logs/replication` directory. ***JSON Error Logger*** Publishes JSON-formatted error log messages to the file system. You can find this log publisher in the `<pd_install>/logs/errors.json` directory. ***Console JSON Access Logger*** Publishes JSON-formatted access log messages to the JVM's standard output or standard error stream. **Note** This log publisher is only recommended when the server is run in no-detach mode and is best suited for use in Docker or other containers that can capture log content written to standard output or standard error. ***Third-Party Error Log Publisher*** Publishes error log messages using a custom log publisher created using the Server SDK. ***Third-Party File-Based Error Log Publisher*** Publishes error log messages to a file using a custom log publisher created using the Server SDK, including enhanced support for log file rotation and retention.
JDBC-based error logs	Stores error log information using a JDBC database connection. Disabled by default.
Syslog-based error logs	Publishes error messages to a syslog port.

Viewing the list of log publishers

View the list of log publishers on the PingDirectory server using the `dsconfig` tool.

About this task

Note

You must specifically configure the Java Database Connectivity (JDBC), syslog, and admin alert log publishers using `dsconfig` before they appear in the list of log publishers.

Steps

- To view the log publishers, run `dsconfig` with the `list-log-publishers` subcommand.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig list-log-publishers
```

Result:

```
Log Publisher                                : Type              : enabled
---------------------------------------------:-------------------:--------
Debug ACI Logger                             : debug-access      : false
Expensive Operations Access Logger           : file-based-access : false
Failed Operations Access Logger              : file-based-access : true
File-Based Access Logger                     : file-based-access : true
File-Based Audit Logger                      : file-based-audit  : false
File-Based Debug Logger                      : file-based-debug  : false
File-Based Error Logger                      : file-based-error  : true
Replication Repair Logger                    : file-based-error  : true
Successful Searches with No Entries Returned : file-based-access : false
```

Enabling or disabling a default log publisher

You can enable or disable any log publisher available on the PingDirectory server using the `dsconfig` tool.

About this task

By default, the following loggers are disabled and should only be enabled when troubleshooting an issue on the server:

- Expensive Operations Access Logger
- File-Based Audit Logger
- File-Based Debug Logger
- Successful Searches with No Entries Returned

Steps

- To enable an access log publisher, run `dsconfig` with the `set-log-publisher-prop` subcommand.

  Example:

  In this example, the Expensive-Operations Access Logger is enabled, which records only those access log messages that take 1000 milliseconds or longer.

  ```
  $ bin/dsconfig set-log-publisher-prop \
    --publisher-name "Expensive Operations Access Logger" --set enabled:true
  ```

Managing access and error log publishers

The access log records every request received and response returned by the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

The access log stores the IDs for the client connection, operation, the LDAP message involved with each client request, and the server response. The information can be used to debug any problems with a client application by correlating the numeric operation identifier to the client request or response.

The PingDirectory server supports multiple classes of access log publishers depending on your logging requirements. The following types of access log publishers are available on the system:

File-Based Access Log Publishers

Provides a character-based TextWriter stream for outputting log records. There are three subclasses of TextWriter access logs:

File-Based Access Logs

Enabled by default. The File-based Access Log publishes access messages to the file system as `<server-root>/logs/access`. The Failed-Operations Log, Expensive-Operations Log, and the Searches with No Entries Returned Log are specialized types of the File-Based Access Log and shows only specific information necessary for troubleshooting purposes.

Admin-Alert Access Logs

Disabled by default. The Admin-Alert Access Log is a specialized type of logger that automatically generates administrative alerts for any operations that match a criteria for this access log publisher.

Syslog-Based Access Logs

Disabled by default. The Syslog Access Log publishes access messages to a syslogd port.

File-Based Audit Logs

Disabled by default. The Audit Log provides detailed information about modifications (writes) processed within the PingDirectory server. The File-based Audit Log publishes access messages to the file system as `<server-root>/logs/audit`.

JDBC-Based Access Logs

Disabled by default. The Java Database Connectivity (JDBC)-based Access Log provides information using a JDBC database connection.

JDBC-Based Error Logs

Disabled by default. The JDBC-based Error Log provides information using a JDBC database connection.

Managing file-based access log publishers

The PingDirectory server supports a flexible and configurable access logging system that provides a full set of customized components to meet your system's logging requirements.

The default access log can be configured to write information to a log file with two records per operation, one for the request received and one for the response returned. It can also be configured to write one message per operation or configured to record information about a subset of operations processed by the server. In addition to modifying existing default log files, you can create custom log publishers to monitor specific properties or connection criteria. For more information, see Creating new log publishers.

Copyright © 2025 Ping Identity Corporation

The PingDirectory server can be configured to use multiple access log publishers writing logs to different files using different configurations. This approach makes it possible to have fine-grained logging for various purposes, such as a log that contains only failed operations, a log that contains only operations requested by root users or a log that contains only operations that took longer than 20ms to complete.

The PingDirectory server provides an additional mechanism to filter access logs to record only a subset of messages of one or more types. The access log filtering mechanism uses the operation criteria (connection, request, result, search-entry, search-reference) to determine whether a given message should be logged based on information associated with the client connection as well as information in the operation request and response messages. For more information, see Configuring filtered logging.

Access log format

The access log has a standard format that lists various elements identifying the connection and operation occurring within the PingDirectory server.

By default, each operation generates one access log message.

The access log displays the following common properties.

Property	Description
Timestamp	Displays the date and time of the operation. Format: DD/ Month/ YYYY:HH:MM:SS <offset from UTC time>
Connection Type	Displays the connection type requested by the client and the response by the server. Examples include the following: • `CONNECT` • `BIND REQUEST/RESULT` • `DISCONNECT` • `SEARCH REQUEST/RESULT` • `MODIFY REQUEST/RESPONSE` • `ABANDON` • `ADD` • `COMPARE` • `DELETE` • `EXTENDED OPERATION` • `MODIFY` • `MODIFY DN`
Connection ID	Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation. The connection ID is unique for a span of time on a single server. Values of the connection ID are re-used when the server restarts or when it has had enough connections to cause the identifier to wrap back to zero.

Copyright © 2025 Ping Identity Corporation

Property	Description
Operation ID	Numeric identifier, starting incrementally with 0, that identifies the operation. The operation ID is unique for a span of time on a single server. Values of the operation ID are re-used when the server restarts or when it has serviced enough operations to cause the identifier to wrap back to zero.
Result Code	LDAP result code that determines the success or failure of the operation result. Result messages include a result element that indicates whether the operation succeeded or failed, the general category for the failure, and an etime element that indicates the length of time in milliseconds that the server spent processing the operation. The PingDirectory server provides a useful tool *<server-root>* `/bin/ldap-result-code` (UNIX, Linux) or *<server-root>* `\bat\ldap-result-code` (Windows), that displays all of the result codes used in the system. You can use the utility if you are not sure what a result code means. For example, use the following: • `ldap-result-code --list` displays all of the defined result codes in the PingDirectory server. • `ldap-result-code --int-value 16654` displays the name of the result code with a numeric value of 16654. • `ldap-result-code --search operation` displays a list of all result codes whose name includes the substring "operation".
Elapsed Time	Displays the elapsed time (milliseconds) during which the operation completed its processing.
Message ID	Numeric identifier, starting incrementally with 1, that identifies the LDAP message used to request the operation.

Access log example

The following example shows output from the access log in `<server-root>/logs/access`.

Copyright © 2025 Ping Identity Corporation

```
[01/Jun/2011:14:48:17 -0500] CONNECT conn=0 from="10.8.1.243" to="10.8.1.243" protocol="LDAP"
[01/Jun/2011:14:48:17 -0500] BIND REQUEST conn=0 op=0 msgID=1 version="3" dn="cn=Directory Manager"
  authType="SIMPLE"
[01/Jun/2011:14:48:17 -0500] BIND RESULT conn=0 op=0 msgID=1 resultCode=0 etime=26.357
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
[01/Jun/2011:14:48:17 -0500] DISCONNECT conn=0 reason="Client Unbind"
... (more output) ...
```

Modifying the access log using dsconfig interactive mode

The File-Based Access Log can be modified to include or exclude all log messages of a given type using the `dsconfig` tool in interactive or non-interactive mode.

About this task
Steps

1. Use `dsconfig` in interactive mode to modify the access log properties.

   Example:

   ```
   $ bin/dsconfig
   ```

2. Follow the prompts to specify the LDAP connection parameters for host name or IP address, connection type (LDAP, SSL, or StartTLS), port number, bind DN and password.
3. On the PingDirectory server main menu, type the number corresponding to the Log Publisher.
4. On the Log Publisher Management menu, enter the option to view and edit an existing log publisher.
5. On the Log Publisher menu, type the number corresponding to File-based Access Logger.
6. On the File-Based Access Log Publisher menu, enter the number corresponding to the property that you want to change, and then follow the prompts.
7. Type `f` to apply the changes.

dsconfig non-interactive mode">

Modifying the access log using `dsconfig` non-interactive mode

Use the `dsconfig` tool in non-interactive mode to modify a log publisher property on the command line or in a script.

About this task

For information on each property, see the PingDirectory server Configuration Reference Guide, which is an HTML document listing the various properties for each PingDirectory server component.

Steps

- Use `dsconfig` with the `--no-prompt` option with the properties you want to modify or set for your access log.

  Example:

Copyright © 2025 Ping Identity Corporation

In this example, enable the properties to include the instance name and startup ID.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Access Logger" \
  --set include-instance-name:true --set include-startup-id:true
```

Modifying the maximum length of log message strings

Change the maximum length of log message strings by setting the `max-string-length` configuration property.

About this task

By default, the PingDirectory server sets the maximum length of log message strings to 2000 characters. This value is configurable for any access log publisher, except the syslog publisher, which is set to 500 characters. If any string has more than the configured number of characters, then that string is truncated and a placeholder is appended to indicate the number of remaining characters in the original string.

Steps

- To set the `max-string-length` property for an access log, run `dsconfig`.

  Example:

  The following command configures the File-based Access Logger to include the instance name and the maximum length of the log message strings to 5000 characters.

  ```
  $ bin/dsconfig set-log-publisher-prop \
    --publisher-name "File-Based Access Logger" \
    --set include-instance-name:true \
    --set max-string-length:5000
  ```

Disabling logging of inter-server periodic search requests

Disable logging of inter-server periodic search requests.

Steps

1. Create a request criteria that matches all search requests with the inter-server request control.

   Example:

   ```
   dsconfig create-request-criteria --criteria-name "Inter-server Searches" \
           --type simple --set operation-type:search \
           --set any-included-request-control:1.3.6.1.4.1.30221.2.5.42
   ```

2. Create a request criteria that matches all requests that are not searches with the inter-server request control.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-request-criteria --criteria-name "Exclude Inter-server Searches" \
        --type aggregate --set "none-included-request-criteria:Inter-server Searches"
```

3. Configure the access logger to use the request criteria you created.

   This disables the logging of internal search requests and their corresponding results to the access log.

   Example:

```
dsconfig set-log-publisher-prop --publisher-name "File-Based Access Logger" \
        --set "request-criteria:Exclude Inter-server Searches"
```

Generating access log summaries

The PingDirectory server provides a convenience tool, `summarize-access-log`, that generates a summary of one or more file-based access logs.

About this task

The summary provides analytical metric information that could be useful for administrators. The following metrics are provided in each summary:

- Total time span covered by the log files
- Number of connections established and the average rate of new connections per second
- IP addresses of up to the top 20 of the clients that most frequently connect to the server, the number of connections by each address, and the percentage of connections of each
- Total number of operations processed, the number of operations of each type, the percentage of each type out of the total number, and the average rate per second for each type of operation
- Average processing time for all operations and for each type of operation
- Histogram of the processing times for each type of operation
- Up to the 20 most common result codes for each type of operation, the number of operations of that type with that result code, and the percentage of operations of that type with that result code
- Number of unindexed searches processed by the server
- Breakdown of the scopes used for search operations with the number of percentage of searches with each scope
- Breakdown of the most common entry counts for search operations with the number and percentage of searches that returned that number of entries
- Breakdown of the most commonly used filter types for searches with a scope other than base (that is, those searches for which the server uses when processing the filter)

  These filters are represented in a generic manner so that any distinct assertion values or substring assertion elements are replaced with question marks and attribute names in all lowercase characters such as `(givenName=John)` would be represented as `(givenName=?)`.

Copyright © 2025 Ping Identity Corporation

Steps

- Use the `bin/summarize-access-log` with the path to one or more access log files.

  Example:

  ```
  $ bin/summarize-access-log /path/to/logs/access
  ```

  Result:

  The system displays the following information.

Copyright © 2025 Ping Identity Corporation

```
Examining access log /path/to/logs/access Examined 500 lines in 1 file covering a total duration of
1 day, 22 hours, 57 minutes, 31 seconds

Total connections established: 69 (0.000/second)
Total disconnects: 69 (0.000/second)

Most common client addresses:
127.0.0.1: 61 (88.406)
10.8.1.209: 8 (11.594)

Total operations examined: 181 ...
(metric for each operation examined) ...

Average operation processing duration: 22.727ms
Average add operation processing duration: 226.600ms
Average bind operation processing duration: 5.721ms
Average delete operation processing duration: 77.692ms
Average modify operation processing duration: 35.530ms
Average search operation processing duration: 4.017ms

Count of add operations by processing time:
... (histogram for add operations) ...

Count of bind operations by processing time:
... (histogram for bind operations) ...

Count of delete operations by processing time:
... (histogram for delete operations) ...

Count of modify operations by processing time:
... (histogram for modify operations) ...

Count of search operations by processing time:
... (histogram for search operations) ...

Most common add operation result codes:
success: 11 (84.615%)
entry already exists: 2 (15.385%)

Most common bind operation result codes:
success: 4 (50.000%)
invalid credentials: 4 (50.000%)

Most common delete operation result codes:
success: 1 (100.000%)

Most common modify operation result codes:
success: 9 (69.231%)
no such object: 4 (30.769%)

Most common search operation result codes:
success: 133 (91.724%)
no such object: 12 (8.276%)

Most common search entry counts:
1: 119 (82.069%)
0: 17 (11.724%)
2: 5 (3.448%)
10: 4 (2.759%)

Most common generic filters for searches with a non-base scope:
(objectclass=?): 19 (61.290%)
(ds-backend-id=?): 12 (38.710%)
```

About log compression

The server supports the ability to compress log files as they are written.

This feature can significantly increase the amount of data that can be stored in a given amount of space so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off when the logger is configured. Because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it rotates that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily available tools. The `summarize-access-log` tool can also work directly on compressed log files rather than requiring them to be uncompressed first.

However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging might want to have a second logger defined that does not use compression and has rotation and retention policies that minimizes the amount of space consumed by those logs while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger.

About log signing

The server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way.

For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees.

Use the `dsconfig` tool to enable the `sign-log` property on a log publisher to turn on cryptographic signing.

Copyright © 2025 Ping Identity Corporation

When enabling signing for a logger that already exists and was enabled without signing, the first log file is not completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled are considered completely valid. For the same reason, if a log file is still open for writing, then signature validation does not indicate that the log is completely valid because the log doesn't include the necessary end signed content indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server or the `bat` directory for Windows systems.

After you have enabled this property, you must disable and then re-enable the log publisher for the changes to take effect.

About encrypting log files

The server lets you encrypt log files as they are written.

The `encrypt-log` configuration property controls whether encryption is enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension. If both encryption and compression are enabled, the extension is `.gz.encrypted`. Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off after the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This reduces the overall size of the log file. The `encrypt-file` tool or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`, is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption is performed with the server's preferred encryption settings definition.

To explicitly specify which definition should be used for the encryption, set the `encryption-settings-definition-id` property with the ID of that definition. You should set the encryption settings definition to be created from a passphrase so that the file can be decrypted by providing that passphrase even if the original encryption settings definition is no longer available. You can also create a randomly generated encryption settings definition, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data might remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written.

To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

Configuring log signing

Configure log signing for a log publisher.

Steps

1. To enable log signing for a log publisher, use `dsconfig`.

   Example:

   In this example, the `sign-log` property is set on the File-based Audit Log Publisher.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
  --set sign-log:true
```

2. Disable and then re-enable the log publisher for the change to take effect.

   Example:

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
  --set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit Logger" \
  --set enabled:true
```

Validating a signed file

The server provides a tool, `validate-file-signature`, that checks if a file has not been tampered with in any way.

Steps

- Run the `validate-file-signature` tool to check if a signed file has been tampered with.

  Example:

  For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

  Result:

```
All signature information in file 'logs/audit' is valid
```

> **Note**
>
> If any validations errors occur, you will see a message similar to the one as follows.
>
> ```
> One or more signature validation errors were encountered
> while validating the contents of file 'logs/audit':
> * The end of the input stream was encountered without
>   encountering the end of an active signature block.
>   The contents of this signed block cannot be trusted
>   because the signature cannot be verified
> ```

Configuring log file encryption

Configure log file encryption for a log publisher.

Steps

1. To enable encryption for a log publisher, use `dsconfig`.

   Example:

Copyright © 2025 Ping Identity Corporation

In this example, the File-based Access Log Publisher `"Encrypted Access"` is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access" \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

2. Decrypt and decompress the file.

Example:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/Data-Sync/decrypted-access' using a
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

Log sanitization

The PingDirectory server allows you to sanitize information as it's written to the access log so that you can prevent the system from logging sensitive information.

> **Note**
>
> To learn about the mechanisms to protect information after it has already been logged, see Sanitizing log files.

The PingDirectory server can sanitize log content on a field-by-field basis for default text-based (`name=value`) and JSON-formatted access logs. You can also use log sanitization for any destination where these messages are written, such as log files, syslog, standard output, and standard error messages.

You can control log content for all access logs or on a per-log or per-field basis, including fields generated by third-party extensions. You can also specify a default behavior for all fields of a specified type, such as applying a default sanitization type for all distinguished names (DNs) and search filters.

Configuration elements

There are three main configuration elements for customizing log sanitization:

Copyright © 2025 Ping Identity Corporation

Log field syntaxes

These define the default behavior for each syntax and can specify additional configuration for these syntaxes (for example, the included/excluded LDAP attributes for distinguished names (DNs) and filters or fields for JSON objects).

For more information, see Customizing log field syntaxes.

Log field behaviors

These can be used to define specific behaviors on a per-field basis and an optional overall default behavior for fields that are not explicitly configured.

For more information, see Customizing log field behaviors.

Access loggers

These can be associated with log field behaviors or can default to the log field syntax configuration.

For more information on the description of the behavior of each log sanitization option, see Log sanitization options.

Log sanitization options

There are six options you can use for sanitizing access log fields as they are being written.

Option	Description
`Preserve`	Preserves the original value without attempting to obscure it. **Note** Some sanitization might be performed, such as truncating very long values and escaping special characters, but this is more for usability than privacy.
`Omit`	Excludes the field completely from the log. Neither the field name nor its value will be present in the log.

Copyright © 2025 Ping Identity Corporation

Option	Description
`Redact Entire Value`	**Includes the field name in log messages, but replaces the entire value with a fixed string that does not reveal anything about the actual value for the field.** **To attempt to preserve the original syntax of a field value, the actual string that is used for the redacted value of a field depends on the syntax of that field. The redacted strings include:** ***String, string list, and Boolean fields*** **These fields will have a redacted value of `{REDACTED}`.** **Note** Because Boolean values can only be true or false, redacted and tokenized representations of Boolean values will not conform to the Boolean syntax. If there is concern about leaking sensitive information through a Boolean field, you should omit the field. ***Integer fields*** **These fields will have a redacted value of `-999999999999999999`.** ***Floating-point fields*** **These fields will have a redacted value of `-999999.999999`.** ***Distinguished name (DN) fields*** **These fields will have a redacted value of `redacted={REDACTED}`.** ***Filter fields*** **These fields will have a redacted value of `(redacted={REDACTED})`.** ***JSON object fields*** **These fields will have a redacted value of `{ "redacted":"{REDACTED}" }`.** ***Generalized time fields*** **These fields will have a redacted value of `99990101000000.000Z`.** ***RFC 3339 timestamp fields*** **These fields will have a redacted value of `9999-01-01T00:00:00.000Z`.**

Copyright © 2025 Ping Identity Corporation

`Redact Value Components`	**Includes the field name in log messages but replaces the value with a string that can redact only certain components of the value without redacting the entire value.** **This preserves some usability of the original value without exposing sensitive information.** **Syntaxes that support redacted value components include:** ***String list*** **Each element in the list will be replaced with `{REDACTED}`, so a list with three elements will be represented as `{REDACTED},{REDACTED},{REDACTED}`.** ***DN*** **Attribute names will be preserved, but attribute values will be redacted. For example, the DN `uid=jdoe,ou=People,dc=example,dc=com` will be redacted as `uid={REDACTED},ou={REDACTED},dc={REDACTED},dc={REDACTED}`.** ***Filter*** **As with DNs, attribute names will be preserved, but attribute values will be redacted. For example, the filter `(&(givenName=John)(sn=Doe))` would be redacted as `(&(uid={REDACTED})(sn={REDACTED}))`.** **Note** You can configure the DN and filter log field syntaxes to include or exclude specified attributes from redaction while preserving the other attribute values: • To specify a set of included sensitive attributes so that only those attributes will have their values redacted, and to preserve all other attribute values, use the `included-sensitive-attribute` property. • To specify a set of excluded sensitive attributes so that only the values of the excluded attributes will be preserved, and to redact all other attribute values, use the `excluded-sensitive-attribute` property. ***JSON objects*** **Field names will be preserved but field values will be replaced with the string `{REDACTED}`.**

Copyright © 2025 Ping Identity Corporation

Option	Description
	Note You can configure the JSON log field syntax to include or exclude specified fields from redaction while preserving the other field values: • To specify a set of included sensitive fields so that only those fields will have their values redacted, and to preserve all other field values, use the `included-sensitive-field` property. • To specify a set of excluded sensitive fields so that only the values of the excluded fields will be preserved, and to redact the values of all other fields, use the `excluded-sensitive-field` property. **If a syntax does not have a value with components, the entire value is redacted.**

Copyright © 2025 Ping Identity Corporation

Option	Description
`Tokenize Entire Value`	Includes the field name in log messages but replaces the entire value with a tokenized representation that's based on the original value but doesn't reveal the value. This is similar to redacting the entire value, but because the tokenized value is based on the original value, and the logic used to perform the tokenization is repeatable, you can identify cases in which the same value appears multiple times in the log even if you do not know the original value. • String, string list, and Boolean fields will have a tokenized value of `{TOKENIZED:` *<token-value>* `}`, where *<token-value>* is the actual value for the token generated from the original value (for example, `{TOKENIZED:NcMNHJxmCwhETFIe}`). • Integer fields will have a tokenized value that starts with `-999999999` and is followed by nine more digits generated from the original value (for example, `-999999999600205901`). • Floating-point fields will have a tokenized value that starts with `-999999`. and is followed by six digits generated from the original value (for example, `-999999.695201`). • DN fields will have a tokenized value of `tokenized={TOKENIZED:` *<token-value>* `}`, where *<token-value>* is the value generated from the normalized string representation of the original DN. • Filter fields will have a tokenized value of `(tokenized={TOKENIZED:` *<token-value>* `})`, where *<token-value>* is the value generated from the normalized string representation of the original filter. • JSON object fields will have a tokenized value of `{ "tokenized":"{TOKENIZED:` *<token-value>* `}" }`, where *<token-value>* is the value generated from the normalized string representation of the original JSON object. • Generalized time and RFC 3339 timestamp fields will have a tokenized value with a year of `8888`, with the remainder of the month, day, hour, minute, second, and sub-second elements generated from the original timestamp.

Copyright © 2025 Ping Identity Corporation

`Tokenize Value Components`	**Behaves in the same way as redacted value components, but replaces the redacted string with a tokenized string. Syntaxes that support tokenized value components include:** ***String list*** **Each element in the list will be tokenized individually.** ***DN*** **Attribute names will be preserved, but attribute values will be tokenized.** ***Filter*** **Attribute names will be preserved, but attribute values will be tokenized.** **Note** You can configure the DN and filter log field syntaxes to include or exclude specified attributes from tokenization while preserving the other attribute values: • To specify a set of included sensitive attributes so that only those attributes will have their values tokenized, and to preserve all other attribute values, use the `included-sensitive-attribute` property. • To specify a set of excluded sensitive attributes so that only the values of the excluded attributes will be preserved, and to tokenize all other attribute values, use the `excluded-sensitive-attribute` property. ***JSON objects*** **Field names will be preserved, but field values will be tokenized.**

Copyright © 2025 Ping Identity Corporation

Option	Description
	Note You can configure the JSON log field syntax to include or exclude specified fields from tokenization while preserving the other field values: • To specify a set of included sensitive fields so that only those fields will have their values tokenized, and to preserve all other field values, use the `included-sensitive-field` property. • To specify a set of excluded sensitive fields so that only the values of the excluded fields will be preserved, and to tokenize the values of all other fields, use the `excluded-sensitive-field` property.

After you have identified the approach you want to take for sanitizing your log content as it is written, see Customizing log field syntaxes or Customizing log field behaviors.

Customizing log field syntaxes

Use customized, syntax-based log sanitization to make results as useful as possible while preserving the privacy of sensitive content.

About this task

The following log field syntaxes are supported by the log sanitization functionality:

- **String**
- **String list**
- **Boolean**
- **Integer**
- **Floating-point number**
- **Distinguished name (DN)**
- **LDAP search filter**
- **JSON object**
- **Generalized time timestamp**
- **RFC 3339 timestamp**

Copyright © 2025 Ping Identity Corporation

The following values are accepted for the `default-behavior` property:

- `preserve`
- `omit`
- `redact-entire-value`
- `redact-value-components`
- `tokenize-entire-value`
- `tokenize-value-components`

> **Note**
>
> For more information on the behavior of each value, see Log sanitization options.

Steps

1. To update the default configuration for log field syntax behavior, run `dsconfig set-log-field-syntax-prop`.

   Example:

   The following example updates the DN syntax to indicate that DNs should use component-based redaction by default through the `--set default-behavior` option, but only for a specific set of attributes, using the `--set included-sensitive-attribute` option:

   ```
   dsconfig set-log-field-syntax-prop \
        --syntax-name "Distinguished Name" \
        --set default-behavior:redact-value-components \
        --set included-sensitive-attribute:uid \
        --set included-sensitive-attribute:givenName \
        --set included-sensitive-attribute:sn \
        --set included-sensitive-attribute:cn \
        --set included-sensitive-attribute:mail
   ```

   > **Note**
   >
   > Unless overridden by a more specific log field behavior configuration, any `uid`, `givenName`, `sn`, `cn`, or `mail` attribute values that appear in DNs are redacted, while keeping the rest of the DN intact.
   > For example, a DN of `uid=jdoe,ou=People,dc=example,dc=com`, might be logged as `uid={REDACTED},ou=People,dc=example,dc=com`.

   For more information on including or excluding specific attributes and fields, see Log sanitization options.

2. To finalize your changes, restart the server:

   ```
   bin/stop-server --restart
   ```

Copyright © 2025 Ping Identity Corporation

Customizing log field behaviors

Use customized log field behaviors on a per-field basis to balance your organization's needs for logs that are both useful and secure.

About this task

You can use the following properties to configure log field behaviors for either predefined fields in either the `WriterBasedAccessLogFields` or `JSONAccessLogFields` or for custom log fields in third party plugins.

Behavior	Predefined field configuration property	Custom field configuration property
Preserve	`preserve-field`	`preserve-field-name`
Omit	`omit-field`	`omit-field-name`
Redact entire value	`redact-entire-value-field`	`redact-entire-value-field-name`
Redact value components	`redact-value-components-field`	`redact-value-components-field-name`
Tokenize entire value	`tokenize-entire-value-field`	`tokenize-entire-value-field-name`
Tokenize value components	`tokenize-value-components-field`	`tokenize-value-components-field-name`

For more information on log field behaviors, see Log sanitization options.

Steps

1. To create customized log field behaviors on a per-field basis, run `dsconfig create-log-field-behavior`.

   Example:

   The following example defines a log field behavior object so that the logger tokenizes the values of log fields that are expected to contain host names or IP addresses:

   ```
   dsconfig create-log-field-behavior \
       --behavior-name "Tokenize Hostnames" \
       --type text-access \
       --set tokenize-value-components-field:connect-from-address \
       --set tokenize-value-components-field:connect-to-address \
       --set tokenize-value-components-field:entry-rebalancing-source-server \
       --set tokenize-value-components-field:entry-rebalancing-target-server \
       --set tokenize-value-components-field:externally-processed-bind-end-client-ip-address \
       --set tokenize-value-components-field:requester-ip-address \
       --set tokenize-value-components-field:servers-accessed \
       --set tokenize-value-components-field:target-host
   ```

   Example:

Copyright © 2025 Ping Identity Corporation

The following example defines a log field behavior object so that the logger tokenizes the entire field value of a third party access log field named `myCustomField`:

```
dsconfig create-log-field-behavior \
    --behavior-name "My Log Field Behavior" \
    --type text-access \
    --set tokenize-entire-value-field-name:myCustomField
```

> **Note**
>
> Because the log field behavior does not define a default behavior, it only affects the manner in which specific fields are logged. The default behavior that is configured for the associated log field syntax is used for all other fields.

2. To associate the log field behavior you created with the loggers in which it should be used, run `dsconfig set-log-publisher-prop`.

   Example:

   The following example sets the default log field behavior created in the first example, `"Tokenize Hostnames"` for the file-based access logger:

   ```
   dsconfig set-log-publisher-prop \
       --publisher-name "File-Based Access Logger" \
       --set log-field-behavior:"Tokenize Hostnames"
   ```

3. To finalize your changes, restart the server:

   ```
   bin/stop-server --restart
   ```

Creating new log publishers

The server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher.

For more information, see Configuring Log Rotation and Configuring Log Retention.

Creating a new log publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher.

   Example:

   This example shows how to create a logger that only logs disconnect operations.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access --publisher-name "Disconnect Logger" \
  --set enabled:true \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set log-connects:false \
  --set log-requests:false --set log-results:false \
  --set log-file:logs/disconnect.log
```

Note

To configure compression on the logger, add the `--set compression-mechanism: gzip` option to the previous command.
Because compression cannot be disabled or turned off after configured for the logger, plan carefully to determine your logging requirements, including log rotation and retention with regards to compressed logs.

2. View log publishers with the following command.

```
$ bin/dsconfig list-log-publishers
```

Creating a log publisher using dsconfig interactive command-line mode

Steps

1. In the command line, enter `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. In the main menu, select the option to configure the log publisher.
4. In the `Log Publisher menu`, select the option to create a new log publisher.
5. Select the Log Publisher type.

   For this example, select File-Based Access Log Publisher.
6. Enter a name for the log publisher.
7. Enable it.
8. Enter the path to the log file relative to the PingDirectory server root.

   For this example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. In the `Log Publisher Properties menu`, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Enter `f` to apply the changes.

Copyright © 2025 Ping Identity Corporation

Configuring log rotation

The PingDirectory server allows you to configure the log rotation policy for the server.

About this task

When any rotation limit is reached, the server rotates the current log and starts a new log.

If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

Time Limit Rotation Policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.

Fixed Time Rotation Policy

Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.

Size Limit Rotation Policy

Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.

Never Rotate Policy

Used in a rare event that does not require log rotation.

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring log rotation listeners

The server provides two log file rotation listener, the copy log file rotation listener and the summarize log file rotation listener, which you can enable with a log publisher.

About this task

Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

Copyright © 2025 Ping Identity Corporation

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file is subject to deletion by a log file retention policy, but the copy is not automatically removed.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types.

Steps

- Use the following command to create a new copy log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

> **Note**
>
> The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that are written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

- Use the following command to create a new summarize log file rotation listener.

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

> **Note**
>
> The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.
> As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring log retention

The server allows you to configure the log retention policy for each log on the server.

Copyright © 2025 Ping Identity Corporation

About this task

When a retention limit is reached, the server removes the oldest archived log before creating a new log. Log retention is only effective if you have a log rotation policy in place.

If you create a new log publisher, you must configure at least one log retention policy.

File Count Retention Policy

Sets the number of log files you want the server to retain. The default file count is 10 logs. If the file count is set to 1, then the log continues to grow indefinitely without being rotated.

Free Disk Space Retention Policy

Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.

Size Limit Retention Policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

Time Limit Retention Policy

Sets the maximum length of time that rotated log files should be retained.

Custom Retention Policy

Create a new retention policy that meets your server's requirements. This requires developing custom code to implement the desired log retention policy

Never Delete Retention Policy

Used in a rare event that does not require log deletion.

Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

  Example:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Configuring filtered logging

The PingDirectory server provides a mechanism to filter access log messages based on specific criteria.

About this task

You can use the filtered log with a custom log publisher to create and generate your own custom logs. Adding new filtered logs and associate publishers doesn't change the behavior of any existing logs. For example, adding a new log that only contains operations that were unsuccessful doesn't result in those operations being removed from the default access log.

Copyright © 2025 Ping Identity Corporation

The following example shows how to create a set of criteria that matches any operation that didn't complete successfully. It then explains how to create a custom access log publisher that logs only operations matching that criteria.

> **Note**
>
> This log does not include messages for connects or disconnects, and only a single message is logged per operation. This message contains both the request and result details.

To run log filtering based on any operation result, such as result code, processing time, and response controls, turn off request logging and set the `include-request-details-in-result-messages` property to `TRUE`.

Because filtering based on the results of an operation can't be done until the operation completes, the server has no idea whether to log the request. Therefore, it might log request messages but not log any result messages. If you can only log result messages and include request details in the result messages, then only messages for operations that match the result criteria are logged. All pertinent information about the corresponding requests are included.

Steps

1. Use the `dsconfig` command in non-interactive mode to create a result criteria object set to `failure-result-codes`, a predefined set of result codes that indicate when an operation didn't complete successfully.

   Example:

   ```
   $ bin/dsconfig create-result-criteria --type simple \
     --criteria-name "Failed Operations" --set result-code-criteria:failure-result-codes
   ```

2. Use `dsconfig` to create the corresponding log publisher that uses the result criteria.

   > **Note**
   >
   > The log rotation and retention policies are also set with this command.

   Example:

   ```
   $ bin/dsconfig create-log-publisher \
     --type file-based-access \
     --publisher-name "Filtered Failed Operations" \
     --set enabled:true \
     --set log-connects:false \
     --set log-disconnects:false \
     --set log-requests:false \
     --set "result-criteria:Failed Operations" \
     --set log-file:logs/failed-ops.log \
     --set include-request-details-in-result-messages:true \
     --set "rotation-policy:7 Days Time Limit Rotation Policy" \
     --set "retention-policy:Free Disk Space Retention Policy"
   ```

3. View the `failed-ops.log` in the `logs` directory and verify that only information about failed operations was written to it.

