Reverting from version 7.0 or later to a pre-7.0 version can be done using the **revert-update** command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 version to 6.2.0.2 or later. These steps are listed when the **update** and **revert-update** tool are run as well. You may need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes may need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the **rebuild-index** tool to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the **logs/config-**

**audit.log** file. If you wish to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.

- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command:

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
 --bindPassword secret \
 --no-prompt set-global-configuration-prop \
 --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, the **revert-update** command can be used to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the **admin** backend) will need to know that the reverted server was downgraded to the **admin** backend. This is done by running the following **dsconfig** command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
 --instance-name <Reverted server instance name> \
 --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made master with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
 --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you wish to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the **changelogDb/** and **db/changelog/** directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent start ups.

### Revert to the most recent server version

#### Steps

Use **revert-update** in the server root directory to revert back to the most recent version of the server.

```
$ PingDirectoryProxy-old/revert-update
```

## Configuring the Directory Proxy Server

---

Once you have initially configured the PingDirectoryProxy Server, you can manage your deployment using the configuration framework and management tools. This chapter briefly describes these tools and provides procedures to help you maintain and update your deployment.

## About the Configuration Tools

The PingDirectoryProxy Server configuration can be accessed and modified in the following ways:

- **Using the Administrative Console** . The PingDirectoryProxy Server provides an Administrative Console for graphical server management and monitoring. The console provides equivalent functionality as the `dsconfig` command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands should you need to back out of a configuration.
- **Using the dsconfig Command-Line Tool**. The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes: interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

## Using the create-initial-proxy-config Tool

The `create-initial-proxy-config` tool can be used to initially configure the Directory Proxy Server. We strongly recommend that you use the `create-initial-proxy-config` tool for your initial Directory Proxy Server configuration. This tool prompts you for basic information about your topology, including external servers, their locations, and credentials for communicating with them. Once the configuration is complete, the tool writes the configuration to a `dsconfig` batch file and allows you to apply the configuration to the local Directory Proxy Server. The tool assumes the following about your topology:

- All servers are accessible through a single user account. This user account must be a root user that is not generally accessible to clients to avoid inadvertent changes, deletions, or backend server availability issues due to reimporting data.
- All servers support the same type of communication security.
- All external servers are any combination of Ping Identity Directory Server, Sun Directory Server, or Red Hat (including Fedora and 389) instances.

If your topology does have these characteristics, you can use the tool to define a basic configuration that is saved to a `dsconfig` batch file. You can then run the `dsconfig` tool to fine-tune the configuration. You can also use this tool to configure an entry balancing configuration, which allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance.

The `create-initial-proxy-config` tool produces a log file called `create-initial-proxy-config.log` that is stored in the local Directory Proxy Server's `logs` directory.

You can only run the `create-initial-proxy-config` tool once for the initial configuration of each Directory Proxy Server instance. To tune your configuration, use the `dsconfig` tool. When installing a second Directory Proxy Server, it will not be necessary to run the `create-initial-proxy-config` tool again, as the Directory Proxy Server setup has the ability to clone the settings from an existing Directory Proxy Server.

This section describes how to use this tool to configure a standard Directory Proxy Server deployment as well as an entry balancing configuration.

## Configuring a Standard Directory Proxy Server Deployment

This section describes how to install a standard Directory Proxy Server deployment using the `create-initial-proxy-config` tool. Remember that you deploy the Directory Proxy Server in pairs. Each pair should be configured identically except for their host name, port, and possibly their location.

## To Configure a Standard Directory Proxy Server Deployment

### Steps

1. After initial installation, select the number to start the `create-initial-proxy-config` tool automatically. Otherwise, run it manually at the command line from the server root directory, `<server-root>/PingDirectoryProxy`.

```
$./bin/create-initial-proxy-config
```

2. The initial proxy configuration presents the assumptions about the underlying Directory Server backend servers. If the servers do not meet the requirements, then you can enter "no" to quit the process.

```
Some assumptions are made about the topology in order to keep this tool simple:
```

- 1) all servers will be accessible via a single user account
- 2) all servers support the same communication security type
- 3) all servers are PingDirectoryProxy Server, Directory Server, Java System 5.x, 6.x, or 7.x, or Red Hat (including Fedora and 389) directory servers

```
If your topology does not have these characteristics you can use this tool to define a basic configuration and then use the 'dsconfig' tool or the Administrative Console to fine tune the configuration.
```

```
Continue? (yes / no) [yes]:
```

3. Enter the DN for the Directory Proxy Server user account, then enter and confirm the password for this account. Note that you should not use `cn=Directory Manager` account for communication between the Directory Proxy Server and the Directory Server. For security reasons, the account used to communicate between the Directory Proxy Server and the Directory Server should not be directly accessible by clients accessing the Directory Proxy Server. For more information about this account, see [Configuring LDAP External Servers](#).

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root DNs,cn=config]:
```

```
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

```
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

4. Specify whether you will be using secure communication with the Directory Server instances.

```
>>>> External Server Communication Security
```

```
Specify the type of security that the Directory Proxy Server will use when communicating with directory server instances:
```

- 1) None
  - 2) SSL
  - 3) StartTLS
- b) back  
q) quit

```
Enter choice [1]:
```

5. Specify the base DNs of the Directory Server instances that will be accessed through the Directory Proxy Server. The Directory Proxy Server will create subtree views using each base DN to define

portions of the external servers' DIT available for client access. You can specify more than one base DN. Press **Enter** when you have finished specifying the DN(s).

```
Enter a base DN of the directory server instances that will be accessed
through the Identity Proxy:
```

```
 b) back
 q) quit
```

```
Enter a DN or choose a menu item [dc=example,dc=com]:
```

6. Next, specify if the entries under your defined subtree view will be split across multiple servers in an entry balanced deployment. For this example, press Enter to accept the default ("no").
7. Define a location for your server, such as the name of your data center or the city where the server is located. This example illustrates defining a location named `east`.

```
Enter a location name or choose a menu item: east
```

8. If you defined more than one location, specify the location that contains the Directory Proxy Server itself.

```
Choose the location for this Directory Proxy Server
```

```
 1) east
 2) west

 b) back
 q) quit
```

```
Enter choice [1]: 1
```

9. Define the hostname:port used by the LDAP external servers. If you have specified more than one location, you will go through this process for each location.

```
Enter a host:port or choose a menu item [localhost:389]: ldap-
east-01.example.com:389
```

10. After each step, the server will attempt to prepare each external server by testing the communication between the Directory Proxy Server and the Directory Server. Select the option "Yes, and all subsequent servers" to indicate that you want the tool to create a proxy user account on all of your LDAP external servers within that location.

```
Would you like to prepare ldap-east-01.example.com:389 for access by the
Directory Proxy Server?
```

```
 1) Yes
 2) No
 3) Yes, and all subsequent servers
 4) No, and all subsequent servers
```

```
Enter choice [1]: 3
```

11. If the proxy user account did not previously exist on your LDAP external server, create the account by connecting as `cn=Directory Manager`.

```
Would you like to create or modify root user 'cn=Proxy User' so that it is
available for this Directory Proxy Server? (yes / no) [yes]:
```

```
Enter the DN of an account on ldap-east-01.example.com:389 with which to
create or manage the 'cn=Proxy
User' account [cn=Directory Manager]:
```

```
Enter the password for 'cn=Directory Manager':
```

```
Created 'cn=Proxy User,cn=Root DNs,cn=config'
```

```
Testing 'cn=Proxy User' privileges Done
Verifying backend 'dc=example,dc=com' Done
```

**12.** Repeat steps 9-12 for the servers in the other location. Then, press **Enter** to finish configuring the location.

**13.** Review the configuration summary. Once you have confirmed that the changes are correct, press **Enter** to write the configuration.

```
>>>> Configuration Summary

External Server Security: SSL
Proxy User DN: cn=Proxy User,cn=Root DNs,cn=config

Location east
 Failover Order: west
 Servers: localhost:1636

Location west
 Failover Order: east
 Servers: localhost:2636

Base DN: dc=example,dc=com
 Servers: localhost:1636, localhost:2636

b) back
q) quit
w) write configuration file

Enter choice [w]:
```

**14.** Next, apply the configuration changes locally to the Directory Proxy Server. If you have any Server SDK extensions, make sure to run the **manage-extension** tool, then press **Enter** to apply the changes to the Directory Proxy Server. Alternatively, you can quit and instead run the **dsconfig** batch file at a later time. Once the changes have been applied, you cannot use the **create-initial-proxy-config** tool to configure this Directory Proxy Server again. Instead, use the **dsconfig** tool.

```
This tool can apply the configuration changes to the local Identity Proxy.
This requires any configured Server SDK extensions to be in place. Do you
want to do
this? (yes / no) [yes]:
```

If you open the generated `proxy-cfg.txt` file or the `logs/config-audit.log` file, you will see that a configuration element hierarchy has been created: locations, health checks, external servers, load-balancing algorithms, request processors, and subtree views.

## About dsconfig Configuration Tool

The **dsconfig** tool is the text-based management tool used to configure the underlying Directory Server configuration. The tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The **dsconfig** tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

### Using dsconfig in Interactive Command-Line Mode

In interactive mode, the **dsconfig** tool offers a filtering mechanism that only displays the most common configuration elements. The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectoryProxy Server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` script without any arguments. You will be prompted for connection and authentication information to the Directory Proxy Server, and then a menu will be displayed of the available operation types.

In some cases, a default value will be provided in square brackets. For example, `[389]` indicates that the default value for that field is port 389. You can press **Enter** to accept the default. To skip the connection and authentication prompts, provide this information using the command-line options of `dsconfig`.

### Using dsconfig Interactive Mode: Viewing Object Menus

Because some configuration objects are more likely to be modified than others, the PingDirectoryProxy Server provides four different object menus that hide or expose configuration objects to the user. The purpose of object levels is to simply present only those properties that an administrator will likely use. The Object type is a convenience feature designed to unclutter menu readability.

The following object menus are available:

- **Basic.** Only includes the components that are expected to be configured most frequently.
- **Standard.** Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.
- **Advanced.** Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be potentially harmful if configured incorrectly.
- **Expert.** Includes all components in the Basic, Standard, and Advanced menus plus other components that should almost never require configuration or that could seriously impact the functionality of the server if not properly configured.

### To Change the dsconfig Object Menu

#### Steps

1. Repeat steps 1–6 in the section using `dsconfig` in To Install the Directory Proxy Server in Interactive Mode.
2. On the **PingDirectoryProxy Server configuration** main menu, type **o** (letter “o”) to change the object level. By default, Basic objects are displayed.
3. Enter a number corresponding to a object level of your choice: 1 for Basic, 2 for Standard, 3 for Advanced, 4 for Expert.
4. View the menu at the new object level. Additional configuration options for the Directory Proxy Server components are displayed.

### Using dsconfig in Non-Interactive Mode

The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Proxy Server by invoking it from the command line. To use administrative scripts to automate configuration changes, run the `dsconfig` command in non-interactive mode, which is convenient scripting applications. Note, however, that if you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

You can use the `dsconfig` tool to update a single configuration object using command-line arguments to provide all of the necessary information. The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the Directory Proxy Server. Global arguments

can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the `dsconfig` tool as follows:

```
$ bin/dsconfig --no-prompt list-backends \
 --hostname server.example.com \
 --port 389 \
 --bindDN uid=admin,dc=example,dc=com \
 --bindPassword password
```

If your system uses SASL GSSAPI (Kerberos), you can invoke `dsconfig` as follows:

```
$ bin/dsconfig --no-prompt list-backends \
 --saslOption mech=GSSAPI \
 --saslOption authid=admin@example.com \
 --saslOption ticketcache=/tmp/krb5cc_1313 \
 --saslOption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you wish to invoke. To always display the advanced properties, use the `--advanced` command-line option.