Copyright © 2025 Ping Identity Corporation

Managing Admin Alert Access Logs

Admin Alert Access Logs are a specialized form of filtered log that automatically generates an administrative alert when criteria configured for the log publisher matches those messages in the access log.

About access log criteria

Configuring an Admin Alert Access Log requires you to configure the criteria for the access log messages.

Each criteria can be either a Simple or an Aggregate type. The Simple type uses the set of properties for the client connection, operation request, and the contents of any operation-specific requests or results. The Aggregate type provides criteria that contains Boolean combination of other operation-specific criteria objects.

For more information, see the Ping Identity Directory Server Configuration Reference.

The criteria can be one or more of the following:

Connection Criteria

Defines sets of criteria for grouping and describing client connections based on several properties, including:

- Protocol
- Client address
- Connection security
- Authentication state

Request Criteria

Defines sets of criteria for grouping and describing operation requests based on several properties, including:

- Properties for the associated client connection
- The type of operation
- Targeted entry
- Request controls
- Target attributes
- Other operation-specific terms

Result Criteria

Defines sets of criteria for grouping and describing operation results based on several properties, including:

- The associated client connection and operation request
- The result code
- Response controls
- Privileges missing or used

Copyright © 2025 Ping Identity Corporation

- Other operation-specific terms

Search Entry Criteria

Defines sets of criteria for grouping and describing search result entries based on several properties, including:

- The associated client connection and operation request
- The entry location and contents
- Included controls

Search Reference Criteria

Defines sets of criteria for grouping and describing search result references based on several properties, including:

- The associated client connection and operation request
- Reference contents
- Included controls

Configuring an Admin Alert Access Log publisher

Before configuring an Admin Alert Access Log, you must establish an administrative alert handler in your system.

Steps

1. To create a criteria object for the Admin Alert Access Log, use `dsconfig`.

   If you are using the `dsconfig` tool in interactive mode, the menu items for the criteria operations are located in the `Standard objects menu`.

   Example:

   For this example, we want to log only write operations that target user entries. The following command matches any of the specified operations whose target entry matches the filter `(objectClass=person)`.

   ```
   $ bin/dsconfig create-request-criteria --type simple \
     --criteria-name "User Updates" \
     --set operation-type:add \
     --set operation-type:delete \
     --set operation-type:modify \
     --set operation-type:modify-dn \
     --set "any-included-target-entry-filter:(objectClass=person)"
   ```

2. To create a log publisher of type `admin-alert-access`, use `dsconfig`.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "User Updates Admin Alert Access Log" \
  --type admin-alert-access \
  --set "request-criteria:User Updates" \
  --set include-request-details-in-result-messages:true \
  --set enabled:true
```

Managing the Syslog-Based Access Log Publishers

The PingDirectory server supports access logging using the syslog protocol that is part of the Berkeley Software Distribution (BSD) operating systems.

Syslog provides a flexible, simple means to generate, store, and transfer log messages that's supported on most UNIX and Linux operating systems.

The quasi-standard syslog message format cannot exceed 1 KB and has three important parts:

PRI

Specifies the message priority based on its facility and severity. The message facility is a numeric identifier that specifies the type of log messages, such as kernel messages and mail system messages. The severity is a numeric identifier that specifies the severity level of the operation that is being reported. Together, the facility and the severity determine the priority of the log message indicated by angled brackets and 1-3 digit priority number. For example, `<0>`, `<13>`, and `<103>` are valid representations of the PRI.

Timestamp and host name

The timestamp displays the current date and time of the log. The host name or IP address displays the source of the log.

Message

Displays the actual log message.

You can configure syslog to handle log messages using log priorities that are based on the message's facility and severity. This feature allows users to configure the logging system so that messages with high severities are sent to a centralized repository while lower severity messages are stored locally on a server.

> **Note**
>
> Because the numeric values of the severity and facility are operating system-dependent, the central repository must only include syslog messages from compatible OS types. Otherwise, the meaning of the PRI field is ambiguous.

Before you begin

You must identify the host name and port to which you want to connect.

Because the Syslog Protocol uses user datagram protocol (UDP) packets, you should use `localhost` and use some additional logging tools, such as `syslog-ng`. UDP is an unreliable and unsecure means to transfer data packets between hosts.

Copyright © 2025 Ping Identity Corporation

Logging with syslog

The PingDirectory server can write log messages using the syslog protocol for both access and error logs.

This allows messages to be aggregated at the system level and potentially forwarded to a centralized system. The messages are written to syslog as they are generated, so attackers do not have a chance to alter these log messages.

If you want to use syslog-based logging, configure the server to log to a syslog server running on the local server over the loopback interface. The local syslog server can then forward the messages to a remote server over a secure connection.

Logging over TCP for improved reliability is supported.

UDP-based communication is in the clear, so a network observer can see all of the log messages. You should only use syslog to log to a local syslog server and have it forward messages to a remote server in a secure manner. TLS encryption for TCP-based communication is optionally supported, so you can safely configure the server to log directly to a remote syslog server.

UDP does not provide any feedback about whether messages are successfully delivered, but TCP does provide this feedback. When using TCP-based logging, you can optionally specify information about multiple syslog servers. If the primary syslog server becomes unavailable, the logger can fail over to an alternative syslog server.

Logging access and error log messages can be logged as JSON objects or in legacy space-delimited text format.

In addition to access and error logging over syslog, loggers that can write JSON-formatted audit and HTTP operation log messages are also provided.

Default access log severity level

All messages are logged at the syslog severity level of 6, which are `Informational: informational` messages.

> **Note**
>
> This value is not standard across different types of UNIX or Linux systems. For more information, consult your operating system.

syslog-facility properties

Syslog Facility Properties

When using syslog, specify a facility for the access log messages. As an advanced property, you can select a number that corresponds to the facility you want to use. The default value for the `syslog-facility` property is `1` for user-level messages.

> **Note**
>
> These values are not standard across different types of UNIX or Linux systems. Consult your particular operating system documentation for properties specific to that system.

Facility	Description
`0`	kernel messages
`1`	user-level messages (default)

Copyright © 2025 Ping Identity Corporation

Facility	Description
`2`	mail system
`3`	system daemons
`4`	security/authorization messages
`5`	messages generated internally by syslogd
`6`	line printer subsystem
`7`	network news subsystem
`8`	UUCP subsystem
`9`	clock daemon
`10`	security/authorization messages
`11`	FTP daemon
`12`	NTP subsystem
`13`	log audit
`14`	log alert
`15`	clock daemon
`16`	local use 0
`17`	local use 1
`18`	local use 2
`19`	local use 3
`20`	local use 4
`21`	local use 5
`22`	local use 6
`23`	local use 7

queue-size property

The `queue-size` property determines the maximum number of log records that can be stored in the asynchronous queue.

Copyright © 2025 Ping Identity Corporation

The default queue size set is 10000, which means that the server continuously flushes messages from the queue to the log. The server does not wait for the queue to fill up before flushing to the log. Lowering this value impacts performance.

Configuring a Syslog-Based Access Log Publisher

About this task

You can configure a Syslog-based Access Log Publisher using the `dsconfig` tool. We recommend that you use syslog locally on localhost and use `syslog-ng` to send the syslog messages to remote syslog servers.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

Steps

- Use `dsconfig` to create a log publisher of type syslog-based-access.

  If you are using the `dsconfig` tool in interactive mode, the menu item for Syslog Facility is an advanced property, which can be exposed by typing `a` (for "show advanced properties") on the Syslog-Based Access Log Publisher menu.

  Example:

```
$ bin/dsconfig create-log-publisher \
--publisher-name "syslog-access" \
--type syslog-based-access \
--set syslog-facility:4 \
--set enabled:true
```

Managing the File-Based Audit Log Publishers

The PingDirectory server provides an audit log, a specialized version of the access log, for troubleshooting problems that might occur during processing.

The log records all changes to the data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. Because the audit log adversely impacts the server's write performance, it is disabled by default.

Audit log format

The audit log uses standard LDIF format so that administrators can analyze what changes occurred to the data. The audit log begins logging when enabled and should be used to debug any issues that might have occurred.

Common properties include:

Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>.

Connection ID

Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation.

Copyright © 2025 Ping Identity Corporation

Operation ID

Numeric identifier, starting incrementally with 0, that identifies the operation.

Modifiers Name

Displays the distinguished name (DN) of the user who made the change.

Update Time

Records the `modifyTimestamp` operational attribute.

Audit log example

The following example shows output from the audit log in the `<server-root>/logs/audit`. The first entry shows when the audit log was enabled. The second entry show changes made to a user entry.

```
# 05/Jun/2011:10:29:04 -0500; conn=0; op=55
dn: cn=File-Based Audit Logger,cn=Loggers,cn=config
changetype: modify
replace: ds-cfg-enabled
ds-cfg-enabled: true

```

Enabling the File-Based Audit Log Publisher

About this task

Enable the File-Based Audit Log Publisher using the `dsconfig` tool. The audit log impacts the PingDirectory server's write performance. Enable it only when troubleshooting.

Steps

- To enable the File-Based Audit Log Publisher, run `dsconfig`.

Copyright © 2025 Ping Identity Corporation

Example:

In this example, the instance name and startup ID are also enabled in the audit log.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --set include-instance-name:true \
  --set include-startup-id:true
```

Obscuring values in the audit log

About this task

Each value of an obscured attribute is replaced in the audit log with `OBSCURED VALUE`.

Steps

- To obscure the values of specific attributes in the audit log, use the `obscure-attribute` property.

  By default, attributes are not obscured because the values of password attributes appear in hashed form rather than in cleartext.

Managing the JDBC Access Log Publishers

You can configure the PingDirectory server to implement a centralized logging system with different databases by connecting to a database.

The PingDirectory server supports the Java Database Connectivity (JDBC) API, which allows access to SQL datastores by means of its JDBC drivers. The JDBC 4.0 API, part of the Java SDK, provides a seamless method to interface with various database types in heterogeneous environments.

Centralized logging simplifies log correlation and analysis tasks and provides security by storing data in a single repository. However, data flow asymmetries might complicate synchronization or network provisioning and could unduly burden the central repository with heavy loads.

Before you begin

Before configuring the Java Database Connectivity (JDBC) Access Log Publisher, you must carry out two essential steps to set up the database.

To set up the database:

- Install the database drivers in the PingDirectory server `lib` directory.
- Define the log mapping tables needed to map access log elements to the database column data.

> **Note**
>
> Only those elements in the log mapping table get logged by the JDBC log publisher.

Copyright © 2025 Ping Identity Corporation

Configuring the JDBC drivers

About this task

The PingDirectory server supports several JDBC drivers available in the market. You should use the JDBC 4 drivers supported in the Java platform. For example, for Oracle databases, you must use the `ojdbc.jar` driver for Java and any associated JAR files (National Language Support `.jar` files and others) required to connect with the particular database. The following databases are supported:

- DB2
- MySQL
- Oracle Call Interface (OCI)
- Oracle Thin
- PostgreSQL
- SQL Server

Steps

- Obtain the `.jar` file or files for your particular database and copy them into the `<server-root>/lib` directory.

Configuring the log field mapping tables

About this task

The log field mapping table associates access log fields with the database column names. Configure the log field mapping table using the `dsconfig` tool, which generates a DDL file that you can import into your database. The DDL file is generated when you create the JDBC Log Publisher.

To uniquely identify a log record, you should map the following fields:

- `timestamp`
- `startupid`
- `message-type`
- `connection-id`
- `operation-type`
- `instance-name`

> **Note**
>
> The table name is not part of this mapping.

The PingDirectory server also provides these options that you can select for creating a log field mapping table:

Complete JDBC Access Log Field Mappings

Maps all 52 object properties.

Copyright © 2025 Ping Identity Corporation

Complete JDBC Error Log Field Mappings

Maps all 8 object properties.

Simple JDBC Access Log Field Mappings

Maps a common set of object properties.

Custom JDBC Access Log Field Mappings

Create a custom set of JDBC log field mappings.

Custom JDBC Error Log Field Mappings

Create a custom set of JDBC error log field mappings.

Steps

1. Use `dsconfig` to create a log field mapping table.
2. In the main menu, enter `o` to change to the `Standard Object menu`, and enter the number corresponding to `Log Field Mapping`.
3. In the `Log Field Mapping management menu`, enter the option to create a new Log Field Mapping.
4. In the `Log Field Mapping template menu`, enter the option to select a complete JDBC Access Log Field mapping to use as a template for your new field mapping.
5. Enter a name for the new field mapping.

   For this example, enter `my-jdbc-test`.
6. In the `Access Log Field Mapping Properties menu`, select a property for which you want to change the value.

   Any property that is undefined is not logged by the JDBC Access Log Publisher.
7. Enter `f` to save and apply the changes.
8. In the `Log Field Mapping Management menu`, enter `q` to exit the menu.
9. View the existing Log Mappings on the system.

   Example:

   ```
   $ bin/dsconfig list-log-field-mappings
   ```

   Result:

   ```
   Log Field Mapping                         : Type
   ------------------------------------------:-------
   Complete JDBC Access Log Field Mappings : access
   Complete JDBC Error Log Field Mappings  : error
   my-jdbc-test                            : access
   Simple JDBC Access Log Field Mappings   : access
   ```

Copyright © 2025 Ping Identity Corporation

Configuring the JDBC Access Log Publisher using dsconfig interactive mode

About this task

After setting up the drivers and the log mapping table, use the `dsconfig` tool to configure the JDBC Access Log Publisher on the PingDirectory server. The following example uses `dsconfig` interactive mode to illustrate the steps required to configure the log publisher and the external database server.

Steps

1. Copy the database `.jar` files to the `<server-root>/lib` directory, and then restart the PingDirectory server.
2. Launch the `dsconfig` tool in interactive command-line mode.

   Example:

   ```
   $ bin/dsconfig
   ```

3. Enter the connection parameters to bind to the PingDirectory server.

   Enter the host name or IP address, type of LDAP connection (LDAP, SSL, or StartTLS) that you are using on the PingDirectory server, the LDAP listener port number, the user bind DN, and the bind DN password.
4. In the main menu, enter the number corresponding to `Log Publisher`.
5. In the `Log Publisher management menu`, enter the option to create a new log publisher.
6. In the `Log Publisher template menu`, enter `n` to create a new Log Publisher.
7. In the `Log Publisher Type menu`, enter the option to create a new JDBC-Based Access Log Publisher.
8. Enter a name for the JDBC Access Log Publisher.
9. In the `Enabled Property menu`, enter the option to enable the log publisher.
10. In the `Server Property menu`, enter the option to create a new JDBC External Server.
11. Enter the name for the JDBC External Server.

    This is a symbolic name used to represent the database management system (DBMS).
12. In the `JDBC Driver Type Property menu`, enter the number corresponding to the type of JDBC database driver type.
13. Enter a name for the `database-name` property.

    This is the DBMS database name. The database name must contain the table referred to in the generated DDL.
14. Enter the host name or IP address (server-host-name) of the external server.
15. Enter the server listener port.

    For this example, enter `1541`.
16. Review the properties for the external server, and then enter `f` to apply the changes.
17. If you need to supply your own JDBC URL, enter `a` for advanced properties to open the `jdbc-driver-url` property and supply the appropriate URL.

Copyright © 2025 Ping Identity Corporation

Example:

The example below shows how to access an Oracle Thin Client connection using a SID instead of a Service.

```
>>>> Configure the properties of the JDBC External Server

PropertyValue(s)
-----------------------------------------------------
1) description  -
2) jdbc-driver-type oraclethin
3) jdbc-driver-url jdbc:oracle:thin@myhost:1541:my_SID
4) database-namejdbc-test
5) server-host-name localhost
6) server-port  1541
7) user-name    -
8) password     -

?) help
f) finish - create the new JDBC External Server
a) hide advanced properties of the JDBC External Server
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

Enter choice [b]: f
```

Result:

When the JDBC Log Publisher is created, the PingDirectory server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file, and you receive the following message.

```
JDBC External Server was created successfully
```

18. Import the DDL file to your database.

Configuring the JDBC Access Log Publisher using dsconfig non-interactive mode

About this task

The following example uses `dsconfig` non-interactive mode to illustrate the steps to configure the log publisher and the external database server presented in the previous section.

Steps

1. Use `dsconfig` with the `--no-prompt` option to create the JDBC external server.

   Example:

   ```
   $ bin/dsconfig --no-prompt create-external-server \
     --server-name jdbc-external \ --type jdbc \
     --set jdbc-driver-type:oraclethin \
     --set database-name:ubid_access_log \
     --set server-host-name:localhost --set server-port:1541
   ```

Copyright © 2025 Ping Identity Corporation

2. Use `dsconfig` to create the log publisher.

   Example:

   ```
   $ bin/dsconfig --no-prompt create-log-publisher \
     --publisher-name jdbc-test \
     --type jdbc-based-access \
     --set enabled:true \
     --set server:jdbc-external \
     --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
   ```

   Result:

   When the JDBC Log Publisher is created, the PingDirectory server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file.

3. Import the DDL file to your database.

   The procedure to configure the JDBC-Based Error Log Publisher is similar to creating a JDBC-Based Access Log Publisher. You can run the previous `dsconfig` command with the `--type jdbc-based-error` as follows.

   ```
   $ bin/dsconfig --no-prompt create-log-publisher \
   --publisher-name jdbc-error-test \
   --type jdbc-based-error \
   --set enabled:true \
   --set server:jdbc-external \
   --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
   ```

Managing the File-Based Error Log Publisher

The Error Log reports errors, warnings, and informational messages about events that occur during the course of the PingDirectory server's operation.

Each entry in the error log records the following properties (some are disabled by default and must be enabled):

Timestamp

Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>

Category

Specifies the message category that is loosely based on the server components.

Severity

Specifies the message severity of the event, which defines the importance of the message in terms of major errors that need to be quickly addressed. The default severity levels are:

- `fatal-error`
- `notice`
- `severe-error`

Copyright © 2025 Ping Identity Corporation

- `severe-warning`

Message ID

Specifies the numeric identifier of the message.

Message

Stores the error, warning, or informational message.

Error log example

The following example displays the error log for the PingDataMetrics server. The log is enabled by default and is accessible in the `<server-root>/logs/errors` file.

```
[21/Oct/2012:05:15:23.048 -0500] category=RUNTIME_INFORMATION severity=NOTICE

```

Modifying the File-Based Error Logs

Steps

- To modify the default File-Based Error Log, use `dsconfig`.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Error Logger" \
  --set include-product-name:true --set include-instance-name:true \
  --set include-startup-id:true
```

Managing the Syslog-Based Error Log Publisher

The PingDirectory server supports a Syslog-Based Error Log Publisher using the same mechanism as the Syslog-Based Access Log Publisher.

Configure the error logger using the `dsconfig` tool.

Syslog error mapping

The PingDirectory server automatically maps error log severities to the syslog severities. The following mappings are used.

Error Log Severities	Syslog Severity
FATAL_ERROR,0	Syslog Emergency
SEVERE_ERROR,1	Syslog Alert
SEVERE_WARNING,2	Syslog Critical
MILD_ERROR,3	Syslog Error
MILD_WARNING,4	Syslog Warn
NOTICE,5	Syslog Notice
INFORMATION,6	Syslog Info
DEBUG,7	Syslog Debug

Configuring a Syslog-Based Error Log Publisher

About this task

Configure a Syslog-based Error Log Publisher using the `dsconfig` tool. You should use syslog locally on `localhost` and use `syslog-ng` to send the data packets over the UDP protocol.

Because syslog implementations differ by vendor, review your particular vendor's syslog configuration.

Steps

- Use `dsconfig` to create a log publisher of type `syslog-based-error`.

  Example:

  In this example, set the syslog facility to 4 for security/authorization messages.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-log-publisher --publisher-name "syslog-error" \
  --type syslog-based-error --set syslog-facility:4 --set enabled:true
```

Creating File-Based Debug Log Publishers

The PingDirectory server provides a File-Based Debug Log Publisher that can be configured when troubleshooting a problem that could occur during server processing.

Because the debug data might be too large to maintain during normal operations, the Debug Log Publisher must be specifically configured and enabled. The Debug Log reports the following types of information:

- Exception data thrown by the server.
- Data read or written to network clients.
- Data read or written to the database.
- Access control or password policy data made within the server.

Use the `dsconfig` tool to create a debug log publisher.

> **Note**
>
> You should only create a debug logger when troubleshooting a problem because of the voluminous output the PingDirectory server generates.

Creating a File-Based Debug Log Publisher

Steps

- To create the debug log publisher, use `dsconfig`.

  The `log-file` property (required) sets the debug log path. You must also specify the rotation and retention policy for the debug log.

  Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "File-Based Debug Logger" \
  --type file-based-debug \
  --set enabled:true \
  --set log-file:/logs/debug \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy"
```

Deleting a File-Based Debug Log Publisher

Steps

- To create the debug log publisher, use `dsconfig`.

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig delete-log-publisher \
  --publisher-name "File-Based Debug Logger"
```

Monitoring PingDirectory metrics with Splunk

Metrics from the PingDirectory server can be sent to Splunk either through StatsD pushed directly to Splunk, or through a Periodic Stats Logger that is monitored by a Splunk Universal Forwarder.

A free Splunk (https://splunkbase.splunk.com/app/5523/) application is provided for the PingDirectory server that customers can use to create dashboards.

Sending PingDirectory metrics with StatsD

You can monitor the PingDirectory server using StatsD and Splunk.

In order to send metrics from PingDirectory to Splunk with StatsD, you will need to create a StatsD Monitoring Endpoint. On the Splunk side you will need to open the corresponding port to receive the metrics.

Configuring a StatsD monitoring endpoint

The Stats Collector is used to create a StatsD monitoring endpoint.

Steps

1. To enable the Stats Collector plugin, run the following command.

```
dsconfig set-plugin-prop \
    --plugin-name "Stats Collector" \
    --set enabled:true
```

2. To create a StatsD monitoring endpoint, run the following command. After running the command, the PingDirectory server will send StatsD messages to your Splunk server over UDP at port 8125.

```
dsconfig create-monitoring-endpoint \
    --endpoint-name StatsDEndpoint \
    --type statsd \
    --set enabled:true \
    --set hostname:your-splunk.example.com \
    --set server-port:8125 \
    --set connection-type:unencrypted-udp
```

Copyright © 2025 Ping Identity Corporation

Configuring Splunk to receive StatsD metrics

Splunk can be used to receive StatsD metrics.

About this task

Run the following commands to configure Splunk to receive StatsD metrics.

Steps

1. Sign on to your Splunk dashboard at `http://your-splunk.example.com:8000`.
2. Go to Settings → Data Inputs.
3. Under Local inputs, click UDP.
4. Click New Local UDP.
5. Enter the following information: `Port: 8125`
6. Click Next.
7. Set `Source type` to Metrics> statsd.
8. Create a new `metrics` index for the input. Make a note of the index name you choose.
9. Set the `App Context` to `PingDirectory App for Splunk`.
10. Click Review.
11. Click Submit.

> **Note**
>
> StatsD metrics are typically sent over UDP. Using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost. To more securely send metrics to Splunk, you can first send your StatsD metrics to a Splunk Universal Forwarder, and have the forwarder communicate with Splunk over SSL

Sending Metrics with the Periodic Stats Logger and the Splunk Universal Forwarder

A Splunk Universal Forwarder can be used to forward PingDirectory server events to Splunk.

The Periodic Stats Logger plugin writes PingDirectory server metrics to a file in the server root. A Splunk Universal Forwarder can be configured to watch this file and forward the metrics to Splunk.

Configuring the Periodic Stats Logger

The PingDirectory server can log various metrics, including LDAP operation counts and GC activity, to a JSON-formatted log.

About this task

Copyright © 2025 Ping Identity Corporation

To configure the PingDirectory server to log to a JSON-formatted log file with various metrics, including LDAP operation counts and GC activity, run the following command. The metrics will be written to `logs/dsstats.json` in the server root.

```
dsconfig set-plugin-prop \
                                        --plugin-name "Stats Logger" \
                                        --set enabled:true \
                                        --set log-file:logs/dsstats.json \
                                        --set log-file-format:json \
                                        --set local-db-backend-info:extended \
                                        --set header-prefix-per-column:true \
                                        --set empty-instead-of-zero:false \
                                        --set per-application-ldap-stats:per-application-and-aggregate
```

Configuring the Splunk Universal Forwarder

You can use the Splunk Universal Forwarder to monitor the `logs/dsstats.json` file and forward the metrics to Splunk.

About this task

The Splunk Universal Forwarder can be configured to monitor the `logs/dsstats.json` file and forward the metrics to Splunk. Under the Splunk Forwarder application files, update the `etc/apps/search/local/inputs.conf` file with the following configuration for `dsstats.json`:

```
[monitor:///path/to/PingDirectory/logs/dsstats.json]
                                        sourcetype=log2metrics_json
                                        index=pdmetrics
                                        disabled=false
                                        host=pd1
```

The index name can be customized, and the host value can be configured to label where the metrics are being forwarded from.

Using the PingDirectory server app for Splunk

You can access several dashboards for monitoring the PingDirectory server.

When you have installed the PingDirectory server application for Splunk, you will have access to several dashboards for monitoring metrics. To use these dashboards, you will need to select the index name and metrics source you configured. If you are sending metrics with StatsD, use the metrics index you defined when creating the UDP input in Splunk, and select the StatsD radio button at the top of each dashboard. If you are sending metrics with the Periodic Stats Logger, use the index you defined in the Splunk Universal Forwarder configuration and select the dsstats.json radio button at the top of each dashboard.

Copyright © 2025 Ping Identity Corporation

Monitoring server metrics with Prometheus

Prometheus is an open-source monitoring application that can be used to track numeric metrics over time. It uses HTTP GET requests to retrieve the metric data in the OpenMetrics text-based format.

The server includes an HTTP servlet extension that can publish the values of a configured set of numeric monitor attributes in this format so that they can be consumed by a Prometheus server.

Enabling Prometheus support in the server

The server is preconfigured with an HTTP servlet extension that can publish a wide variety of metrics for use by Prometheus.

To enable the servlet extension, add it to an HTTP or HTTPS connection handler, and either disable and re-enable the connection handler or restart the server. For example:

```
dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --add "http-servlet-extension:Prometheus Monitoring" \
     --set enabled:false

dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --set enabled:true
```

The servlet extension offers several configuration properties that can be used to customize its behavior. They include:

`base-context-path`

The path that the Prometheus server can use to consume any published metrics. By default, this is `/metrics`.

`include-instance-name-label`

Indicates whether all published metrics should include an `instance` label whose value is the name of the server instance.

`include-product-name-label`

Indicates whether all published metrics should include a `product` label whose value is the name of the server product, such as `Ping Identity Directory Server` for the PingDirectory server.

`include-location-name-label`

Indicates whether all published metrics should include a `location` label whose value is the name of the configured location for the server instance.

`always-include-monitor-entry-name-label`

Indicates whether all published metrics should include a `monitor_entry` label whose value is the name of the monitor entry (the value of the `cn` attribute) from which the metric was taken.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Even if this property is set to false, the server will still add this label to metrics in cases where there are multiple monitor entries with the same object class.

`include-monitor-object-class-name-label`

Indicates whether all published metrics should include a `monitor_object_class` label whose value is the name of the object class for the monitor entry from which the metric was taken.

`include-monitor-attribute-name-label`

Indicates whether all published metrics should include a `monitor_attribute` label whose value is the name of the monitor attribute from which the metric was taken.

`label-name-value-pair`

An optional set of name-value pairs for labels that should be included in all metrics published by the server. If provided, each item should use an equal sign to separate the label name from the value, such as `label_name=label_value`.

> **Important**
>
> Label names must:
>
> - Start with a letter or underscore
> - Only contain letters, digits, and underscores
> - Be unique
>
> Label values can be any non-empty string.

After the servlet extension has been enabled, you can verify that the metric information is available by retrieving it with a simple HTTP GET request using a web browser or a command-line tool like `curl` or `wget`.

For example, to retrieve the Prometheus metrics from the server `ds.example.com` using an HTTPS connection handler listening on port 8443 and the `default base-context-path` value of `/metrics`, use a URL of `https://ds.example.com:8443/metrics`.

Customizing published metrics

The server is preconfigured with a wide variety of definitions that publish the values of specified monitor attributes as metrics that can be consumed by Prometheus. However, you can also configure additional metrics by creating Prometheus monitor attribute metrics.

Each of these definitions includes the following configuration properties:

`metric-name`

The name of the metric as it should be published for use in Prometheus. The metric name must start with a letter or an underscore and must contain only letters, digits, and underscores. This is required, and all metric definitions must have a unique name.

Copyright © 2025 Ping Identity Corporation

`monitor-attribute-name`

The name of the monitor attribute whose value should be published as a Prometheus metric. This is required, and only single-valued attributes are supported. The value must be an integer or floating-point number.

`monitor-object-class-name`

The name of the object class for the monitor entry that contains the attribute to publish as a Prometheus metric. This is required.

`metric-type`

The data type for the metric to be published. This is required, and the value should be one of the following:

- `counter` — Indicates that the value is one that increases over time as certain events occur in the server. This can include values that simply increment each time the event occurs, such as counting the number of connections accepted by the server since it started, but it can also include values that increase by larger amounts, such as counting the total number of bytes transferred in responses.
- `gauge` — Indicates that the value is one that can go up or down over time and whose value represents the current state of some aspect of the server, such as the number of connections that are currently established.

`filter`

An optional search filter that can be used to indicate that the metric should only be published for monitor entries that match this filter. If this is not specified, then the metric is published for any monitor entry with the specified attribute and object class.

`metric-description`

An optional human-readable string that describes the purpose for the metric or that provides some other additional information about it.

`label-name-value-pair`

An optional set of name-value pairs for labels that should be included in the definition for the metric. If provided, each item should use an equal sign to separate the label name from the value, such as `label_name=label_value`. Label names must start with a letter or underscore and must only contain letters, digits, and underscores. Label values can be any non-empty string.

> **Note**
>
> Metric-specific labels override server-wide labels, so if a metric-specific label is defined with the same name as a label that would otherwise be applied to all metrics, then the metric-specific value will be used instead of the server-wide value.

For example, to create a Prometheus metric that exposes the value of the `currentConnections` attribute of the general monitor entry, you could use a configuration change like:

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-prometheus-monitor-attribute-metric \
        --extension-name "Prometheus Monitoring" \
        --metric-name general_monitor_current_connections \
        --set monitor-attribute-name:currentConnections \
        --set monitor-object-class-name:ds-general-monitor-entry \
        --set metric-type:gauge \
        --set "metric-description:The number of connections currently established"
```

If you want to remove any of the metrics that are included in the out-of-the-box configuration, then remove the definition for that metric from the server configuration.

Consuming metrics with Prometheus

After the server has been configured to publish its metrics, you can configure Prometheus to consume them.

The basic process is to update the server's `prometheus.yml` file to add a `job` element to the `scrape_configs` section for the server from which the metrics should be retrieved, as in the following example:

```
- job_name: "ds.example.com:8443"
  metrics_path: "/metrics"
  scheme: "https"

  tls_config:
    ca_file: ds.example.com-ca-certificate.pem

  static_configs:
    - targets: ["ds.example.com:8443"]
```

See the Prometheus documentation for complete details.

Managing notifications and alerts

The PingDirectory server provides delivery mechanisms for account status notifications and administrative alerts using SMTP, Java Management Extensions (JMX), or SNMP in addition to standard error logging.

Alerts and events reflect state changes within the server that might be of interest to a user or monitoring service.

Notifications are typically the delivery of an alert or event to a user or monitoring service.

> **Note**
>
> Account status notifications are only delivered to the account owner, notifying a change in state in the account.

Account status notifications

The PingDirectory server supports notification handlers that can notify users, administrators, or both of significant changes related to password policy state for user entries.

Copyright © 2025 Ping Identity Corporation

The following notification handlers are available:

Error Log Account Status Notification Handler

Sends alerts to the error log when an account event occurs. Enabled by default.

SMTP Account Status Notification Handler

Sends notifications to designated email address. Disabled by default, but you can enable it using the `dsconfig` command.

Account status notification types

Notification handlers send alerts when one of the following account status events occurs during password policy processing.

Account Status Notification Types

Account Status Notification Types	Description
`account-disabled`	Generates a notification when a user account is disabled by an administrator.
`account-enabled`	Generates a notification when a user account is enabled by an administrator.
`account-expired`	Generates a notification when a user authentication attempt fails because the account has expired.
`account-idle-locked`	Generates a notification when a user authentication attempt fails because the account has been locked after idling for too long.
`account-permanently-locked`	Generates a notification when a user account is permanently locked, requiring administrative action to unlock the account after too many failed authentication attempts.
`account-reset-locked`	Generates a notification when an authentication attempt fails because the user account is locked after the user failed to change a password that was reset by an administrator within the required interval.
`account-temporarily-locked`	Generates a notification when a user account is temporarily locked after too many failed attempts.
`account-unlocked`	Generates a notification when a user account is unlocked by an administrator.
`password-changed`	Generates a notification when a user changes his or her own password.
`password-expired`	Generates a notification when a user authentication fails because the password has expired.
`password-expiring`	Generates a notification the first time a password expiration warning is encountered for a user password.

Copyright © 2025 Ping Identity Corporation

Account Status Notification Types	Description
`password-reset`	Generates a notification when a user's password is reset by an administrator.

Working with the Error Log Account Status Notification Handler

The Error Log Account Status Notification Handler is enabled by default and sends alerts when one of the account status events occur.

You can view the log at `logs/error`.

Disabling the Error Log Account Status Notification Handler

Steps

- To disable the Error Log Handler, use the `dsconfig` tool.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  ---handler-name "Error Log Handler" --set enabled:false
```

Removing a notification type from the Error Log Handler

Although you can remove an account status notification type from the Error Log Handler, it's not recommended.

About this task

For a list of notification types, see Account status notification types.

Steps

- To remove an account status notification type, use the `dsconfig` tool with the `--remove` option.

  Example:

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "Error Log Handler" \
  --remove account-status-notification-type: password-reset
```

Working with the SMTP Account Status Notification Handler

You can enable account status notifications to be sent to designated email addresses of end users, administrators, or both through an outgoing SMTP server. The email message is automatically generated from template files that contain the text to use in the message body. For example, the message subject for the account-disabled event is:

Copyright © 2025 Ping Identity Corporation

```
account-disabled: Your directory account has been disabled.
```

The message templates are located in the `config/messages` directory. The typical message body template is as follows:

```
Your directory account has been disabled.

For further assistance, please contact a server administrator.
```

By default, the sender address is notifications@example.com, but you can configure your own address.

Before you enable the SMTP Account Status Notification Handler, you must configure the PingDirectory server to use at least one mail server as shown below. You can configure an SMTP server using `dsconfig` and the `set-global-configuration-prop` option.

Configuring the SMTP server

Steps

1. To configure a simple mail server, use the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig create-external-server --server-name smtp1 \
     --type smtp --set server-host-name:smtp.example.com
   ```

2. To configure an SMTP server, use the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set smtp-server:smtp1
   ```

   This command adds the server to the global list of mail servers that the PingDirectory server can use.

Configuring a StartTLS connection to the SMTP server

Steps

1. To configure a StartTLS connection to the server, use the `dsconfig` command.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-external-server \
  --server-name myTLSServer --type smtp \
  --set server-host-name:tls.smtp.example.com \
  --set server-port:587 \
  --set smtp-security:starttls \
  --set user-name:MyAccountName \
  --set password:AAD5yZ+DjvwiYkBSMer6GQ6B3szQ6gSSBjA=
```

2. To configure a newly-created SMTP server, use the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     -set smtp-server:myTLSServer
   ```

   This command adds the server to the global list of mail servers that the PingDirectory server can use.

Configuring an SSL connection to the SMTP server

Steps

1. To create an external SMTP server using SSL, run the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig create-external-server \
     --server-name ssl.smtp.example.com \
     --type smtp --set server-host-name:stmp.gmail.com \
     --set server-port:465 \
     --set smtp-security:ssl \
     --set "user-name:my.name@example.com" \
     --set password:xxxxxx --set "smtp-timeout:10s"
   ```

2. To configure an SMTP server, run the `dsconfig` command.

   Example:

   ```
   $ bin/dsconfig set-global-configuration-prop \
     --set smtp-server:ssl.smtp.example.com
   ```

   This command adds the server to the global list of mail servers that the PingDirectory server can use.

Enabling the SMTP account status notification handler

Steps

- To enable the SMTP account status notification handler, use the `dsconfig` command.

  Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "SMTP Handler" --set enabled:true \
  --set "recipient-address:admin@example.com" \
  --set "sender-address:acct-status-notifications@example.com
```

Viewing the account status notification handlers

After you enable the SMTP server, you can view the list of account status notification handlers.

Steps

- To view the list of account status notification handlers, run the `dsconfig` command.

  Example:

  ```
  $ bin/dsconfig list-account-status-notification-handlers
  ```

  Result:

  ```
  Account Status Notification Handler : Type        : enabled
  ------------------------------------:-----------:--------
  Error Log Handler                       : error-log : true
  SMTP Handler                         : smtp      : true
  ```

Associating account status notification handlers with password policies

To generate notifications when password policy state changes occur in the server, you must configure the password policy that governs the entry being updated to use one or more account status notification handlers.

About this task

By default, password policies are not configured with such handlers, so no account status notifications are generated.

The `account-status-notification-handler` property controls the set of account status notification handlers for a password policy. You can be configure that property using `dsconfig` or the Administrative Console.

Steps

- To configure the `account-status-notification-handler` notification handler property, run `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-password-policy-prop \
    --policy-name "Default Password Policy" \
    --set "account-status-notification-handler:Error Log Handler"
  ```

  This command updates the default password policy to trigger the error log account status notification handler for any appropriate password policy state changes.

Copyright © 2025 Ping Identity Corporation

Administrative alert handlers

The server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The PingDirectory provides several alert handler implementations, including:

- Error Log Alert Handler. Sends administrative alerts to the configured server error logger(s).
- Exec Alert Handler. Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the PingDirectory. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- Groovy Scripted Alert Handler. Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- JMX Alert Handler. Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- SMTP Alert Handler. Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- SNMP Alert Handler. Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- SNMP Subagent Alert Handler. Sends SNMP traps to a primary agent in response to administrative alerts generated within the server.
- Third Party Alert Handler. Provides alert handler implementations created in third-party code using the Server SDK.

Administrative alert types

The PingDirectory server can generate administrative alerts when the events occur.

A full listing of system alerts and their severity is available at `<server-root>/docs/admin-alerts-list.csv`.

Configuring the JMX connection handler and alert handler

You can configure the Java Management Extensions (JMX) connection handler and the alert handler using the **`dsconfig`** tool.

To allow users to receive JMX notifications, enable the `jmx-read` and `jmx-notify` privileges. By default, these privileges aren't granted to any users, including root users or global administrators.

For security reasons, you should create a separate user account that has only these privileges.

You can also configure the JMX connection handler and the alert handler using **`dsconfig`** in interactive command-line mode, which is visible in the `Standard object menu`.

Configuring the JMX connection handler

About this task

Copyright © 2025 Ping Identity Corporation

To enable the JMX connection handler:

Steps

1. Run `dsconfig`.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "JMX Connection Handler" \
     --set enabled:true \
     --set listen-port:1689
   ```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges using the `ldapmodify` tool using an LDIF representation.

   Example:

   ```
   dn: cn=JMX User,cn=Root DNs,cn=config
   changetype: add
   objectClass: top
   objectClass: person
   objectClass: organizationalPerson
   objectClass: inetOrgPerson
   objectClass: ds-cfg-root-dn-user
   givenName: JMX
   sn: User
   cn: JMX User
   userPassword: password
   ds-cfg-inherit-default-root-privileges: false
   ds-cfg-alternate-bind-dn: cn=JMX User
   ds-privilege-name: jmx-read
   ds-privilege-name: jmx-notify
   ```

Configuring the JMX alert handler

About this task

To configure the Java Management Extensions (JMX) alert handler:

Steps

- Run `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
    --set enabled:true
  ```

Copyright © 2025 Ping Identity Corporation

Configuring the SMTP alert handler

To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

About this task

By default, there is no configuration entry for an SMTP alert handler.

Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

  Example:

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%\%alert-type\%\%" \
  --set "message-body:Administrative alert:\\n\%\%alert-message\%\%"
```

Configuring the SNMP subagent alert handler

You can configure the SNMP subagent alert handler using the `dsconfig` tool, which is visible in the `Standard object menu`.

About this task

Before you begin, you need an SNMP subagent capable of communicating using SNMP2c. For more information about SNMP, see Monitoring using SNMP.

The PingDirectory server also supports an SNMP alert handler, which is used in deployments that do not enable an SNMP subagent.

To configure the SNMP subagent alert handler:

Steps

- Run `dsconfig`.

  Example:

  In this example:

  - The `server-host-name` is the address of the system running the SNMP subagent.
  - The `server-port` is the port number on which the subagent is running.
  - The `community-name` is the name of the SNMP community that is used for the traps.

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

Email account status notification handler

The e-mail account status notification handler enables the server to send messages that can contain either a plain-text body, an HTML-formatted body, or both.

If you configure the server to send both plain-text and HTML-formatted bodies, the recipient's email client determines which version to display. Messages can optionally include a set of attachments.

The `config/account-status-notification-email-templates` directory contains a set of template files that the server can use to generate multi-part email messages to send to end users and server administrators when certain events occur.

A separate template is used for each type of event so that the message contents, recipients, and other details can be customized for specific events.

> **Important**
>
> There is a known issue with the `password-expiring.template` file. Replace `%` with `$` in the following sentence in the `<body>` section of the template:
> `Your password will expire at %password_expiration_time_of_day on $password_expiration_date ($time_until_expiration from now).`

Account status notification types

The following account status notification types are available.

- `account-temporarily-locked` — A user's account has been temporarily locked because of too many failed authentication attempts. The account will remain locked until a configured length of time elapses, or until the password is reset by an administrator.
- `account-permanently-locked` — A user's account has been permanently locked because of too many failed authentication attempts. The account will remain locked until the password is reset by an administrator.
- `account-idle-locked` — An authentication attempt failed because it has been too long (longer than the `idle-lockout-interval` configured in the associated password policy) since the user last successfully authenticated to the server. The account will remain locked until the password is reset by an administrator.
- `account-reset-locked` — An authentication attempt failed because the user's account was in a "must change password" state following an administrative password reset, but the user did not choose a new password in a timely manner (within the `max-password-reset-age` duration configured in the associated password policy). The account will remain locked until the password is reset again by an administrator.
- `account-unlocked` — A locked user account has been unlocked (for example, by an administrative password reset).

Copyright © 2025 Ping Identity Corporation

- `account-disabled` — A user's account has been administratively disabled (by setting the `ds-pwp-account-disabled` operational attribute to `true` in the user entry). The user will not be allowed to authenticate until this attribute is removed or its value is set to `false`.
- `account-enabled` — A user's account has been administratively enabled (by setting the `ds-pwp-account-disabled` operational attribute to `false` in the user entry, or by removing this attribute from the entry).
- `account-not-yet-active` — An authentication attempt failed because the user account is configured with an activation time (via the `ds-pwp-account-activation-time` operational attribute in the user's entry) that is in the future. The user will not be allowed to authenticate until this time arrives, until the activation time is removed, or until the activation time is set to a time in the past.
- `account-expired` — An authentication attempt failed because the user account is configured with an expiration time (via the `ds-pwp-account-expiration-time` operational attribute in the user's entry) that is in the past. The user will not be allowed to authenticate until the expiration time is removed or set to a time in the future.
- `password-expired` — An authentication attempt failed because the user's password has expired. The user will not be allowed to authenticate until their password is reset by an administrator (or until they change their own password if `allow-expired-password-changes` is set to `true` in the associated password policy).
- `password-expiring` — The user successfully authenticated, but their password will expire in the near future (as determined by the `password-expiration-warning-interval` setting in the associated password policy). This notification type will only be generated the first time that a user authenticated within a given warning interval.
- `password-reset` — A user's password has been reset by an administrator.
- `password-changed` — A user changed their own password.
- `account-created` — A new account was created in an add request that matches the criteria specified in the `account-creation-notification-request-criteria` property of the account status notification handler configuration.
- `account-updated` — An existing account was updated in a modify or modify DN request that matches the criteria specified in the `account-update-notification-request-criteria` property of the account status notification handler configuration.

Message template file format

An email message for the email account status notification handler contains the following structure:

- A required header section describing the sender, recipients, subject, and other header elements

  This section must appear exactly once, and it must be the first section of the template file.

- An optional section providing a plain-text version of the message body

  This section can appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.

- An optional section providing an HTML-formatted version of the message body

  This section can appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.

- An optional section providing information about an attachment to include in the message

Copyright © 2025 Ping Identity Corporation

This section can be included zero, one, or multiple times, and all attachment sections must appear after all other sections.

Header section

A message template file must start with a header section that specifies the recipient and sender addresses, the message subject, and the values of any custom headers that should appear in the message. It also indicates whether the template should be enabled and used to send email messages.

The header section must begin with the line `----- BEGIN HEADERS -----` and can contain several name-value pairs that provide information about the message. Each name-value pair should appear on a separate line, and the name and value must be separated by a colon and optional spaces. The header section can include the following:

ENABLED

Specifies whether this template is enabled and should be used to generate an email message.

This element must be present and must have a value of either `true` or `false`. This is primarily intended for cases in which a message should only be generated under certain circumstances.

> **Tip**
>
> If you don't want a message sent for a particular notification type, don't specify a template file for that notification type in the configuration for the multi-part email account status notification handler.

TO

Specifies a primary recipient for the email message. This recipient is visible to all recipients.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

To specify multiple `TO` recipients, specify this element multiple times.

It can be omitted if the message should have only `CC` or `BCC` recipients, but the message must have at least one `TO`, `CC`, or `BCC` recipient.

CC

Specifies a carbon-copied recipient for the email message. This recipient isvisible to all recipients.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

To specify multiple `CC` recipients, specify this element multiple times.

It can be omitted if the message should have only `TO` or `BCC` recipients, but the message must have at least one `TO`, `CC`, or `BCC` recipient.

BCC

Specifies a blind carbon-copied recipient for the email message. This recipient is not visible to other recipients.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

Copyright © 2025 Ping Identity Corporation

To specify multiple `BCC` recipients, specify this element multiple times.

It can be omitted if the message should have only `TO` or `CC` recipients, but the message must have at least one `TO`, `CC`, or `BCC` recipient.

FROM

Specifies the address from which the email message should appear to be sent.

This value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

This element must be specified exactly once.

REPLY-TO

Specifies the default address to which users should send replies.

The value can be either an email address, such as `jdoe@example.com`, or a name followed by the email address in angle brackets, such as `John Doe <jdoe@example.com>`.

This element is optional and can only be specified once.

SUBJECT

Specifies the subject for the email message.

This element must be specified exactly once.

HEADER

Defines a custom header for the email message.

The header value itself should be a name-value pair with the name and value separated by a colon and optional spaces, such as `X-Custom-Header-Name:Custom Header Value`.

This is an optional element and can be specified multiple times to specify multiple headers with the same or different names.

Body sections

The header section must be followed by plain-text body sections, HTML-formatted body sections, or both. Each of these sections consists of free-form text that can span multiple lines and continues until the beginning of the next section or the end of the template file is reached.

If a plain-text body is included, it must begin with the line `----- BEGIN PLAIN-TEXT BODY -----`. If an HTML-formatted body is included, it must begin with the line `----- BEGIN HTML BODY -----`. At least one of these sections must be included. If an HTML-formatted body section is included, you should add a plain-text body for the benefit of clients that prefer plain text or cannot handle HTML content. Any blank lines at the beginning or end of the body text are removed, but blank lines in the middle of the body are preserved.

Copyright © 2025 Ping Identity Corporation

Attachment sections

The template can contain any number of optional attachment sections that describe any attachments that should be included in the message. Specify each attachment in its own section at the end of the template, after the header, plain-text, and HTML-formatted body sections. Each attachment section must begin with the line `----- BEGIN ATTACHMENT -----` and can include the following elements, using the same colon-delimited syntax used in the header section:

`FILENAME`

The name (without any path information) of the file to be attached. This must be specified, and the file must exist in the same directory as the template file.

`CONTENT-TYPE`

The `MIME` type for the attachment. This is an optional element. If it is not specified, a default content-type of `application/octet-stream` is used.

`INLINE`

If present, this value must be either `true` or `false`. If it is omitted, a default value of `false` is assumed.

If `true`, indicates that the attachment should be an inline attachment. For example, if you include an image that should be referenced within the HTML body, the image source path should be `cid:` followed by the filename, such as `cid:company-logo.png`.

Customizing the message content

Before the server parses the template file to generate a message, it pre-processes the file with the Apache Velocity templating engine. This enables you to customize the message content with information from the account status notification, details from the associated user entry, and other information. For more information about Apache Velocity, see https://velocity.apache.org/.

The following variables are defined for use with custom directives.

Variable	Description
`$account_entry`	The entry for the user associated with the account status notification.
`$notification_type`	The name of the notification type for the account status notification.
`$notification_message`	A human-readable message that provides a basic description of the account status notification.

Copyright © 2025 Ping Identity Corporation

Variable	Description
`$before_entry`	**A version of the associated entry as it appeared before the operation was processed.** **Note** This is only available for notifications generated as a result of modify or modify distinguished name (DN) operations.
`$after_entry`	**A version of the associated entry as it appeared after the operation was processed.** **Note** This is only available for notifications generated as a result of modify or modify DN operations.

In addition to the built-in directives provided by Velocity, the following custom directives are also available.

Directive	Syntax	Description
`#getEntryDN`	*entry*, *variableName*	**Retrieves a string representation of the provided entry's DN and stores it in the specified Velocity context variable.**
`#getHasAttribute`	*entry*, *attributeName*, *variableName*	**Determines if the provided entry includes the specified attribute. If it contains the specified attribute, a value of `true` is stored in the specified Velocity context variable. If not, a value of `false` is stored.**
`#getUserAttributeNames`	*entry*, *variableName*	**Retrieves a list of the names of the user attributes contained in the provided entry and stores this list in the specified Velocity context variable.**
`#getOperationalAttributeNames`	*entry*, *variableName*	**Retrieves a list of the names of the operational attributes contained in the provided entry and stores this list in the specified Velocity context variable.**

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#getAttributeValue`	*entry*, *attributeName*, *variableName*	Retrieves the first value for the indicated attribute from the provided entry and stores it in the specified Velocity context variable. If the attribute is not present in the entry, the variable is removed from the context.
`#getAttributeValues`	*entry*, *attributeName*, *variableName*	Retrieves the list of values for the indicated attribute from the provided entry and stores this list in the specified Velocity context variable. If the attribute is not present in the entry, an empty list is stored.
`#getEntryMatchesLDAPFilter`	*entry*, *filterString*, *variableName*	Determines if the provided entry matches the LDAP filter with the given string representation. If the entry matches, a value of `true` is stored in the Velocity context variable. Otherwise, a value of `false` is stored.
`#getJSONObjectValue`	*entry*, *attributeName*, *variableName*	Retrieves the first value that can be parsed as a JSON object for the indicated attribute and stores this object in the specified variable in the Velocity context. If the attribute does not exist in the provided entry, or if none of its values can be parsed as a JSON object, the variable is removed from the context.
`#getJSONObjectValues`	*entry*, *attributeName*, *variableName*	Retrieves a list of all values that can be parsed as JSON objects for the indicated attribute and stores this list in the specified variable in the Velocity context. If the attribute does not exist in the provided entry, or if none of its values can be parsed as JSON objects, an empty list is stored.

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#getJSONFieldValue`	*jsonObject*, *fieldName*, *variableName*	Retrieves the first value for the indicated field from the provided JSON object and stores its string representation in the specified Velocity context variable. Nested fields can be targeted by using the period as a delimiter between field names. For example, `name.first` targets the `first` field inside a JSON object that is a value for the outer `name` field. If the field does not exist in the provided object, the variable is removed from the context.
`#getJSONFieldValues`	*jsonObject*, *fieldName*, *variableName*	Retrieves all values for the indicated field from the provided JSON object and stores a list of their string representations in the specified Velocity context variable. Nested fields can be targeted by using the period as a delimiter between field names. For example, `name.first` targets the `first` field inside a JSON object that is a value for the outer `name` field. If the field does not exist in the provided object, or if its value is an empty array, an empty list is stored.
`#getJSONObjectMatchesFilter`	*jsonObject*, *jsonObjectFilterString*, *variableName*	Determines if the provided JSON object matches the JSON object filter with the given string representation. If the JSON object matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
`#getEntry`	*entryDN*, *variableName*	Retrieves the entry with the provided DN from the server and stores it in the specified Velocity context variable. If the entry does not exist, the variable is removed from the context.

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#searchForEntries`	***baseDN***, ***scopeString***, ***filterString***, ***variableName***	Performs an internal search with the provided base DN; scope, which must be one of `base`, `one`, `sub`, or `subordinates`; and filter; and stores the list of matching entries in the specified variable in the context. If the search does not match any entries, if it matches more than 20 entries, or if the search criteria is not indexed, then an empty list is stored.
`#getParentDN`	***entryDN***, ***variableName***	Determines the parent DN for the provided entry DN and stores it in the specified Velocity context variable. If the provided DN contains only a single component, an empty string is stored. If the provided DN is the null DN, and therefore does not have a parent, the variable is removed from the context.
`#getIsAttributeModified`	***beforeEntry***, ***afterEntry***, ***attributeName***, ***variableName***	Determines if the indicated attribute has been modified between the provided before and after representations of the entry. If the attribute has been modified, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#getIsAnyAttributeModified`	*beforeEntry*, *afterEntry*, *attributeName1*, *attributeName2*, ..., *variableName*	Determines if at least one of the listed attributes has been modified between the provided before and after representations of the entry. If at least one of the listed attributes has been modified, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored. The first two arguments to this directive must be the before and after representations of the target entry, and the last argument must be the name of the variable in which to store the result. All arguments in between these are treated as the names or OIDs of the attributes for which to make the determination. At least one attribute name or OID must be provided.
`#getModifiedAttributeNames`	*beforeEntry*, *afterEntry*, *variableName*	Determines which attributes have been modified between the provided before and after representations of the entry, and stores a list of their names in the specified Velocity context variable If the provided entries are identical, an empty list is stored.
`#getModifiedAttributeAddedValues`	*beforeEntry*, *afterEntry*, *attributeName*, *variableName*	Retrieves a list of the values that have been added between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only removed from the attribute, an empty list is stored.

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#getModifiedAttributeRemovedValues`	*beforeEntry*, *afterEntry*, *attributeName*, *variableName*	Retrieves a list of the values that have been removed between the provided before and after representations of an entry for the indicated attribute, and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only added to the attribute, an empty list is stored.
`#getOperationMatchesConnectionCriteria`	*criteriaDN*, *variableName*	Determines if the operation that triggered the notification matches the connection criteria defined in the entry with the specified DN. If it matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
`#getOperationMatchesRequestCriteria`	*criteriaDN*, *variableName*	Determines if the operation that triggered the notification matches the request criteria defined in the entry with the specified DN. If it matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
`#getNotificationPropertyNames`	*variableName*	Retrieves a list of the names of the account status notification properties that are defined for the notification and stores this list in the specified Velocity context variable.
`#getNotificationPropertyValue`	*propertyName*, *variableName*	Retrieves the first value for the given account status notification property and stores it in the specified Velocity context variable. If the property is not defined, the variable is removed from the context. See the following table for *propertyName* values.

Copyright © 2025 Ping Identity Corporation

Directive	Syntax	Description
`#getNotificationPropertyValues`	*propertyName*, *variableName*	Retrieves the list of values for the given account status notification property and stores this list in the specified Velocity context variable. If the property is not defined, an empty list is stored. See the following table for *propertyName* values.
`#getFormattedTimestamp`	*timestamp*, *formatString*, *variableName*	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the provided format string, which must be compatible with the `java.text.SimpleDateFormat` class, and stores it in the specified Velocity context variable. The default time zone of the JVM is used.
`#getFormattedTimestamp`	*timestamp*, *formatString*, *timeZone*, *variableName*	Retrieves a representation of the provided timestamp, which must be in generalized time form, formatted with the given format string, which must be compatible with the `java.text.SimpleDateFormat` class, in the indicated time zone, which must be compatible with the `java.time.ZoneId` class, and stores it in the specified Velocity context variable.
`#getFileExistsInTemplateDirectory`	*fileName*, *variableName*	Determines if a file with the provided name, which must not contain path information, exists in the same directory as the template. If the file exists, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.

The following account status notification properties are available for use in conjunction with the `#getNotificationPropertyValue` and `#getNotificationPropertyValues` directives.

Property	Description
`notification-type`	The name of the account status notification type.

Copyright © 2025 Ping Identity Corporation

Property	Description
`notification-time`	A generalized time representation of the time that the notification was generated.
`account-dn`	The DN of the entry for the associated user account.
`password-policy-dn`	The DN of the password policy that governs the associated user account.
`password-changed-time`	A generalized time representation of the time the user's password was last changed.
`seconds-since-password-change`	The number of seconds since the account's password was last changed.
`time-since-password-change`	A human-readable duration indicating the length of time since the user's password was last changed.
`account-is-usable`	The value is `true` if the account is considered usable, or `false` if it is not usable. The account is considered unusable if, for example, the account is locked, expired, or not yet active; if the password is expired; if the user must choose a new password; and so on.
`account-usability-errors`	A list of human-readable strings providing information about any errors that currently affect the account's usability.
`account-usability-warnings`	A list of human-readable strings providing information about any warning conditions that have the potential to affect the account's usability in the near future.
`account-usability-notices`	A list of human-readable strings providing information about any notable account state conditions that are not expected to affect the account's usability in the near future.
`account-is-disabled`	The value is `true` if the account has been administratively disabled, or `false` if it has not been administratively disabled.
`account-is-not-yet-active`	The value is `true` if the account has an activation time in the future, or `false` if not.
`account-activation-time`	A generalized time representation of the account activation time, if defined.

Copyright © 2025 Ping Identity Corporation

Property	Description
`seconds-until-account-activation`	The number of seconds until the account becomes active if it has an activation time in the future.
`time-until-account-activation`	A human-readable duration indicating the length of time until the account becomes active if it has an activation time in the future.
`seconds-since-account-activation`	The number of seconds since the account became active if it has an activation time in the past.
`time-since-account-activation`	A human-readable duration indicating the length of time since the account became active if it has an activation time in the past.
`account-is-expired`	The value is `true` if the account has an expiration time in the past, or `false` if not.
`account-expiration-time`	A generalized time representation of the account expiration time, if defined.
`seconds-until-account-expiration`	The number of seconds until the account expires if it has an expiration time in the future.
`time-until-account-expiration`	A human-readable duration indicating the length of time until the account expires if it has an expiration time in the future.
`seconds-since-account-expiration`	The number of seconds since the account expired if it has an expiration time in the past.
`time-since-account-expiration`	A human-readable duration indicating the length of time since the account expired if it has an expiration time in the past.
`account-is-failure-locked`	The value is `true` if the account has been temporarily or permanently locked because of too many failed authentication attempts, or `false` if not.
`failure-locked-time`	A generalized time representation of the time that the account became failure-locked, if applicable.
`account-unlock-time`	A generalized time representation of the time that the account will be automatically unlocked, if it is temporarily locked because of too many failed authentication attempts.
`seconds-until-unlock`	The number of seconds until the account unlock time, if applicable.

Copyright © 2025 Ping Identity Corporation

Property	Description
`time-until-unlock`	A human-readable duration indicating the length of time until the account unlock time, if applicable.
`failure-lockout-count`	The number of failed authentication attempts required to lock an account, if configured.
`failure-lockout-duration-seconds`	The number of seconds that a failure-locked account will be prevented from authenticating, if defined.
`failure-lockout-duration`	A human-readable duration that indicates how long a failure-locked account will be prevented from authenticating, if defined.
`account-is-idle-locked`	The value is `true` if the account is locked because it has been too long since the user last authenticated, or `false` if not.
`idle-lockout-interval-seconds`	The maximum number of seconds that can pass between successful authentications before an account becomes idle-locked, if configured.
`idle-lockout-interval`	A human-readable duration that indicates how much time can pass between successful authentications before an account becomes idle-locked, if configured.
`last-login-time`	A generalized time representation of the time that the user last successfully authenticated, if available.
`seconds-since-last-login`	The number of seconds that have passed since the user last successfully authenticated, if available.
`time-since-last-login`	A human-readable duration indicating the length of time that has passed since the user last successfully authenticated, if available.
`last-login-ip-address`	The IP address of the client from which the user last authenticated, if available.
`account-is-reset-locked`	The value is `true` if the account is locked because the user failed to choose a new password in a timely manner after an administrative password reset, or `false` if not.
`maximum-password-reset-age-seconds`	The maximum number of seconds that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.

Copyright © 2025 Ping Identity Corporation

Property	Description
`maximum-password-reset-age`	A human-readable duration indicating the maximum length of time that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
`must-change-password`	The value is `true` if the user will be required to choose a new password before they are allowed to perform any other operations on the server, or `false` if not.
`account-was-unlocked`	The value is `true` if the account had been locked but was just unlocked by the associated operation, or `false` if not.
`password-is-expired`	The value is `true` if the account has an expired password, or `false` if not.
`password-is-expiring`	The value is `true` if the account has a password that will expire in the near future, as determined by the password-expiration-warning-interval property in the associated password policy, or `false` if not.
`maximum-password-age-seconds`	The maximum number of seconds that an account is permitted to keep the same password before it expires, if defined.
`maximum-password-age`	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
`maximum-password-age`	A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
`password-expiration-time`	A generalized time representation of the time that the account's password did or will expire, if applicable.
`seconds-until-password-expiration`	The number of seconds until the account's password will expire, if it has an expiration time in the future.
`time-until-password-expiration`	A human-readable duration indicating the length of time until the account's password will expire, if it has an expiration time in the future.
`seconds-since-password-expiration`	The number of seconds since the account's password expired, if it has an expiration time that is in the past.
`time-since-password-expiration`	A human-readable duration indicating the length of time since the account's password expired, if it has an expiration time in the past.

Copyright © 2025 Ping Identity Corporation

Property	Description
`old-password`	The clear-text password that the account had before the associated operation was processed, if available.
`new-password`	The clear-text password that the account has after the associated operation was processed, if available.
`new-generated-password`	The clear-text password that was generated for the account by the associated operation, if applicable.
`requester-ip-address`	The IP address of the client that requested the associated operation, if available.
`requester-dn`	The DN of the account that requested the associated operation.
`operation-type`	The name of the operation type for the associated operation.
`operation-id`	A string representation of the operation ID for the associated operation.
`connection-id`	A string representation of the connection ID for the associated operation.
`server-uuid`	A string representation of the unique identifier generated for the server instance that processed the associated operation.
`instance-name`	The instance name for the server instance that processed the associated operation.

Working with the Alerts Backend

The PingDirectory server stores recently-generated admin alerts in an Alerts Backend under the `cn=alerts` branch.

The backend makes it possible to obtain admin alert information over LDAP. The backend's primary job is to process search operations for alerts. It does not support `add`, `modify`, or `modify DN` operations of entries in the `cn=alerts` backend.

The alerts persist on the server in the `config/alerts.ldif` file so they can survive server restarts. By default, the alerts remain in the system for seven days before being removed. Administrators can configure the number of days alerts are retained by using the `dsconfig` tool.

The administrative alerts of `Warning` level or worse that have occurred in the last 48 hours are viewable from the output of the status command-line tool and in the administrative console.

Copyright © 2025 Ping Identity Corporation

Viewing information in the Alerts Backend

About this task

To view admin alerts:

Steps

- Run `ldapsearch`.

  Example:

  ```
  $ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
    --bindPassword secret --baseDN cn=alerts "(objectclass=ds-admin-alert)"
  ```

  Result:

  ```
  dn: ds-alert-id=3d1857a2-e8cf-4e80-ac0e-ba933be59eca,cn=alerts
  objectClass: top
  objectClass: ds-admin-alert
  ds-alert-id: 3d1857a2-e8cf-4e80-ac0e-ba933be59eca
  ds-alert-type: server-started
  ds-alert-severity: info
  ds-alert-type-oid: 1.3.6.1.4.1.32473.2.11.33
  ds-alert-time: 20110126041442.622Z
  ds-alert-generator: com.unboundid.directory.server.core.directory.server
  ds-alert-message: The Directory Server has started successfully
  ```

Modifying the alert retention time

Steps

- To change the retention time of admin alerts, run `dsconfig`.

  Example:

  ```
  $ bin/dsconfig set-backend-prop --backend-name "alerts" \
    --set "alert-retention-time: 2 weeks"
  ```

  After this time, the information is purged from the PingDirectory server. The minimum retention time is 0 milliseconds, which immediately purges the alert information.

- To view the `alert-retention-time` property, use `dsconfig`.

  Example:

  ```
  $ bin/dsconfig get-backend-prop --backend-name "alerts" \
    --property alert-retention-time
  ```

  Result:

Copyright © 2025 Ping Identity Corporation

```
Property: Value(s)
---------------------:---------
alert-retention-time : 2 w
```

Configuring duplicate alert suppression

About this task

The `duplicate-alert-time-limit` property specifies the length of time that must pass before duplicate messages are sent over the administrative alert framework.

The `duplicate-alert-limit` property specifies the maximum number of duplicate alert messages that can be sent over the administrative alert framework in the time limit specified in the `duplicate-alert-time-limit` property.

To configure the maximum number of times an alert is generated within a particular timeframe for the same condition:

Steps

- Run `dsconfig`.

  Example:

```
$ bin/dsconfig set-global-configuration-prop \
  --set duplicate-alert-limit:2 \
  --set "duplicate-alert-time-limit:3 minutes"
```

Working with alarms, alerts, and gauges

Alarms, alerts, and gauges alert administrators to changes in server conditions that might require attention.

Alarms

An alarm represents a stateful condition of the server or a resource that might indicate a problem, such as low disk space or external server unavailability.

Alarms have severity, name, and message. Alarms will always have a Condition property, and can have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. You can configure alarms to generate alerts when the alarm's severity changes.

You can configure the Alarm Manager, which governs the actions performed when an alarm state is entered, through the `dsconfig` tool and the administrative console. A complete list of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

The server complies with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state might result in one or more alerts.

An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Copyright © 2025 Ping Identity Corporation

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. You can view alarms with the `status` tool. As with other alert types, you can configure alert handlers can to manage the alerts generated by alarms.

Alerts

There are two alert types supported by the server: standard and alarm-specific.

The server constantly monitors for conditions that might need administrator attention, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`.

You can configure the server to generate alarm-specific alerts as well as standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

Gauges

A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state.

Numeric gauges monitor continuous values like CPU load or free disk space. Indicator gauges monitor enumerated set of values such as `server available` or `server unavailable`. Gauges generate alarms when the gauge's severity changes because of changes in the monitored value.

The server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. You can tailor existing gauges to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered.

Use the Stats Logger to view historical information about the value and severity of all system gauges. For more information, see Profiling server performance using the Stats Logger.

Viewing information in the Alarms Backend

About this task

Use `ldapsearch` to view alarms.

Steps

- To display the listing for the CPU usage alarm, run the following command.

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --baseDN cn=alarms "(objectclass=ds-admin-alarm)"
```

Result:

Copyright © 2025 Ping Identity Corporation

```
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
objectClass: top
objectClass: ds-admin-alarm
ds-alarm-id: CPU Usage (Percent)-Host System
ds-alarm-condition: CPU Usage (Percent)
ds-alarm-specific-resource: Host System
ds-alarm-severity: CRITICAL
ds-alarm-previous-severity: CRITICAL
ds-alarm-details: Gauge CPU Usage (Percent) for Host System
       has value 99, having had a value of 83.13 in the
       previous interval. The severity is critical, having
       assumed this severity Thu Sep 25 10:24:20 CDT 2014
       when the value crossed threshold 80
ds-alarm-additional-text: If CPU use is high, check the server's current workload
       and other processes on this system and make any needed adjustments. Reducing
       the load on the system will lead to better response times
ds-alarm-start-time: 20140925152420.004Z
ds-alarm-critical-last-time: 20140925152420.004Z
ds-alarm-critical-total-duration-millis: 0
```

Testing alerts and alarms

After alarms and alert handlers are configured, you can manually increase the severity of a gauge to verify that the server takes the appropriate action when an alarm state change.

You can then use the `status` tool to verify alarms and alerts.

Testing alarms and alerts

Steps

1. Use `dsconfig` to configure a gauge and set the `override-severity` property to critical.

   The following example configures the CPU Usage (Percent) gauge.

   Example:

   ```
   $ dsconfig set-gauge-prop \
     --gauge-name "CPU Usage (Percent)" \
     --set override-severity:critical
   ```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts.

   The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms.

   Example:

   The sample output has been shortened to show just the alarms and alerts information.

Copyright © 2025 Ping Identity Corporation

```
$ bin/status

Shown are alarms of severity [Warning,Minor,Major,Critical]
Use the --alarmSeverity option to filter this list
```

Indeterminate alarms

The server raises indeterminate alarms for a server condition for which a severity cannot be determined.