**Note:** Global arguments can appear anywhere on the command line (including before the subcommand, and after or intermingled with subcommand-specific arguments). The subcommand-specific arguments can appear anywhere after the subcommand.

### To Get the Equivalent `dsconfig` Non-Interactive Mode Command

#### Steps

1. Using `dsconfig` in interactive mode, make changes to a configuration but do not apply the changes (that is, do not enter "f").
2. Enter `d` to view the equivalent non-interactive command.
3. View the equivalent command (seen below), and then press **Enter** to continue. For example, based on an example in the previous section, changes made to the `db-cache-percent` returns the following:

```
Command line to apply pending changes to this Local DB Backend:
dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host since it is presumed that the command would be used to connect to a different remote host.

### Using `dsconfig` Batch Mode

The PingDirectory Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command will fail and abort the batch process without applying any changes to the Directory Server. The `dsconfig` command supports a `--batch-continue-on-error` option which instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `"\"` line continuation character for long commands that require multiple lines.

The Directory Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to PingDirectory Server machines.

### To Configure the Directory Proxy Server in dsconfig Batch Mode

#### Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Proxy Server. The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `"\"` line continuation character for long commands that require multiple lines.

```
This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

Here we create the entry-count placement algorithm with the
default behavior of adding entries to the smallest backend
dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

Note that once the entry-count placement algorithm is created
and enabled, we can delete the round-robin algorithm.
Since an entry-balancing proxy must always have a placement
algorithm, we add a second algorithm and then delete the
original round-robin algorithm created during the setup
procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. Use `dsconfig` with the `--batch-file` option to read and execute the commands.

## Topology Configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a master/slave architecture for mirroring shared data across the topology. All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group. Servers can be added to an existing topology at installation.

**Note:** To remove a server from the topology, it must be uninstalled with the `uninstall` tool.

### Topology Master Requirements and Selection

A topology master server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers. The master always sends a digest of its subtree contents on each update. If the node has a different digest than the master, it knows it's not synchronized. The servers will pull the entire subtree from the master if they detect that they are not synchronized. A server may detect it is not synchronized with the master under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its master, then it knows it's not synchronized.
- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The master of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a master, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the master. If a new server can be the master, it will communicate that to the other servers, if no other server has advertised that it should be the master. This ensures that all servers accept the same master at approximately the same time (within a few milliseconds of each other). If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master. (The master server itself is considered while determining this majority.)
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a **mirrored-subtree-manager-no-master-found** alarm is raised. If one of the servers in the topology is forced as master with the **force-as-master-for-mirrored-data** option in the Global Configuration object, a **mirrored-subtree-manager-forced-as-master-warning** warning alarm is raised. If multiple servers have been forced as masters, then a **mirrored-subtree-manager-forced-as-master-error** critical alarm will be raised.

## Topology Components

When a server is installed, it can be added to an existing topology, which will clone the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

### Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, **force-as-master-formirrored-data**. This should be set to true on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a master because a majority of servers is not available. A server with this setting enabled will be assigned the role of master, if no suitable master can be determined.

The Config File Handler Backend defines three topology (**mirrored-subtree**) settings:

- **mirrored-subtree-peer-polling-interval** – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that may warrant a new master selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable master is found, the polling frequency is adjusted to 100 milliseconds until a new master is selected.
- **mirrored-subtree-entry-update-timeout** – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the master on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if master selection is in progress at the time the update operation was received.
- **mirrored-subtree-search-timeout** – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

### Topology settings

Topology meta-data is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

### Monitor Data for the Topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology.

Topology data includes the following:

- The server ID of the current master, if the master is not known.
- The instance name of the current master, or if a master is not set, a description stating why a master is not set.
- A flag indicating if this server thinks that it should be the master.
- A flag indicating if this server is the current master.
- A flag indicating if this server was forced as master.
- The total number of configured peers in the topology group.
- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its master, or another node in the topology if the master is unknown.
- The amount of time in milliseconds where multiple masters were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as master.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master.
- The number of operations processed by this server as master that were successful.
- The number of operations processed by this server as master that failed to validate.
- The number of operations processed by this server as master that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the master.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the master.

### Certificates

Depending on the circumstances, PingDirectory Server uses one of the following certificates:

- Inter-server certificate – Used for internal purposes, like the following examples:
  - Replication authentication
  - Inter-server authentication in the topology registry
  - Reversible password encryption
  - Encrypted backups and LDIF exports
- Server certificate – Presented by the server when a client uses a protocol like LDAPS or HTTPS to initiate a secure connection. A client must trust the server's certificate to obtain a secure connection to it.

The following sections describe these certificates in more detail.

#### Inter-server certificate

Generated during installation, the inter-server certificate is stored under the alias `ads-certificate` in a file named `ads-truststore`, which resides in the server's `/config` directory. This certificate contains the key pair for the local server as well as for the certificates of all trusted servers, and has a lifetime of 20 years before expiring.

The local server's public key is signed by its own private key, making it a *self-signed certificate*. The alias is hard-coded to `ads-certificate`, and the keystore file is hard-coded to `ads-truststore`. This behavior cannot be modified during setup.

**Warning:**

- Although some customers feel uncomfortable with the self-signed nature of the inter-server certificate, we recommend that you do not replace it with a CA-signed certificate for the following reasons:
  - If the inter-server certificate is replaced incorrectly, serious problems can occur during topology authentication.
  - The inter-server certificate is used for internal purposes only.
- If the server's access logs contain authentication (bind) errors, the inter-server certificate is most likely configured inappropriately. In the topology registry, this certificate is persisted in the **`inter-server-certificate`** property of a server instance.

*Replace the inter-server certificate*

About this task

Because the inter-server certificate is also stored in the topology registry, it can be replaced on one server and mirrored to all other servers in the topology. Changes are mirrored automatically to the other servers in the topology.

**Important:** Before attempting to replace the inter-server certificate, ensure that all servers in the topology are updated to version 7.0 or later.

The inter-server certificate is stored in human-readable, PEM-encoded format and can be updated by using the `dsconfig` tool. While the certificate is being replaced, existing authenticated connections continue to work. If the server is restarted, or if a topology change requires a reset of peer connections, the server continues authenticating with its peers, all of whom trust the new certificate.

To replace the inter-server certificate with no downtime, complete the following tasks:

Steps

1. Prepare a new keystore with the replacement key pair.
2. Import the earlier trusted certificates into the new keystore.
3. Update the server configuration to use the new certificate by adding it to the server's list of certificates in the topology registry.  
After this step is performed, other servers will trust the certificate.
4. Replace the server's `ads-truststore` file with the new one.
5. Retire the previous certificate by removing it from the topology registry.

Next steps

The following sections describe these tasks in more detail.

Prepare a new keystore with the replacement key pair

The self-signed certificate can be replaced with an existing key pair. As an alternative, the certificate that is associated with the original key pair can be used.

Use an existing key pair

If a private key and certificate in PEM-encoded format already exist, both the original private key and the self-signed certificate can be replaced in `ads-truststore` by using the `manage-certificates` tool. Depending on your operating system, the **`manage-certificates`** tool is located in the server's `bin` or `bat` directory.

**i Important:** If the existing key pair is not in PEM-encoded format, convert it to a format that is compatible with the server's `ads-truststore` keystore file format before proceeding.

If you replace the entire key pair instead of only the certificate that is associated with the original private key, your existing backups and LDIF exports might be rendered invalid. To avoid this scenario, perform this step immediately after setup, or at least before the key pair is used. After the first use, change only the certificate associated with the private key to extend its validity period, or to replace it with a certificate that is signed by a different CA.

The following command imports existing certificates into a new keystore file named `ads-truststore.new`:

```
manage-certificates import-certificate \
 --keystore ads-truststore.new \
 --keystore-type JKS \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --private-key-file existing.key \
 --certificate-file existing.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Order the certificates that use the `--certificate-file` option in such a manner that each subsequent certificate functions as the issuer for the previous one. The server certificate is listed first, any intermediate certificates are listed next, and the root CA certificate is listed last. Because some deployments do not feature an intermediate issuer, you might need to import only the server certificate and a single issuer.

Replace the certificate associated with the original key pair

About this task

Alternatively, to replace the certificate that is associated with the original server-generated, `ads-certificate` private key, perform the following steps:

Steps

1. Create a CSR for the `ads-certificate`, as follows:

```
manage-certificates generate-certificate-signing-request \
 --keystore ads-truststore \
 --keystore-type JKS \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --use-existing-key-pair \
 --subject-dn "CN=ldap.example.com,O=Example Corporation,C=US" \
 --output-file ads.csr
```

2. Submit `ads.csr` to a CA for signing.

3. Export the server's private key into `ads.key`, as follows:

```
manage-certificates export-private-key \
 --keystore ads-truststore \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --output-file ads.key
```

4. Import the certificates obtained from the CA – including the CA-signed server certificate, the root CA certificate, and any intermediate certificates – into `ads-truststore.new`, as follows:

```
manage-certificates import-certificate \
```

```
--keystore ads-truststore.new \
--keystore-type JKS \
--keystore-password-file ads-truststore.pin \
--alias ads-certificate \
--private-key-file ads.key \
--certificate-file new-ads.crt \
--certificate-file intermediate.crt \
--certificate-file root-ca.crt
```

## Import earlier trusted certificates into the new keystore

### About this task

The new `ads-truststore` file, `ads-truststore.new`, contains only the server's new key pair. You must import the currently trusted certificates of other servers in the topology.

To export trusted certificates from `ads-truststore` and import them into `ads-truststore.new`, perform the following steps for each trusted certificate:

### Steps

1. Locate the currently trusted certificates, as follows:

```
manage-certificates list-certificates \
--keystore ads-truststore
```

2. For each alias other than `ads-certificate`, or whose fingerprint does not match `ads-certificate`, perform the following steps:

- a. Export the trusted certificate from `ads-truststore`, as follows:

```
manage-certificates export-certificate \
--keystore ads-truststore \
--keystore-password-file ads-truststore.pin \
--alias <trusted-cert-alias> \
--export-certificate-chain \
--output-file <trust-cert-alias>.crt
```

- b. Import the trusted certificate into `ads-truststore.new`, as follows:

```
manage-certificates import-certificate \
--keystore ads-truststore.new \
--keystore-type JKS \
--keystore-password-file ads-truststore.pin \
--alias <trusted-cert-alias> \
--certificate-file <trusted-cert-alias>.crt
```

## Update the server configuration to use the new certificate

### About this task

Before updating the server to use the appropriate key pair, update the `inter-server-certificate` property for the server instance in the topology registry. To support the transition from an existing certificate to a new one, earlier and newer certificates might appear within their own beginning and ending headers in the `inter-server-certificate` property.

To update the server configuration to use the new certificate, perform the following steps:

## Steps

1. Export the server's previous `ads-certificate` into `old-ads.crt`, as follows:

```
manage-certificates export-certificate \
 --keystore ads-truststore \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --output-file old-ads.crt
```

2. Concatenate the previous and new certificate into one file.

On Windows, use a text editor like Notepad. On Unix, use the following command:

```
cat old-ads.crt new-ads.crt > old-new-ads.crt
```

3. Use `dsconfig` to update the `inter-server-certificate` property for the server instance in the topology registry, as follows:

```
$ bin/dsconfig -n set-server-instance-prop \
 --instance-name <instance-name> \
 --set "inter-server-certificate<old-new-ads.crt"
```

Replace the previous `ads-truststore` file with the new one

Because the server still uses the previous `ads-certificate`, you must replace the previous `ads-truststore` file with `ads-truststore.new` in the server's `config` directory when you want the new `ads-certificate` to go into effect:

```
$ mv ads-truststore.new ads-truststore
```

Retire the previous certificate

Retire the previous certificate by removing it from the topology registry after it expires, as follows:

```
$ dsconfig -n set-server-instance-prop \
 --instance-name <instance-name> \
 --set "inter-server-certificate<chain.crt"
```

Existing encrypted backups and LDIF exports remain unaffected. Because the public key is the same in the previous and new server certificates, the private key can decrypt them.

### Server certificate

During setup, administrators have the option of using self-signed certificates or CA-signed certificates for the server certificate. Where possible, we encourage the use of CA-signed certificates. Self-signed certificates are recommended only for demonstration and proof-of-concept environments.

If you specify the option `--generateSelfSignedCertificate` during setup, the server certificate is generated automatically with the alias `server-cert`. The key pair consists of the private key and the self-signed certificate, and is stored in a file named `keystore`, which resides in the server's `/config` directory. The certificates for all the servers that the server trusts are stored in the `truststore` file, which is also located under the server's `/config` directory.

To override the server certificate alias and the files that store the key pair and certificates, use the following arguments during setup:

- `--certNickname`
- `--use*Keystore`
- `--use*Truststore`

For more information about these arguments, refer to the setup tool's Help and the Installation Guide.

**i Important:** If the server's access logs contain authentication (bind) errors, the inter-server certificate is most likely configured inappropriately. In the topology registry, this certificate is persisted in a Server Instance Listener's listener-certificate property.

### *Replace the server certificate*

#### About this task

Regardless of whether the server was set up with self-signed or CA-signed certificates, the steps to replace the server certificate are nearly identical.

This task makes the following assumptions:

- You are replacing the self-signed server certificate.
- The certificate alias is `server-cert`.
- The private key is stored in `keystore`.
- The trusted certificates are stored in `truststore`.
- The `keystore` and `truststore` use the JKS keystore format.

If a PKCS#12 keystore format was used for the `keystore` and `truststore` files during setup, change the `--keystore-type` argument in the `manage-certificate` commands to `PKCS12` in the relevant steps.

**i Important:** Before attempting to replace the inter-server certificate, ensure that all servers in the topology are updated to version 7.0 or later.

While the certificate is being replaced, existing secure connections continue to work. If the server is restarted, or if a topology change requires a reset of peer connections, the server continues authenticating with its peers, all of whom trust the new certificate.

To replace the server certificate with no downtime, complete the following tasks:

#### Steps

1. Prepare a new keystore with the replacement key pair.
2. Import the earlier trusted certificates into the new `truststore` file.
3. Update the server configuration to use the new certificate by adding it to the server's list of listener certificates in the topology registry.  
After this step is performed, other servers will trust the certificate.
4. Replace the server's `keystore` and `truststore` files with the new ones.
5. Retire the previous certificate by removing it from the topology registry.

#### Next steps

The following sections describe these tasks in more detail.

#### Prepare a new keystore with the replacement key pair

The self-signed certificate can be replaced with an existing key pair. As an alternative, the certificate that is associated with the original key pair can be used.

#### Use an existing key pair

If a private key and certificate already exist in PEM-encoded format, they can replace both the original private key and the self-signed certificate in `keystore` (instead of replacing the self-signed certificate associated with the original server-generated private key). Use the `manage-certificates` tool that, depending on your operating system, is located in the server's `bin` or `bat` directory.

The following command imports existing certificates into a new keystore file named `keystore.new`:

```
manage-certificates import-certificate \
 --keystore keystore.new \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --private-key-file existing.key \
 --certificate-file existing.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Order the certificates that use the `--certificate-file` option in such a manner that each subsequent certificate functions as the issuer for the previous one. The server certificate is listed first, any intermediate certificates are listed next, and the root CA certificate is listed last. Because some deployments do not feature an intermediate issuer, you might need to import only the server certificate and a single issuer.

Replace the certificate associated with the original key pair

#### About this task

If the certificate that is associated with the original server-generated private key (`server-cert`) has expired or must be replaced with a certificate from a different CA, perform the following steps to replace it:

#### Steps

1. Create a CSR file for the `server-cert`, as follows:

```
manage-certificates generate-certificate-signing-request \
 --keystore keystore \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --use-existing-key-pair \
 --subject-dn "CN=ldap.example.com,O=Example Corporation,C=US" \
 --output-file server-cert.csr
```

2. Submit `server-cert.csr` to a CA for signing.
3. Export the server's private key into `server-cert.key`, as follows:

```
manage-certificates export-private-key \
 --keystore keystore \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --output-file server-cert.key
```

4. Import the certificates obtained from the CA – including the CA-signed server certificate, the root CA certificate, and any intermediate certificates – into `keystore.new`, as follows:

```
manage-certificates import-certificate \
 --keystore keystore.new \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --private-key-file server-cert.key \
 --certificate-file server-cert.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Import earlier trusted certificates into the new keystore

### About this task

The trusted certificates of other servers in the topology must be imported into the new `truststore` file. To export trusted certificates from `truststore` and import them into `truststore.new`, perform the following steps for each trusted certificate:

### Steps

1. Locate the currently trusted certificates, as follows:

```
manage-certificates list-certificates \
 --keystore truststore
```

2. For each alias other than `server-cert`, or whose fingerprint does not match `server-cert`, perform the following steps:

- a. Export the trusted certificate from `truststore`, as follows:

```
manage-certificates export-certificate \
 --keystore truststore \
 --keystore-password-file truststore.pin \
 --alias <trusted-cert-alias> \
 --export-certificate-chain \
 --output-file trusted-cert-alias.crt
```

- b. Import the trusted certificate into `truststore.new`, as follows:

```
manage-certificates import-certificate \
 --keystore truststore.new \
 --keystore-type JKS \
 --keystore-password-file truststore.pin \
 --alias <trusted-cert-alias> \
 --certificate-file trusted-cert-alias.crt
```

### Update the server configuration to use the new certificate

#### About this task

Before updating the server to use the appropriate key pair, update the `listener-certificate` property for the server instance's LDAP listener in the topology registry. To support the transition from an existing certificate to a new one, earlier and newer certificates might appear within their own beginning and ending headers in the `listener-certificate` property.

To update the server configuration to use the new certificate, perform the following steps:

### Steps

1. Export the server's previous `server-cert` into `old-server-cert.crt`, as follows:

```
manage-certificates export-certificate \
 --keystore keystore \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --output-file old-server-cert.crt
```

2. Concatenate the previous and new certificate into one file.

On Windows, use a text editor like Notepad. On Unix, use the following command:

```
cat old-server-cert.crt new-server-cert.crt > old-new-server-cert.crt
```

3. Use `dsconfig` to update the `listener-certificate` property for the server instance's LDAP listener in the topology registry, as follows:

```
$ bin/dsconfig -n set-server-instance-listener-prop \
 --instance-name <instance-name> \
 --listener-name ldap-listener-mirrored-config \
 --set "listener-certificate<old-new-server-cert.crt"
```

Replace the keystore and truststore files with the new ones

Because the server still uses the previous `server-cert`, you must replace the earlier `keystore` and `truststore` files with the new ones in the server's `config` directory when you want the new `server-cert` to take effect.

```
$ mv keystore.new keystore
 mv truststore.new truststore
```

Retire the previous certificate

Retire the previous certificate by removing it from the topology registry after it expires, as follows:

```
$ dsconfig -n set-server-instance-listener-prop \
 --instance-name <instance-name> \
 --listener-name ldap-listener-mirrored-config \
 --set "listener-certificate<new-server-cert.crt"
```

## Using the Configuration API

PingDirectoryProxy Server provides a Configuration API, which may be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's `host:port` in the `/config` context. Due to the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used for hosting the Configuration extension.

### Authentication and Authorization with the Configuration API

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Configuration \
 --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

### Relationship Between the Configuration API and the `dsconfig` Tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes may be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes may be excluded from responses by specifying the `excludedAttributes` parameter.

Operations supported by the API are those typically found in REST APIs:

| HTTP Method | Description                                                                                                                                                                                                                                                                                                                                                                                 | Related <code>dsconfig</code> Example                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| GET         | Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> . Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .                                                                                           | <code>get-backend-prop</code> , <code>list-backends</code> , <code>get-global-configuration-prop</code> |
| POST        | Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .                                                                                                                                                                                                                                                                          | <code>create-backend</code>                                                                             |
| PUT         | Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> . | <code>set-backend-prop</code> , <code>set-global-configuration-prop</code>                              |
| PATCH       | Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                 | <code>set-backend-prop</code> , <code>set-global-configuration-prop</code>                              |
| DELETE      | Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                                   | <code>delete-backend</code>                                                                             |

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. The URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

### GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

```
{

### GET List Example

The following is a sample GET request for all local backends:

```

GET /config/backends/
Host: example.com:5033
Accept: application/scim+json

```

The response (which has been shortened):

```

{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],

### PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API, supports a subset of possible values for the path attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

```

{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
}

```

```
}

```

is analogous to:

```
$ dsconfig set-backend-prop
 --backend-name userRoot \
 --set "description:A new backend"

```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

```
{
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --add je-property:je.env.backgroundReadLimit=0

```

- An operation to remove a value from a multi-valued property. In this case, `path` specifies a SCIM filter identifying the value to remove:

```
{
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.cleaner.adjustUtilization=false

```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is value:

```
{
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.nodeMaxEntries=32

```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --reset id2childrenIndexEntryLimit

```

The following is the full example request. The API responds with the entire modified configuration object, which may include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

```
PATCH /config/backends/userRoot
```

```
Host: example.com:5033
Accept: application/scim+json
```

```
{
 "schemas" : ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
 "Operations" : [{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
 }, {
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
 }, {
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
 }, {
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
 }, {
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
 }]
}
```

}
}
}

```

## Configuration API Paths

The Configuration API is available under the `/config` path. A full listing of supported sub-paths is available by accessing the base `/config/ResourceTypes` endpoint:

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Sample response (abbreviated):

```
{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],
 "totalResults": 520,
 "Resources": [
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "dsee-compat-access-control-handler",
 "name": "DSEE Compat Access Control Handler",
 "description": "The DSEE Compat Access Control
 Handler provides an implementation that uses syntax
 compatible with the Sun Java System Directory Server
 Enterprise Edition access control handler.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-
access-control-handler"
 }
 },
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "access-control-handler",
 "name": "Access Control Handler",
 "description": "Access Control Handlers manage the
 application-wide access control. The server's access
 control handler is defined through an extensible
 interface, so that alternate implementations can be created.
 Only one access control handler may be active in the server
 at any given time.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
 }
 },
 {
 ...
 }
]
}
```

The response's `endpoint` elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name such as `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

### Sorting and Filtering Objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both get and list operations.

| GET Parameter | Description                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filter        | Values can be simple SCIM filters such as <code>id eq "userRoot"</code> or compound filters like <code>meta.resourceType eq "Local DB Backend" and baseDn co "dc=example,dc=com"</code> . |
| sortBy        | Specifies a property value by which to sort.                                                                                                                                              |
| sortOrder     | Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.                                                                                                    |
| startIndex    | 1-based index of the first result to return.                                                                                                                                              |
| count         | Indicates the number of results per page.                                                                                                                                                 |

### Updating Properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
 "description" : "A new description."
}
```

Response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot",
 "meta": {
 "resourceType": "Local DB Backend",
 "location": "http://example.com:5033/config/backends/userRoot"
 },
 "backendID": "userRoot",
 "backgroundPrime": "false",
 "backupFilePermissions": "700",
 "baseDN": [
 "dc=example,dc=com"
],
 "checkpointOnCloseCount": "2",
 "cleanerThreadWaitTime": "120000",
 "compressEntries": "false",
```

```

"continuePrimeAfterCacheFull": "false",

"subtreeDeleteSizeLimit": "100000",
"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled"
}

```

## Administrative Actions

Updating a property may require an administrative action before the change can take effect. If so, the server will return 200 Success, and any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
 "required-actions": [
 {
 "property": "baseContextPath",
 "type": "'componentRestart",
 "synopsis": "In order for this modification to take effect, the
component
 must be restarted, either by disabling and re-enabling it,
or
 by restarting the server"
 },
 {
 "property": {
 "type": "other",
 "synopsis": "If this limit is increased, then the
 contents of the backend must be exported to LDIF
 and re-imported to allow the new limit to be used
 for any id2children keys that had already hit the
 previous limit."
 }
 }
]
}
```

## Updating Servers and Server Groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified. For example:

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

## Configuration API Responses

Clients of the API should examine the HTTP response code in order to determine the success or failure of a request. The following are response codes and their meanings:

| Response Code  | Description                                                                                                                                                                                                                                            | Response Body                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| 200 Success    | The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object. | List of objects, or object properties, administrative actions. |
| 204 No Content | The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.                                                                                                                             | None.                                                          |

| Response Code              | Description                                                                                                                                                                                                                                               | Response Body                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| 400 Bad Request            | The request contents are incorrectly formatted or a request is made for an invalid API version.                                                                                                                                                           | Error summary and optional message. |
| 401 Unauthorized           | User authentication is required. Some user agents such as browsers may respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.                                                       | None.                               |
| 403 Forbidden              | The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint such as an object is edit-only and cannot be deleted.                                                                           | None.                               |
| 404 Not Found              | The requested path does not refer to an existing object or object relation.                                                                                                                                                                               | Error summary and optional message. |
| 409 Conflict               | The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referred to by another object. | Error summary and optional message. |
| 415 Unsupported Media Type | The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.                                                                                                                                            | None.                               |
| 500 Server Error           | The server encountered an unexpected error. Please report server errors to customer support.                                                                                                                                                              | Error summary and optional message. |

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages may change, and their presence may depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:Error"
],

## Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectoryProxy Server. The Directory REST API gives developers, who are more comfortable with REST than LDAP, access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and SCIM provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access

to identity data. But because it is a less common standard for identity stores, it may not offer as much functionality or be as easy to use as the Directory REST API.

Rather than trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

The Directory REST API can be used for the following operations:

| HTTP operation | Resource endpoint                                         | Description                                           | Allowed query parameters                                                                                                                                                       |
|----------------|-----------------------------------------------------------|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DELETE         | <code>/directory/v1/{dn}</code>                           | Delete an entry.                                      |                                                                                                                                                                                |
| GET            | <code>/directory/v1</code>                                | Get metadata about the API and server.                |                                                                                                                                                                                |
| GET            | <code>/directory/v1/{dn}</code>                           | Retrieve a single entry.                              | <ul style="list-style-type: none"> <li>▪ expand</li> <li>▪ includeAttributes</li> <li>▪ excludeAttributes</li> </ul>                                                           |
| GET            | <code>/directory/v1/{dn}/subtree</code>                   | Search an entry's descendants.                        | <ul style="list-style-type: none"> <li>▪ filter</li> <li>▪ searchScope</li> <li>▪ cursor</li> <li>▪ limit</li> <li>▪ includeAttributes</li> <li>▪ excludeAttributes</li> </ul> |
| GET            | <code>/directory/v1/schemas</code>                        | Retrieve the schemas of all available object classes. |                                                                                                                                                                                |
| GET            | <code>/directory/v1/schemas/{objectclass}</code>          | Retrieve schema for object class.                     |                                                                                                                                                                                |
| GET            | <code>/directory/v1/schemas/_operationalAttributes</code> | Retrieve schema for operational attributes.           |                                                                                                                                                                                |
| GET            | <code>/directory/v1/me</code>                             | Alias for retrieving the current user.                |                                                                                                                                                                                |
| PATCH          | <code>/directory/v1/{dn}</code>                           | Modify an entry (add or delete values).               | expand                                                                                                                                                                         |
| POST           | <code>/directory/v1</code>                                | Create a new entry.                                   | expand                                                                                                                                                                         |
| PUT            | <code>/directory/v1/{dn}</code>                           | Modify or rename an entry.                            | expand                                                                                                                                                                         |

The Directory REST API has the following properties, and can be configured with `dsconfig`:

- **basic-auth-enabled**: Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users will need a Bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic auth is enabled by default.
- **identity-mapper**: If HTTP Basic authentication is enabled, the identity mapper referenced by this DN must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.

- **access-token-validator**: Specifies the subset of this server's Access Token Validators (by DN), which may be used to validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server may be used. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.
- **access-token-scope**: The scope which must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication can be used. By default, no value is provided. Changes to this value take effect immediately.
- **audience**: A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
- **max-page-size**: The maximum number of entries to be returned in one page from the search endpoint (actual results returned may be lower due to the limit query parameter on the request and the actual number of available results). The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
- **schemas-endpoint-objectclass**: The list of object classes that will be returned by the `/schemas/` endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

The following example uses `dsconfig` to configure an `objectClass` entity:

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST
API" \
 --add schemas-endpoint-objectclass:ubidPerson
```

## Generating a Summary of Configuration Components

The Directory Proxy Server provides a `config-diff` tool that generates a summary of the configuration in a local or remote directory server instance. The tool is useful when comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers to your network. The tool can interact with the local configuration regardless of whether the server is running or not.

Run the `config-diff --help` option to view other available tool options.

### To Generate a Summary of Configuration Components

#### Steps

- Run the `config-diff` tool to generate a summary of the configuration components on the directory server instance. The following command runs a summary on a local online server.

```
$ bin/config-diff
```

- The following example compares the current configuration of the local server to the baseline, pre-installation configuration, ignoring any changes that could be made by the installer, and writes the output to the `configuration-steps.dsconfig` file. This provides a script that can be used to configure a newly installed server identically to the local server:

```
$ bin/config-diff --sourceLocal \
 --sourceBaseline \
 --targetLocal \
 --exclude differs-after-install \
 --outputFile configuration-steps.dsconfig
```

## Configuring Server Groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group. After you have set up a server group, you can

make an update on one server using **dsconfig**, then you can apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **dsconfig** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **dsconfig** in interactive command-line mode, you will be asked if you want to apply the change to a single server or to all servers in the server group.

### About the Server Group Example

You can create an administrative server group using the **dsconfig** tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group as outlined in Replication Configuration.

The following example procedure adds three Directory Proxy Server instances into the server group labelled "group-one".

### To Create a Server Group

#### Steps

1. Create a group called "group-one" using **dsconfig**.

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group. If you have set up replication between a set of servers, these server entries will have already been created by the **dsreplication enable** command.

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server1
```

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server2
```

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

```
$ bin/dsconfig set-global-configuration-prop \
 --set configuration-server-group:group-one
```

4. Test the server group. In this example, enable the log publisher for each directory server in the group, server-group, by using the `--applyChangeTo server-group` option.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set enabled:true \
 --applyChangeTo server-group
```

5. View the property on the first directory server instance.

```
$ bin/dsconfig get-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

6. Repeat step 5 on the second and third directory server instance.
7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

```
$ bin/dsconfig set-log-publisher-prop \
```

```
--publisher-name "File-Based Audit Logger" \
--set enabled:disabled \
--applyChangeTo single-server
```

8. View the property on the first directory server instance. The first directory server instance should be disabled.

```
$ bin/dsconfig get-log-publisher-prop \
--publisher-name "File-Based Audit Logger" \
--property enabled
```

```
Property : Value(s)
-----:-----
enabled : false
```

9. View the property on the second directory server instance. Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

```
$ bin/dsconfig get-log-publisher-prop \
--publisher-name "File-Based Audit Logger" \
--property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

## Domain Name Service (DNS) Caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

- **network-address-cache-ttl** – Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
- **network-address-outage-cache-enabled** – Caches host name-to-IP address results in the event of a DNS outage. This is set to true by default, meaning name resolution results are cached. Unexpected service interruptions may occur during planned or unplanned maintenance, network outages or an infrastructure attack. This cache may allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays due to unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` and/or `options single-request` in `/etc/resolv.conf`.
- If IPv6 requests specifically are causing issues, Add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

## IP Address Reverse Name Lookups

PingDirectoryProxy Server does not explicitly perform numeric IP address-to-host name lookups. However, address masks configured in Access Control Lists (ACLs), Connection Handlers, Connection Criteria, and Certificate handshake processing may trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- `ACI dns`: bind rules under *Managing Access Control* (Directory Server and Directory Proxy Server)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication* (Directory Server)

- Connection Criteria: *Restricting Server Access Based on Client IP Address* (Directory Server and Directory Proxy Server)
- Connection Handlers: restrict server access using Connection Handlers (Configuration Reference Guide for all servers)

## Configuring Traffic Through a Load Balancer

If a PingDirectoryProxy Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, then it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address must be recorded to the trace log, enable **X-Forwarded-\*** handling in both the intermediate HTTP server and PingDirectoryProxy Server. For PingDirectoryProxy Servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP), and set **use-forwarded-headers** to **true**.
- When **use-forwarded-headers** is set to **true**, the server will use the client IP address and port information in the **X-Forwarded-\*** headers instead of the address and port of the entity that's actually sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the **from** field of the HTTP REQUEST and HTTP RESPONSE messages.

On the load balancer, configure settings to provide the **X-Forwarded-\*** information, such as **X-Forwarded-Host**: . See the product documentation for the device type.

## Managing Root Users Accounts

The PingDirectory Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file (for example, under `cn=Root DNs, cn=config`). The root user is the LDAP-equivalent of a UNIX super-user account and inherits its read-write privileges from the default root privilege set. Root users can be created and updated with the `dsconfig` tool. Root user entries are stored in the server's configuration. The following is a sample command to create a new root user:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
 --set last-name:Smith \
 --set first-name:Joanne \
 --set user-id:jsmith \
 --set 'email-address:jsmith@example.com' \
 --set mobile-telephone-number:8889997777 \
 --set home-telephone-number:5556667777 \
 --set work-telephone-number:4445556666
```

To limit full access to all of the Directory Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change. Having separate user accounts for each administrator also makes it possible to enable password policy functionality (such as password expiration, password history, and requiring secure authentication) for each administrator.

### Default Root Privileges

The PingDirectory Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

**Note:** Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

**Default Root Privileges**

| Privilege                               | Description                                                                                                                                                               |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| audit-data-security                     | Allows the associated user to execute data security auditing tasks.                                                                                                       |
| backend-backup                          | Allows the user to perform backend backup operations.                                                                                                                     |
| backend-restore                         | Allows the user to perform backend restore operations.                                                                                                                    |
| bypass-acl                              | Allows the user to bypass access control evaluation.                                                                                                                      |
| config-read                             | Allows the user to read the server configuration.                                                                                                                         |
| config-write                            | Allows the user to update the server configuration.                                                                                                                       |
| disconnect-client                       | Allows the user to terminate arbitrary client connections.                                                                                                                |
| ldif-export                             | Allows the user to perform LDIF export operations.                                                                                                                        |
| ldif-import                             | Allows the user to perform LDIF import operations.                                                                                                                        |
| lockdown-mode                           | Allows the user to request a server lockdown.                                                                                                                             |
| manage-topology                         | Allows the user to modify topology setting.                                                                                                                               |
| metrics-read                            | Allows the user to read server metrics.                                                                                                                                   |
| modify-acl                              | Allows the user to modify access control rules.                                                                                                                           |
| password-reset                          | Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.   |
| permit-get-password-policy-state-issues | Allows the user to access password policy state issues.                                                                                                                   |
| privilege-change                        | Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.                            |
| server-restart                          | Allows the user to request a server restart.                                                                                                                              |
| server-shutdown                         | Allows the user to request a server shutdown.                                                                                                                             |
| soft-delete-read                        | Allows the user access to soft-deleted entries.                                                                                                                           |
| stream-values                           | Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT. |
| third-party-task                        | Allows the associated user to invoke tasks created by third-party developers.                                                                                             |
| unindexed-search                        | Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.                                                                            |
| update-schema                           | Allows the user to update the server schema.                                                                                                                              |
| use-admin-session                       | Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.                             |

The Directory Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

## Other Available Privileges

| Privilege                                  | Description                                                                                                                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bypass-pw-policy                           | Allows the associated user bypass password policy rules and restrictions.                                                                                                                                   |
| bypass-read-aci                            | Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations. |
| jmx-notify                                 | Allows the associated user to subscribe to receive JMX notifications.                                                                                                                                       |
| jmx-read                                   | Allows the associated user to perform JMX read operations.                                                                                                                                                  |
| jmx-write                                  | Allows the associated user to perform JMX write operations.                                                                                                                                                 |
| permit-externally-processed-authentication | Allows the associated user accept externally processed authentication.                                                                                                                                      |
| permit-proxied-mschapv2-details            | Allows the associated user to permit MS-CHAP V2 handshake protocol.                                                                                                                                         |
| proxied-auth                               | Allows the associated user to accept proxied authorization.                                                                                                                                                 |

## Configuring Locations

PingDirectoryProxy Server defines locations, both for the LDAP external servers and the proxy server instances themselves. A location defines a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers would be configured as two locations in the Directory Proxy Server. Each location is associated with a name and an ordered list of failover locations, which could be used if none of the servers in the preferred location are available. You can define these locations using the Administrative Console or the command line.

The Directory Proxy Server itself is also associated with a location. This location is specified in the global configuration properties of the Directory Proxy Server. If the load balancing algorithm's `use-location` property is set to true, then the load balancing component of the Directory Proxy Server refers to the Directory Proxy Server's location to determine the external servers it prefers to communicate with.

### To Configure Locations Using `dsconfig`

#### Steps

1. Use the `dsconfig` tool to configure the LDAP external server locations.