In most cases these alarms are benign and do not issue alerts, nor do they appear in the output of the `status` tool or Administrative Console by default.

These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication might produce indeterminate alarms if a server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There might be messages that can help determine the issue.

The following is sample output from the `status` tool run with the `–alarmSeverity=indeterminate` option.

```

Managing SCIM servlet extensions

The PingDirectory server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. The SCIM 1.1 implementation is provided by the servlet extension named SCIM. The SCIM 2.0 implementation is provided by the servlet extension named SIMC2.

Copyright © 2025 Ping Identity Corporation

Managing SCIM 1.1 and 2.0 servlet extensions

The PingDirectory and PingDirectoryProxy servers provide two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications securely and quickly. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

SCIM 1.1 servlet extension configuration

This SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

Understanding the basic concepts of SCIM can help you use the SCIM 1.1 extension to meet your deployment needs. SCIM allows you to:

- Provision identities. Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- Provision groups. SCIM also allows you to manage groups.
- Interoperate using a common schema. SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

> **Note**
>
> SCIM 1.1 will be deprecated in a future release.

The server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes

Copyright © 2025 Ping Identity Corporation

SCIM Feature	Supported
User resources	Yes
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes
Query result sorting*	Yes
Query result pagination*	Yes (Directory server, not Directory Proxy server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

`*` denotes an optional feature of the SCIM protocol.

`**` denotes a the Server extension to the basic SCIM functionality.

Summary of SCIM 1.1 protocol support

the server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

The Identity Access API

The PingDirectory server, PingDirectoryProxy server, and PingDataSync server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access PingDirectory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (for example, 'Users' and 'Groups'), only LDAP object classes (for example, `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there can be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (for example, `top` → `person` → `organizationalPerson` → `inetOrgPerson`, and so forth), a client application can access an entry in multiple ways because of the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the server.

Configuring SCIM 1.1

This section discusses details about the PingDirectory server and PingDirectoryProxy server implementations of the SCIM protocol.

Before reading these topics, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

Creating your own SCIM 1.1 application

To create your own System for Cross-domain Identity Management (SCIM) 1.1 application, you must download the SCIM 1.1 SDK.

SCIM is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes, and is available for download. It provides developers with a simple, concrete API to interact with a SCIM service provider.

> **Note**
>
> The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the **`scim-resource.xml`** configuration file, but not if the SCIM attribute is a core SCIM attribute.

Copyright © 2025 Ping Identity Corporation

Configuring the SCIM 1.1 servlet extension

The PingDirectory server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (for example, changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

Configuring SCIM manually
About this task

The following example procedure assumes that you have configured the PingDirectory server using the default settings, which means that SSL and the HTTPS Connection Handler have not been configured. The example also shows the `dsconfig` non-interactive commands. You can easily use the `dsconfig` interactive commands, which uses a menu-driven interface. If you use the `dsconfig` interactive, you must change to the Standard or Advanced object menu to access many of these configuration settings.

Steps

1. Set up your certificates. Follow the examples shown in Managing certificates. You should have a keystore and truststore set up in the `config` directory. Make sure that the keystore.pin and truststore.pin are set.
2. Enable the key manager provider. The key manager provider accesses the certificate during the SSL handshaking process. If running `dsconfig` interactive, open the main menu, select "Key Manager Provider" → "View and edit an existing Key Manager Provider" → "JKS" (or the type of certificate you are working with) → "enabled" and then set the value to "true". Click "finish" to save the setting.

   Example:

   ```
   $ bin/dsconfig create-key-manager-provider \
     --provider-name JKS \
     --type file-based --set enabled:true
     --set key-store-file:config/keystore \
     --set key-store-type:JKS
     --set key-store-pin-file:config/keystore.pin
   ```

3. Enable the trust manager provider. The trust manager provider determines if a presented certificate can be trusted. If running `dsconfig` interactive, open the main menu, select "Trust Manager Provider" → "View and edit an existing Trust Manager Provider" → "JKS" (or the type of certificate you are working with) → "enabled" and then set the value to "true". Click "finish" to save the setting.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig create-trust-manager-provider
  --provider-name JKS \
  --type file-based --set enabled:true \
  --set trust-store-file:config/truststore \
  --set trust-store-type:JKS \
  --set trust-store-pin-file:config/truststore.pin
```

4. Configure the HTTPS Connection Handler. If not already created, this command creates and enables the connection handler, specifies the SCIM HTTP servlet extension and sets the listen port to a port of your choice, in this example, use 8443. The command also specifies the type of key manager and trust manager providers and sets the log publisher to "HTTP Detailed Access." If running `dsconfig` interactive, open the main menu, select "Connection Handler" → "View and edit an existing Connection Handler" → "HTTPS Connection Handler". Change the parameters to match your setup, and then, click "finish" to save the setting.

   Example:

   ```
   $ bin/dsconfig create-connection-handler \
     --handler-name "HTTPS Connection Handler" \
     --type http --set enabled:true \
     --set listen-port:8443 \
     --set use-ssl:true \
     --set http-servlet-extension:SCIM \
     --set "http-operation-log-publisher:HTTP Detailed Access" \
     --set key-manager-provider:JKS --set trust-manager-provider:JKS
   ```

   If the HTTPS Connection Handler already exists, use the following:

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --add http-servlet-extension:SCIM
   ```

5. Turn on the connection handler.

   Example:

   ```
   $ bin/dsconfig set-connection-handler-prop \
     --handler-name "HTTPS Connection Handler" \
     --add http-servlet-extension:SCIM
   ```

6. Add access controls to allow access to LDAP controls used by the SCIM Servlet Extension. These controls are the Post-Read Request Control (1.3.6.1.1.13.2), Server-Side Sort Request Control (1.2.840.113556.1.4.473), Simple Paged Results Control (1.2.840.113556.1.4.319), and Virtual List View Request Control (2.16.840.1.113730.3.4.9). We recommend using the following command to add access control instructions, rather than its `dsconfig` interactive equivalent.

   Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 || 1.2.840.113556.1.4.473 || 1.2.840.113556.1.4.319 ||
2.16.840.1.113730.3.4.9")
    (version 3.0;acl "Authenticated access to controls used by the SCIM servlet
     extension"; allow (all) userdn="ldap:///all";)'
```

7. Add access controls to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its `dsconfig` interactive equivalent.

   Example:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id ||
    createTimestamp || modifyTimestamp")
    (version 3.0;acl "Authenticated read access to operational attributes \
    used by the SCIM servlet extension"; allow (read,search,compare)
    userdn="ldap:///all";)'
```

8. Optional. The SCIM HTTP Connection Handler automatically uses a detailed HTTP log publisher, which is implemented in a proprietary format. If you need a standard W3C common log format publisher, enter the following command. If running `dsconfig` interactive, open the main menu, select "Log Publisher" → "Create a new Log Publisher" → "new Log Publisher created from scratch" → "File Based Access Log Publisher", enter the parameters to match your setup, and then, click "finish" to save the setting. Go back to the main menu, select "Connection Handler" → "HTTPS Connection Handler", and then add "HTTP Common Access" to the `http-operation-log-publisher` property. Click "finish" to save the setting.

   Example:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access" \
  --type common-log-file-http-operation --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add "http-operation-log-publisher:HTTP Common Access"
```

9. Optional. To support searching or filtering by DN using the Identity Access API, you can enable the entryDN virtual attribute. If running `dsconfig` interactive, open the main menu, select "Virtual Attribute" → "View and edit an existing Virtual Attribute" → "Entry DN", and then change the enabled property to "true". Click "finish" to save the setting.

   Example:

```
$ bin/dsconfig set-virtual-attribute-prop --name entryDN --set enabled:true
```

Copyright © 2025 Ping Identity Corporation

10. Optional. To support pagination, create some Virtual List View indexes. If running `dsconfig` interactive, open the main menu, select "Local DB VLV Index" → "Create a new Local DB VLV Index" and then enter the properties needed for your setup. Click "finish" to save the setting. Repeat again for the "ascending-sn" index. Then, run the `rebuild-index` command to let the VLV Indexes take effect.

    Example:

    ```
    $ bin/dsconfig create-local-db-vlv-index --backend-name userRoot \
      --index-name ascending-uid --set base-dn:dc=example,dc=com \
      --set scope:whole-subtree \
      --set "filter:(objectclass=inetorgperson)" \
      --set "sort-order:+uid"

    $ bin/dsconfig create-local-db-vlv-index --backend-name userRoot \
      --index-name ascending-sn \
      --set base-dn:dc=example,dc=com \
      --set scope:whole-subtree \
      --set "filter:(objectclass=inetorgperson)" \
      --set "sort-order:+sn"

    $ bin/rebuild-index --baseDN dc=example,dc=com \
      --index vlv.ascending-uid \
      --index vlv.ascending-sn
    ```

Enabling resource versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

Steps

1. Enable the `ds-entry-checksum` virtual attribute.

    Example:

    ```
    $ bin/dsconfig set-virtual-attribute-prop \
        --name ds-entry-checksum \
        --set enabled:true
    ```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

    Example:

    ```
    $ bin/dsconfig set-access-control-handler-prop \
        --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-
    create-time || modifyTimestamp || ds-update-time")(version 3.0;acl "Authenticated read access to operational
    attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
    ```

3. Add new access controls required by SCIM for read access to operational attributes with the addition of the `ds-entry-checksum`:

    Example:

Copyright © 2025 Ping Identity Corporation

```
$ bin/dsconfig set-access-control-handler-prop \
    --add  'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-
create-time || modifyTimestamp || ds-update-time || ds-entry-checksum")(version 3.0;acl "Authenticated read
access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare)
userdn="ldap:///all"'
```

4. Enable SCIM resource versioning using the entry checksum virtual attribute:

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
       --extension-name SCIM \
       --set entity-tag-ldap-attribute:ds-entry-checksum
   ```

   Result:

   If enabled, the value of the `ds-entry-checksum` attribute is returned as the `ETag` header value when accessing the resource through SCIM, and is checked against the `If-Match` header when updating the resource. When accessing the resource through LDAP, use the `ds-entry-checksum` attribute instead.

Configuring the SCIM servlet extension using the batch script
About this task

The following example procedure assumes that you have set up your certificates, keystore, and truststore.

Steps

1. Open the `<server-root>/config/scim-config-ds.dsconfig` script in a text editor.
2. For the optional elements (W3C common log, filtering by DN, and VLV Indexes, remove the comment (#) symbol on the `dsconfig` commands. Save the file when finished editing.
3. To enable the SCIM servlet extension, run the `dsconfig` batch file. Remember to include the bind parameters.

   Example:

   ```
   $ bin/dsconfig --batch-file config/scim-config-ds.dsconfig
   ```

SCIM 1.1 servlet extension authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the PingDirectory server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

Copyright © 2025 Ping Identity Corporation

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, the Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

Configuring basic authentication using an identity mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of cn.

   Example:

   ```
   $ bin/dsconfig create-identity-mapper \
     --mapper-name "CN Identity Mapper" \
     --type exact-match \
     --set enabled:true \
     --set match-attribute:cn
   ```

2. Configure the SCIM servlet to use the new Identity Mapper.

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM \
     --set "identity-mapper:CN Identity Mapper"
   ```

Enabling OAuth authentication

About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

Steps

1. Install your OAuth token handler on the server using `dsconfig`.

   Example:

   ```
   $ bin/dsconfig create-oauth-token-handler \
     --handler-name ExampleOAuthTokenHandler \
     --type third-party \
     --set extension-class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
   ```

2. Configure the SCIM servlet extension to use it as follows:

Copyright © 2025 Ping Identity Corporation

Example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set oauth-token-handler:ExampleOAuthTokenHandler
```

Verifying the SCIM 1.1 servlet extension configuration

About this task

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To verify the SCIM servlet extension configuration:

Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off curl's verification of the server certificate, since the example PingDirectory server is using a self-signed certificate.

  Example:

  ```
  $ curl -u "cn=Directory Manager:password" \
  -k "https://localhost:8443/scim/ServiceProviderConfigs"

  {"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
  "patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
  "maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
  "changePassword":{"supported":true},"sort":{"supported":true},
  "etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
  "description":"The HTTP Basic Access Authentication scheme. This scheme is
  not considered to be a secure method of user authentication (unless used in
  conjunction with some external secure system such as SSL), as the user
  name and password are passed over the network as cleartext.","specUrl":
  "http://www.ietf.org/rfc/rfc2617","documentationUrl":
  "http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
  ```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the PingDirectory server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

  Example:

  ```
  $ curl -u "user.0:password" \
    -k "https://localhost:8443/scim/ServiceProviderConfigs"
  ```

Configuring the Identity Access API

After you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API.

To allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- include-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value "*" to allow all object classes. If "*" is used, then the SCIM servlet uses the same case used in the server LDAP Schema.
- exclude-ldap-objectclass. Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- include-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will be exposed. If specified, only entries under these base DNs will be accessible. No parent-child relationships in the DNs are allowed here.
- exclude-ldap-base-dn. Specifies a multi-valued property that lists the base DNs that will not be exposed. If specified, entries under these base DNs will not be accessible. No parent-child relationships in the DNs are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

Configuring the Identity Access API

Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

   Example:

   ```
   $ bin/dsconfig set-http-servlet-extension-prop \
     --extension-name SCIM --set 'include-ldap-objectclass:*' \
     --set include-ldap-base-dn:ou=People,dc=example,dc=com
   ```

   Result:

   The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

Copyright © 2025 Ping Identity Corporation

Disabling core SCIM resources

Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

> **Note**
>
> When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using **`dsconfig`**, the changes take effect immediately without any restart required.

Verifying the Identity Access API configuration

Steps

- Perform a curl request to verify the Identity Access API configuration.

  Result:

```
$ curl -k -u "cn=directory manager:password" \
  -H "Accept: application/json" \
  "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
     attributes=entryDN,uid,givenName,sn,entryUUID"
     {"schemas":["urn:scim:schemas:core:1.0","urn:unboundid:schemas:scim:ldap:1.0"],
      "id":"56c9fd6b-f870-35ef-9959-691c783b7318",
      "meta":{"lastModified":"2013-01-11T23:38:26.489Z",
      "location":"https://example.com:443/v1/top/56c9fd6b-f870-35ef-9959-691c783b7318"},
      "urn:unboundid:schemas:scim:ldap:1.0":{"givenName":["Rufus"],"uid":["user.1"],
      "sn":["Firefly"],"entryUUID":["56c9fd6b-f870-35ef-9959-691c783b7318"],
      "entrydn":"uid=user.1,ou=people,dc=example,dc=com"}}
```

Monitoring the SCIM servlet extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension.

The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

Copyright © 2025 Ping Identity Corporation

Testing SCIM query performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll\
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

Monitoring resources using the SCIM extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

Copyright © 2025 Ping Identity Corporation

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
  --bindPassword password --baseDN cn=monitor \
  --searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called host.

About the HTTP log publishers

HTTP operations can be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.

Copyright © 2025 Ping Identity Corporation

- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "'['dd/MM/yyyy:HH:mm:ss Z']'"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, see the `dsconfig` command-line tool help.

Configuring advanced SCIM 1.1 extension features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

Managing the SCIM 1.1 schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

Copyright © 2025 Ping Identity Corporation

About the SCIM schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances can be present for each resource. Attributes can be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

Mapping the LDAP schema to the SCIM resource schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration can be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DNs of the PingDirectory server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that might contain binary data are declared using "dataType=binary" in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes that might contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema might contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server can choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

Copyright © 2025 Ping Identity Corporation

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

resource element">

About the `resource` element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

attribute element">

About the `attribute` element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as urn:scim:schemas:core:1.0. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is false.

Copyright © 2025 Ping Identity Corporation

An attribute element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
- `simple`: specifies a simple, singular SCIM attribute.
- `complex`: specifies a complex, singular SCIM attribute.
- `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
- `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

simple element">

About the `simple` element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: binary, boolean, dateTime, decimal, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A simple element contains the following XML element:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

complex element">

About the `complex` element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

simpleMultivalued element">

About the `simpleMultivalued` element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is email.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (in other words, the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

Copyright © 2025 Ping Identity Corporation

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

complexMultiValued element">

About the `complexMultiValued` element

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is address.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard type, primary, and display sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

subAttribute element">

About the `subAttribute` element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is false.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: binary, boolean, dateTime, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

canonicalValue element">

About the `canonicalValue` element

Copyright © 2025 Ping Identity Corporation

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

mapping element">

About the `mapping` element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in Mapping LDAP entries to SCIM using the SCIM-LDAP API.

subMapping element">

About the `subMapping` element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in Mapping LDAP Entries to SCIM Using the SCIM-LDAP API.

LDAPSearch element">

About the `LDAPSearch` element

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DNs to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any <Resource> elements, and then referenced within them via an ID attribute.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `LDAPSearch` element can be added as a top-level element outside of any <Resource> elements, and then referenced within them via an ID attribute.

About the `resourceIDMapping` element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or the PingDirectory server, meaning that a value is automatically provided by the server (as would be the case if the mapped LDAP attribute is entryUUID).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

LDAPAdd element">

About the `LDAPAdd` element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template can reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

fixedAttribute element">

About the `fixedAttribute` element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value merge indicates that the fixed values should be merged with the existing values. The value overwrite indicates that the existing values are to be overwritten by the fixed values. The value preserve indicates that no changes should be made. The default value is merge.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

Copyright © 2025 Ping Identity Corporation

Validating the updated SCIM schema

The Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

Mapping SCIM resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute can result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource can also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID can be stored in the server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin can be used by the server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the PingDirectory Server Administration Guide.

> **Note**
>
> Resource IDs cannot be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the `<resourceIDMapping>` Element".

Using pre-defined transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations can be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM dateTime data type values to LDAP Generalized Time syntax values and vice-versa.

Copyright © 2025 Ping Identity Corporation

- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the $ character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

Mapping LDAP entries to SCIM using the SCIM-LDAP API

In addition to the SCIM SDK, the Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
    <groupId>com.unboundid.product.scim</groupId>
    <artifactId>scim-ldap</artifactId>
    <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory. NOTE: The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

SCIM authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the PingDirectory server and the PingDirectoryProxy server using the OAuthTokenHandler API (meaning through a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

SCIM logging

The PingDirectory server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use "`origin=scim`" in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Copyright © 2025 Ping Identity Corporation

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

SCIM monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- HTTPConnectionHandlerStatisticsMonitorProvider — Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- SCIMServletMonitorProvider — Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, "`user-patch-404:26`".

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

Managing the SCIM 2.0 servlet extension

The PingDirectory server provides a servlet extension that implements version 2.0 of the System for Cross-domain Identity Management (SCIM) specification. The SCIM 2.0 extension does not replace the existing SCIM 1.1 extension, and there are significant differences in how they are configured..

Supported SCIM 2.0 endpoints

PingDirectory server supports the following SCIM 2.0 endpoints:

Endpoint	Description	Supported HTTP methods
`/ServiceProviderConfig`	Provides metadata that indicates the PingDirectory server's authentication scheme (which is always OAuth 2.0) and its support for features that are optional in the SCIM standard. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET
`/Schemas`	Lists the SCIM schemas that are configured for use on PingDirectory server, and defines the various attributes available to resource types. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	GET

Copyright © 2025 Ping Identity Corporation

Endpoint	Description	Supported HTTP methods
`/Schemas/<schema>`	Retrieves a specific SCIM schema, as specified by the schema ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	**GET**
`/ResourceTypes`	Lists all of the SCIM resource types that are configured for use on PingDirectory server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	**GET**
`/Resourcetypes/<resourceType>`	Retrieves a specific SCIM resource type, as specified by its ID. This endpoint is a metadata endpoint and is not subject to ACI restrictions.	**GET**
`<resourceType>`	Creates a new resource (**POST**) or lists and filters resources (**GET**).	**GET**, **POST**
`/<resourceType>/.search`	Lists and filters resources. This is used if passing query parameters in the URL is undesirable.	**POST**
`/<resourceType>/<resourceId>`	Retrieves a single resource (**GET**), modifies a single resource (**PUT**, **PATCH**), or deletes a single resource (**DELETE**).	**GET**, **PUT**, **PATCH**, **DELETE**

Configuring SCIM 2.0 on your server

Review the following topics to configure SCIM 2.0 on your server instance.

> **Note**
>
> There is a known issue with dot notation support for SCIM 2.0 sub-attributes.

Copyright © 2025 Ping Identity Corporation

Creating your own SCIM 2.0 application

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at https://github.com/pingidentity/scim2.

Authentication requirements for SCIM 2.0 requests

All SCIM requests on a PingDirectory server must use OAuth 2.0 bearer token authentication. Bearer tokens are evaluated using the SCIM 2 servlet extension's configured Access Token Validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server will not process any SCIM requests unless it has at least one encryption-settings definition in its encryption-settings database. You can create the necessary definition(s) with the encryption-settings command-line tool. See Encrypting sensitive data for more information. NOTE: Encryption settings need to be defined on the Proxy and all backend PD servers, and the encryption settings should match.

Defining permissions for SCIM 2.0 requests

Whether or not a SCIM request is executed on a server depends primarily on both the configured Access Control Instructions (ACIs) in the server and the scopes which are present in the provided OAuth bearer token used to authenticate the request.

SCIM 2.0 requests can be authorized in one of the two following ways:

- By default, requests are processed using the `cn=SCIM2 Servlet,cn=Root DNs,cn=config` service account. Whether a requested operation is allowed depends on the ACIs that apply to the operation, which can include both the rights granted to that service account and any rights granted to scopes contained in the OAuth bearer token using the `oauthscope` ACI bind rule.
- If user mapping is enabled, the subject of the OAuth bearer token is mapped to an account in the server. In this case, whether a requested operation is allowed depends on the ACIs that apply to the mapped user for the requested operation. You can also use the `oauthscope` bind rule to grant rights based on scopes in the presented token.

Because of implementation details, access to the `objectclass` operational LDAP attribute is necessary for SCIM requests to properly execute. However, you shouldn't give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree you want to expose to clients. See *Configuring permissions for SCIM 2.0 operations* for an example of this.

> **Note**
>
> ACIs that don't use the `oauthscope` bind rule can still apply to requested operations. For example, an ACI that grants unconditional read access to any authenticated LDAP user will also grant unconditional read access to SCIM requests regardless of the provided `OAuth` scopes because the requests are processed through the service account.

Copyright © 2025 Ping Identity Corporation

Enabling user mapping for SCIM 2.0 operations

Access token validator identity mapping ties a local user account to an operation performed in the SCIM 2.0 servlet in the PingDirectory server.

About this task

> **Note**
>
> This topic applies only to the PingDirectory server.

The default configuration for the PingDirectory server for the SCIM 2.0 servlet doesn't require an access token to map to a local user, and operations are recorded in the logs as the `SCIM2 Servlet` user. For more detailed logging and auditing, enable the `map-access-tokens-to-local-users` property to require access tokens to map to a local user.

> **Note**
>
> The users that are being mapped to the access tokens must have the necessary access control rights required to perform the operations that the SCIM 2.0 servlet will invoke on their behalf.
> You should update the authorization server to issue tokens that include the `scim2` scope alongside any other scopes you need for access control purposes.

The `map-access-tokens-to-local-users` property is an optional configuration with the three settings shown in the following table.

Setting	Definition
`Disabled` (default)	The server doesn't attempt to map SCIM 2.0 access tokens to local users and operations are processed under the authority of the `SCIM2 Servlet` user.
`Optional`	The server attempts to map SCIM 2.0 access tokens to local users and, if successful, the operations are processed under the authority of that user. The distinguished name (DN) of the mapped user appears in the access logs. If unsuccessful, the server falls back to the default behavior.
`Required`	The server must map the SCIM 2.0 access token to one local user or the operation is rejected.

To set the `map-access-tokens-to-local-users` property:

Steps

- Run `dsconfig` with the `set-http-servlet-extension-prop` option.

  Choose from:

  - To set the property to `required`, run the following command.

Copyright © 2025 Ping Identity Corporation

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:required
```

- To set property to `optional`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:optional
```

- To reset the property to the default setting, `disabled`, run the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set map-access-tokens-to-local-users:disabled
```

SCIM 2.0 components

Unlike the SCIM 1.1 servlet extension, the SCIM 2.0 system is configured through the Administrative Console or with the `dsconfig` command-line tool. The SCIM 2.0 system consists of the following components:

- SCIM resource types
- SCIM schemas
  - SCIM attributes
  - SCIM sub-attributes
- SCIM attribute mappings (mapping resource types only)
- Correlated LDAP Data Views

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes that are available to each resource. If enabled for use, a SCIM resource type must also have a designated LDAP structural objectclass as well as an associated base DN.

The two types of SCIM resource types, mapping and pass-through, differ based on the definitions of the SCIM schema the resource types use.

- An LDAP mapping SCIM resource type requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.
- An LDAP pass-through SCIM resource type, by contrast, does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically, based on the underlying LDAP schema. Use a pass-through SCIM resource type when you need to get started quickly.

Copyright © 2025 Ping Identity Corporation

A SCIM schema defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

A SCIM attribute defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it is required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it is defined as a complex attribute.

A SCIM attribute mapping defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectory server.

A Correlated LDAP Data View allows a single SCIM resource that consists of attributes that are retrieved from multiple LDAP entries (see *Correlated LDAP data views*).

Correlated LDAP data views

Correlated LDAP data views can be attached to a SCIM resource type to allow that resource type to use attributes from other LDAP entries. A SCIM resource type can have multiple data views configured.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

- `primary-correlation-attribute`: The LDAP attribute from the SCIM Resource Type whose value will be used to match entries in the data view. This property must be defined.
- `secondary-correlation-attribute`: The LDAP attribute from the data view whose value will be matched with the primary-correlation-attribute. This property must be defined.
- `ldap-correlation-attribute-pair`: Optional correlation attribute pairs. If these are configured, entries between the SCIM resource type and the correlated LDAP data view must also have matching values for the specified attributes for them to be returned together.

> **Note**
>
> A correlated LDAP Data View cannot provide attributes from more than one LDAP entry at a time. If there are multiple LDAP entries with secondary-correlation-attribute values that match the primary-correlation-attribute from the SCIM resource type's entry, an error will be thrown.

Correlated LDAP data views share many configuration settings with SCIM resource types. The following exceptions are below:

If the correlated LDAP data view is attached to a pass-through SCIM resource type, its attributes will appear as schema extensions, similar to the following:

Copyright © 2025 Ping Identity Corporation

```
{
      ...
        "uid": [
        "user.8"
        ],
        "entryDN": "uid=user.8,ou=people,dc=example,dc=com",
        "urn:pingidentity:schemas:correlated:Document": {
            "documentIdentifier": [
            "user.8"
            ],
            "description": [
            "This is the description for the document user.8 under ou=Documents,dc=example,dc=com."
            ],
            ...
        },
        ...
        "schemas": [
        "urn:pingidentity:schemas:correlated:Document",
        "urn:pingidentity:schemas:passthrough:PassthroughUsers"
        ]
}
```

If the correlated LDAP data view is attached to a Mapping SCIM resource type, its attributes must be mapped to a schema used by the SCIM resource type. This is done through the `correlated-ldap-data-view` property in a SCIM attribute mapping.

Configuring an LDAP Mapping SCIM 2.0 resource type

About this task

This example shows how to add a simple mapping SCIM 2.0 resource type to a PingDirectory server, backed by the `inetOrgPerson` LDAP objectclass. This example assumes that the server has been configured using the default settings, meaning that sample data has been imported into the server and that data encryption has been set up.

Steps

1. Create the SCIM schema that the resource type will use:

   ```
   dsconfig create-scim-schema \
   --schema-name urn:pingidentity:schemas:User:1.0 \
   --set display-name:User
   ```

2. Under this schema, add the following SCIM attributes.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name displayName
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--set type:complex
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name familyName
dsconfig create-scim-subattribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name name \
--subattribute-name formatted
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:User:1.0 \
--attribute-name userName
```

3. Create the LDAP mapping SCIM resource type on the PingDirectory server.

```
dsconfig create-scim-resource-type \
--type-name Users \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Users \
--set structural-ldap-objectclass:inetOrgPerson \
--set include-base-dn:ou=People,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:User:1.0
```

4. Run the following commands to create the SCIM attribute mappings.

Copyright © 2025 Ping Identity Corporation

```
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name displayName \
--set scim-resource-type-attribute:displayName \
--set ldap-attribute:displayName
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.formatted \
--set scim-resource-type-attribute:name.formatted \
--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name name.familyName \
--set scim-resource-type-attribute:name.familyName \
--set ldap-attribute:sn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Users \
--mapping-name userName \
--set scim-resource-type-attribute:userName \
--set ldap-attribute:uid \
--set searchable:true
```

5. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator. Note that Mock Access Token Validators should never be used in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
--validator-name "SCIM2 Mock Validator" \
--type mock \
--set enabled:true
dsconfig set-http-servlet-extension-prop \
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

6. Send the following request to the SCIM `/ResourceTypes` endpoint to confirm that the new resource type has been added.

```
curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}'
```

7. The following JSON object should appear in the response in the "Resources" array:

Copyright © 2025 Ping Identity Corporation

```
{
...
"Resources": [{
"schemas":["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
"id":"Users",
"name":"Users",
"endpoint":"Users",
"schema":"urn:pingidentity:schemas:Users:1.0",
"meta":{
"resourceType":"ResourceType",
"location":"https://localhost:8443/scim/v2/ResourceTypes/Users"
}
}]
...
}
```

Configuring a correlated LDAP data view

About this task

The following example shows how to add a correlated LDAP data view to a LDAP mapping SCIM resource type on a PingDirectory server. The SCIM resource type will be a user, and the correlated LDAP data view will allow access to a document that matches their user ID.

In this example, a new PingDirectory server is set up using custom sample data. When configuring the correlation, administrators should use attributes that are inherently either immutable or non-volatile, such as `uid` or `entryUUID`. This prevents errors produced by a conflict between the values of primary and secondary correlation attributes.

> **Note**
>
> Administrators can make the correlation SCIM attributes immutable by setting the `--set mutability:read-only` property when defining an attribute in the SCIM schema configuration. That way, SCIM requests cannot modify the values of those attributes.

Steps

1. **Copy the following text into the server root directory and save it as `entries.ldif.template`:**

Copyright © 2025 Ping Identity Corporation

```
define suffix=dc=example,dc=com
define maildomain=example.com
define numusers=101

branch: [suffix]
subordinateTemplate: admin:1
aci: (targetattr="*")(version 3.0; acl "Grant full access for the scim2allaccess OAuth 2 scope";
allow (all) oauthscope="scim2allaccess";)

branch: ou=People,[suffix]
subordinateTemplate: person:[numusers]

branch: ou=Documents,[suffix]
subordinateTemplate: document:[numusers]

template: admin
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
uid: admin
givenName: Admin
sn: User
cn: Admin User
userPassword: password

template: person
rdnAttr: uid
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
employeeNumber: <sequential:0>
uid: user.{employeeNumber}
sn: {uid}
cn: {uid}
userPassword: password

template: document
rdnAttr: documentIdentifier
objectClass: top
objectClass: document
documentIdentifier: user.<sequential:0>
description: This is the description for the document {documentIdentifier} under
ou=Documents,dc=example,dc=com.
```

2. Run the following command:

```
$ bin/make-ldif --templateFile entries.ldif.template --ldifFile entries.ldif
```

3. Run setup for the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

Make sure to import the created `entries.ldif` file and set up encryption settings. After this is done, set up the SCIM resource type and the Correlated LDAP Data View.

4. Run the following command to define the SCIM schema:

```
"dsconfig create-scim-schema --schema-name urn:example:Users \
  --set "description:Users schema" --set display-name:Users
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name email --set required:true --set multi-valued:true
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name uid --set required:true --set mutability:read-only
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentId
dsconfig create-scim-attribute --schema-name urn:example:Users \
  --attribute-name documentDescription"
```

5. Run the following command to create the SCIM resource type:

```
dsconfig create-scim-resource-type \
  --type-name Users \
  --type ldap-mapping \
  --set core-schema:urn:example:Users \
  --set enabled:true \
  --set endpoint:Users \
  --set structural-ldap-objectclass:inetOrgPerson \
  --set include-base-dn:ou=people,dc=example,dc=com \
  --set create-dn-pattern:entryUUID=generated,ou=people,dc=example,dc=com
```

6. Run the following command to create the Correlated LDAP Data View:

```
dsconfig create-correlated-ldap-data-view \
  --type-name Users \
  --view-name Document \
  --set structural-ldap-objectclass:document \
  --set include-base-dn:ou=documents,dc=example,dc=com \
  --set create-dn-pattern:entryUUID=generated,ou=documents,dc=example,dc=com \
  --set primary-correlation-attribute:uid \
  --set secondary-correlation-attribute:documentIdentifier
```

7. Run the following command to create the attribute mappings for the SCIM resource type attributes.

   Note that the `correlated-ldap-data-view` property is not set.

Copyright © 2025 Ping Identity Corporation

```
# The uid attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name uid \
  --set scim-resource-type-attribute:uid --set ldap-attribute:uid \
  --set writable:false --set searchable:true

# The email attribute, provided by the base SCIM Resource Type
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name email \
  --set scim-resource-type-attribute:email --set ldap-attribute:mail \
  --set searchable:true
```

8. Run the following command to create the `DocumentId` attribute mapping for the correlated LDAP data view attributes.

> **Note**
>
> The only meaningful difference between mappings for SCIM resource type attributes and correlated LDAP data view attributes is the value of the `correlated-ldap-data-view` property.

```
# The documentId attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name document.id \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentId --set ldap-attribute:documentIdentifier

# The documentDescription attribute
dsconfig create-scim-attribute-mapping --type-name Users \
  --mapping-name description \
  --set correlated-ldap-data-view:Document \
  --set scim-resource-type-attribute:documentDescription \
  --set ldap-attribute:description
```

9. Run the following command to send a SCIM request:

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Users \
  -H 'Authorization: Bearer {"active":true, "scope":"scim2allaccess"}'
```

The response should look similar to the following. Notice that `'uid'` and `'documentId'` have the same value, as they are in a correlation attribute pair.

Copyright © 2025 Ping Identity Corporation

```
{
    "schemas": [
        "urn:ietf:params:scim:api:messages:2.0:ListResponse"
    ],
    "totalResults": 101,
    "Resources": [
        {
            "uid": "user.8",
            "id": "3715c022-1f34-36d9-bebc-7e74912106ec",
            "documentDescription": "This is the description \
            for the document user.8 under ou=Documents,dc=example,dc=com.,
            "documentId": "user.8",
            "meta": {
                "resourceType": "Users",
                "location": "https://localhost:8443/scim/v2/Users/3715c022-1f34-36d9-bebc-7e74912106ec"
            },
            "schemas": [
                "urn:example:Users"
            ]
        },
    ...
}
```

Configuring permissions for SCIM 2.0 operations

About this task

This example shows how to correctly configure permissions so POST requests with the "userAdd" scope will succeed. This example assumes that you have set up an LDAP mapping SCIM 2.0 Resource Type for the `inetOrgPerson` objectclass (see *Configuring an LDAP Mapping SCIM 2.0 resource type*).