```
$ bin/dsconfig
```

2. Type the host name or IP address for your Directory Proxy Server, or press **Enter** to accept the default, localhost.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Type the number corresponding how you want to connect to the Directory Proxy Server, or press **Enter** to accept the default, LDAP.

```
How do you want to connect?
1) LDAP
2) LDAP with SSL
3) LDAP with StartTLS
```

4. Type the port number for your Directory Proxy Server, or press **Enter** to accept the default, 389.

```
Directory Proxy Server port number [389]:
```

5. Type the administrator's bind DN or press **Enter** to accept the default (cn=Directory Manager), and then type the password.

```
Administrator user bind DN [cn=Directory Manager]:
```

```
Password for user 'cn=Directory Manager':
```

6. In the Directory Proxy Server main menu, enter the number corresponding to location configuration. Then, enter the number to create a new location.
7. Enter the name of the new location. This example demonstrates configuring a location called East. Enter **f** to finish configuring the location. Repeat this procedure to create a location called West.

```
>>>> Enter a name for the location that you want to create: east
```

```
>>>> Configure the properties of the location
```

| Property                                                           | Value(s) |
|--------------------------------------------------------------------|----------|
| 1) description                                                     | -        |
| 2) preferred-failover-location                                     | -        |
| ?) help                                                            |          |
| f) finish - create the new location                                |          |
| d) display the equivalent dsconfig arguments to create this object |          |
| b) back                                                            |          |
| q) quit                                                            |          |

```
Enter choice [b]: f
```

8. Next, edit the configuration of an existing location, in this example a location named East.

```
>>>> Location menu
```

```
What would you like to do?
```

- 1) List existing locations
- 2) Create a new location
- 3) View and edit an existing location
- 4) Delete an existing location

- b) back
- q) quit

```
Enter choice [b]: 3
```

```
>>>> Select the location from the following list:
```

- 1) East
- 2) West

- b) back
- q) quit

```
Enter choice [b]: 1
```

9. Define the preferred failover location property for East. This property provides alternate locations that can be used if servers in this location are not available. If more than one location is provided, the Directory Proxy Server tries the locations in the order listed.

```
>>>> Configure the properties of the Location
```

| Property | Value(s) |
|----------|----------|
|----------|----------|

```

1) description -
2) preferred-failover-location -

?) help
f) finish - create the new location
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

Enter choice [b]: 2

...

Do you want to modify the 'preferred-failover-location' property?

1) Add one or more values

?) help
q) quit

Enter choice [1]: 2

Select the locations you wish to add:

1) East
2) West
3) Create a new location
4) Add all locations

...

Enter one or more choices separated by commas[b]: 2

```

#### 10. Verify and apply your change to the property.

```

Do you want to modify the 'preferred-failover-location' property?

1) Use the value: West
2) Add one or more values
3) Remove one or more values
4) Leave undefined
5) Revert changes

?) help
q) quit

Enter choice [1]:

>>>> Configure the properties of the location

Property Value(s)

1) description -
2) preferred-failover-location West

?) help
f) finish - apply any changes to the Location
d) display the equivalent dsconfig command lines to either
 re-create this object or only to apply pending changes
b) back
q) quit

Enter choice [b]: f

```

11. Repeat steps 8 and 9 for the West location, assigning it a failover location of East.

### To Modify Locations Using dsconfig

#### Steps

1. Use the `dsconfig` tool to configure the LDAP external server locations.

```
$ bin/dsconfig
```

2. Type the host name or IP address for your Directory Proxy Server, or press **Enter** to accept the default, localhost.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Type the number corresponding how you want to connect to the Directory Proxy Server, or press **Enter** to accept the default, LDAP.

```
How do you want to connect?
```

- ```
1) LDAP
2) LDAP with SSL
3) LDAP with StartTLS
```

4. Type the port number for your Directory Proxy Server, or press **Enter** to accept the default, 389.

```
Directory Proxy Server port number [389]:
```

5. Type the administrator's bind DN or press **Enter** to accept the default (cn=Directory Manager), and then type the password.

```
Administrator user bind DN [cn=Directory Manager]:
```

```
Password for user 'cn=Directory Manager':
```

6. In the Directory Proxy Server main menu, enter the number corresponding to Global Configuration. Then enter the number to view and edit the Global Configuration.
7. Enter the number associated with the location configuration property.

```
Enter choice [b]: 2
```

8. Specify a new location for this Directory Proxy Server instance, in this example the East location. Operations involving communications with other servers may prefer servers in the same location to ensure low-latency responses.

```
>>>> Configuring the 'location' property
```

```
...
```

```
Do you want to modify the 'location' property?
```

- ```
1) Leave undefined
2) Change it to the location: East
3) Change it to the location: West
4) Create a new location
```

```
b) back
```

```
q) quit
```

```
Enter choice [b]: 2
```

9. Enter **f** to finish the operation.

```
Enter choice [b]: f
```

## Configuring Batched Transactions

You can configure the Directory Proxy Server to use batched transactions in both simple and entry-balanced configurations. The batched transactions feature supports two implementations: the standard LDAP transactions per RFC 5805 and the PingDirectoryProxy Server proprietary implementation, known as the *multi-update extended operation*. Batched transactions can be used through the Directory Proxy Server in both simple and entry-balanced configurations although only in cases in which all operations within the transaction request may be processed within the same backend server and within the same Berkeley DB JE backend. Batched transactions cannot be processed across multiple servers or multiple Directory Server backends.

The multi-update extended operation makes it possible to submit multiple updates in a single request. These updates may be processed either as individual operations or as a single atomic unit. When the Directory Proxy Server receives a Start Batched Transaction request, it will queue all associated operations in memory until the End Batched Transaction request is received with the intention to commit, at which point the set of operations is sent as a single multi-update extended request to the Directory Server.

Add, delete, modify, modify DN, and password modify extended operations may be included in the set of operations processed during a batch transaction. The operations are processed sequentially in the order in which they were included in the extended request. If an error occurs while processing an operation in the set, then the server can be instructed to continue the processing or to cancel any remaining operations. If the operations are not cancelled, you can configure the server to process all operations as a single atomic unit.

Because of this use of multi-update, the external Directory Server must be configured to allow multi-update extended requests made by the Directory Proxy Server on behalf of the DN submitting the batched transaction. For example, the following Directory Server `dsconfig` command grants anonymous access to the multi-update extended request. The submitter of the request still needs access rights for the individual operations within the multiple-update.

```
$ bin/dsconfig set-access-control-handler-prop \
 --add 'global-aci: (extop="1.3.6.1.4.1.30221.2.6.17") (version 3.0;
 acl "Anonymous access to multi-update extended request"; allow (read)
 userdn="ldap:///anyone");'
```

### To Configure Batched Transactions

About this task

Batched transactions are managed by the Batched Transactions Extended Operation Handler. You can use it to configure the start transaction and end transaction operations used to indicate the set of add, delete, modify, modify DN, and/or password modify operations as a single atomic unit.

Steps

1. You can configure batched transactions using the `dsconfig` command as follows:

```
$ bin/dsconfig set-extended-operation-handler-prop \
 --handler-name "Batched Transactions" \
 --set enabled:true
```

2. Configure the external servers to allow the multi-update extended operation by granting access rights to the feature. See example in the previous section.

## Configuring Server Health Checks

You can use the PingDirectoryProxy Server to configure different types of health checks for your deployment. The health checks define external server availability as either being available, unavailable, or degraded. The external server health is given a value from 0 to 10, which is used to determine if the server

is available and how that server compares to other servers with the same state. Load-balancing algorithms can be used to check the score and prefer servers with higher scores over those with lower scores.

An individual health check can be defined for use against all external servers or assigned to individual external servers, as determined by the `use-for-all-servers` parameter within the health check configuration object. If `use-for-all-servers` is set to true, the Directory Proxy Server applies the health check to all external servers in all locations. If `use-for-all-servers` is set to false, then the health check is only employed against an external server if the configuration object for that external server lists the health check.

For more information about health checks and the type of health checks supported by PingDirectoryProxy Server, see [About LDAP Health Checks](#).

### About the Default Health Checks

By default, the Directory Proxy Server has two health check instances enabled for use on all servers:

- **Consume Admin Alerts.** This health check detects administrative alerts from the Directory Server, as soon as they are issued, by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the Directory Server. When the Directory Proxy Server is notified by the Directory Server of a new alert, it immediately retrieves the base `cn=monitor` entry of the Directory Server. If this entry has a value for the `unavailable-alert-type` attribute, then the Directory Proxy Server will consider it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the Directory Proxy Server will consider it degraded.
- **Get Root DSE.** This health check detects if the root DSE entry exists on the LDAP external server. As this entry always exists on a PingDirectory Server, the absence of the entry suggests that the LDAP external server may be degraded or unavailable.

### About Creating a Custom Health Check

You can create a new health check from scratch or use an existing health check as a template for the configuration of a new health check. If you choose to create a custom health check, you can create one of the following types:

- **Admin Alert Health Check.** This health check watches for administrative alerts generated by the LDAP external server to determine whether the server has entered a degraded or unavailable state.
- **Groovy Scripted LDAP Health Check.** This health check allows you to create custom LDAP health checks in a dynamically-loaded Groovy script, which implements the `ScriptedLDAPHealthCheck` class defined in the Server SDK.
- **Replication Backlog Health Check.** While the Admin Alert Health Check consumes replication backlog alerts emitted from external servers, a finer definition of external server health based on replication backlog can be defined with this health check. If a server falls too far behind in replication, then the Directory Proxy Server can stop sending requests to it. A server is classified as degraded or unavailable if the threshold is reached for the number of backlogged changes, the age of the oldest backlogged change, or both.
- **Search LDAP Health Check.** This health check performs searches on an LDAP external server and gauges the health of the server depending if the expected results were returned within an acceptable response time. For example, if an error occurs while attempting to communicate with the server, then the server is considered unavailable. You can also apply filters to the results to use values within the monitor entry as indicators of server health.
- **Third Party LDAP Health Check.** This health check allows you to define LDAP health check implementations in third-party code using the Server SDK.
- **Work Queue Busyness Health Check.** This health check may be used to monitor the percentage of time that worker threads in backend servers spend processing requests.

## To Configure a Health Check Using dsconfig

### Steps

1. Use the `dsconfig` tool to configure the LDAP external server locations.

```
$ bin/dsconfig
```

2. Type the host name or IP address for your Directory Proxy Server, or press **Enter** to accept the default, `localhost`.

```
Directory Proxy Server host name or IP address [localhost]:
```

3. Type the number corresponding how you want to connect to the Directory Proxy Server, or press **Enter** to accept the default, LDAP.

```
How do you want to connect?
```

- ```
1) LDAP
2) LDAP with SSL
3) LDAP with StartTLS
```

4. Type the port number for your Directory Proxy Server, or press **Enter** to accept the default, 389.

```
Directory Proxy Server port number [389]:
```

5. Type the administrator's bind DN or press **Enter** to accept the default (`cn=Directory Manager`), and then type the password.

```
Administrator user bind DN [cn=Directory Manager]:
```

```
Password for user 'cn=Directory Manager':
```

6. In the Directory Proxy Server main menu, enter the number corresponding to LDAP health checks. Enter the number to create a new LDAP Health Check, then press `n` to create a new health check from scratch.

7. Select the type of health check you want to create. This example demonstrates the creation of a new search LDAP health check.

```
>>> Select the type of LDAP Health Check that you want to create:
```

## Configuring LDAP External Servers

The LDAP external server configuration element defines the connection, location, and health check information necessary for the Directory Proxy Server to communicate with the server properly.

PingDirectoryProxy Server includes a tool, `prepare-external-server`, for configuring communication between the Directory Proxy Server and the LDAP backend server. After you add a new LDAP external server to an existing installation, we strongly recommend that you run this tool to automatically create the user account necessary for communications. The `prepare-external-server` tool does not make configuration changes to the local Directory Proxy Server, only the external server is modified. When you run this tool, you must supply the user account and password that you specified for the Directory Proxy Server during configuration, `cn=Proxy User` by default.

**i Important:** You should not use `cn=Directory Manager` as the account to use for communication between the Directory Proxy Server and the Directory Server. For security reasons, the account used to communicate between the Directory Proxy Server and the Directory Server should not be directly

accessible by clients accessing the Directory Proxy Server. The account that you choose should meet the following criteria:

- For all server types, it should not exist in the Directory Proxy Server but only in the backend directory server instances.
- For Ping Identity Directory Server, this user should be a root user.
- For Ping Identity Directory Server, this user should not automatically inherit the default set of root privileges, but instead should have exactly the following set of privileges: `bypass-read-acl`, `config-read`, `lockdown-mode`, `proxied-auth`, and `stream-values`.
- For Sun Directory Servers, the account should be created below the `cn=Root DNs,cn=config` entry and the `nsSizeLimit`, `nsTimeLimit`, `nsLookThroughLimit`, and `nsIdleTimeout` values for the account should be set to -1. You also need to create access control rules to grant the user account appropriate permissions within the server. The `prepare-external-server` tool handles all of this work automatically.

### About the `prepare-external-server` Tool

Use the `prepare-external-server` tool if you have added LDAP external servers using `dsconfig`. The `create-initial-proxy-config` tool automatically runs the `prepare-external-server` tool to configure server communications so that you do not need to invoke it separately. The `create-initial-proxy-config` tool verifies that the proxy user account exists and has the correct password and required privileges. If it detects any problems, it prompts for manager credentials to rectify them.

If you want the `prepare-external-server` tool to add the LDAP external server's certificates to the Directory Proxy Server's trust store, you must include the `--proxyTrustStorePath` option, and either the `--proxyTrustStorePassword` or the `--proxyTrustStorePasswordFile` option. The default location of the Directory Proxy Server trust store is `config/truststore`. The pin is encoded in the `config/truststore.pin` file.

For example, run the tool as follows to prepare a PingDirectory Server on the remote host, `ds-east-01.example.com`, listening on port 1389 for access by the Directory Proxy Server using the default user account `cn=Proxy User`:

```
prepare-external-server --hostname ds-east-01.example.com \
--port 1389 --baseDN dc=example,dc=com --proxyBindPassword secret
```

When the `prepare-external-server` command above is executed, it creates the `cn=Proxy User` Root DN entry as well as an access control rule in the Directory Server to grant the proxy user the proxy access right.

**Note:** For non-Ping Identity servers, the `--baseDN` argument is required for the `prepare-external-server` tool. The base DN is used to create the global ACI entries for these servers.

### To Configure Server Communication Using the `prepare-external-server` Tool

About this task

The following example illustrates how to run the `prepare-external-server` tool to prepare a Directory Server on the remote host, `ds-east-01.example.com`, listening on port 1636. The Directory Server is being accessed by a Directory Proxy Server that uses the default user account `cn=Proxy User,cn=Root DNs,cn=config`. Since a password to the truststore is not provided, the truststore defined in the `--proxyTrustStorePath` is referenced in a read-only manner.

## Steps

- Use the **prepare-external-server** tool to prepare the Directory Server. Follow the prompts to set up the external server.

```
$./PingDirectoryProxy/bin/prepare-external-server \
--baseDN dc=example,dc=com \
--proxyBindPassword password \
--hostname ds-east-01.example.com \
--useSSL \
--port 1636 \
--proxyTrustStorePath /full/path/to/trust/store \
--proxyTrustStorePassword secret
```

```
Testing connection to ds-east-01.example.com:1636
```

```
Do you wish to trust the following certificate?
```

```
Certificate Subject: CN=ds-east-01.example.com, O=Example Self-Signed
Certificate
```

```
Issuer Subject: CN=ds-east-01.example.com, O=Example Self-Signed
Certificate
```

```
Validity: Thu May 21 08:02:30 CDT 2009 to Wed May 16 08:02:30 CDT
2029
```

```
Enter 'y' to trust the certificate or 'n' to reject it.
```

```
y
```

```
The certificate was added to the local trust store
```

```
Done
```

```
Testing 'cn=Proxy User' access to ds-east-01.example.com:1636 Failed
to bind as
'cn=Proxy User'
```

```
Would you like to create or modify root user 'cn=Proxy User' so that it is
available
for this Directory Proxy Server? (yes / no) [yes]:
```

```
Enter the DN of an account on ds-east-01.example.com:1636 with which to
create or
manage the 'cn=Proxy User' account [cn=Directory Manager]:
```

```
Enter the password for 'cn=Directory Manager':
```

```
Created 'cn=Proxy User,cn=Root DNs,cn=config'
```

```
Testing 'cn=Proxy User' privileges Done
```

## To Configure an External Server Using dsconfig

### Steps

1. Use the **dsconfig** tool to create and configure external servers. Then, specify the host name, connection method, port number, and bind DN as described in previous procedures.

```
$ bin/dsconfig
```

2. In the Directory Proxy Server main menu, enter the number corresponding to external servers. Then, enter the number to create a new external server.

**3. Select the type of server you want to create. This example creates a new Ping Identity Directory Server.**

```
>>>> Select the type of external server that you want to create:
```

- 1) Ping Identity DS external server
- 2) JDBC external server
- 3) LDAP external server
- 4) Sun DS external server
  
- ?) help
- c) cancel
- q) quit

```
Enter choice [c]: 1
```

**4. Specify a name for the new external server. In this example, the external server is named east1.**

```
>>>> Enter a name for the Ping Identity DS external server that you want
to create: east1
```

**5. Configure the host name or IP address of the target LDAP external server.**

```
Enter a value for the 'server-host-name' property: east1.example.com
```

**6. Next, configure the location property of the new external server.**

```
Do you want to modify the 'location' property?
```

- 1) Leave undefined
- 2) Change it to the location: East
- 3) Change it to the location: West
- 4) Create a new location
  
- ?) help
- q) quit

```
Enter choice [1]: 2
```

**7. Next, define the bind DN and bind password.**

```
Do you want to modify the 'bind-dn' property?
```

- 1) Leave undefined
- 2) Change the value
  
- ?) help
- q) quit

```
Enter choice [1]: 2
```

```
Enter a value for the 'bind-dn' property [continue]: cn=Proxy User,cn=Root
DNs,cn=config
```

```
Enter choice [b]: 6
```

```
...
```

```
Do you want to modify the 'password' property?
```

- 1) Leave undefined
- 2) Change the value
- ?) help
- q) quit

```
Enter choice [1]: 2
Enter a value for the 'password' property [continue]:
Confirm the value for the 'password' property:
```

8. Enter `f` to finish the operation.

```
Enter choice [b]: f
```

```
The Ping Identity DS external server was created successfully.
```

Once you have completed adding the server, run the **prepare-external-server** tool to configure communications between the Directory Proxy Server and the Ping Identity Directory Server(s).

## To Configure Authentication with a SASL External Certificate

### About this task

By default, the Directory Proxy Server authenticates to the Directory Server using LDAP simple authentication (with a bind DN and a password). However, the Directory Proxy Server can be configured to use SASL EXTERNAL to authenticate to the Directory Server with a client certificate.

Have Directory Proxy Server instances installed and configured to communicate with the backend Directory Server instances using either SSL or StartTLS. After the servers are configured, perform the following steps to configure SASL EXTERNAL authentication.

### Steps

1. Create a JKS keystore that includes a public and private key pair for a certificate that the Directory Proxy Server instance(s) will use to authenticate to the Directory Server instance(s). Run the following command in the instance root of one of the Directory Proxy Server instances. When prompted for a keystore password, enter a strong password to protect the certificate. When prompted for the key password, press **ENTER** to use the keystore password to protect the private key:

```
$ keytool -genkeypair \
 -keystore config/proxy-user-keystore \
 -storetype JKS \
 -keyalg RSA \
 -keysize 2048 \
 -alias proxy-user-cert \
 -dname "cn=Proxy User,cn=Root DNs,cn=config" \
 -validity 7300
```

2. Create a **config/proxy-user-keystore.pin** file that contains a single line that is the keystore password provided in the previous step.
3. If there are other Directory Proxy Server instances in the topology, copy the **proxy-user-keystore** and **proxy-user-keystore.pin** files into the **config** directory for all instances.
4. Use the following command to export the public component of the proxy user certificate to a text file:

```
$ keytool -export \
 -keystore config/proxy-user-keystore \
 -alias proxy-user-cert \
 -file config/proxy-user-cert.txt
```

5. Copy the **proxy-user-cert.txt** file into the **config** directory of all Directory Server instances. Import that certificate into each server's primary trust store by running the following command from the server root. When prompted for the keystore password, enter the password contained in the **config/truststore.pin** file. When prompted to trust the certificate, enter **yes**.