Steps

1. If the SCIM Resource Type being targeted already has a value for the `create-dn-pattern` property, skip to step 2. Otherwise, the following `dsconfig` command can be used:

```
dsconfig set-scim-resource-type-prop \
  --type-name Users \
  --set create-dn-pattern:entryUUID=generated,ou=People,dc=example,dc=com
```

2. Send the following request to the SCIM `/Users` endpoint:

```
curl -k -X POST \
  https://localhost:8443/scim/v2/Users/ \
  -H 'Authorization: Bearer {"active":true}' \
  -H 'Content-type: application/json' \
  --data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

Copyright © 2025 Ping Identity Corporation

The response from the server should have a status of 403 and contain a correlation ID, similar to the following:

```
{
  "schemas":["urn:ietf:params:scim:api:messages:2.0:Error"],
  "status":"403",
  "detail":"Request failed:
correlationID='faa707b3-5d48-42e6-9e78-2c8dbb1e2cac'"
}
```

This is the expected response since this SCIM request does not have the permission needed to write to an entry. See *Troubleshoot the SCIM 2.0 servlet extension* for instructions on viewing the full server error message.

3. An ACI should now be added to the `ou=People,dc=example,dc=com` subtree. This will grant permission to add entries to the said subtree as long as the SCIM request includes the 'userAdd' scope. This can be done by running the following **`ldapmodify`** command. Note that this ACI does not grant write access to attributes, which means modify operations will fail. You can find more information about configuring ACIs in Overview of access control.

```
$ ldapmodify
dn:ou=People,dc=example,dc=com
changetype:modify
add:aci
aci:(version 3.0; acl "ACI for userAdd scope"; allow (add)
oauthscope="userAdd";)
```

4. Send the POST request to the SCIM `/Users` endpoint again, this time including the `userAdd` scope in the bearer token:

```
curl -k -X POST \
https://localhost:8443/scim/v2/Users \
-H 'Authorization: Bearer {"active":true, "scope":"userAdd"}' \
-H 'Content-type: application/json' \
--data '{"username":"user.test", "name":{"formatted":"Test",
"familyName":"User"}, "schemas":["urn:pingidentity:schemas:User:1.0"]}'
```

The response from the server should now contain the created SCIM resource, which should also contain values for the name and username attributes, similar to the following:

Copyright © 2025 Ping Identity Corporation

```
{
"name":{
"familyName":"User",
"formatted":"Test"
},
"username":"user.test",
"id":"6f9a89b8-e766-478c-9667-def049daf6bc",
"meta":{
"resourceType":"Users",
"location":"https://localhost:8443/scim/v2/Users/6f9a89b8-e766-478c-9667-def
049daf6bc"
},
"schemas":["urn:pingidentity:schemas:User:1.0"]
}
```

SCIM 2.0 searches

To prevent exhausting server resources, we recommend capping the total number of resources that are matched by a search. The configuration for each SCIM 2.0 resource type contains a `lookthrough-limit` property that defines this limit (the default `lookthrough-limit` value is 500).

If a search request exceeds the lookthrough limit, the client receives a 400 response with an error message similar to the following:

```
{
  "detail": "The search request matched too many results",
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
  "scimType": "tooMany",
  "status": "400"
}
```

To prevent this error, you have these options:

- The client must refine its search filter to return fewer matches.
- Configure paged searches as explained in *Using paged SCIM searches*.

Using paged SCIM searches

When searching large data sets, the results can be numerous and produce errors about a request matching too many results relative to the lookthrough limit. Paged searches avoid these errors and also reduce memory utilization.

About this task

The PingDirectory server does SCIM searches using LDAP requests. After you complete the steps below, PingDirectory creates LDAP requests that include request controls to sort and page the search results before returning the results.

If your SCIM searches result in an error because the request matched too many results, as discussed in *SCIM 2.0 searches*, you can avoid the error by using paged searches.

Copyright © 2025 Ping Identity Corporation

Complete the following steps for each search.

Steps

1. Decide your SCIM search.

   > **Note**
   >
   > To get paged results, your search must include at least one of these parameters: startIndex, count, or sortBy.

   For example, your search might look like the following search.

   ```
   https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st eq
   "TX"&sortBy=sn&sortOrder=ascending
   ```

   Here is the corresponding encoded version.

   ```
   https://<directory-hostname>:<directory-port>/scim/v2/Users/?
   filter=st%20eq%20%22TX%22&sortBy=sn&sortOrder=ascending
   ```

   On your PingDirectory server, collect some information to use later. Find the SCIM resource type, `structural-ldap-objectclass`, `include-base-dn`, and `include-filter` values by running this command.

   ```
   $ dsconfig get-scim-resource-type-prop --type-name  <SCIM-resource-type-name>  \
   --property structural-ldap-objectclass \
   --property include-base-dn \
   --property include-filter
   ```

2. On the PingDirectory server, complete the following steps.

   1. Create a Virtual List View (VLV) index for your search.

      Each SCIM search that you want to produce paged results must have its own VLV index.

      Create this index using `dsconfig create-local-db-vlv-index` with the following options.

Option	Description
`--index-name`	Names the index.
`--backend-name`	Specifies the name of the local database backend in which to place the index. The default database backend for PingDirectory is userRoot.
`--set base-dn`	Specifies the desired base dn. This value must match the value of the `include-base-dn` property that you found in the previous step.
`--set scope`	Is always `whole-subtree`.

Copyright © 2025 Ping Identity Corporation

Option	Description
`--set filter`	Specifies the filter. Specify `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` where `<name-of-SCIM-resource-type-objectclass>` is the name of the objectclass used by the SCIM resource type, which you found in the previous step. If the SCIM resource type has the `include-filter` property set, also specify that property value in the filter. For example, if the filter for the objectclass is `(objectclass=inetorgperson)` and the `include-filter` value is `(st=CA)`, specify the `--set filter` argument as `"(&(objectclass=inetorgperson)(st=CA))"`. Specify the LDAP attributes for all the components of your SCIM search filter. For example, if a mapping SCIM resource type maps the LDAP attribute `st` to the SCIM attribute `address.region` and the SCIM search filter requires that `address.region eq TX`, then this filter must include `(st = TX)` instead of `(address.region = TX)`.
`--set sort-order`	Specifies whether to sort ascending (+) or descending (-) and the LDAP attribute to sort by.If the SCIM search does not specify the `sortBy` parameter, specify the sort order as `+entryUUID`.

Recall the original, decoded SCIM search, shown here.

```
https://<directory-hostname>:<directory-port>/scim/v2/Users/?filter=st eq
"TX"&sortBy=sn&sortOrder=ascending
```

For example, to create a VLV index for that search, run the following command.

```
$ dsconfig create-local-db-vlv-index --index-name sn \
--backend-name userRoot --set base-dn:ou=people,dc=example,dc=com \
--set scope:whole-subtree \
--set filter:"(&(objectclass=inetorgperson)(st=TX))" --set sort-order:+sn
```

2. Stop the server. Rebuild the index. Start the server. Run the `rebuild-index` command specifying the baseDN and the name of the index.

```
$ rebuild-index --baseDN  <baseDN-value>  --index  <name-of-index>
```

For example, run these commands.

Copyright © 2025 Ping Identity Corporation

```
$ stop-server
$ rebuild-index --baseDN dc=example,dc=com --index vlv.sn
$ start-server
```

3. Run your SCIM search filter.

> **Note**
>
> The search can include only the filter you specified with `--set filter` in the earlier step without the `"(objectclass=<name-of-SCIM-resource-type-objectclass>)"` portion.

In addition to the Virtual List View request control, the PingDirectory server adds a Server Side request control to the LDAP request. These request controls require certain parameters be set. To satisfy this requirement, the server uses the following parameters. If the client does not provide values for one of the parameters, the search uses the corresponding default value shown in the following table.

Parameter	Default
startIndex	1
count	The value of the `lookthrough-limit` property of the SCIM resource type being searched. That default is 500.
sortBy	entryUUID With this default, the results appear unsorted.
sortOrder	ascending

SCIM 2.0 PATCH operations

When using a PATCH request to modify a SCIM 2.0 resource that has one or more required SCIM 2.0 attributes, the requester must have permissions to read the values of these required attributes in addition to write permissions for the attributes being modified, even if the PATCH request does not alter said requirements.

For example, assume we want to modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents:

Copyright © 2025 Ping Identity Corporation

```
{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
  "id": "urn:test:schema:person",
  "attributes": [
    {
      "name": "uid",
      "type": "string",
      "multiValued": false,
      "required": true,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "cn",
      "type": "string",
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    }
  ],
  ...
        }
```

The following PATCH operation will fail if the SCIM 2 service account does not have access to both `uid` and `cn`:

```
{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
  "Operations":[{
        "op":"add",
        "path":"cn",
         "value": "new cn value"
  }]
        }
```

Troubleshoot the SCIM 2.0 servlet extension

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something similar to the following:

Copyright © 2025 Ping Identity Corporation

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": "400",
  "detail": "Request failed: correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

To view these messages, the Debug Trace Logger needs to be enabled. You can do this through the Administrative Console or with the following `dsconfig` command:

```
dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
                        --set enabled:true --add scim-message-type:error
```

After the Debug Trace Logger is enabled, the server will begin logging information related to SCIM operations to the file /logs/debug-trace , which will look somewhat like the following:

```
[09/Jun/2020:05:23:10.992 -0500] HTTP REQUEST requestID=3
correlationID="073eb1a8-8c51-48b3-83a0-380e1d4b4ab9" product="Ping Identity
Directory Server" instanceName="example" startupID="Xt9fJg==" threadID=173
from=[0:0:0:0:0:0:0:1]:53978 method=POST
url="https://0:0:0:0:0:0:0:1:9443/scim/v2/Users"
```

Note the presence of correlationID in these messages. By matching the id in the HTTP responses to the messages in the debug-trace log, the appropriate LDAP error message can be determined.

Disabling the SCIM 2.0 servlet extension

If you do not need to expose data through the SCIM 2 servlet, you can disable the SCIM 2.0 servlet extension by removing the SCIM2 HTTP servlet extension from the HTTPS connection handler, or from any other HTTP connection handler, and restart the handler:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --remove http-servlet-extension:SCIM2 \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

Copyright © 2025 Ping Identity Corporation

Troubleshooting a multiple correlation entry error

When using secondary store adapters in PingAuthorize or correlated Lightweight Directory Access Protocol (LDAP) data views with the System for Cross-domain Identity Management (SCIM) 2 implementation in PingDirectory or PingDirectoryProxy, an error is displayed in the SCIM 2 response to the user request if multiple entries have a secondary correlation attribute value that matches the primary correlation attribute value. The error is applicable to each product.

There are three options for resolving this error:

- Configure one or more correlation attribute pairs on the secondary store adapter or correlated LDAP data view so that for each primary entry, there is only one other entry with matching secondary correlation attribute values. This is the recommended option.
- Modify the server data so that for each primary entry, there is only one other entry with a matching secondary correlation attribute value.

  > **Note**
  >
  > Because this option requires making changes to individual entries, it is not efficient for larger servers.

- Remove the secondary store adapter or correlated LDAP data view.

  > **Important**
  >
  > Because this option involves complete removal of the feature, only do it if the other options do not resolve the error.

Managing the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory server.

About this task

Instead of trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient. For more information, see PingDirectory REST API Reference and the Developer portal.

The Directory REST API gives developers who are more comfortable with REST than LDAP access to arbitrary directory data in a way that ensures that directory data remains consistent regardless of whether it is accessed from LDAP or REST.

The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

Although both the Directory REST API and System for Cross-domain Identity Management (SCIM) provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data, but because it's a less common standard for identity stores, it might not offer as much functionality or be as user-friendly as the Directory REST API.

The Directory REST API can be used for the following operations.

Copyright © 2025 Ping Identity Corporation

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	`/directory/v1/{{dn}}`	Delete an entry	Not applicable
GET	`/directory/v1`	Get metadata about the API and server	Not applicable
GET	`/directory/v1/{{dn}}`	Retrieve a single entry	• `expand` • `includeAttributes` • `excludeAttributes`
GET	`/directory/v1/{{dn}}/subtree`	Search an entry's descendants	• `filter` • `searchScope` • `cursor` • `limit` • `includeAttributes` • `excludeAttributes`
GET	`/directory/v1/schemas`	Retrieve the schemas of all available object classes	Not applicable
GET	`/directory/v1/schemas/{objectclass}`	Retrieve schema for a specific object class	Not applicable
GET	`/directory/v1/schemas/_operationalAttributes`	Retrieve schema for operational attributes	Not applicable
GET	`/directory/v1/me`	Alias for retrieving the current user	Not applicable
PATCH	`/directory/v1/{{dn}}`	Modify an entry (add or delete values)	`expand`
POST	`/directory/v1`	Create a new entry	`expand`
POST	`/directory/v1/suggestPassword`	Generate a new password suggestion	Not applicable
POST	`/directory/v1/passwordRequirements`	Get password quality requirements	Not applicable

Copyright © 2025 Ping Identity Corporation

HTTP operation	Resource endpoint	Description	Allowed query parameters
POST	`/directory/v1/{{dn}}/changePassword`	Modify an existing password	Not applicable
PUT	`/directory/v1/{{dn}}`	Modify or rename an entry	`expand` **Important** You can't update a user's `userPassword` or `authPassword` attributes with this operation. Instead, use the `/directory/v1/{{dn}}/changePassword` endpoint to update passwords.

Steps

- Configure the Directory REST API with any of the following properties using `dsconfig`:

Command	Description
`basic-auth-enabled`	Specifies whether users can connect to the service with HTTP basic authentication. If disabled, users need a bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic authentication is enabled by default.
`identity-mapper`	If HTTP basic authentication is enabled, the identity mapper referenced by this distinguished name (DN) must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.
`access-token-validator`	Specifies the subset of this server's access token validators (by DN), which can validate bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server can be used. For changes to take effect, the server must be restarted, or any HTTP connection handlers referencing this service disabled and re-enabled.

Copyright © 2025 Ping Identity Corporation

Command	Description
`access-token-scope`	The scope that must be present in bearer tokens in order to be accepted by this service. If no value is provided, bearer token authentication is disabled, and only basic authentication is used. By default, no value is provided. Changes to this value take effect immediately.
`audience`	A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
`max-page-size`	The maximum number of entries to be returned in one page from the search endpoint. Actual results returned might be lower because of the limit query parameter on the request and the actual number of available results. The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
`schemas-endpoint-objectclass`	The list of object classes that will be returned by the `/directory/v1/schemas` to retrieve the schemas of all available object classes in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

Example:

The following example uses `dsconfig` to configure an `objectClass` entity:

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

Managing Server SDK extensions

The server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your server. Extension bundles are installed from a .zip archive or a file system directory. You can use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The `manage-extension` tool can only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

Available types of extensions

The Server SDK provides support for creating several different types of extensions for Ping Identity server products, including the PingDirectory server, the PingDirectoryProxy server, and the PingDataSync server. Some of those extensions include:

Cross-Product Extensions

- **Access Loggers**
- **Alert Handlers**
- **Error Loggers**
- **Key Manager Providers**
- **Monitor Providers**
- **Trust Manager Providers**
- **OAuth Token Handlers**
- **Manage Extension Plugins**

PingDirectory Server Extensions

- **Certificate Mappers**
- **Change Subscription Handlers**
- **Extended Operation Handlers**
- **Identity Mappers**
- **Password Generators**
- **Password Storage Schemes**
- **Password Validators**
- **Plugins**
- **Tasks**
- **Virtual Attribute Providers**

PingDirectoryProxy Server Extensions

- **LDAP Health Checks**
- **Placement Algorithms**

Copyright © 2025 Ping Identity Corporation

- Proxy Transformations

PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

DevOps and infrastructure as code

Derived from the words development and operations, the term DevOps refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- Pets — With the pets service model, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- Cattle — With the cattle service model, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-primary datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Before server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to

Copyright © 2025 Ping Identity Corporation

obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see Server profiles.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

Limitations when automating PingDirectory server deployments

PingDirectory server is a stateful application. User data is associated with it, and servers in a topology must be able to communicate bidirectionally with each other. The deployment of stateful applications is generally more challenging to automate than the deployment of stateless applications. However, by following certain industry-wide best practices, the deployment of stateful applications becomes easier to manage.

For stateful applications, we recommend maintaining a well-known network identifier for a server that does not change over its lifetime. Without this guarantee, the deployment automation workflows for the PingDirectory server software does not work as expected. On infrastructure platforms like Amazon Web Services (AWS), servers are generally assigned cattle-like internal host names. This strategy is acceptable if a well-defined external name is registered in a service discovery or lookup service, such as DNS.

Another important recommendation for stateful applications is the use of external, redundant persistent storage that is always available, and that functions independently of the server itself. Servers might come and go, but they are always guaranteed to be attached to the same persistent storage when they are resurrected. Although the PingDirectory server software does not require this guarantee, we recommend it for simpler, less error-prone deployment automation and for easier disaster recovery. For more information, see Deployment automation.

Server profiles

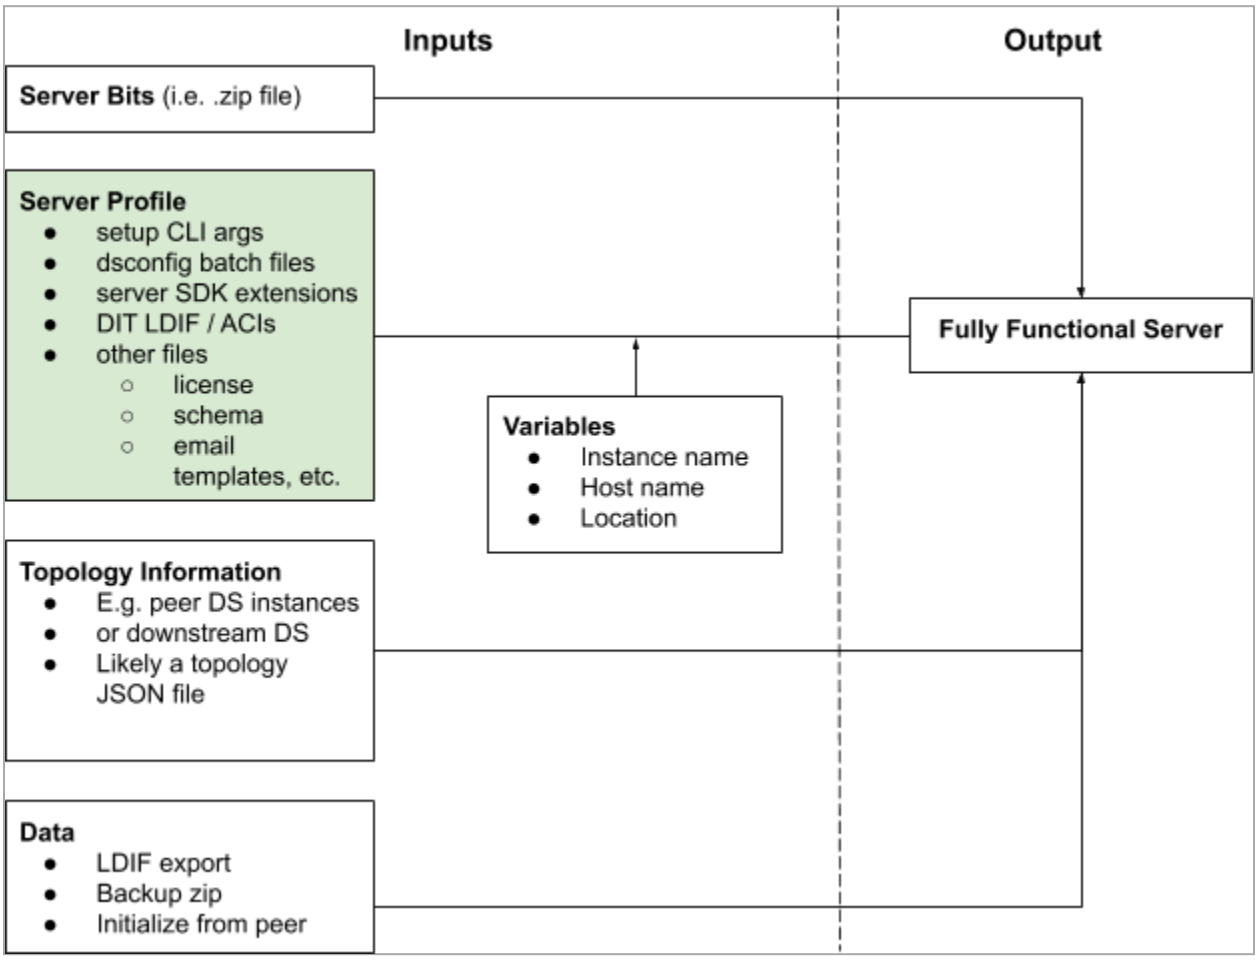
Regardless of the service model that your company follows, server profiles help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Initial DIT
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks – like Docker, Kubernetes, and Ansible – is reduced considerably.

Copyright © 2025 Ping Identity Corporation

The following image shows the role that a server profile plays in building a fully functional running server.



As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see Variable substitution.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

Copyright © 2025 Ping Identity Corporation

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the `manage-profile replace-profile` subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, `manage-profile setup` can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files before its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the `manage-profile` tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Variable substitution

You can use the `manage-profile` tool to substitute different variables in server profiles.

The `manage-profile` tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example of how you can set user-defined variables by using a variables file in the server profile.

```
HOSTNAME=testserver.example.com
PORT=389
```

The following table describes built-in variables that can also be referenced in the server profile. Use these variables in the format previously described.

Built-in variable	Description
`PING_SERVER_ROOT`	Evaluates to the absolute path of the server's root directory
`PING_PROFILE_ROOT`	Evaluates to the individual profile's root directory **Note** Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

Copyright © 2025 Ping Identity Corporation

For more information about the tool's usage, run the command `bin/manage-profile --help`.

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- ldif/
  |   |-- userRoot/
  |-- misc-files/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
  |-- variables-ignore.txt
```

setup-arguments.txt

When creating a profile, the first step is to add arguments to the `setup-arguments.txt` file, located in the `resources/server-profile-template.zip` archive.

When you run the `manage-profile setup` command, these arguments are passed to the server's setup tool. To view the arguments available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive command-line interface (CLI) arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the server profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/ and pre-setup-dsconfig/

You can include `dsconfig` batch files in the server profile with information about changes to apply to the out-of-box system configuration. Any batch files in the server profile must include a `.dsconfig` extension. `dsconfig` batch files in the server profile can't make changes to any topology configuration, including topology admins and server instances, so you should make topology configuration changes outside of the server profile.

The batch files can be placed in the following server profile directories:

Copyright © 2025 Ping Identity Corporation

`dsconfig/`

Contains information about changes to apply after the `manage-profile` tool runs `setup`, copies any post-setup files into place, and installs any Server SDK extensions contained in the server profile. The `dsconfig/` directory should be used for most configuration changes applied to the server.

`pre-setup-dsconfig/`

Holds information about changes to apply immediately before the `manage-profile` tool runs `setup`. You should only use the `pre-setup-dsconfig/` directory when setting up the server with a pre-existing encryption settings database and applying the changes required for configuring and activating the cipher stream provider needed to access the encryption settings database.

Note

If multiple batch files are present in the directory that the `manage-profile` tool is using, the files are processed in ascending lexicographic order. For example, `00-base.dsconfig` is processed before `01-second.dsconfig`.

Tip

You can use the `config-diff` tool to create a `dsconfig` batch file that reproduces the current topology configuration.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the server-root/pre-setup directory.

ldif/

Use LDIF files in the server profile to supply a base DIT, but not to import user data. Add LDIF files under the `ldif` directory. Place each LDIF file in a subdirectory that indicates the backend to which it is imported, such as `ldif/userRoot/` for the `userRoot` backend.

LDIF files require an `.ldif` extension and are ordered lexicographically.

server-sdk-extensions/

Add server SDK extension `.zip` files to the `server-sdk-extensions` directory. Include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Copyright © 2025 Ping Identity Corporation

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

> **Note**
>
> Use `PING_PROFILE_ROOT` only with files that are not needed after initial setup, such as password files in `setup-arguments.txt`. Do not use the `PING_PROFILE_ROOT` variable for files needed while the server is running. The `manage-profile` tool creates a temporary copy of the server profile that is deleted after the tool completes, so files are not accessible under `PING_PROFILE_ROOT` when the server is running. For files you need while the server is running, such as keystore and truststore files, copy the files into the server root using the profile's `server-root/pre-setup` directory, and then refer to the files using the `PING_SERVER_ROOT` variable.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

Copyright © 2025 Ping Identity Corporation

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

manage-profile generate-profile

To create a server profile from a configured server, use the `generate-profile` subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by `generate-profile`, and must be provided values when other `manage-profile` subcommands use the generated profile.

LDIF files must also be added manually to the generated profile.

The `--excludeSetupArguments` option generates a server profile without a setup-arguments.txt file. This is useful when generating server profiles for use with Docker images.

manage-profile setup

To apply a server profile to an unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to do the following:

1. Copy the `server-root/pre-setup` files to the server root.
2. Apply changes for any batch files contained in the `pre-setup-dsconfig` directory.
3. Run the setup tool.
4. Copy the `server-root/post-setup` files to the server root.
5. Install any Server SDK extensions.
6. Apply changes for any `dsconfig` batch files.
7. Import any LDIF files contained in the `ldif` directory structure.
8. Start the server.

`manage-profile setup` creates a copy of the profile in a temporary directory specified by the `--tempProfileDirectory` option. The tool leaves the server running upon completion unless you use the `--doNotStart` option.

manage-profile replace-profile

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration. New LDIF files from the replacement server profile are not imported.

Copyright © 2025 Ping Identity Corporation

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

The `--skipValidation` option skips the validation step when running on an offline server

> **Note**
>
> When you run the **`manage-profile replace-profile`** tool with an SDK extension included in the new profile, the tool invokes the **`setup`** command.
>
> The **`manage-profile replace-profile`** tool can update the server version when needed. It can also directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to **`dsconfig`**.

Server profiles in a pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see About the manage-profile tool.

Copyright © 2025 Ping Identity Corporation

Topology-management tools

Because PingDirectory server topology-management tools like `dsreplication` and `remove-defunct-server` feature internal retries, external deployment automation scripts are not required to incorporate retries. This approach mitigates transient failures and makes servers more robust in automated environments.

To support this approach, `dsreplication` and `remove-defunct-server` include a `--retryTimeoutSeconds` option, which specifies a timeout value for the entire command. If the command fails, it is retried until the timeout value is reached. The command is not aborted if the timeout expires mid-execution, so it is guaranteed to be executed at least once. The default value of zero indicates the command does not have a timeout and is not retried upon initial failure.

The `remove-defunct-server tool` can also be used to complete the following tasks:

- Remove an online server.

  Because a server runs as a container's main process, and because shutting down a server re-spins the container, this task was impossible to complete in deployment automation environments that use containers. Automation scripts often resorted to hacks like impersonating an offline server by taking down the LDAP connection handler. In environments where security concerns prevented the use of LDAP, removing an online server was never an option.

- Remove servers without forcing a topology primary when you do not have a quorum majority of online severs.

  The topology registry uses a primary-secondary architecture in which all write requests are chained through a single write-primary. When a primary could not be nominated, the topology becomes read-only. To work around this issue, a single server had to be forced as a primary to apply changes.

- Remove servers concurrently.

The `--ignoreOnline` option can be used to remove an online server, and the `--retryTimeoutSeconds` option can be used to increase robustness in concurrent environments.

Finally, `dsreplication enable` provides internal support for a seed server before the replication topology exists. To prevent the creation of separate islands of replicating servers when simultaneously enabling replication on multiple hosts with a topology JSON file, the server that appears first in lexicographical order in the topology JSON file is designated as the seed server. When enabling replication on the seed server itself with the topology JSON file, it stops and returns a `ERROR_SEED_AND_TARGET_SERVER_ARE_THE_SAME` code. This precaution avoids deadlocking a `dsreplication` process when replication is invoked concurrently. On the seed server itself, deployment automation scripts can treat this code as being successful.

Deployment automation

Automated workflows help shift the deployment process from a pets service model to a cattle service model. The primary tools that are required to manage the replication topology are `dsreplication` and `remove-defunct-server`.

Another key to every topology-management workflow is the `topology.json` file, which represents the intended state of the topology at any time. An administrator should create this file manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.

The following code shows an example `topology.json` file:

Copyright © 2025 Ping Identity Corporation

```
{
  "serverInstances" : [
    {
      "instanceName" : "ds-0",
      "hostname" : "ds-0.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-1",
      "hostname" : "ds-1.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-2",
      "hostname" : "ds-2.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-3",
      "hostname" : "ds-3.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    ...
  ]
}
```

The remaining sections in this chapter describe the deployment automation that is necessary to satisfy the following workflows:

- **Setting up the initial topology**
- **Initializing data on all servers**
- **Replacing crashed instances and scaling up**

Copyright © 2025 Ping Identity Corporation

- Scaling down
- Rolling updates

Consistent network identifiers are required for each server instance. Additionally, we strongly recommend persistent storage for all server bits. The required level of automation changes slightly when this recommendation is not followed, as noted in each section.

Setting up the initial topology

About this task

The `server.uuid` file in the server's `config` directory indicates whether the server is being set up initially or being updated.

> **Note**
>
> If you're not using persistent storage, set up a new server and skip step 3. If you are using persistent storage, start on step 3.

For more information about server profiles, see Server profiles.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation.

   When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using `manage-topology export`.

2. To install and configure a server instance, run the `manage-profile` command with the `setup` option.

   Example:

   ```
   manage-profile setup \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties
   ```

3. If you're using persistent storage, replace the current server profile. Otherwise, proceed to step 4. To replace the current profile, run the `manage-profile replace-profile` command from a second, extracted server install package on the same host as the existing server.

   Example:

   ```
   manage-profile replace-profile \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties
     --serverRoot /path/to/existing/server
   ```

4. To enable replication within the topology, run `dsreplication` with the `enable` option.

   Example:

Copyright © 2025 Ping Identity Corporation

```
dsreplication enable \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

5. To initialize the replication data, run `dsreplication` with the `initialize` option.

   Example:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json
```

Prefer topology administrator accounts over root users

In PingDirectory server, administrative accounts can be placed in any of three places.

- They can be created as root users. These accounts exist in the configuration (after `cn=Root DNs,cn=config`) and are not synchronized across server instances. If you want to use root accounts across multiple servers, then you must create the account in each server and keep it up to date across all of them. Root user accounts can optionally automatically inherit a default set of privileges, and you can also explicitly grant and revoke privileges as needed.
- They can be created as topology administrators. These accounts also exist in the configuration (after `cn=Topology Admin Users,cn=topology,cn=config`), and these accounts are automatically synchronized between server instances within the same topology. Topology administrators can also automatically inherit a default set of privileges, and you can also explicitly grant or revoke privileges.
- They can be created in the user data. These accounts will be replicated across all directory servers and they can be used to authenticate to PingDirectory and PingDirectoryProxy servers, but they cannot be used to authenticate to PingDataSync or PingDataMetrics servers. They cannot automatically inherit a default set of privileges, but you can explicitly grant privileges to them as needed. Accounts created in the user data can also be unavailable if the backend containing that data is offline, such as when performing an online restore, replica initialization, or LDIF import.

We recommend using topology administrator accounts over root users or accounts created in the user data. Topology administrators have all of the same capabilities as root users, and their accounts are also automatically synchronized across all servers in the topology so there is no need to apply the same change across multiple servers.

See the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file for more information about creating topology administrator accounts. The contents of the `config/sample-dsconfig-batch-files/create-topology-admin-user.dsconfig` batch file are shown below:

Copyright © 2025 Ping Identity Corporation

```
# Although setup automatically creates an initial root user account that can
# be used to manage the server, we strongly recommend creating a separate
# account for each administrator rather than using a single shared account.
# This offers several benefits, including:
#
# * It is easier to determine which administrator performed a given action.
# * There is no need to share credentials or coordinate password changes.
# * It is easier to use strong authentication options like certificates or
#   two-factor mechanisms.
# * You can customize the level of access that each administrator has.
#
# We also recommend creating topology admin user accounts rather than root
# user accounts.  If you create a root user account, then it is only created
# in that one instance.  If you create a topology admin user, then that
# account will be available in all instances in the topology.
#
# Because administrative accounts are very powerful, they are high-priority
# targets for attackers to try to compromise.  They should be required to have
# strong credentials, and you may wish to require that they use strong
# authentication mechanisms (see other dsconfig batch files for configuring
# password validators and other password policy features).  You may also want
# to give them usernames that are not likely to be guessed by an attacker,
# even if they know information about the individuals administering the
# service.  For example, you may not want to use their name in the DN or
# username, choosing instead something that is less predictable or even
# completely random like a UUID.
#
# Once each administrator has their own account, we recommend that you disable
# or remove the initial root user created during setup.  See the
# disable-or-remove-the-initial-root-user.dsconfig batch file for more
# information about that.

#
# NOTE:  Do not edit this file directly.  Changing this file could prevent it
# from being updated during a server upgrade.  If you want to alter the
# dsconfig commands below before applying the configuration changes, copy this
# file to another directory and edit that copy.
#

# Create a new topology administrator account.  In this example, the user will
# be able to read the configuration but will not be allowed to update it, and
# will be given the bypass-read-acl privilege rather than bypass-acl, which
# only ensures they will be able to read entries but they will not be
# permitted to update them unless permitted by the server's access control
# configuration.  They will also only be permitted to communicate with the
# server over a secure connection, and they will only be permitted to
# authenticate with the EXTERNAL or UNBOUNDID-TOTP mechanisms.
dsconfig create-topology-admin-user \
     --user-name "[USER_NAME]" \
     --set "password:[PASSWORD]" \
     --set "first-name:[FIRST_NAME]" \
     --set "last-name:[LAST_NAME]" \
     --set "user-id:[USER_NAME]" \
     --set inherit-default-root-privileges:true \
```

Copyright © 2025 Ping Identity Corporation

```
    --set privilege:bypass-read-acl \
    --set privilege:-bypass-acl \
    --set privilege:-config-write \
    --set search-result-entry-limit:0 \
    --set time-limit-seconds:0 \
    --set look-through-entry-limit:0 \
    --set idle-time-limit-seconds:0 \
    --set require-secure-authentication:true \
    --set require-secure-connections:true \
    --set "allowed-authentication-type:SASL EXTERNAL" \
    --set "allowed-authentication-type:SASL UNBOUNDID-TOTP"
```

Initializing data on all servers

About this task

Skip this step if you are using one of the following methods to load data during the initial setup:

- Each server instance imports the same user data from one or more LDIF backup files
- Data is synchronized from another source, such as an Active Directory server, to all servers
- No data is imported initially

Data must be imported and available on a single server only. Servers that do not feature user data must be initialized reliably and quickly. NOTE: The absence of user data during the initial setup does not prevent the the environment from being set up correctly.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the **`manage-topology export`** subcommand.
2. Import data into one of the server instances, as follows:

   ```
   import-ldif --backendID userRoot \
     --ldifFile userData0.ldif \
     --ldifFile userData1.ldif
   ```

3. Initialize data on each server by using this server as the initial source:

   ```
   dsreplication initialize \
     --topologyFilePath /path/to/topology.json \
     --retryTimeoutSeconds 120
   ```

   For the sake of simplicity, other **`dsreplication`** options are not shown.