```
$ keytool -import \
 -keystore config/truststore \
 -alias proxy-user-cert \
```

```
-file config/proxy-user-cert.txt
```

- Update the configuration for each Directory Proxy Server instance to create a new key manager provider that will obtain its certificate from the `config/proxy-user-keystore` file. Run the following `dsconfig` command:

```
$ dsconfig create-key-manager-provider \
 --provider-name "Proxy User Certificate" \
 --type file-based \
 --set enabled:true \
 --set key-store-file:config/proxy-user-keystore \
 --set key-store-type:JKS \
 --set key-store-pin-file:config/proxy-user-keystore.pin
```

- Update the configuration for each LDAP external server in each Directory Proxy Server instance to use the newly-created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication. Run the following `dsconfig` command:

```
$ dsconfig set-external-server-prop \
 --server-name ds1.example.com:636 \
 --set authentication-method:external \
 --set "key-manager-provider:Proxy User Certificate"
```

### Results

After these changes, the Directory Proxy Server should re-establish connections to the LDAP external server and authenticate with SASL EXTERNAL. Verify that the Directory Proxy Server is still able to communicate with all backend servers by running the `bin/status` command. All of the servers listed in the "--- LDAP External Servers ---" section should be available. Review the Directory Server access log can to make sure that the BIND RESULT log messages used to authenticate the connections from the Directory Proxy Server include `authType="SASL"`, `saslMechanism="EXTERNAL"`, `resultCode=0`, and `authDN="cn=Proxy User,cn=Root DNs,cn=config"`.

## Configuring Load Balancing

You can distribute the load on your Directory Proxy Server using one of the load-balancing algorithms provided with PingDirectoryProxy Server. By default, the Directory Proxy Server prefers local servers over non-local servers, unless you set the `use-location` property of the load-balancing algorithm to false. Within a given location, the Directory Proxy Server prefers available servers over degraded servers. This means that if at all possible, the Directory Proxy Server sends requests to servers that are local and available before considering selecting any server that is non-local or degraded.

**Note:** If the `use-location` property is set to true, then the load is balanced only among available external servers in the same location. If no external servers are available in the same location, the Directory Proxy Server will attempt to use available servers in the first preferred failover location, and so on. The failover based on no external servers with AVAILABLE health state can be customized to allow the Directory Proxy Server to prefer local DEGRADED health servers to servers in a failover location. See the online *PingDirectoryProxy Server Configuration Reference Guide* for more information on the `prefer-degraded-servers-over-failover` property.

The Directory Proxy Server provides the following load-balancing algorithms:

- Failover load balancing.** This algorithm forwards requests to servers in a given order, optionally taking the location into account. If the preferred server is not available, then it will fail over to the alternate server in a predefined order. This balancing method can be useful if certain operations, such as LDAP writes, need to be forwarded to a primary external server, with secondary external servers defined for failover if necessary.

This algorithm also offers load spreading to multiple failover servers. If the failover load-balancing algorithm is configured with one or more load-spreading base DNs, then requests that target entries below a load-spreading base DN can be balanced across any of the servers with the same health check

state and location. Requests targeting a specific portion of the data will consistently be routed to the same server, but requests targeting a different portion of the data may be sent to a different server.

- **Fewest operations load balancing.** This algorithm forwards requests to the backend server with the fewest operations currently in progress and tends to exhibit the best performance.
- **Health weighted load balancing.** This algorithm assigns weights to servers based on their health scores and, optionally, their locations. For example, servers with a higher health check score will receive a higher proportion of the requests than servers with lower health check scores.
- **Single server load balancing.** This algorithm forwards all operations to a single external server that you specify.
- **Weighted load balancing.** This algorithm uses statically defined weights for sets of servers to divide load among external servers. External servers are grouped into weighted sets, the values of which, when added to all of the weighted sets for the load balancing algorithm, represent a percentage of the load the external servers should receive.
- **Criteria based load balancing.** This algorithm allows you to balance your load across a server topology depending on the types of operations received or the client issuing the request.

For example, ds1 and ds2 are assigned to a weighted set named Set-80 and assigned the weight 80. The external servers ds3 and ds4 are assigned to the weighted set Set-20 and assigned the weight 20. When both sets, Set-80 and Set-20, are assigned to the load balancing algorithm, 80 percent of the load will be forwarded to ds1 and ds2, while the remaining 20 percent will be forwarded to ds3 and ds4.

### Configure Failover Load-balancing for Load Spreading

If the failover load-balancing algorithm is configured with one or more load-spreading base DNs, then requests that target entries below a load-spreading base DN may be balanced across any of the servers with the same health check state and location. Requests targeting a specific portion of the data will consistently be routed to the same server, but requests targeting a different portion of the data may be sent to a different server.

Load spreading is useful for deployments in which the DIT contains a large number of branches below a common parent, and in which most operations (including search operations, as indicated by the search base DN) only target entries at least one level below that common parent. For example, this may be useful for a multi-tenant deployment in which all of the entries for a given tenant are within their own branch, and all of the tenant branches reside below a common parent.

Load spreading is configured with the `load-spreading-base-dn` property. The value(s) of this property are the base DN(s) below which the tenant entries reside. For example, in a deployment with a DIT like the following, the `load-spreading-base-dn` value would be set to `ou=customers,dc=example,dc=com`:

- `dc=example,dc=com`
  - `ou=customers,dc=example,dc=com`
    - `ou=Customer 1,ou=customers,dc=example,dc=com`
    - `ou=Customer 2,ou=customers,dc=example,dc=com`
    - `ou=Customer 3,ou=customers,dc=example,dc=com`
    - ...

If the `load-spreading-base-dn` property is not configured, the failover load-balancing algorithm will use the default behavior. If the property is configured with one or more values, but a client requests an operation that targets an entry that is not below any of the configured base DNs, then that operation will be handled using the default behavior. When the `load-spreading-base-dn` property is configured with one or more values, the load-balancing algorithm will continue to generate the same list of lists, but the order of the servers within each list will be determined using the following algorithm:

1. If the list is empty or contains only a single item, then leave it unchanged and skip the remaining steps.
2. Identify the RDN component from the target entry DN that is exactly one level below one of the `load-spreading-base-dn` values. If the targeted entry is not below any of the configured `load-`

**spreading-base-dn** values, then the order of servers in each of those lists will be based only on the order in which they appear in the load-balancing algorithm's **backend-server** property. The remaining steps are skipped.

3. Compute a SHA-1 digest from the normalized string representation of the identified RDN component. SHA-1 is notably faster than more secure digest algorithms, and it does a very good job at distributing bits across the entire range of the 160 bits that it generates.
4. Create a non-negative integer from the last 31 bits of the computed SHA-1 digest.
5. Compute a modulus using the integer value as the dividend, and the number of servers in the current list as the divisor. This will yield an integer value that is between 0 and (list.size() - 1), inclusive.
6. If the modulus computed is equal to zero, no further action is necessary. If not, move a number of servers equal to the computed modulus from the beginning of the list to the end of the list. The order of the elements that are moved should be preserved.

For example, consider a **load-spreading-base-dn** value of

`"ou=customers,dc=example,dc=com"`, a list that contains three servers (ds1, ds2, and ds3, in that order), and a modify request that targets the entry with DN

`"uid=jdoe,ou=People,ou=Acme,ou=customers,dc=example,dc=com"`. The RDN component immediately below the **load-spreading-base-dn** is `"ou=Acme"`. The normalized string representation of that RDN component is `"ou=acme"`, and the hexadecimal representation of the SHA-1 digest of that is `"f0c69713535daf8816038f1bceab70380c92b83e"`. The last 31 bits of that SHA-1 digest are 0c92b83e hex, which is 210942014. With 210942014 modulo 3 is 2, which means that the first two servers are moved from the beginning of the list to the end of the list, resulting in an order of ds3, ds1, ds2.

While this algorithm will spread the load across multiple backend servers, it does not mean that there will be an even distribution of the load across all of those servers. The load-balancing algorithm will still prioritize based on location and health check state, so the load will generally be spread only across the available servers in the same location as the Directory Proxy Server. Second, assuming that the entries that are immediate children of a **load-spreading-base-dn** are the tops of the branches that define tenants, some tenants will still be targeted more heavily than others (because they have more entries, or because their entries are accessed more frequently). The modulo operation may therefore not result in an even distribution across those servers.

## To Configure Load Balancing Using dsconfig

### Steps

1. Use the **dsconfig** tool to create and configure a load-balancing algorithm.

```
$ bin/dsconfig
```

Specify the host name, connection method, port number, and bind DN as described in previous procedures.

2. In the Directory Proxy Server main menu, enter the number associated with load-balancing algorithms.
3. Select an existing load-balancing algorithm to use as a template or select n to create a new load-balancing algorithm from scratch.

```
>>>>Choose how to create the new Load Balancing Algorithm:
```

```
n) new Load Balancing Algorithm created from scratch
t) use an existing Load Balancing Algorithm as a template
b) back
q) quit
```

```
Enter a choice [n]: n
```

4. Select the type of load-balancing algorithm that you want to create. Depending on type of algorithm you select, you will be guided through a series of configuration properties, such as providing a name and selecting an LDAP external server.

```
>>>> Select the type of Load Balancing Algorithm that you want to
create:
```

- ```

1)  Failover Load Balancing Algorithm
2)  Fewest Operations Load Balancing Algorithm
3)  Health Weighted Load Balancing Algorithm
4)  Single Server Load Balancing Algorithm
5)  Weighted Load Balancing Algorithm