Replacing crashed instances and scaling up

About this task

The automation for this scenario is identical to the automation for Setting up the initial topology.

Scaling down

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. If the server is not present in the topology JSON file, remove it from the topology, as follows:

   ```
   remove-defunct-server --topologyFilePath /path/to/topology.json \
     --ignore-online \
     --serverInstanceName instance-name
     --retryTimeoutSeconds 120
   ```

   For the sake of simplicity, LDAP bind options are omitted.

Rolling updates

About this task

The presence of the file `server.uuid` in the PingDirectory server's `config` directory indicates whether the server is being set up initially or being updated.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Extract the new server bits to a directory.
3. From the same directory's `bin` directory, replace the new server profile, as follows:

   ```
   manage-profile replace-profile \
     --profile /path/to/server-profile \
     --profileVariablesFile /path/to/instance-specific-variables.properties \
     --serverRoot /path/to/existing/server
   ```

Copyright © 2025 Ping Identity Corporation

Command-line tools

The server provides a full suite of command-line tools necessary for administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

Available command-line tools

PingDirectory provides the following command-line tools, which you can run in interactive, non-interactive, or script mode.

Tools Help

For	Use this option	Example
Information about arguments and subcommands Usage examples	`--help`	`dsconfig --help`
A list of subcommands	`--help-subcommands`	`dsconfig --help-subcommands`
More information about a subcommand	`--help` with the subcommand	`dsconfig list-log-publishers --help`

Command-Line Tools

`audit-data-security`	Invoke data security audit processing in order to identify potential risks or other notable security characteristics contained in directory data. This tool schedules an internal task with the server that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items. The list of available auditors can be obtained using `dsconfig list-data-security-auditors --advanced --property name`. Either the `--includeAuditor` or the `--excludeAuditor` arguments can be used to limit the scope of the audit. Additionally, the entries scanned can be limited by specifying the backends to scan, or by specifying an LDAP filter that is used to selected entries to be processed. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`authrate`	Perform repeated authentications against the PingDirectory server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.

Copyright © 2025 Ping Identity Corporation

`backup`	Back up one or more directory server backends. Each backend backup is stored in a separate backend backup directory. A backend backup directory can contain multiple backups of the backend. Each backend backup directory contains a `backup.info` file providing information about each backup in the directory and an archive file for each backup. The name of the archive file includes both the backend ID and the backup ID. The backup ID can be provided to the backup command, or an ID is generated from a current timestamp. Each backup can be optionally compressed, encrypted, hashed or signed. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the directory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`base64`	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
`check-replication-domains`	Scan the `replicationChanges` database for all known replication domains and identify any obsolete replicas still listed as part of a topology. Run this tool before upgrading replicated topologies to help avoid lockdown mode. Learn more about Discovering obsolete replicas.
`collect-support-data`	Collect and package system information useful in troubleshooting problems. The information is packaged as a zip archive that can be sent to a technical support representative. Information collected can include configuration files, server monitor entries, portions of log files, JVM thread stack dumps, system metrics, and other data that might be helpful in diagnosing problems, understanding server performance, or otherwise assisting with support requests. Although the tool will do its best to obscure or omit sensitive data, and the entire archive can be encrypted if you desire, you might want to review the resulting support data archive to ensure verify its contents. Further, the archive will include a summary of any potential problems or concerns that are identified in the course of collecting the support data.

Copyright © 2025 Ping Identity Corporation

`config-diff`	Compares directory server configurations and produces a `dsconfig` batch file needed to bring the source inline with the target. Its uses include comparing multiple servers for configuration differences, producing a batch file to reconfigure a server from scratch from the out-of-the-box configuration, and comparing a local server against an expected configuration. Both the source and the target configurations can be retrieved over LDAP, accessed from the local server's file system, extracted from a specific file, or retrieved from every server in a configuration server group. Also, with the exception of accessing a configuration from a specific file, the source and/or target configurations can be compared as they existed at any point in the past, including the baseline, pre-installation configuration. Some configuration differences (those that will always differ between instances, like instance-name) are excluded by default to reduce the amount of spurious output, but these can be included by specifying the `--includeExpectedDifferences` command. Further differences can be excluded with the `--exclude` option. This tool attempts to generate a batch file that can be applied to the source server without any errors. However, there are some edge case configurations that the tool is not sophisticated enough to handle. For example, it cannot handle two peer configuration objects that would require swapping values for a property (for example, evaluation-order-index) that must be unique within the server. It will still generate a `dsconfig` batch file that includes these changes, but they might be rejected by the server. In these rare cases, the batch file can be hand edited so that it can be applied to a running server or it can be applied with the server shut down using `dsconfig --offline`.
`create-rc-script`	Create a Run Control (RC) script that you can use to start, stop, and restart the PingDirectory server on UNIX-based systems.
`create-systemd-script`	Create a systemd script to start and stop the PingDirectory server on Linux-based systems.
`dbtest`	Inspect the contents of the PingDirectory server local DB backends that store their information in Berkeley DB Java Edition databases. Only backends of type local DB can be inspected by this tool. Each local DB backend has a root container, identified by the backend ID. Each root container has an entry container for each base distinguished name (DN) in the backend. Each entry container has several database containers that store entries, attribute indexes and system indexes. The `dbtest` command allows the contents of root containers, entry containers and database containers to be inspected.
`deliver-one-time-password`	Generate and deliver a one-time password to a user through some out-of-band mechanism. That password can then be used to authenticate using the UNBOUNDID-DELIVERED-OTP SASL mechanism.

Copyright © 2025 Ping Identity Corporation

`deliver-password-reset-token`	Generate and deliver a single-use token to a user through some out-of-band mechanism. The user can provide that token to the password modify extended request in lieu of the user's current password in order to select a new password.
`dsconfig`	View and edit the PingDirectory server configuration. This utility offers three primary modes of operation, the interactive mode, the non-interactive mode, and the batch mode: • The interactive mode supports viewing and editing the configuration using an intuitive, menu driven environment. Running `dsconfig` in interactive provides a user-friendly, menu-driven interface for accessing and configuring the server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` shell script or batch file without any arguments. • The non-interactive mode provides a simple way to make arbitrary changes to the PingDirectory server by invoking it on the command-line. If you want to use administrative scripts to automate the configuration process, then run the `dsconfig` command in non-interactive mode. • The batch mode reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting in that it minimizes LDAP connections and JVM invocations that normally occur with each `dsconfig` call. You can view the `logs/config-audit.log` file to review the configuration changes made to the PingDirectory server and to use them in the batch file.
`dsjavaproperties`	Configure the JVM options used to run the PingDirectory server and its associated tools. The options managed by this tool are stored in `config/java.properties`. Typically, you should not edit that file directly. Instead, run the tool specifying `--jvmTuningParameter` arguments to customize JVM options appropriate for this system. Note that the changes will only apply to this PingDirectory server installation. No modifications will be made to your environment variables. Memory and other settings for the JVM tools, including the `start-server` tool, can be tuned during initialization by specifying one or more instances of the `--jvmTuningParameter` option when invoking this tool. Supported values are as follows: • `NONE`: Explicitly specify no parameters. • `AGGRESSIVE`: This system is dedicated to running only this server. The amount of memory allocated to this server will be computed accordingly. • `SEMI_AGGRESSIVE`: This system is shared by multiple server processes. The amount of memory allocated to this server will be computed accordingly. If no parameters are specified, the parameters specified by the previous invocation of this tool or setup will be used. Use the `NONE` option to explicitly specify no parameters.

Copyright © 2025 Ping Identity Corporation

`dsreplication`	Manage data replication between two or more PingDirectory server instances. For replication to work, you must first to enable replication using the **`enable`** subcommand. Then, you initialize the contents of one of the servers with the contents of the other using the **`initialize`** subcommand.
`dump-dns`	Obtain a listing of all of the DNs for all entries below a specified base DN in the PingDirectory server.
`encode-password`	Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.
`encrypt-file`	Encrypt or decrypt data using a key generated from a user-supplied passphrase, a key generated from an encryption settings definition, or a key shared among servers in the topology. The data to be processed can be read from a file or standard input, and the resulting data can be written to a file or standard output. You can use this command to encrypt and subsequently decrypt arbitrary data, or to decrypt encrypted backups, LDAP Data Interchange Format (LDIF) exports, and log files generated by the server.
`encryption-settings`	Manage the server encryption settings database. More information about the cipher algorithms and transformations available for use can be found in the Java Cryptography Architecture Reference Guide, as well as the Standard Algorithm Name Documentation for your chosen JDK implementation used by this server.
`enter-lockdown-mode`	Request that the PingDirectory server enter lockdown mode, during which it only processes operations requested by users holding the `lockdown-mode` privilege. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the `lockdown-mode` privilege.
`export-ldif`	Export data from the PingDirectory server backend in LDIF form. To export data from a remote PingDirectory server, the server must be running and connection parameters must be supplied. You can specify options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The data can be appended to an existing file instead of overwriting it, and the output can be optionally compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.

Copyright © 2025 Ping Identity Corporation

`export-reversible-passwords`	Requests that the server export entries from a specified backend in LDIF form, including clear-text representations of any passwords encoded with a reversible storage scheme. Include the following arguments to configure the output of the tool: **`--filter`** The export only includes entries matching the specified filter. **`--exportNonReversiblePasswords`** The export includes entries with non-reversible passwords. **`--exportEntriesWithoutPasswords`** The export includes entries that don't have passwords. **`--includeAdditionalAttribute`** The exported entries include the specified attribute(s) in addition to the user's DN and password. You can use `"*"` to include all user attributes and `"+"` to include all operational attributes. **`--includeVirtualAttributes`** The exported entries include the values of virtual attributes in addition to real attributes. This tool can only be used over a secure connection and when authenticated as a user with the `permit-export-reversible-passwords` privilege. The server encrypts the output using a key generated from either a user-supplied passphrase or an encryption settings definition.

Copyright © 2025 Ping Identity Corporation

`extract-data-recovery-log-changes`	Extracts changes matching a given set of criteria from a PingDirectory server audit log so that they can be replayed (for example, as part of a disaster recovery process) or reverted (for example, to back out changes made in error). This tool is designed to be used in conjunction with the server's data recovery log files (in the `logs/data-recovery` directory). It can be used in conjunction with other audit log files, but for best results, the logger should be configured to operate in reversible form, to include the requester DN and IP address, and to include information about any intermediate client control that might have been provided in the request. This tool must not be used with a log file that the server can update while the tool is running, or that can have some content stored in an unwritten buffer (which is especially likely if the log is compressed or encrypted). To use this tool with the server online, you should only specify a log file that has already been rotated to ensure that no more writes will be made to that file. If necessary, use the `rotate-log` tool to force the current active file to be rotated. To use this tool to revert an inappropriate set of changes, run it with `--direction revert` and an additional set of arguments that identify which changes should be reverted (for example, based on the address of the client, the authorization DN of the requester, the time frame in which the changes were applied, etc.). To use this tool to replay changes that were previously applied (for example, after restoring an old backup or importing an old LDIF file), run it with `--direction replay` and an appropriate set of arguments to select the desired set of changes. Also, make sure to use `dsreplication pre-external-initialization` before performing the restore or import and applying the changes, and then use `dsreplication post-external-initialization` after the changes have been applied. See the PingDirectory Server Administration Guide for additional information. This tool will extract changes from the selected log file (and any previously rotated files, unless the `--doNotFollowRotationChain` argument is provided) and output them in LDIF change format. If the `--outputFile` argument is provided, then the changes will be written to that file; otherwise, they will be written to standard output. If changes are to be written to a file, then the output will be compressed if the input files were compressed (unless the `--doNotCompressOutput` argument was provided), and the output will be encrypted if the input files were encrypted (unless the `--doNotEncryptOutput` argument was provided). You might want to first run the tool without specifying an output file so that you can verify that the selected changes are correct. Once you are certain that the appropriate changes have been selected, you can use a tool like `ldapmodify` or `parallel-update` to apply those changes to the server.
`generate-totp-shared-secret`	Generate a shared secret that you can use to generate time-based one-time password (TOTP) authentication codes for use in authenticating with the UNBOUNDID-TOTP SASL mechanism or with the validate TOTP password extended operation.
`identify-references-to-missing-entries`	Identify entries containing one or more attributes which reference entries that do not exist. This might require the ability to perform unindexed searches and/or the ability to use the simple paged results control.

Copyright © 2025 Ping Identity Corporation

`identify-unique-attribute-conflicts`	Identify unique attribute conflicts. That is, it can identify values of one or more attributes that are supposed to exist only in a single entry but are found in multiple entries.
`import-ldif`	Import LDIF data into a PingDirectory server backend. Connection parameters are not required when importing to a local PingDirectory server that is not running. However, connection parameters are required if the server is remote, or if it is running locally and it is inconvenient to have to stop it for the import. You can use the options to include or exclude specific attributes and branches of the tree, and to include or exclude entries matching a given filter. The input file can be compressed. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`indent-ldap-filter`	Parse a provided LDAP filter string and display it a multi-line form that makes it easier to understand its hierarchy and embedded components. If possible, the tool might also simplify the provided filter in certain ways (for example, by removing unnecessary levels of hierarchy, like an AND embedded in an AND).
`ldap-debugger`	Intercept and decode LDAP communication.

Copyright © 2025 Ping Identity Corporation

`ldap-diff`	**Compare the contents of two LDAP servers.** **The `ldap-diff` tool outputs the difference between data stored in two LDAP servers into an LDIF file. This file could be used with the `ldapmodify` command to bring the source directory server in sync with the target directory server. The specific entries to compare can be controlled with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. Specific attributes can also be excluded by prepending a `^` character to the attribute. On Windows operating systems, excluded attributes must be quoted. For example: `"^attrToExclude"`. When retrieving entries from a PingDirectory server, the `@objectClassName` notation can be used to compare only attributes that are defined for a given objectClass.** **This command can be used on servers actively being modified, without reporting false positives caused by replication delays, by checking differing entries multiple times. By default, it will re-check each differing entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. The output is formatted so that delete operations come first, modify operations come next, and add operations come last. This gives the best chance that the resulting output file can be used to bring the source server into sync with the target server without causing any conflicts. This takes into account attribute uniqueness constraints as well as the requirement that child entries be deleted before parents and parents be added before children.** **The directory user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the PingDirectory server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry** • `ds-cfg-default-root-privilege-name: unindexed-search` • `ds-cfg-default-root-privilege-name: bypass-acl` • `ds-rlim-size-limit: 0` • `ds-rlim-time-limit: 0` • `ds-rlim-idle-time-limit: 0` • `ds-rlim-lookthrough-limit: 0` **For servers from other vendors, consult their documentation for configuring the proper privileges.** **The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For directories that contain tens of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by `ldap-diff` can be customized by editing the `ldap-diff.java-args` parameter in the `config/java.properties` file and running the `dsjavaproperties` command.**

Copyright © 2025 Ping Identity Corporation

`ldap-result-code`	Display and query LDAP result codes. This tool can be used to list all known defined LDAP result codes, retrieve the name of the result code with a given integer value, or search for all result codes with names containing a given substring. At most, one of the `--list`, `--int-value`, and `--search` arguments can be provided. If none of them is provided, then the `--list` option will be chosen by default.
`ldapcompare`	Perform compare operations in an LDAP directory server. Compare operations can be used to efficiently determine whether a specified entry has a given value. The exit code for this tool will indicate whether processing was successful or unsuccessful, and to provide a basic indication of the reason for unsuccessful attempts. By default, it will use an exit code of zero (which corresponds to the LDAP 'success' result) if all compare operations completed with a result code of either 'compare false' or 'compare true' (integer values 5 and 6, respectively), but if the `--useCompareResultCodeAsExitCode` argument is provided, only one compare assertion is performed, and it yields an exit code of 'compare false' or 'compare true', then the numeric value for that result code will be used as the exit code. If any error occurs during processing, then the exit code will be a nonzero value that reflects the first error result that was encountered. The attribute type and assertion value to use for the compare operations will typically be provided as the first unnamed trailing argument provided on the command line. It should be formatted with the name or OID of the target attribute type followed by a single colon and the string representation of the assertion value. Alternatively, the attribute name or OID can be followed by two colons and the base64-encoded representation of the assertion value, or it can be followed by a colon and a less-than symbol to indicate that the assertion value should be read from a file (in which case the exact bytes of the file, including line breaks, will be used as the assertion value). The DNs of the entries to compare can either be provided on the command line as additional unnamed trailing arguments after the provided attribute-value assertion, or they can be read from a file whose path is provided using the `--dnFile` argument. If the attribute-value assertion is provided on the command line as an unnamed trailing argument, then the same assertion will be performed for all operations. If multiple types of assertions should be performed, then you can use the `--assertionFile` argument to specify the path to a file containing both attribute-value assertions and entry DNs.
`ldapdelete`	Delete one or more entries from an LDAP directory server. You can provide the DNs of the entries to delete using named arguments, trailing arguments, a file, or standard input. Alternatively, you can identify entries to delete using a search base DN and filter.
`ldapmodify`	Apply a set of add, delete, modify, and/or modify DN operations to a directory server. Supply the changes to apply in LDIF format, either from standard input or from a file specified with the `ldifFile` argument. Change records must be separated by at least one blank line.

Copyright © 2025 Ping Identity Corporation

`ldappasswordmodify`	Update the password for a user in an LDAP directory server using the password modify extended operation (as defined in RFC 3062), a standard LDAP modify operation, or an Active Directory-specific modification. Unless the password change method is explicitly specified (using the `--passwordChangeMethod` argument), this tool will attempt to automatically determine which method is the most appropriate for the target server using information provided in the server's root DSE. If the server advertises support for the password modify extended operation, then that method will be used. If it appears to be an Active Directory server, then an Active Directory-specific password-change method will be selected, using a regular LDAP modify operation to update the `unicodePwd` attribute with a specially encoded value. Otherwise, a regular LDAP modify operation will be used to update the value of a specified password attribute. The new password to be set for the user can be specified in one of several ways. It can be directly provided on the command line, read from a specified file, interactively prompted from the user, or automatically generated by this tool. If the new password is not specified using any of those methods, and if the password is to be updated using the password modify extended operation, then the new password field of the request will be left blank so that the server generates a new password for the user and includes it in the response to the client. If no new password is specified and some other password change method is selected, then the tool will exit with an error. The current password for the user can also be specified. This is optional, although some servers might require a user to provide their current password when setting a new one. If a current password is provided (whether given as a command-line argument, read from a specified file, or interactively requested from the user), and if a regular LDAP modify operation is used to change the password, then the resulting modify request will include a deletion of the current value and an addition of the new value. If no current password is provided, then the modify request will replace any existing password(s) with the new value.
`ldapsearch`	Process one or more searches in an LDAP directory server. The criteria for the search request can be specified in several different ways, including providing all of the details directly using command-line arguments, providing all of the arguments except the filter using command-line arguments and specifying a file that holds the filters to use, or specifying a file that includes a set of LDAP URLs with the base DN, scope, filter, and attributes to return.

Copyright © 2025 Ping Identity Corporation

`ldif-diff`	Compare the contents of two files containing LDIF entries. The output will be an LDIF file containing the add, delete, and modify change records needed to convert the data in the source LDIF file into the data in the target LDIF file. This tool works best with small LDIF files because it reads the entire contents of the source and target LDIF files into memory so they can be quickly compared. If you encounter an out-of-memory error while running the tool, you might need to increase the amount of memory available to the JVM used to invoke it. The amount of memory available to the JVM can be customized by invoking the JVM with the `-Xms` and `-Xmx` arguments, which specify the initial and maximum amounts of memory that it can use, respectively. These arguments should be immediately followed, without any intervening space, by an integer and a unit to specify the amount of memory to be used. The unit can be either `m` to indicate that the size is in megabytes, or `g` to indicate that it is in gigabytes. For example, `-Xms512m` indicates that the JVM should be given an initial heap size of 512 megabytes, while `-Xmx2g` indicates that it should be given a maximum heap size of two gigabytes. When invoking the **`ldif-diff`** tool included in the installation of a Ping Identity server product, you can edit the `config/java.properties` file to specify the arguments to use when invoking the JVM. After modifying the file, run the **`dsjavaproperties`** tool to ensure that those changes will be used for subsequent tool invocations.
`ldifmodify`	Apply a set of changes (including add, delete, modify, and modify DN operations) to a set of entries contained in an LDIF file. The changes will be read from a second file (containing change records rather than entries), and the updated entries will be written to a third LDIF file. Unlike **`ldapmodify`**, the **`ldifmodify`** command cannot read the changes to apply from standard input. All of the change records will be read into memory before processing begins, so it is important to ensure that the tool is given enough memory to hold those change records. However, it will only operate on a single source entry at a time, so the size of the source LDIF file does not significantly impact the amount of memory that the tool requires. Note that the tool will attempt to correctly handle multiple changes affecting the same entry. However, because it only operates on one entry at a time, it cannot always behave in exactly the same way as if it were applying the changes over LDAP to a server populated with the source LDIF file. For example, it is not possible to reject an attempt to delete an entry that has subordinates, so any delete will be treated as a subtree delete. Further, not all types of modify DN change records are supported. In particular, modify DN change records are not permitted if they target any entry that has been targeted by a previous change record (for example, renaming an entry that was created by a previous add change record). Finally, it cannot perform other types of validation, like ensuring that all of the necessary superior entries exist when adding a new entry, or ensuring that a modify DN will not introduce a conflict with an existing entry.
`ldifsearch`	Search one or more LDIF files to identify entries matching a given set of criteria.

Copyright © 2025 Ping Identity Corporation

`leave-lockdown-mode`	Request that the PingDirectory server leave lockdown mode and resume normal operation. While in lockdown mode, the PingDirectory server rejects all requests from users that do not hold the lockdown-mode privilege. Note that the PingDirectory server can place itself in lockdown mode under certain conditions (for example, if it detects a security problem like a malformed access control rule that might have otherwise resulted in exposure of sensitive data).
`list-backends`	List the backends and base DNs configured in the PingDirectory server.
`load-ldap-schema-file`	Loads the schema definitions contained in a specified LDIF file into the schema for a running server. This tool can only be used in conjunction with a server instance running on the local system.
`make-ldif`	Generate LDIF data based on a definition in a template file. See the server's `config/MakeLDIF` directory for example template files. In particular, the `examples-of-all-tags.template` file shows how to use all of the tags for generating values.
`manage-account`	Retrieve or update information about the current state of a user account. Processing will be performed using the password policy state extended operation, and you must have the `password-reset` privilege to use this extended operation.
`manage-certificates`	Manage certificates and private keys in a JKS, PKCS #12, PKCS #11, or BCFKS key store.
`manage-extension`	Install or update PingDirectory server extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectory server. Extension bundles are installed from a zip archive or file system directory. The server will be restarted if running to activate the extension(s).
`manage-profile`	Generate, compare, install, and replace server profiles. Server profiles define a format for the configuration of a server, including `dsconfig`, initial DIT, setup arguments, server SDK extensions, and other files. These are combined into one concrete structure. This tool provides subcommands that can be used to generate a new profile from an existing server, to set up a new server, and to replace an existing server's profile with a different profile. A template server profile file structure can be found in the resource/ directory.
`manage-tasks`	Access information about pending, running, and completed tasks scheduled in the PingDirectory server.

Copyright © 2025 Ping Identity Corporation

`manage-topology`	Manage the topology registry. The topology registry is a branch of the configuration DIT (`cn=Topology,cn=config`). It stores all metadata about server instances, including their instance and listener certificates, secret keys, server groups and administrative user accounts. In addition, it also stores information about the replication topology (replication server ID and replication domain ID) when replication is enabled among servers in a Directory topology. Last but not least, it stores the license key required to install the server. Changes to the topology registry on one server are automatically mirrored to other servers in the topology. The **`dsconfig`** tool, configuration API, or the management console can be used to make changes to the topology registry. This tool allows some additional capability such as exporting the contents of the registry as a JSON file.
`migrate-ldap-schema`	Migrate schema information from an existing LDAP server into a PingDirectory server instance. This tool can be used to migrate schema information from an existing LDAP server into this PingDirectory server instance. The source server can be any standards-compliant LDAPv3 server. All attribute type and object class definitions, which are contained in the source LDAP server but not in the target PingDirectory server instance, will be either added to the target instance or written to a schema file.
`migrate-sun-ds-config`	Update an instance of the PingDirectory server to match the configuration of an existing Sun Java System Directory Server 5.x, 6.x, or 7.x. This tool can be used to compare the configuration of Sun Java System Directory Server 5.x, 6.x, or 7.x and PingDirectory server instances in order to identify any differences and update the PingDirectory server configuration to more closely match that of the Sun server instance.
`modrate`	Perform repeated modifications against an LDAP directory server.
`move-subtree`	Move all entries in a specified subtree from one server to another.
`oid-lookup`	Search the OID registry to retrieve information about items that match a given OID or name. The string to use to search the OID registry should be provided as an unnamed trailing argument. All items in the OID registry will be examined, and any items that contain the provided string in its OID, name, type, origin, or URL will be matched. If no search string is provided, the entire OID registry will be displayed.

Copyright © 2025 Ping Identity Corporation

`parallel-update`	Use multiple concurrent threads to apply a set of add, delete, modify, and modify DN operations read from an LDIF file. As with other tools like **`ldapmodify`**, changes in the LDIF file to be processed should be ordered such that if there are any dependencies between changes (for example, if one add change record creates a parent entry and another add change record creates a child of that parent), prerequisite changes come before the changes that depend on them. When this tool is preparing to process a change, it will determine whether the new change depends on any other changes that are currently in progress, and if so, will delay processing that change until its dependencies have been satisfied. If a change does not depend on any other changes that are currently being processed, then it can be processed in parallel with those changes. This tool will keep track of any changes that fail in a way that indicates they succeed if re-tried later (for example, an attempt to add an entry that fails because its parent does not exist, but its parent can be created later in the set of LDIF changes), and can optionally re-try those changes after processing is complete. Any changes that are not retried, as well as changes that still fail after the retry attempts, will be written to a rejects file with information about the reason for the failure so that an administrator can take any necessary further action upon them.
`populate-composed-attribute-values`	Populate entries in one or more backends with attribute values generated by one or more composed attribute plugins. This tool uses the configuration from a specified set of composed attribute plugin instances to identify which entries to update and what changes to apply. It can be used as an alternative to exporting the data to LDIF and re-importing to ensure that existing entries have an appropriate set of composed attribute values. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`profile-viewer`	View information in data files captured by the PingDirectory server profiler. Profiler data files are generated by the Profiler plugin. To create these data files, set the profile-action attribute of the Profiler configuration object to 'start' to begin collection. Set the `profile-action` attribute to `stop` to end collection and have the plugin write the file to `logs/profile`.{timestamp}.

Copyright © 2025 Ping Identity Corporation

`re-encode-entries`	Re-encode all or a specified portion of the entries in a local DB backend. This tool can be used to initiate a task that will cause a local DB backend to re-encode all or a specified subset of the entries that it contains. The contents of the entries will not be altered, but this provides a useful mechanism for applying significant changes to the way that entries are actually stored in the backend (for example, to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled). This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the manage-tasks tool.
`rebuild-index`	Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than with the server offline. Running in offline mode will often provide significantly better performance and require significantly less database cleaning, particularly for indexes containing keys that match a large number of entries and have high index entry limit and exploded index entry threshold values. Also note that rebuilding an index with the server online will prevent the server from using that index while the rebuild is in progress, so some searches might behave differently while a rebuild is active than when it is not. An index must be rebuilt if the database already contains data when the index is configured. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be rebuilt include attribute indexes, VLV indexes, and JSON field indexes. **Note** PingDirectory does not support the rebuilding of system indexes, regardless of whether the rebuild is attempted online or offline. If you need to rebuild a system index, you must export the backend to LDIF and re-import it. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`register-yubikey-otp-device`	Registers a YubiKey OTP device with the PingDirectory server for a specified user so that the device can be used to authenticate that user in conjunction with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. Alternately, it can be used to deregister one or more YubiKey OTP devices for a user so that they can no longer be used to authenticate that user.

Copyright © 2025 Ping Identity Corporation

`reload-http-connection-handler-certificates`	Reload HTTPS Connection Handler certificates. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-attribute-type-from-schema`	Safely remove an attribute type definition from the server schema. The tool will perform an appropriate set of validation before actually removing the attribute type from the schema. The below conditions must be satisfied before the attribute type can be removed. • The requester must have the update-schema privilege. • The attribute type must not be referenced by any other schema element. • The attribute type must not be defined in any schema file that is included with the PingDirectory server. Only custom attribute types can be removed from the schema. • The attribute type must not be referenced in the server configuration (for example, it must not be indexed by any backend). • The attribute type must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`remove-backup`	Safely remove a backup from the specified PingDirectory server backend. This tool deletes the specified backup archive and updates the backup descriptor accordingly. As an alternative to removing a specific backup, you can automatically remove backups outside of specified count or age criteria. The `--retainFullBackupCount` argument can be used to indicate that the specified number of full backups should be retained, and any other full backups in the directory are eligible to be removed. The `--retainFullBackupAge` argument can be used to indicate that any full backups older than the specified age are eligible to be removed.
`remove-defunct-server`	Remove a server from this server's topology. This tool will remove the specified server from the topology. In general, the `uninstall` tool should be used to remove a server from the topology. The `remove-defunct-server` tool should only be used if a prior attempt to uninstall a server was unsuccessful or the system where the server was installed is no longer available, leaving the server permanently inaccessible from the topology. If the defunct server is online and is able to reach other servers in the topology, running remove-defunct-server from it will cleanly remove it from the topology. If it cannot reach the other servers, then remove-defunct-server must also be run from one of the online servers.

Copyright © 2025 Ping Identity Corporation

`remove-object-class-from-schema`	Safely remove an object class definition from the server schema. The tool will perform an appropriate set of validation before actually removing the object class from the schema. The below conditions must be satisfied before the object class can be removed. • The requester must have the update-schema privilege. • The object class must not be referenced by any other schema element. • The object class must not be defined in any schema file that is included with the PingDirectory server. Only custom object classes can be removed from the schema. • The object class must not be referenced in the server configuration. • The object class must not be present in any entry that exists in any backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`replace-certificate`	Replace the listener certificate for this PingDirectory server instance.
`restore`	Restore a backup of a PingDirectory server backend. Only one backend can be restored at a time by the restore command. The PingDirectory server should be stopped unless task connection options are supplied for a running server. You can list the backups contained in a particular backend backup directory. A backup taken on one system can be restored on another system. This tool features both an offline mode of operation as well as the ability to schedule an operation to run within the PingDirectory server's process. To schedule an operation supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.
`revert-update`	Revert this server package's most recent update.
`review-license`	Review and/or indicate your acceptance of the license agreement defined in `legal/LICENSE.txt`.

Copyright © 2025 Ping Identity Corporation

`rotate-log`	Trigger the rotation of one or more log files. If the file argument is provided one or more times to specify the target log file paths, then only those log files will be rotated. If the file argument is not given, then the server will trigger rotation for all supported log files. You must have the `config-read` and `config-write` privileges to run this tool, and you must have the necessary access control rights to create and monitor entries in the task backend. This tool schedules an operation to run within the PingDirectory server's process. LDAP connection options must be supplied that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the **`manage-tasks`** tool.
`sanitize-log`	Sanitize the contents of a server log file to remove potentially sensitive information while still attempting to retain enough information to make it useful for diagnosing problems or understanding load patterns. The sanitization process operates on fields that consist of name-value pairs. The field name is always preserved, but field values might be tokenized or redacted if they might include sensitive information. Supported log file types include the file-based access, error, sync, and resync logs, as well as the operation timing access log and the detailed HTTP operation log. Sanitize the audit log using the **`scramble-ldif`** tool.
`schedule-exec-task`	Schedule an exec task to run a specified command in the server. To run an exec task, several conditions must be satisfied: • The server's global configuration must have been updated to include `com.unboundid.directory.server.tasks.ExecTask` in the set of allowed-task values • The requester must have the `exec-task` privilege • The command to execute must be listed in the `exec-command-whitelist.txt` file in the server's `config` directory. The absolute path (on the server system) of the command to execute must be specified as the first unnamed trailing argument to this program, and the arguments to provide to that command (if any) should be specified as the remaining trailing arguments. The server root is used as the command's working directory, so any arguments that represent relative paths are interpreted as relative to that directory.
`search-and-mod-rate`	Perform repeated searches against an LDAP directory server and modify each entry returned.
`search-logs`	Search across log files to extract lines matching the provided patterns, like the **`grep`** command-line tool. The benefits of using the **`search-logs`** tool over **`grep`** are its ability to handle multi-line log messages, extract log messages within a given time range, and the inclusion of rotated log files.
`searchrate`	Perform repeated searches against an LDAP directory server.

Copyright © 2025 Ping Identity Corporation

`server-state`	View information about the current state of the PingDirectory server process.
`set-delegated-admin-aci`	Request that the PingDirectory server assign appropriate ACI for configured delegated administrators of the Delegated Admin API.
`setup`	Perform the initial setup for a server instance. This tool features both interactive and non-interactive modes for accepting the product license terms and initially configuring a server instance.
`start-server`	Start the PingDirectory server.
`status`	Display basic server information. This tool prints information about the server, such as version, connection handlers, and data sources. Some information might not be available if the server is not running, or if authentication credentials are missing or do not have sufficient privileges, or if the invoking user does not have sufficient file system access rights.
`stop-server`	Stop or restart the server. This tool is used to stop or restart the local instance of the server (by omitting LDAP connection options), or a remote server (by interacting with it over LDAP). In addition, this tool is used to schedule the server for shutdown at a later time using the server's task interface.
`subtree-accessibility`	List or update the set of subtree accessibility restrictions defined in the PingDirectory server.
`sum-file-sizes`	Calculate the sum of the sizes for a set of files. This tool is used to find the sum of the sizes of one or more files. If any of the files specified is a directory then it will be recursively processed.
`summarize-access-log`	Examine one or more access log files to display several metrics about operations processed within the server.
`sync-pipe-view`	PingDataSync only: Display the detailed configuration of a sync pipe or pipes in PingDataSync and all commands necessary to replicate a specified sync pipe. You can use the `sync-pipe-view` tool online with the PingDataSync server connection credentials or you can use the tool offline. The sync pipe information can be output in a text, CSV, JSON, or tab-delimited format and can be output to a file. The `sync-pipe-view` tool features both an interactive mode and a non-interactive mode.
`transform-ldif`	Apply one or more changes to entries or change records read from an LDIF file, writing the updating records to a new file. This tool can apply a variety of transformations, including scrambling attribute values, redacting attribute values, excluding attributes or entries, replacing existing attributes, adding new attributes, renaming attributes, and moving entries from one subtree to another.

Copyright © 2025 Ping Identity Corporation

`uninstall`	Uninstall the PingDirectory server. This tool removes the entire server or individual server components from the file system. If this server is a member of a replication topology, you must first remove references to this server in the other servers using the `dsreplication disable` command.
`update`	Update a deployed server so its version matches the version of this package.
`validate-acis`	Validate a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the PingDirectory server. Note that output generated by this tool will be LDIF, but each entry in the output will have exactly one ACI, so entries which have more than one ACI will appear multiple times in the output with different ACI values.
`validate-file-signature`	Validate file signatures. For best results, file signatures should be validated by the same instance used to generate the file. However, it might be possible to validate signatures generated on other instances in a replicated topology.
`validate-ldap-schema`	Validate an LDAP schema read from one or more LDIF files.
`validate-ldif`	Validate the contents of an LDIF file against the server schema.
`verify-index`	Verify that indexes in a backend using the Berkeley DB Java Edition are consistent with the entry data contained in the database. The backend containing the provided base DN must be a local DB backend. The types of indexes that can be verified include system indexes, attribute indexes and VLV indexes. Any errors found during verification are written to the output. The verification process is exhaustive and can take a long time.
`watch-entry`	Launch a window to watch an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can be modified as well. This tool is primarily intended to demonstrate replication or synchronization functionality.

Saving options in a file

The PingDirectory server supports the use of a tools properties file (`config/tools.properties`) to simplify command-line invocations by reading in a set of options for each tool from a text file.

Properties files are convenient when quickly testing the PingDirectory server in multiple environments.

Each property takes the form of a name-value pair that defines predetermined values for a tool's options.

The PingDirectory server supports the following types of properties:

- Default properties that apply to all command-line utilities
- Tool-specific properties

Copyright © 2025 Ping Identity Corporation

Evaluation of command-line options and file options

You can specify options for a command-line tool on the command line, in a properties file, or both.

Options you specify on a tool's command line take priority over options in a properties file.

Consider the following scenarios.

Command-line options	Server uses ...
No command-line options	The options in the default `<server-root>/config/tools.properties` file.
Command-line options other than the `--propertiesFilePath <my-properties-file>` option	The command-line options, which take priority if the options are also in the `<server-root>/config/tools.properties` file. The file options for options that are only in the default `<server-root>/config/tools.properties` file.
Only the `--propertiesFilePath <my-properties-file>` option	The options in `<my-properties-file>`.
The `--propertiesFilePath <my-properties-file>` option and other command-line options	The command-line options, which take priority if the options are also in `<my-properties-file>`. The file options for options that are only in `<my-properties-file>`.
The `--noPropertiesFile` option and other command-line options	Only the options you specify on the command line, ignoring the default properties file.

Example

Consider this example properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The server checks command-line options and file options to determine the options to use, as explained below.

- All options presented with the tool on the command line take precedence over any options in a properties file.

  In the following example, the command runs with the options specified on the command line (`--port` and `--baseDN`). With the `port` value both on the command line and in the properties file, the command-line value takes priority. The command uses the `bindDN` and `bindPassword` values specified in the properties file.

  ```
  $ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
    --propertiesFilePath bin/tools.properties "(objectclass=*)"
  ```

Copyright © 2025 Ping Identity Corporation

- If you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the server uses only the options in the specified properties file:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)"
```

- If you do not specify any command-line options, the server attempts to locate the default properties file in the following location:

```
<server-root>/config/tools.properties
```

By moving your `tools.properties` file from `<server-root>/bin` to `<server-root>/config`, you do not have to specify the `--propertiesFilePath` option. That change shortens the previous command to the following command:

```
$ bin/ldapsearch "(objectclass=*)"
```

Creating a tools properties file

You can set properties that apply to all tools or are tool-specific. These properties serve as defaults for the command-line options they represent.

Steps

1. Use a text editor to open the default tools properties file (`config/tools.properties`) or a different properties file.

> **Note**
>
> If you use a file other than `config/tools.properties`, invoke the tool with the `--propertiesFilePath` option to specify the path to your properties file.

2. Set or change properties that apply to all tools.

   Use the standard Java properties file format (name=value) to set properties. For example, the following properties define a set of Lightweight Directory Access Protocol (LDAP) connection parameters.

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> Properties files do not allow quotation marks of any kind around values.
> Escape spaces and special characters.
> Whenever you specify a path, do not use `~` to refer to the home directory. The server does not expand the `~` value when read from a properties file.

3. Set or change properties that apply to specific tools.

   Tool-specific properties start with the name of the tool followed by a period. These properties take precedence over properties that apply to all tools. The following example sets two ports: one that applies to all tools (`port=1389`) and a tool-specific one that `ldapsearch` uses instead (`ldapsearch.port=2389`).

   ```
   hostname=server1.example.com
   port=1389
   ldapsearch.port=2389
   bindDN=cn=Directory\ Manager
   ```

4. Save your changes and close the file.

dsconfig batch files">

Sample `dsconfig` batch files

The `config/sample-dsconfig-batch-files` directory contains `dsconfig` batch files that you can use to configure various aspects of the server. For example, these files can enable additional security capabilities or take advantage of features that might require customization from one environment to another.

Each file includes comments that describe the purpose and benefit of its configuration change. You can choose which of the changes you want to apply.

You need to customize some of the batch files to provide values that might vary from one environment to another. To apply a batch file that requires changes, copy it to another directory and edit the copy. Leave the files in the `config/sample-dsconfig-batch-files` directory unchanged so that they can be updated when you upgrade the server. To specify the path to the file that contains the changes to apply, use the `dsconfig` tool (`bin/dsconfig` on UNIX-based systems or `bat\dsconfig.bat` on Windows) with the `--batch-file` argument.

You should also provide the arguments needed to connect and authenticate to the server. The `--no-prompt` argument ensures that the tool does not block while waiting for input if any necessary arguments are missing. Consider this example.

```
bin/dsconfig --hostname localhost \
  --port 636 --useSSL --trustStorePath config/truststore \
  --bindDN "uid=admin,dc=example,dc=com" \
  --bindPasswordFile admin-password.txt \
  --batch-file config/hardening-dsconfig-batch-files/reject-insecure-request.dsconfig \
  --no-prompt
```

Copyright © 2025 Ping Identity Corporation

Running task-based tools

The PingDirectory server has a Tasks subsystem that allows you to schedule basic operations, such as `backup`, `restore`, `rotate-log`, `schedule-exec-task`, `stop-server`, and others. All task-based tools require the `--task` option that explicitly indicates the tool is to run as a task rather than in offline mode.

The following table shows the options that you can use for task-based operations:

Options for task-based operations

Option	Description
`--task`	Indicates that the tool is invoked as a task. The `--task` option is required. If you invoke a tool as a task without this `--task` option, then a warning message is displayed stating that it must be used. If the `--task` option is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message is displayed and the tool exits with an error.
`--start <startTime>`	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation is to start. A value of '0' causes the task to be scheduled for immediate execution. After the scheduled run, the tool exits immediately.
`--dependency <taskID>`	Specifies the ID of a task upon which this task depends. A task does not start execution until all its dependencies have completed execution. You can use this option multiple times in a single command.
`--failedDependencyAction <action>`	Specifies the action this task takes if one of its dependent tasks fail. Valid action values are: • `CANCEL` (the default) - Cancels the task. • `DISABLE` - Disables the task so that it is not eligible to run until you manually enable it again. • `PROCESS` - Runs the task.
`--startAlert`	Generates an administrative alert when the task starts running.
`--errorAlert`	Generates an administrative alert when the task fails to complete successfully.
`--successAlert`	Generates an administrative alert when the task completes successfully.
`--startNotify <emailAddress>`	Specifies an email address to notify when the task starts running. You can use this option multiple times in a single command.
`--completionNotify <emailAddress>`	Specifies an email address to notify when the task completes, regardless of whether it succeeded or failed. You can use this option multiple times in a single command.

Copyright © 2025 Ping Identity Corporation

Option	Description
`--errorNotify <emailAddress>`	Specifies an email address to notify if an error occurs when this task executes. You can use this option multiple times in a single command.
`--successNotify <emailAddress>`	Specifies an email address to notify when this task completes successfully. You can use this option multiple times in a single command.

Introduction to the PingDirectoryProxy server

This section gives an overview of PingDirectoryProxy features and components.

PingDirectoryProxy is a fast and scalable LDAPv3 gateway for the PingDirectory server. Administrators can configure the PingDirectoryProxy server architecture to control how client requests are routed to backend servers.

Overview of the PingDirectoryProxy features

The following overview describes the PingDirectoryProxy server's features and capabilities.

The PingDirectoryProxy server is a fast, scalable, and easy-to-use LDAP proxy server that provides high availability and additional security for the PingDirectory server while remaining largely invisible to client applications. From a client perspective, request processing is the same, whether communicating with the PingDirectory server directly or going through the PingDirectoryProxy server.

The PingDirectoryProxy server provides the following features:

High availability

The PingDirectoryProxy server allows you to transparently fail over between servers if a problem occurs as well as ensuring that the workload is balanced across the topology. If a client does not support following referrals, the server can follow them on the client's behalf.

Copyright © 2025 Ping Identity Corporation

Data mapping and transformation

The PingDirectoryProxy server can perform distinguished name (DN) mapping and attribute mapping to allow clients to interact with the server using older names for directory content. It allows clients to continue working when they would not be able to work directly with the PingDirectory server, either because of changes that have occurred at the data layer or to inherent design limitations in the clients.

Horizontal scalability and performance

Reads can be horizontally scaled using load balancing. In large data centers, if the data set is too large to be cached or to provide horizontal scalability for writes, the PingDirectoryProxy server can automatically split the data across multiple systems. This feature allows the PingDirectoryProxy server to improve scalability and performance of the PingDirectory server environment.

Load balancing and failover

You can spread the workload across multiple directory servers in a large data center using load-balancing algorithms. Load balancing is also useful when a server becomes degraded or non-responsive because client process requesting directs to a different server.

Security and access control

The PingDirectoryProxy server can add additional firewall capabilities as well as constraints and filtering to help protect the PingDirectory server from attacks. You can use a PingDirectoryProxy server in a DMZ as opposed to allowing clients to directly access the PingDirectoryProxy server in the internal network or providing the data in the DMZ. It can help provide secure access to the data and you can define what actions clients are allowed to do. For example, you can prevent clients from making modifications to data when connected through a VPN no matter what their identity or permissions.

Tracking of operations across the environment

In the past, administrators have complained that when they see a request in the access log they have no idea where it came from and cannot track it back to a particular client. The PingDirectoryProxy server contains controls that allow administrators to track requests back to the client that issued them. Whenever the PingDirectoryProxy server forwards a request to the PingDirectory server, it includes a control in the request so that the PingDirectory server's access log has the IP address of the client, address and connection ID of the PingDirectory server. In the response back to the client, it similarly includes information about the PingDirectory server that processed the request, such as the connection ID and operation ID. This feature makes it easier for administrators to monitor in their environment.

Monitoring and management tools

Because the PingDirectoryProxy server uses many of the components of PingDirectory, it can leverage them to provide protocol support, logging, management tools for configuration and monitoring, and schema. You can use the DataMetricsServer, the `dsconfig` tool, and the administrative console to manage the PingDirectoryProxy server.

Overview of the PingDirectoryProxy server components and terminology

This section describes each PingDirectoryProxy server component in more detail.

The PingDirectoryProxy server provides the following components and functionalities for the proxy capabilities:

- Locations

Copyright © 2025 Ping Identity Corporation

- LDAP External Servers
- LDAP Health Checks
- Load-Balancing Algorithms
- Data Transformations
- Request Processors
- Server Affinity Providers
- Subtree Views
- Connection Pools
- Client Connection Policies
- Entry Balancing

About locations

You can assign a location to the PingDirectoryProxy server and each of the backend LDAP external servers for routing requests and failover response preferences.

Locations define a group of servers with similar response time characteristics. Each location consists of a name and an ordered list of preferred failover locations. These locations can determine how to route requests so that the server forwards requests to the PingDirectoryProxy server in the same data center over those in remote locations.

For example, a deployment consists of three data centers, one in New York, one in Chicago, and one in Los Angeles. In the New York data center, applications that reside in this data center prefer communicating with directories in this data center. If none of the servers are available, it prefers to failover to the data center in Chicago rather than the data center in Los Angeles, so the New York location contains an ordered list in which the Chicago location is preferred over the Los Angeles data center for failover.

Follow these guidelines for assigning locations in the PingDirectoryProxy server:

- If you have multiple data centers, assign a separate location for each one.
- In most environments, all PingDirectoryProxy server instances should have the same configuration except for the attribute that specifies the location of the server itself.

Learn more about Configuring locations.

About LDAP external servers

PingDirectoryProxy allows you to configure different types of LDAP external servers.

You can configure information about the directory server instances accessed by PingDirectoryProxy. The default configuration for each type is tuned to be the best possible configuration for each.

The configuration information includes the following:

- Server connection information, such as IP address, port, and security layer

Copyright © 2025 Ping Identity Corporation

- Location
- Authentication information
- Methods for authenticating and authorizing clients
- Server-specific health checks
- Types of operations allowed

  For example, some LDAP external servers might allow only reads and others allow reads and writes so that the PingDirectoryProxy server can recognize this and accommodate it.

For more information about configuring LDAP external servers, see Configuring LDAP external servers.

About LDAP health checks

LDAP health checks provide information about the status and availability of LDAP external servers. Configure the PingDirectoryProxy server health checks that work best for your environment.

PingDirectoryProxy provides the following health checks:

Measure the response time for searches and examine the entry contents

The health check might retrieve a monitoring entry from a server and base the health check result on whether the entry was returned, how long it took to be returned, and whether the value of the returned entry matches what was expected.

Monitor the replication backlog

If a server falls too far behind in replication, then the PingDirectoryProxy server can stop sending requests to it. A server is classified as `degraded` or `unavailable` if the threshold is reached for the number of missing changes, the age of the oldest missing change, or both.

Consume Directory Server administrative alerts

If the PingDirectory server indicates there is a problem, such as an index that must be rebuilt, then it flags itself as `degraded` or `unavailable`. When the PingDirectoryProxy server detects this, it stops sending requests to the server. The PingDirectoryProxy server detects administrative alerts as soon as they are issued by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the PingDirectory server.

When the PingDirectoryProxy server is notified by the PingDirectory server of a new alert, it immediately retrieves the base `cn=monitor` entry of the PingDirectory server. If this entry has a value for the `unavailable-alert-type` attribute, then the PingDirectoryProxy server considers it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the PingDirectoryProxy server considers it `degraded`. Clients of the PingDirectoryProxy server can use a similar mechanism to detect and react when server flags itself as `degraded` or `unavailable`.

Monitor the busyness of the server

If a server becomes too busy, you can mark it as `degraded` or `unavailable` so that less heavily-loaded servers are preferred.

Copyright © 2025 Ping Identity Corporation

Results

The health check results contain the following server states:

`Available`

Completely accessible for use.

`Degraded`

The server can be used if necessary but has a condition which can make it less desirable than other servers. For example, it is slow to respond or has fallen behind in replication.

`Unavailable`

Completely unsuitable for use. For example, the server is offline or is missing critical data.

Health check results include a numeric score that has a value between 1 and 10. This score helps rank servers with the same state. For example, two servers are available and one has a score of 8 and the other a score of 7, you can configure the PingDirectoryProxy server to prefer the server with the higher score.

The results of health checks are made available to the load-balancing algorithms to help determine where to send requests. The PingDirectoryProxy server attempts to use servers with a state of `available` before trying servers with a state of `degraded`. It never attempts to use servers with a state of `unavailable`.

Some load-balancing algorithms also take the health check score into account, such as the health-weighted load-balancing algorithm that prefers servers with higher scores over those with lower scores. You should configure the algorithms that work best for you environment.

Frequency

The PingDirectoryProxy server periodically invokes health checks to monitor each LDAP external server and initiates health checks in response to failed operations. It checks the health of the LDAP external servers at intervals configured in the LDAP server's `health-check-frequency` property. The PingDirectoryProxy server contains safeguards to ensure that only one health check is in progress at any time against a backend server to avoid affecting its ability to process other requests.

To associate a health check with an LDAP external server and set the health check frequency, you must configure the `health-check` and `health-check-frequency` properties of the LDAP external server.

For more information about configuring the properties of the external server, see Configuring an external server using `dsconfig`.

Server states and search response times

In some cases, an LDAP health check defines different sets of criteria for promoting and demoting the state of a server. A `degraded` server might need to meet more stringent requirements to be reclassified as `available` than originally for it to be considered `degraded`.

If response time is used in the process of determining the health of a server, then the PingDirectoryProxy server might have a faster response time threshold for transitioning a server from `degraded` back to `available` than the threshold used to consider it `degraded` in the first place. This threshold difference helps avoid cases in which a server repeatedly transitions between the two states because it is operating near the threshold.

Copyright © 2025 Ping Identity Corporation

For example, the health check used to measure search response time is configured to mark any server as `degraded` when the search response time is greater than 1 second. You can configure that the response time must be less than 500 ms before the server is made available again so that the PingDirectoryProxy server does not flip back and forth between `available` and `degraded`.

For more information about configuring health checks, see Configuring server health checks.

About load-balancing algorithms

Load-balancing algorithms determine which server in a set of similar servers to use to process a client request.

The PingDirectoryProxy server provides the following load-balancing algorithms:

Fewest operations

Forwards request to the backend server with the fewest operations currently in progress.

Single server

Sends requests to the same server and doesn't attempt to fail over to another server if the target server is unavailable.

Weighted

Administrators explicitly assign numeric weights to individual servers or sets of servers to control how likely they are to be selected for processing requests relative to other servers.

Health-based weighting

Uses the health check score to assign weights to each of the servers so that a server with a higher score gets a higher percentage of the traffic than a server with a lower score. The proportion of traffic received is the difference between their health check scores.

Failover

Sends requests to a given server first. If that server fails, then the request sends to another specified server as specified in the ordered failover server list.

Learn more about Configuring load balancing.

Algorithm criteria

The algorithm takes the following criteria into account:

Location of the server

Servers in the same location as the PingDirectoryProxy server are preferred over those in alternate locations.

Health of the server

Servers that are `available` are preferred over those that are `degraded`. In some cases, the health check score can be used to further differentiate between servers with the same health check state.

Copyright © 2025 Ping Identity Corporation

Route requests consistency

Requests from a single client can be consistently routed to the same PingDirectoryProxy server instance to avoid problems such as propagation delay from replication.

Operation retries

Retries the operation in an alternate server if the request fails or the operation times out. You can control if the retry is allowed and, if so, how many times to retry and the time out interval.

Proxy transformations

Proxy transformations are used to rewrite requests and responses as they pass through the PingDirectoryProxy server. Proxy data transformations are helpful for clients that use an old schema or that contain a hard-coded schema.

Use the PingDirectoryProxy server proxy transformations to:

- Provide a distinghuished name (DN) and attribute mapping altering both requests to the server as well as responses from the server.

  For example, a client sends a request to `o=example.com` even though the directory server handling the request uses `dc=example,dc=com`. The PingDirectoryProxy server can transparently remap the request so that the server can process it and map it back to the original DN of the client request when the value is returned.

- Alternatively, if a client tries to use the attribute `userID`, the PingDirectoryProxy server can map it to `uid` before sending the request on to the backend LDAP server. The PingDirectoryProxy server then remaps the response to `userID` when the value is returned.

- Suppress a specified attribute so that it is never returned to clients. Also, it can cause the server to reject requests which target that particular attribute.

- Prevent entries that match a given search filter from being returned to clients.

For more information about configuring proxy transformations, see Configuring proxy transformations.

About request processors

A request processor encapsulates the logic for handling an operation, ensuring that a given operation is handled appropriately.

The request processor can:

- Process the operation directly

- Forward the request to another server

- Hand off the request to another request processor

PingDirectoryProxy server request processors can be used to forward certain controls, including the batch transaction control and the LDAP join control. The batch transaction control must target a single Berkeley DB backend. For more information about the controls, see LDAP SDK for Java documentation.

PingDirectoryProxy provides the following types of request processors:

Copyright © 2025 Ping Identity Corporation

Proxying request processors

Forwards operations received by the PingDirectoryProxy server to other LDAP external servers.

Entry-balancing request processors

Splits data across multiple servers. They determine which set of servers are used to process a given operation. They then hand off operations to proxying request processors so that requests can be forwarded to one of the servers in the set.

Failover request processors

Perform ordered failover between other types of request processors, sometimes with different behavior for different types of operations.

Learn more about Configuring request processors.

About server affinity providers

The PingDirectoryProxy server supports the ability to forward a sequence of requests to the same external server if specific conditions are met, called server affinity.

Use the server affinity provider to establish an affinity to a particular backend server for certain operations.

The following provider configurations and server affinity methods are available in the PingDirectoryProxy server:

Client connection Server Affinity

Requests from the same client connection consistently route to the same backend server.

Client IP address Server Affinity

All requests coming from the same client system consistently route to the same backend server.

Bind DN Server Affinity

All requests from the same user consistently route to the same backend server.

For information about configuring server affinity, see Configuring server affinity.

About subtree views

A subtree view can be used to make a portion of the directory information tree (DIT) available to a client by associating a request processor with a base distinguished name (DN).

A subtree views allow you to route operations concerning one set of data to a particular set of data sources and operations concerning another set of data to another set of data sources. Multiple subtree views are involved in processing a request, such as searches that have a scope that is larger than the subtree view.

The subtree view includes using a single base DN to identify the portion of the DIT. They might have hierarchical relationships: for example, one subtree view is configured for `dc=example,dc=com` and another for `ou=People,dc=example,dc=com`.

Copyright © 2025 Ping Identity Corporation

For information about configuring a subtree view, see Configuring subtree views.

About the connection pools

PingDirectoryProxy maintains either one or two connection pools to the backend server, depending on the type of backend server you use.

PingDirectoryProxy maintains either one pool for all types of operations or two separate pools for processing bind and non-bind operations from clients. When PingDirectoryProxy establishes connections, it authenticates them using the authentication mechanism defined in the configuration of the external server.

These connections are re-used for all types of operations forwarded to the backend server. You can configure the bind distinguished name (DN) and password in the PingDirectoryProxy server.

When a client sends a bind request to the PingDirectoryProxy server, the server looks at the type of bind request that was sent:

- If the bind request is a SASL bind request, authentication is processed by the PingDirectoryProxy server itself and does not forward to the backend server, however, the PingDirectoryProxy server can use information contained in the backend server as needed.
- If the bind request is a simple bind request, and the bind DN is within the scope of data supplied by the backend server, the PingDirectoryProxy server forwards the client request to the backend server so that it uses the credentials provided by the client.

Regardless of the authentication method the client uses, the PingDirectoryProxy server remembers the identity of the client after the authentication completes. For any subsequent requests sent by that client, the server uses the configured authorization method to identify the client to the backend server.

Even though the operation is forwarded over a connection that is authenticated as a user defined in the PingDirectoryProxy server configuration, the request processes through the backend server under the authority of the end client.

About client connection policies

Client connection policies define the general behavior the server exhibits when communicating with a set of clients.

Each policy contains the following:

- A set of connection criteria that define which client is associated with the policy based on information the server has about the client, including:
  - Client address
  - Protocol used
  - Secure communication mechanism
  - Location of the client's entry in the PingDirectoryProxy server
  - Contents of the client's entry

  These criteria are the same as those used for filtered logging. For example, different client connection policies could be established for different classes of users, such as root and non-root users.

Copyright © 2025 Ping Identity Corporation

- A set of constraints on the type of operations a client can request. You can specify whether a particular type of operation is allowed for clients.

  For some operation types, such as extended operations, you can allow only a particular subset of an operation type, such as a particular extended operation.

- A set of subtree views that define information about the parts of the directory information tree (DIT) the client can access.

When a client connection is established, only one client connection policy is applied. If the criteria for several policies match the same client connection, the evaluation order index is used as a tiebreaker. If no policy matches, the client connection is terminated. If the client binds, changing its identity, or uses StartTLS to convert from an insecure connection to a secure connection, then the connection is evaluated again to determine if it matches the same or a different client connection policy. The connection is terminated if it no longer matches any policy.

Learn more about Client connection policy configuration.

About entry balancing

Entry balancing allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

Entry balancing can take advantage of a global index. A global index is an in-memory cache used for quickly determining which set or sets of servers to use to process a request based on the entry distinguished names (DNs) and attribute values.

For information about configuring entry balancing, see Deploying an entry-balancing proxy configuration.

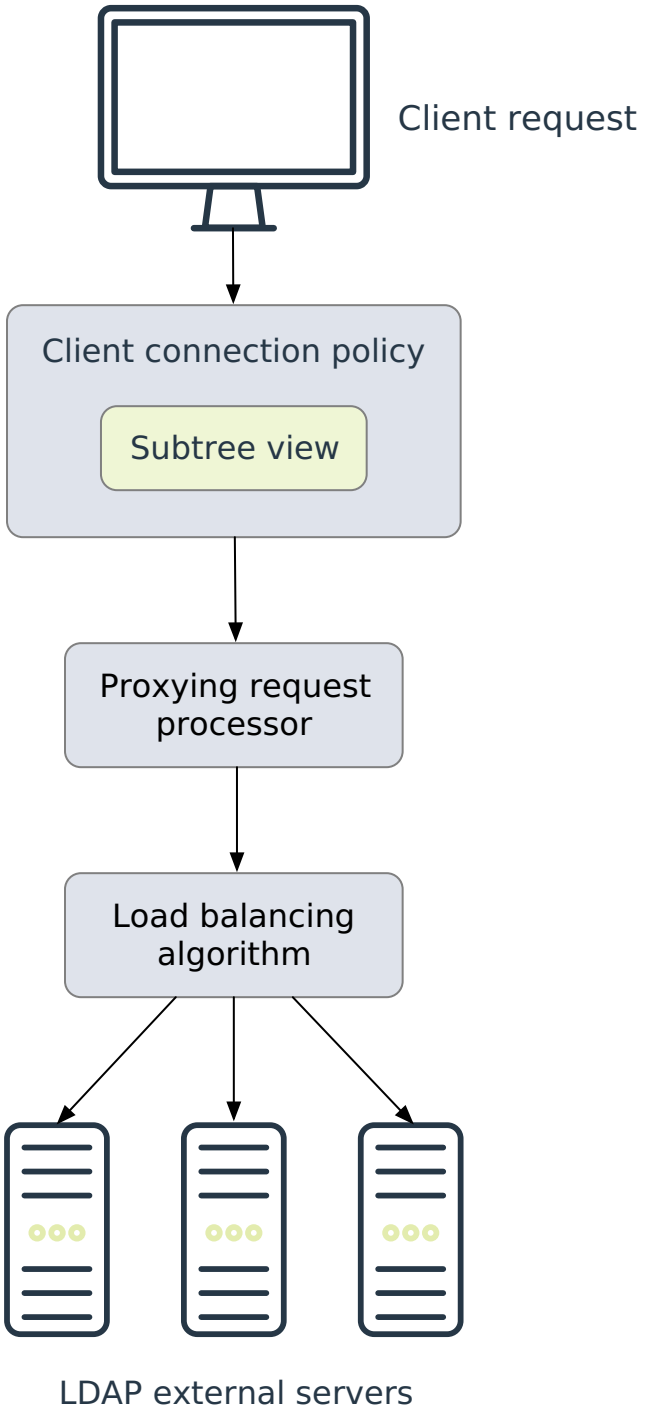
Server component architecture

This section provides an overview of the process flow between the PingDirectory server components for a simple proxy deployment and an entry-balancing deployment.

Architecture of a simple PingDirectory server deployment

A simple PingDirectory server deployment is illustrated in the following figure.

Copyright © 2025 Ping Identity Corporation



Processing steps

1. A client request is initiated.
2. The client connection policy processes the client request.
3. The client connection policy contains a subtree view, which defines the portion of the directory information tree (DIT) available to clients and determines if the DIT is available.
4. After the PingDirectory server determines that the DIT is available, it passes the request to the request processor, which defines the logic for processing the request.

Copyright © 2025 Ping Identity Corporation

5. The request processor passes the request to a load-balancing algorithm, which determines the server in a set of servers responsible for handling the request.
6. The request is passed to the LDAP external server.

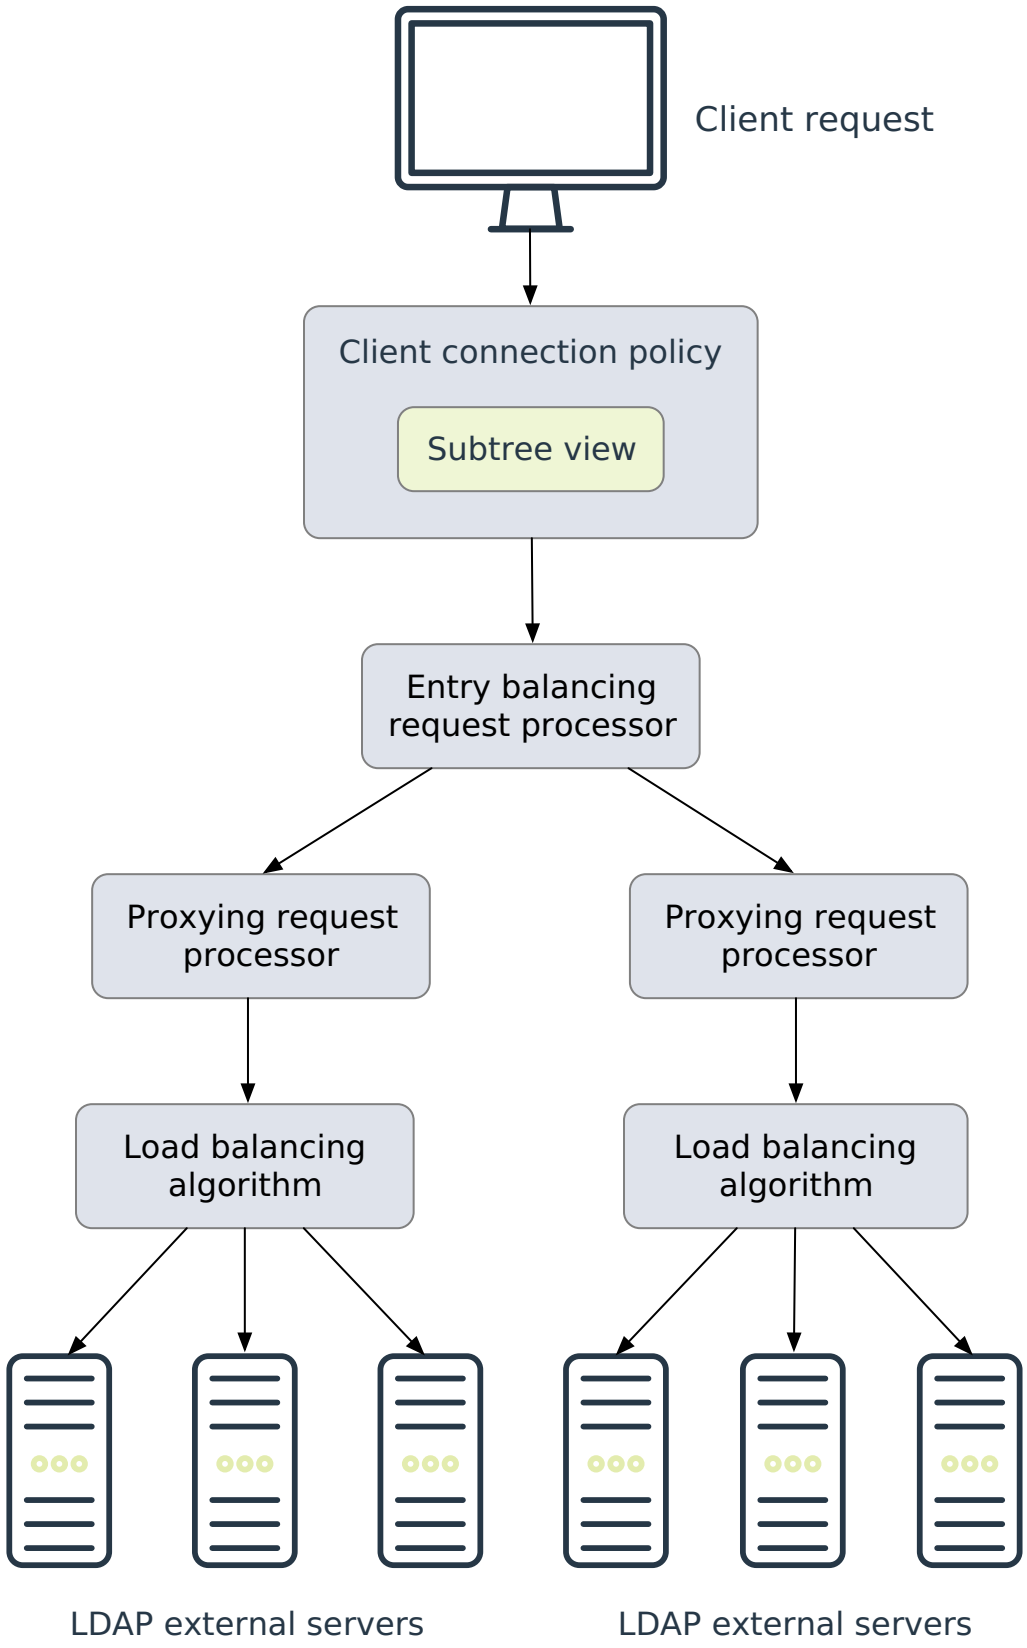
> **Note**
>
> The LDAP external server contains properties that define the server's location in a topology and the health checks used to determine if the server is functioning properly.
> This information can be used by the load-balancing algorithm for determining how to route requests.

Architecture of an entry-balancing PingDirectory server deployment

Entry balancing is used when the data set is too large to fully cache on a single server or when the write performance requirements of an environment are higher than can be achieved with a single replicated set of servers. In such cases, the data can be split across multiple sets of servers, increasing the memory available for caching and the overall write performance in proportion to the number of server sets.

The following figure shows how a client request is treated in an entry-balancing PingDirectory server deployment.

Copyright © 2025 Ping Identity Corporation



1. A client request is initiated.

2. The client connection policy processes the client request.

Copyright © 2025 Ping Identity Corporation

3. The client connection policy contains a subtree view, which determines how the PingDirectoryProxy server communicates with a set of clients. It contains a subtree view that represents the base distinguished name (DN) for the entire deployment. The data set splits beneath this base DN.
4. The PingDirectory server passes the request to the entry-balancing request processor.

   The entry-balancing request processor contains a global attribute index property, which helps the request processor determine which server set contains the entry and how to properly route the request. It also contains a placement algorithm, which helps it select the server set in which to place new entries created by add requests.
5. The entry-balancing request processor has beneath it multiple proxying request processors that handle multiple unique sets of data.
6. The proxying request processors passes the request to a load-balancing algorithm, which determines which LDAP external server should handle the request.

   > **Note**
   >
   > As with a simple proxy deployment, this LDAP external server contains properties that define the server's location and the health checks that determine if the server is functioning properly.
7. The request is passed to the LDAP external server.

For information about entry-balancing replication, see Overview of replication in an entry-balancing environment.

PingDirectoryProxy server configuration overview

The following topic provides an overview of the component configurations for your PingDirectoryProxy server deployment.

Configuring locations for your deployment

A location is a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers are configured as two locations in the PingDirectoryProxy server. Each location is associated with a name and an ordered list of failover locations to use if none of the servers in the preferred location are available.

Configuring the PingDirectoryProxy server location

You update the configuration to specify the location of the PingDirectoryProxyserver instance.

Configuring health checks for the LDAP external servers

You configure at what point the PingDirectoryProxy server considers an LDAP external server to be available, of degraded availability, or unavailable. Each health check can be configured to be used automatically for all LDAP external servers or for a specified set of servers.

Configuring the LDAP external servers

You define each of the external directory servers, including the server type. You can configure Ping Identity directory servers, Java System Directory Servers, or generic LDAP servers. You also assign the server-specific health checks configured previously.

Copyright © 2025 Ping Identity Corporation

Configuring the load-balancing algorithm

You configure the load-balancing algorithm that the PingDirectoryProxy server uses to determine which server in a set of similar servers to use to process a client request. The PingDirectoryProxy server provides default algorithms. You can create new algorithms either using an existing algorithm as a template or creating one from scratch.

Configuring the proxying request processor

You configure proxying request processors that forward operations received by the PingDirectoryProxy server to other LDAP external servers.

Configuring subtree views

A subtree view defines the portion of the directory information tree (DIT) available to a client. Each subtree view can be associated with a load-balancing algorithm to help distribute the work load.

Configuring the client connection policy

You configure policies to classify how the PingDirectoryProxy server manages different client connections. The client connection policy can be used to control the types of operations that a client might perform and the portion of the DIT that the client can access. Restrictions configured in a client connection policy take precedence over any capabilities granted by access control or privileges.

Running the server as a Microsoft Windows service

The server can run as a Windows service, which enables you to sign out of a machine without stopping the server.

Registering the server as a Windows service

Register the server as a Windows service using the Windows command prompt.

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin\stop-server`.

   You cannot register a server while it is running.

2. To register the server as a service, from a Windows command prompt, run `bat\register-windows-service.bat`.

3. After registration, start the server from the Windows Services Control Panel or with the `bat\start-server.bat` command.

> **Note**
>
> Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

Copyright © 2025 Ping Identity Corporation

Running multiple service instances

Only one instance of a particular service can run at one time.

About this task

Services are distinguished by the `wrapper.name` property in the `<server-root>\config\wrapper-product.conf` file.

Steps

1. To run additional service instances, change the `wrapper.name` property on each additional instance.
2. Add or change descriptions of the service in the `wrapper-product.conf` file.

Deregistering and uninstalling services

To uninstall a service, you must first deregister it.

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled.

Steps

1. To remove the service from the Windows registry, use the `bat\deregister-windows-service.bat` file.
2. To uninstall the server, run the `uninstall.bat` script.

Configuring log files for services

About this task

The log files are stored in `<server-root>\logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or the file reaches its maximum size. Only the last three log files are retained.

Steps

1. These configurations can be changed in the `<server-root>\config\wrapper.conf` file.

Configuring the PingDirectoryProxy server

After you have set up the PingDirectoryProxy server, you can manage your deployment using the configuration framework and management tools.

About the configuration tools

You can access and modify the server configuration in two ways.

Copyright © 2025 Ping Identity Corporation

Administrative console

The server provides an administrative console for graphical server management and monitoring. The console functions are equivalent to the `dsconfig` tool for viewing or editing configurations.

All configuration changes using the administrative console are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands if you need to undo a configuration.

`dsconfig` *Command-line tool*

The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes:

- Interactive command-line mode
- Non-interactive command-line mode
- Batch mode

All configuration changes made using this tool are recorded in `logs/config-audit.log`.

Using the create-initial-proxy-config tool

The `create-initial-proxy-config` tool can be used to initially configure the PingDirectoryProxy server. We strongly recommend that you use the `create-initial-proxy-config` tool for your initial server configuration. This tool prompts you for basic information about your topology, including external servers, their locations, and credentials for communicating with them. When the configuration is complete, the tool writes the configuration to a `dsconfig` batch file and allows you to apply the configuration to the local PingDirectoryProxy server. The tool assumes the following about your topology:

- All servers are accessible through a single user account. This user account must be a root user that is not generally accessible to clients to avoid inadvertent changes, deletions, or backend server availability issues caused by reimporting data.
- All servers support the same type of communication security.
- All external servers are any combination of PingDirectory server, Sun Directory Server, or Red Hat (including Fedora and 389) instances.

If your topology does have these characteristics, you can use the tool to define a basic configuration that is saved to a `dsconfig` batch file. You can then run the `dsconfig` tool to fine-tune the configuration. You can also use this tool to configure an entry balancing configuration, which allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

The `create-initial-proxy-config` tool produces a log file called `create-initial-proxy-config.log` that is stored in the local PingDirectoryProxy server's `logs` directory.

You can only run the `create-initial-proxy-config` tool once for the initial configuration of each PingDirectoryProxy server instance. To tune your configuration, use the `dsconfig` tool. When installing a second PingDirectoryProxy server, it will not be necessary to run the `create-initial-proxy-config` tool again, because the PingDirectoryProxy server setup has the ability to clone the settings from an existing Directory Proxy Server.

This section describes how to use this tool to configure a standard PingDirectoryProxy server deployment as well as an entry balancing configuration.

Copyright © 2025 Ping Identity Corporation

Configuring a standard PingDirectoryProxy server deployment

Install a standard PingDirectoryProxy server deployment using the `create-initial-proxy-config` tool.

About this task

> **Note**
>
> Remember that you deploy PingDirectoryProxy servers in pairs. Each pair should be configured identically except for their host name, port, and possibly their location.

Steps

1. After initial installation, select the number to start the `create-initial-proxy-config` tool automatically, or run it manually at the command line from the server root directory, `<server-root>/PingDirectoryProxy`.

```
$ ./bin/create-initial-proxy-config
```

2. If the servers do not meet the displayed configuration requirements, you can enter `no` to quit the process.

```
Some assumptions are made about the topology in order to keep this tool simple:

        1) all servers will be accessible via a single user account
        2) all servers support the same communication security type
        3) all servers are PingDirectoryProxy, Directory Server,
           Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389)
           directory servers

If your topology does not have these characteristics you can use this tool to define a basic
configuration and then use the 'dsconfig' tool or the Administrative Console to
fine tune the configuration.

Continue? (yes / no) [yes]:
```

3. Enter the distinguished name (DN) for the PingDirectoryProxy server user account, and then enter and confirm the password for this account.

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

> **Note**
>
> You should not use `cn=Directory Manager` account for communication between the PingDirectoryProxy server and the PingDirectory server.
> For security reasons, the account used to communicate between the PingDirectoryProxy server and the PingDirectory server should not be directly accessible by clients accessing the PingDirectoryProxy server.
> For more information about this account, see Configuring LDAP external servers.

Copyright © 2025 Ping Identity Corporation

4. Specify whether to use secure communication with the PingDirectory server instances.

```
>>>> External Server Communication Security

Specify the type of security that the Directory Proxy Server will use when communicating with
directory server instances:

   1)  None
   2)  SSL
   3)  StartTLS

   b)  back
   q)  quit

Enter choice [1]:
```

5. Enter the base DNs of the PingDirectory server instances that will be accessed through the PingDirectoryProxy server. Press Enter when you have finished specifying the DNs.

```
Enter a base DN of the directory server instances that will be accessed through the Identity Proxy:

    b)  back
    q)  quit

Enter a DN or choose a menu item [dc=example,dc=com]:
```

   The PingDirectoryProxy server will create subtree views using each base DN to define portions of the external servers' directory information tree (DIT) available for client access. You can specify more than one base DN.

6. Specify whether the entries under your defined subtree view will be split across multiple servers in an entry balanced deployment.

   Press Enter to accept the default setting of no.

7. Define a location for your server, such as the name of your data center or the city where the server is located.

```
Enter a location name or choose a menu item: east
```

8. (Optional) If you defined more than one location, specify the location that contains the PingDirectoryProxy server itself.

Copyright © 2025 Ping Identity Corporation

```
Choose the location for this Directory Proxy Server

    1)  east
    2)  west

    b)  back
    q)  quit

Enter choice [1]: 1
```

9. Define the host:port used by the LDAP external servers.

```
Enter a host:port or choose a menu item [localhost:389]: ldap-east-01.example.com:389
```

> **Note**
>
> If you have specified more than one location, you will complete this process for each location.

10. Select the option Yes, and all subsequent servers to indicate that you want the tool to create a proxy user account on all of your LDAP external servers within that location.

```
Would you like to prepare ldap-east-01.example.com:389 for access by the Directory Proxy Server?

    1) Yes
    2) No
    3) Yes, and all subsequent servers
    4) No, and all subsequent servers

Enter choice [1]: 3
```

11. If the proxy user account does not already exist on your LDAP external server, create the account by connecting as `cn=Directory Manager`.

```
Would you like to create or modify root user 'cn=Proxy User' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:
Enter the DN of an account on ldap-east-01.example.com:389 with which to create or manage the
'cn=Proxy
User' account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

12. Repeat steps 9-12 for the servers in the other location. When finished, press Enter to finish configuring the location.

13. Review the configuration summary. After you have confirmed that the changes are correct, press Enter to write the configuration.

Copyright © 2025 Ping Identity Corporation

```
>>>> Configuration Summary

  External Server Security:  SSL
  Proxy User DN:             cn=Proxy User,cn=Root DNs,cn=config

  Location east
    Failover Order: west
    Servers: localhost:1636

  Location west
    Failover Order: east
    Servers: localhost:2636

  Base DN: dc=example,dc=com
    Servers: localhost:1636, localhost:2636

    b)  back
    q)  quit
    w)  write configuration file

Enter choice [w]:
```

14. Enter `yes` to apply the configuration changes locally to the PingDirectoryProxy server.

```
This tool can apply the configuration changes to the local Identity Proxy. This requires any
configured Server SDK extensions to be in place. Do you want to do
this? (yes / no) [yes]:
```

> **Note**
>
> If you have any Server SDK extensions, be sure to run the **`manage-extension`** tool first, then press Enter to apply the changes to the PingDirectoryProxy server.

Alternatively, you can quit and run the `dsconfig` batch file at a later time.

After the changes have been applied, you cannot use the `create-initial-proxy-config` tool to configure this PingDirectoryProxy server again. Use the `dsconfig` tool to modify your configuration instead.

Result

If you open the generated `proxy-cfg.txt` file or the `logs/config-audit.log` file, you see that a configuration element hierarchy has been created, listing locations, health checks, external servers, load-balancing algorithms, request processors, and subtree views.

About the dsconfig configuration tool

The `dsconfig` tool is the text-based management tool used to configure the underlying server configuration.

The `dsconfig` tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

Copyright © 2025 Ping Identity Corporation

The `dsconfig` tool offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, you should keep the server running when you access the configuration for the server to give the user feedback about the validity of the configuration.

To view the options for the dsconfig tool, change to the `PingDirectory/bin` directory, and enter `./dsconfig --help`. Example output is shown below.

Copyright © 2025 Ping Identity Corporation

```
./dsconfig --help

View and edit the Directory Server configuration.
This utility offers three primary modes of operation, the interactive mode, the non-interactive mode
and batch mode.  The interactive mode supports viewing and editing the configuration via an intuitive,
menu driven environment.  Running dsconfig in interactive command-line mode provides a user-friendly,
menu-driven interface for accessing and configuring the server. To start dsconfig in interactive
command-line mode, simply invoke the dsconfig shell script or batch file without any arguments.

The dsconfig non-interactive command-line mode provides a simple way to make arbitrary changes to the
Ping Identity Directory Server by invoking it on the command-line. If you want to use administrative
scripts to automate the configuration process, then run the dsconfig command in non-interactive mode.

The dsconfig tool provides a batching mechanism that reads multiple dsconfig invocations from a file
and executes them sequentially.  The batch file provides advantages over standard scripting in that it
minimizes LDAP connections and JVM invocations that normally occur with each dsconfig call.  You can
view the logs/config-audit.log file to review the configuration changes made to the Ping Identity
Directory Server and use them in the batch file.

Subcommands

  See the Usage section for instructions on viewing the list of supported subcommands.

Usage:  dsconfig  {options}
        where {options} include:

    --applyChangeTo [server-group|server-group-force|single-server]
        Controls whether changes apply to a single server or all servers in the configuration server group
    --offline
        Interact with the local configuration while the server is offline.  Not for use while the server
        is running
    -r, --reason {reason}
        A string describing the reason for the configuration change
    --help-classifications
        Display subcommands relating to connection and operation classification
    --help-core-server
        Display subcommands relating to core
    --help-database
        Display subcommands relating to backends, indexing, and caching
    --help-logging
        Display subcommands relating to logging, monitoring, and notifications
    --help-replication
        Display subcommands relating to replication
    --help-security
        Display subcommands relating to security and authorization
    --help-topology
        Display subcommands relating to topology
    --help-user-management
        Display subcommands relating to authentication and password management
    --help-web
        Display subcommands relating to web services and applications
    --help-subcommands
        Display all subcommands
```

Copyright © 2025 Ping Identity Corporation

```
  Configuration Options

    --advanced
        Allow the configuration of advanced components and properties

  LDAP Connection Options

    -Z, --useSSL
        Use SSL for secure communication with the server
    -q, --useStartTLS
        Use StartTLS to secure communication with the server
    --useNoSecurity
        Use no security when communicating with the server
    -h, --hostname {host}  [Default: localhost]
        Directory Server hostname or IP address
    -p, --port {port}  [Default: 389]
        Directory Server port number
    -D, --bindDN {bindDN}  [Default: cn=Directory Manager]
        DN used to bind to the server
    -w, --bindPassword {bindPassword}
        Password used to bind to the server
    -j, --bindPasswordFile {bindPasswordFile}
        Bind password file
    -o, --saslOption {name=value}
        SASL bind options (can be specified multiple times)
    -X, --trustAll
        Trust all server SSL certificates
    -P, --trustStorePath {truststorePath}  [Default: /Users/rowannabobo/Desktop/PingDirectory_9.2/config/
truststore]
        Certificate truststore path
    -T, --trustStorePassword {truststorePassword}
        Certificate truststore PIN
    -U, --trustStorePasswordFile {path}
        Certificate truststore PIN file
    --trustStoreFormat {trustStoreFormat}
        Certificate truststore format
    -K, --keyStorePath {keystorePath}
        Certificate keystore path
    -W, --keyStorePassword {keystorePassword}
        Certificate keystore PIN
    -u, --keyStorePasswordFile {keystorePasswordFile}
        Certificate keystore PIN file
    --keyStoreFormat {keyStoreFormat}
        Certificate keystore format
    -N, --certNickname {nickname}
        Nickname of the certificate for SSL client authentication

  Utility Input/Output Options

    -v, --verbose
        Use verbose mode
    -Q, --quiet
        Use quiet mode
    -n, --no-prompt
        Use non-interactive mode.  If data in the command is missing, you will not be prompted and the
```

Copyright © 2025 Ping Identity Corporation

```
        tool will fail
    -F, --batch-file {batchFilePath}
        Path to a file containing a sequence of dsconfig commands to run
    --batch-continue-on-error
        Force the execution of all commands in the batch file on the server even if prevalidation fails.
        Execution will also continue even if one of the commands fails.
        Please note that commands affecting multiple servers can still fail to execute unless the
        --applyChangeTo argument is provided with the value server-group-force. Only applies if the batch
        file argument is also supplied.
    --dry-run
        Validate configuration changes but do not apply them. This option can only be used along with the
        -F/--batch-file option
    --propertiesFilePath {propertiesFilePath}
        Path to the file that contains default property values used for command-line arguments
    --noPropertiesFile
        Specify that no properties file will be used to get default command-line argument values
    --script-friendly
        Use script-friendly mode

  General Options

    -V, --version
        Display Directory Server version information
    -?, -H, --help
        Display general usage information
    --help-ldap
        Display help for using LDAP options
    --help-sasl
        Display help for using SASL options
    --help-debug
        Display help for using debug options

Examples

  Start dsconfig in interactive mode:

    dsconfig

  Use non-interactive mode to change the amount memory used for caching database contents and to specify
  common parent DNs that should be compacted in the underlying database:

    dsconfig --no-prompt --bindDN uid=admin,dc=example,dc=com \
         --bindPassword password set-backend-prop --backend-name userRoot \
         --set db-cache-percent:40 \
         --add compact-common-parent-dn:ou=accts,dc=example,dc=com \
         --add compact-common-parent-dn:ou=subs,dc=example,dc=com

  Use batch mode to read and execute a series of commands in a batch file:

    dsconfig --bindDN uid=admin,dc=example,dc=com --bindPassword password \
         --no-prompt --batch-file /path/to/config-batch.txt

  List information about all available configuration properties for all objects, including inherited
properties:
```

Copyright © 2025 Ping Identity Corporation

```
    dsconfig list-properties --offline --inherited

  For examples and help with LDAP options see --help-ldap.  For help with SASL authentication, see --help-
sasl
```

Using dsconfig in interactive command-line mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements.

About this task

The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory server.

Steps

1. To start `dsconfig` in interactive command-line mode, invoke the `dsconfig` script without any arguments.

   Result:

   You are prompted for connection and authentication information to the PingDirectoryProxy server, and then a menu displays the available operation types.

2. To accept the default values, press Enter.

   > **Note**
   >
   > In some cases, a default value is provided in square brackets. For example, [389] indicates that the default value for that field is port 389.

3. To skip the connection and authentication prompts, provide the connection and authentication information using the command-line options of `dsconfig`.

Changing the dsconfig object menu

The purpose of object levels is to present only those properties that an administrator will likely use.

About this task

Because some configuration objects are more likely to be modified than others, the PingDirectory server provides four different object menus that hide or expose configuration objects to the user. The `object` type is a convenience feature designed to improve menu readability.

The following object menus are available:

Basic

Only includes the components that are configured most frequently.

Copyright © 2025 Ping Identity Corporation

Standard

Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.

Advanced

Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be harmful if configured incorrectly.

Expert

Includes all components in the Basic, Standard, and Advanced menus plus other components that almost never require configuration, or that could seriously impact the functionality of the server if not properly configured.

To change the `dsconfig` object menu:

Steps

1. Using `dsconfig`, repeat steps 1–6 in Installing the PingDirectory server in interactive mode.
2. On the PingDirectory Server configuration main menu, enter the letter `o` to change the object level.

   Basic objects are displayed by default.
3. Enter a number corresponding to an object level of your choice.

   Choose from:

   - Enter `1` for Basic.
   - Enter `2` for Standard.
   - Enter `3` for Advanced.
   - Enter `4` for Expert.
4. Review the menu at the new object level.

   Additional configuration options for the server components are displayed.

Using dsconfig in non-interactive mode

The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the server by invoking it from the command line.

Steps

1. To use administrative scripts to automate configuration changes, run the `dsconfig` command in non-interactive mode.

   Non-interactive mode is convenient for scripting applications.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> If you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

2. **Use the `dsconfig` tool to update a single configuration object using command-line arguments to provide all of the necessary information.**

   Example:

   The following shows the general format for the non-interactive command line.

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

> **Note**
>
> The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the PingDirectory server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the **`dsconfig`** tool, as shown.
>
> ```
> $ bin/dsconfig --no-prompt list-backends \
>   --hostname server.example.com \
>   --port 389 \
>   --bindDN uid=admin,dc=example,dc=com \
>   --bindPassword password
> ```

3. **If your system uses SASL GSSAPI (Kerberos), invoke `dsconfig` as shown.**

```
$ bin/dsconfig --no-prompt list-backends \
  --saslOption mech=GSSAPI \
  --saslOption authid=admin@example.com \
  --saslOption ticketcache=/tmp/krb5cc_1313 \
  --saslOption useticketcache=true
```

4. **To always display the advanced properties, use the `--advanced` command-line option.**

> **Note**
>
> The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you want to invoke.
> Global arguments can appear anywhere on the command line, including before the subcommand and after or intermingled with subcommand-specific arguments. The subcommand-specific arguments can appear anywhere after the subcommand.

dsconfig non-interactive mode command">

Copyright © 2025 Ping Identity Corporation

Getting the equivalent `dsconfig` non-interactive mode command

Find the command you want to use in non-interactive command-line mode by looking it up in interactive mode.

Steps

1. Use `dsconfig` in interactive mode to make changes to a configuration, but do not enter the letter `f` to apply the changes.

   To view the equivalent non-interactive command, enter `d`.

   View the equivalent command, and then press Enter to continue.

   Result:

   Based on an example in the previous section, changes made to the `db-cache-percent` returns the following message.

   ```
   Command line to apply pending changes to this Local DB Backend: dsconfig set-backend-prop --backend-
   name userRoot --set db-cache-percent:40
   ```

   The command does not contain the LDAP connection parameters required for the tool to connect to the host because the command is presumed to be used to connect to a different remote host.

Using dsconfig batch mode

Configure the server in `dsconfig` batch mode.

About this task

The PingDirectory server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially.

The batch file provides advantages over standard scripting by minimizing LDAP connections and Java virtual machine (JVM) invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command fails and aborts the batch process without applying any changes to the server. The `dsconfig` command supports a `--batch-continue-on-error` option that instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a `\` line continuation character for long commands that require multiple lines.

The server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Oracle to PingDirectory server machines.

Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the server.

Copyright © 2025 Ping Identity Corporation

> **Note**
>
> The items in this file should be in the same format as those accepted by the **`dsconfig`** command.
> The batch file can have blank lines for spacing and lines starting with a pound sign (**`#`**) for comments.
> The batch file also supports a "\" line continuation character for long commands that require multiple lines.

Example:

```
# This  dsconfig  operation creates the exAccountNumber global attribute index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. To read and execute the commands, run `dsconfig` with the `--batch-file` option.

Using the PingDirectory server or the PingDirectoryProxy server with PingFederate OAuth tokens

Configure an access token validator to use PingFederate OAuth tokens with PingDirectory.

Before you begin

You need the following information:

- The runtime engine service port of the PingFederate server, usually 9031
- The client ID of an OAuth 2.0 client configured on the PingFederate server
- The client secret of the OAuth 2.0 client
- The IP address of the PingFederate server

About this task

Copyright © 2025 Ping Identity Corporation

After you configure a PingFederate server to issue OAuth 2 tokens, you must make these tokens compatible with SCIM 2.0 operations on the PingDirectory server or the PingDirectoryProxy server.

This section explains how to set up an access token validator to handle this task.

Steps

1. Register the PingFederate server using the following command.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port>  \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

> **Note**
>
> In this example, the hostname verification method is set to `allow-all` and the Blind Trust manager provider is used for the sake of simplicity. You should not use these settings for production environments.

2. Create the access token validator using the following command.

```
dsconfig create-access-token-validator \
                        --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:client-id  \
  --set client-secret:client-secret
```

> **Note**
>
> Take the *client-id* and *client-secret* values from the PingFederate OAuth 2 client that will be used with the PingDirectory server or PingDirectoryProxy.

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command.

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. Test the validator by sending a GET request to `/scim/v2/ServiceProviderConfig`.

   This endpoint does not require any scopes to access, just a valid bearer token. The sever should return a response similar to the following.

Copyright © 2025 Ping Identity Corporation

```

Topology configuration

Topology configuration enables automatic server grouping and configuration change mirroring. It uses a primary and secondary architecture for mirroring shared data across the topology.

All writes and updates are forwarded to the primary, which forwards them to all other servers. Reads can be served by any server in the group, and servers can be added to an existing topology at installation.

> **Note**
>
> To remove a server from the topology, you must uninstall it with the uninstall tool.

Copyright © 2025 Ping Identity Corporation

Topology primary requirements and selection

A topology primary server receives configuration changes from other servers in the topology, verifies the changes, and then makes the changes available to all connected servers.

When updating, the primary sends a digest of its subtree contents. If the node's digest differs from the primary's, the server node knows it is not synchronized. The servers pull the entire subtree from the primary if they detect that they are not synchronized.

A server detects it is not synchronized with the primary under the following conditions:

- The server's subtree digest differs from the primary's digest at the end of its periodic polling interval.
- One or more servers have been added to or removed from the topology.

The primary of the topology is selected by prioritizing servers based on:

- Minimum supported product version
- Availability
- Server version
- Earliest start time
- Startup UUID (smaller is preferred)

After determining a primary, the topology data is reviewed from all available servers, every five seconds by default, to determine if any new information identifies a better server primary. If a new server can be the primary and no other servers have indicated that they should be the primary, it will communicate its eligibility to the other servers. This ensures that all servers accept the same primary at approximately the same time, within a few milliseconds of each other. If there is no better primary, the initial primary maintains the role.

After the best primary has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that primary.

  The primary server itself is considered while determining this majority.

- There is only a single primary in the entire topology.

If either of these conditions is not met, the topology is without a primary and the peer polling frequency is reduced to 100 milliseconds to find a new primary as quickly as possible. If there is no primary in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as primary with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as primaries, then a `multiple-servers-forced-as-masters` alarm is raised.

Topology components

When you install a server, you can add it to an existing topology, cloning the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Copyright © 2025 Ping Identity Corporation

Server configuration settings

Configuration settings for the topology are configured in the global configuration and in the config file handler backend. They are topology settings, but they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The global configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if the topology cannot determine a primary because most of the servers are not available. A server with this setting enabled is assigned the role of primary if no suitable primary can be determined.

The config file handler backend defines three topology `mirrored-subtree` settings:

`mirrored-subtree-peer-polling-interval`

Specifies the frequency at which the server polls its topology peers to identify any changes warranting a new primary selection. A lower value ensures a faster failover, but it also causes more traffic among the peers. The default value is 5 seconds. If no suitable primary is found, the polling frequency adjusts to 100 milliseconds until a new primary is selected.

`mirrored-subtree-entry-update-timeout`

Specifies the maximum length of time to wait for an entry update operation, such as add, delete, modify or modify-dn, to be applied by the primary on all of the servers in the topology. The default is 10 seconds, but updates can take up to twice as long if primary selection is in progress at the time the update operation is received.

`mirrored-subtree-search-timeout`

Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology metadata is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to identify changes in the topology.

Topology data includes the following:

- The server ID of the current primary, if the primary is not known
- The instance name of the current primary or if a primary is not set, a description stating why a primary is not set
- A flag indicating which server thinks that it should be the primary
- A flag indicating which server is the current primary
- A flag indicating a server that was forced as primary

Copyright © 2025 Ping Identity Corporation

- The total number of configured peers in the topology group
- The peers connected to this server
- The current availability of this server
- A flag indicating that a server is not synchronized with its primary or another node in the topology if the primary is unknown
- The amount of time in milliseconds that multiple primaries were detected by this server
- The amount of time in milliseconds that no suitable server is found to act as primary
- A SHA-256 digest encoded as a base-64 string for the current subtree contents

The following metrics are included if this server has processed any operations as primary:

- The number of operations processed by this server as primary
- The number of successful operations processed by this server as primary
- The number of operations processed by this server as primary that failed to validate
- The number of operations processed by this server as primary that failed to apply
- The average amount of time taken in milliseconds by this server to process operations as the primary
- The maximum amount of time taken in milliseconds by this server to process an operation as the primary

Using the Configuration API

The PingDirectory server provides a Configuration API when updating the server configuration with LDAP is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers allow the application/json content type.

About this task

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP.

Steps

- To add the extension to one of the server's HTTP Connection Handlers, run the following code.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

> **Note**
>
> By default, the extension is enabled for new installations. You can enable the extension for existing deployments.

Result:

Copyright © 2025 Ping Identity Corporation

The API is made available on the HTTPS Connection Handler's host:port in the `/config` context. Because of the potentially sensitive nature of the server's configuration, use the HTTPS Connection Handler for hosting the configuration extension.

Authentication and authorization with the Configuration API

Use this topic for how to make changes for customizing authentication and authorization access with the Configuration API.

Authentication

Clients must use HTTP basic authentication to authenticate to the Configuration API. If the username value is not a distinguished name (DN), then it resolves to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a username. To customize this behavior, either customize the default identity mapper or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. The following code provides an example.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

Authorization

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACI.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

The Configuration API and the dsconfig tool relationship

The Configuration API is designed to mirror the **`dsconfig`** tool, using the same names for properties and object types.

Property names are presented as hyphen case in **`dsconfig`** and as camel-case attributes in the API. In API requests that specify property names, case is not important. `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the **`dsconfig list-connection-handlers`** command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a local database backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the **`dsconfig`** tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the System for Cross-domain Identity Management (SCIM) specification. Request specific attributes using the attributes query parameter, whose value must be a comma-delimited list of properties to be returned, such as `attributes=baseDN,description`. You can exclude attributes from responses by specifying the `excludedAttributes` parameter.

Configuration API operations supported in REST APIs

HTTP Method	Description	Related dsconfig Example
GET	Lists the properties of an object when used with a path representing an object, such as `/config/global-configuration` or `/config/backends/userRoot`. Can also list objects when used with a path representing a parent relation, such as `/config/backends`.	• `get-backend-prop` • `list-backends` • `get-global-configuration-prop`
POST	Creates a new instance of an object when used with a relation parent path, such as `/config/backends`.	`create-backend`
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as `/config/backends/userRoot`.	• `set-backend-prop` • `set-global-configuration-prop`
PATCH	Updates the properties of an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	• `set-backend-prop` • `set-global-configuration-prop`
DELETE	Deletes an existing object when used with a path representing an object, such as `/config/backends/userRoot`.	`delete-backend`

Note

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.
Object names, such as userRoot in the description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent, %, character. The following URL is for accessing the HTTP Connection Handler object.

```
/config/connection-handlers/http%20connection%20handler
```

GET example

This topic provides an example of a GET request and response concerning the userRoot backend for reference.

GET request

The following code example is a GET request for information about the `userRoot` backend.

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

GET response

The following code example is the response.

```

PATCH example

Modify the Configuration API using the HTTP PATCH method.

The PATCH request body is a JSON object formatted according to the System for Cross-domain Identity Management (SCIM) patch request. The Configuration API supports a subset of possible values for the path attribute that indicates the configuration attribute to modify.

Modify the configuration object's attributes according to the information in the following table, which details the comparable `dsconfig modify-[object]` options to each PATCH request.

Operations and PATCH requests to modify the configuration object's attributes

Operation	PATCH request	Comparable dsconfig modify-[object] options
Set the single-valued `description` attribute to a new value.	`{ "op" : "replace", "path" : "description", "value" : "A new backend." }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --set "description:A new backend"`
Add a new value to the multi-valued `jeProperty` attribute.	`{ "op" : "add", "path" : "jeProperty", "value" : "je.env.backgroundReadLimit=0" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --add je-property:je.env.backgroundReadLimit=0`
Remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove.	`{ "op" : "remove", "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.cleaner.adjustUtilization=false`

Copyright © 2025 Ping Identity Corporation

Operation	PATCH request	Comparable dsconfig modify-[object] options
Second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify and a SCIM filter whose attribute is the following value.	`{ "op" : "remove", "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --remove je-property:je.nodeMaxEntries=32`
Option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value.	`{ "op" : "remove", "path" : "id2childrenIndexEntryLimit" }`	`$ dsconfig set-backend-prop --backend-name userRoot \ --reset id2childrenIndexEntryLimit`

Example

The following is the full example request.

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

Example

The API responds with the entire modified configuration object, which can include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions. The following is an example response.

           that had already hit the previous limit."
      }
    ]
  }
}
```

Configuration API paths

The Configuration API and supported sub-paths are available under the `/config` path.

A full listing of supported sub-paths is available when you access the base `/config/ResourceTypes` endpoint.

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted or created. These paths can be differentiated from others by their singular, rather than plural, relation name, such as `global-configuration`.

Copyright © 2025 Ping Identity Corporation

Example

The following sample response is abbreviated.

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
              Handler provides an implementation that uses syntax
              compatible with the Sun Java System Directory Server
              Enterprise Edition access control handler.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-access-control-handler"
      }
    },
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "access-control-handler",
      "name": "Access Control Handler",
      "description": "Access Control Handlers manage the
              application-wide access control. The server's access
              control handler is defined through an extensible
              interface, so that alternate implementations can be created.
              Only one access control handler may be active in the server
                        at any given time.",
      "endpoint": "/access-control-handler",
      "meta": {
        "resourceType": "ResourceType",
        "location": "http://example.com:5033/config/ResourceTypes/access-control-handler"
      }
    },
    {
 ...
```

The response's `endpoint` elements enumerate all available sub-paths. You can use the path `/config/access-control-handler` in the example to get a list of existing access control handlers and create new ones. You can use a path containing an object name, such as `/config/backends/{backendName}` (where `{backendName}` corresponds to an existing backend like `userRoot`) to obtain an object's properties, update the properties, or delete the object.

Sort and filter objects

The Configuration API supports System for Cross-domain Identity Management (SCIM) parameters for filter, sorting, and pagination.

Copyright © 2025 Ping Identity Corporation

Search operations can specify a SCIM filter to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both GET and list operations.

GET Parameter	Description