?)  help
c)  cancel
q)  quit
```

```
Enter choice [c]: 3
```

5. Review the configuration properties for your new load-balancing algorithm. If you are satisfied, enter `f` to finish.

Configuring Criteria-Based Load-Balancing Algorithms

You can configure alternate load-balancing algorithms that determine how they function according to request or connection criteria. These algorithms allow you to balance your load across a server topology depending on the types of operations received or the client issuing the request. They are called criteria-based load-balancing algorithms and are configured using at least one connection criteria or request criteria. For example, you can configure criteria-based load-balancing algorithms to accomplish the following:

- Route write operations to a single server from a set of replicated servers, to prevent replication conflicts, while load balancing all other operations across the full set of servers.
- Route all operations from a specific client to a single server in a set of replicated servers, eliminating errors that arise from replication latency, while load balancing operations from other clients across the full set of servers. This configuration is useful for certain provisioning applications that need to write and then immediately read the same data.

When a request is received, the proxying request processor first iterates through all of the criteria-based load-balancing algorithms in the order in which they are listed, to determine whether the request matches the associated criteria. If there is a match, then the criteria-based load-balancing algorithm is selected. If there is not a match, then the default load-balancing algorithm is used.

Preferring Failover LBA for Write Operations

An administrator can configure the Directory Proxy Server to use Criteria-Based Load-Balancing Algorithms to strike a balance between providing a consistent view of directory server data for applications that require it and taking advantage of all servers in a topology for handling read-only operations, such as search and bind. The flexible configuration model supports a wide range of criteria for choosing which Load-Balancing Algorithm to use for each operation. In most Directory Proxy Server deployments, using a Failover Load-Balancing Algorithm for at least ADD, DELETE, and MODIFY-DN operations if not for all types of write operations is recommended.

Each Proxying Request Processor configured in the Directory Proxy Server uses a Load-Balancing Algorithm to choose which Directory Server to use for a particular operation. The Load-Balancing Algorithm takes several factors into account when choosing a server:

- The availability of the directory servers.
- The location of the directory servers. By default Load-Balancing Algorithms prefer directory servers in the same location as the Directory Proxy Server.
- Whether the Directory Server is degraded for any reason, such as having a Local DB Index being rebuilt.

- The result of configured Health Checks. For instance, a server with a small replication backlog can be preferred over one with a larger backlog.
- Recent operation routing history.

How these factors are used depends on the specific Load-Balancing Algorithm. The two most commonly used Load-Balancing Algorithms are the Failover Load-Balancing Algorithm and the Fewest Operations Load-Balancing Algorithm. These two algorithms are similar when determining which Directory Servers are the possible candidates for a specific operation. The algorithms use the same criteria to determine server availability and health, and by default they will prefer Directory Servers in the same location as the Directory Proxy Server. However, they differ in the criteria they use to choose between available servers.

The Failover Load-Balancing Algorithm will send all operations to a single server until it is unavailable, and then it will send all operations to the next preferred server, and so on. This algorithm provides the most consistent view of the topology to clients because all clients (at least those in the same location as the Directory Proxy Server) will see the same, up-to-date view of the data, but it leaves unused capacity in the failover instances since most topologies include multiple Directory Server replicas within each data center.

On the other hand, the Fewest Operations Load-Balancing Algorithm does the best job of efficiently distributing traffic among multiple servers since it chooses to send each operation to the server that has the fewest number of outstanding operations--that is, the server from the Directory Proxy Server's point of view that is the least busy. (Note: the Fewest Operations Load-Balancing Algorithm routes traffic to the least loaded server, which in a lightly-loaded environment can result in an imbalance since the first server in the list of configured servers is more likely to receive a request.) This algorithm naturally routes to servers that are more responsive as well as limiting the impact of servers that have become unreachable. However, this implies that consecutive operations that depend on each other can be routed to different Directory Servers, which can cause issues for some types of clients:

- If two entries are added in quick succession where the first entry is the parent of the second in the LDAP hierarchy, then the addition of the child entry could fail if that operation is routed to a different Directory Server instance than the first ADD operation, and this happens within the replication latency.
- Some clients add or modify an entry and then immediately read the entry back from the server, expecting to see the updates reflected in the entry.

In these situations, it is desirable to configure the `<keyword keyref="PROXY_SERVER_BASE_NAME"/>` to route dependent requests to the same server.

The server affinity feature (see [Configuring Server Affinity](#)) achieves this in some environments but not in all because the affinity is tracked independently by each Directory Proxy Server instance, and some clients send requests to multiple proxies. It is common for a client to not connect to the Directory Proxy Servers directly but instead to connect through a network load balancer, which in turn opens connections to the Directory Proxy Servers. Each individual client connection will be established to a single Directory Proxy Server so that operations on that connection will be routed to the same Directory Proxy Server, and server affinity configured within the Directory Proxy Server will ensure those operations will be routed to the same Directory Server. However, many clients establish a pool of connections that are reused across operations, and within this pool, connections will be established through the load balancer to different Directory Proxy Servers. Dependent operations sent on different connections could then be routed to different Directory Proxy Servers, and then on to different Directory Servers.

A Failover Load-Balancing Algorithm addresses this issue by routing all requests to a single server, but that leaves unused search capacity on the other instances. A Criteria Based Load-Balancing Algorithm enables the proxy to route certain types of requests (or requests from certain clients) using a different Load-Balancing Algorithm than the default. For instance, all write operations (i.e., ADD, DELETE, MODIFY, and MODIFY-DN) could be routed using a Failover Load-Balancing Algorithm, while all other operations (bind, search, and compare) use a Fewest Operations Load-Balancing Algorithm. And in addition, if there are clients that are particularly sensitive to reading entries immediately after modifying them, additional Connection Criteria can be specified to all operations from those clients using the Failover Load-Balancing Algorithm. Note that, routing all write requests to a single server in a location instead of evenly across servers does not limit the overall throughput of the system since all servers ultimately have to process all write operations either from the client directly or via replication.

Another benefit of using the Failover Load-Balancing Algorithm for write operations is reducing replication conflicts. The Ping Identity Directory Server follows the traditional LDAP replication model of eventual consistency. This provides very high availability for handling write traffic even in the presence of network partitions, but it can lead to replication conflicts. Replication conflicts involving modify operations can be automatically resolved, leaving the servers in a consistent state where each attribute on each entry reflects the most recent update to that attribute. However, conflicts involving ADD, DELETE, and MODIFY-DN operations cannot always be resolved automatically and can require manual involvement from an administrator. By routing all write operations (or at least ADD, DELETE, and MODIFY-DN operations) to a single server, replication conflicts can be avoided.

There are a few points to consider when using a Failover Load-Balancing Algorithm:

- When using the Failover Load-Balancing Algorithm in a configuration with multiple locations, the Load-Balancing Algorithm will fail over between local instances before failing over to servers in a remote location. The list of servers in the `backend-server` configuration property of the Load-Balancing Algorithm should be ordered such that preferred local servers should appear before failover local servers, but the relative order of servers in different locations is unimportant as the `preferred-failover-location` of the Directory Proxy Server's configuration is used to decide which remote location to fail over to. It is also advisable that the order of local servers match the `gateway-priority` configuration settings of the "Replication Server" configuration object on the Directory Server instances. This can reduce the WAN replication delay because the Directory Proxy Server will then prefer to send writes to the Directory Server with the WAN Gateway role, avoiding an extra hop to the remote locations.
- For Directory Proxy Server configurations that include multiple Proxying Request Processors, including Entry-Balancing environments, each Proxying Request Processor should be updated to include its own Criteria-Based Load-Balancing Algorithm.

To Route Operations to a Single Server

About this task

The following example shows how to extend a Directory Proxy Server's configuration to use a Criteria Based Load Balancing Algorithm to route all write requests to a single server using a Failover Load Balancing Algorithm. The approach outlined here can easily be extended to support alternate criteria as well as more complex topologies using multiple locations or Entry Balancing.

This example uses a simple deployment of a Directory Proxy Server fronting three Directory Servers: `ds1.example.com`, `ds2.example.com`, and `ds3.example.com`.

Once these configurations changes are applied, the Directory Proxy Server will route all write operations to `ds1.example.com` as long as it is available and then to `ds2.example.com` if it is not, while routing other types of operations, such as searches and binds, to all three servers using the Fewest Operations Load Balancing Algorithm.

Steps

1. First, create a location.

```
dsconfig create-location --location-name Austin
```

2. Update the failover location for your server.

```
dsconfig set-location-prop --location-name Austin
```

3. Set the location as a global configuration property.

```
dsconfig set-global-configuration-prop --set location:Austin
```

4. Set up the health checks for each external server.

```
dsconfig create-ldap-health-check \
--check-name ds1.example.com:389_dc_example_dc_com-search-health-check \
```

```
--type search --set enabled:true --set base-dn:dc=example,dc=com

dsconfig create-ldap-health-check \
--check-name ds2.example.com:389_dc_example_dc_com-search-health-check \
--type search --set enabled:true --set base-dn:dc=example,dc=com

dsconfig create-ldap-health-check \
--check-name ds3.example.com:389_dc_example_dc_com-search-health-check \
--type search --set enabled:true --set base-dn:dc=example,dc=com
```

5. Create the external servers.

```
dsconfig create-external-server --server-name ds1.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds1.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADoPkhx22qpiBQJ7T0X4wH7 \
--set health-check:ds1.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds2.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds2.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AAAvqVYsEavey80T0QfR60I \
--set health-check:ds2.example.com:389_dc_example_dc_com-search-health-check

dsconfig create-external-server --server-name ds3.example.com:389 \
--type Ping Identity-ds \
--set server-host-name:ds3.example.com --set server-port:389 \
--set location:Austin --set "bind-dn:cn=Proxy User,cn=Root DNs,cn=config" \
--set password:AADOkveb0TtYR9xpkVrNgMtF \
--set health-check:ds3.example.com:389_dc_example_dc_com-search-health-check
```

6. Create a Load Balancing Algorithm for dc=example,dc=com.

```
dsconfig create-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-fewest-operations \
--type fewest-operations --set enabled:true \
--set backend-server:ds1.example.com:389 \
--set backend-server:ds2.example.com:389 \
--set backend-server:ds3.example.com:389
```

7. Create a Request Processor for dc=example,dc=com.

```
dsconfig create-request-processor \
--processor-name dc_example_dc_com-req-processor \
--type proxying \
--set load-balancing-algorithm:dc_example_dc_com-fewest-operations
```

8. Create a Subtree View for dc=example,dc=com.

```
dsconfig create-subtree-view \
--view-name dc_example_dc_com-view \
--set base-dn:dc=example,dc=com \
--set request-processor:dc_example_dc_com-req-processor
```

9. Update the client connection policy for dc=example,dc=com.

```
dsconfig set-client-connection-policy-prop \
--policy-name default \
--add subtree-view:dc_example_dc_com-view
```

10. Create a new Request Criteria object to match all write operations.

```
dsconfig create-request-criteria \
--criteria-name any-write \
--type simple --set "description:All Write Operations" \
--set operation-type:add --set operation-type:delete \
--set operation-type:modify --set operation-type:modify-dn
```

11. Create a new Failover Load Balancing Algorithm listing the servers that should be included. Note the order that the servers are listed here is the failover order between servers.

```
dsconfig create-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-failover \
--type failover --set enabled:true \
--set backend-server:ds1.example.com:389 \
--set backend-server:ds2.example.com:389 \
--set backend-server:ds3.example.com:389
```

12. Tie the Request Criteria and the Failover Load Balancing Algorithm together into a Criteria Based Load Balancing Algorithm.

```
dsconfig create-criteria-based-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-write-traffic-lba \
--set "description:Failover LBA For All Write Traffic" \
--set request-criteria:any-write \
--set load-balancing-algorithm:dc_example_dc_com-failover
```

13. Update the Proxying Request Processor to use the Criteria Based Load Balancing Algorithm.

```
dsconfig set-request-processor-prop \
--processor-name dc_example_dc_com-req-processor \
--set criteria-based-load-balancing-algorithm:dc_example_dc_com-write-traffic-lba
```

To Route Operations from a Single Client to a Specific Set of Servers

About this task

To create a type of server affinity, where all operations from a single client are routed to a specific set of servers, follow a similar process as in the previous use case. Instead of request criteria, configure connection criteria. These connection criteria identify clients that could be adversely affected by replication latency. These clients will use the Failover Load Balancing Algorithm rather than the default Fewest Operations Load Balancing Algorithm.

For example, an administrative tool includes a "delete user" function. If the application immediately re-queries the directory for an updated list of users, the just-deleted entry must not be included. To configure a criteria-based load balancing algorithm to support this use case, perform the following:

- Create a failover load balancing algorithm that lists the same set of servers as the existing fewest operation load balancing algorithm.
- Create connection criteria that match the clients for which failover load balancing should be applied, rather than fewest operations load balancing.
- Create a criteria-based load balancing algorithm that references the two configuration objects created in the previous steps.
- Assign the new load balancing algorithm to the proxying request processor.

The following procedure provides examples of each of these steps.

Steps

1. Create the new failover load balancing algorithm using `dsconfig` as follows:

```
dsconfig create-load-balancing-algorithm \
```

```
--algorithm-name client_one_routing_algorithm \
--type failover --set enabled:true \
--set backend-server:east1.example.com:389 \
--set backend-server:east2.example.com:389
```

2. To route operations from a single client to a single server in a set of replicated servers, create connection criteria using **dsconfig** as follows:

```
dsconfig create-connection-criteria \
--criteria-name "Client One" --type simple \
--set included-user-base-dn:cn=Client One,ou=Apps,dc=example,dc=com
```

3. Configure a criteria-based load balancing algorithm and assign it to the proxying request processor. Use the load balancing algorithm and connection criteria created in the previous steps:

```
dsconfig create-criteria-based-load-balancing-algorithm \
--algorithm-name dc_example_dc_com-client-operations \
--set load-balancing-algorithm:dc_example_dc_com-failover \
--set "request-criteria:Client One Requests"
```

4. Assign the new criteria-based load balancing algorithm to the proxying request processor using **dsconfig** as follows:

```
dsconfig set-request-processor-prop \
--processor-name dc_example_dc_com-req-processor \
--add criteria-based-load-balancing-algorithm:dc_example_dc_com-client-operations
```

Understanding Failover and Recovery

Once a previously degraded or unavailable server has recovered, it should be eligible to start receiving traffic within the time configured for the `health-check-frequency` property, 30 seconds by default. However, failover and recovery also depend on the load-balancing algorithm in use.

The load-balancing algorithm provides an ordered list of servers to check, with the number of servers in the list based on the maximum number of retry attempts. The server checks to see if affinity should be used and, if so, whether an affinity is set for that load-balancing algorithm. If there is an affinity to a particular server and that server is classified as available, then that server will always be the first in the list.

Next, the Directory Proxy Server creates a two-dimensional matrix of servers based on the health check state (with available preferred over degraded and unavailable not considered at all) and location (with backend servers in the same location as the Directory Proxy Server most preferred, then servers in the first failover location, then the second, and so on). Within each of these sets, and ideally at least one server in the local data center is classified as available, the load-balancing algorithm selects the servers in the order of most preferred to least preferred based on whatever logic the load-balancing algorithm uses. The load-balancing algorithm keeps selecting servers until enough of them have been selected to satisfy the maximum number of possible retries.

The load-balancing algorithm includes a configuration option that allows you to decide whether to prefer location over availability and vice-versa. For example, is a local degraded server more or less preferred than a remote available server? By default, the algorithm will prefer available servers over degraded ones, even if it has to go to another data center to access them. You can change the load-balancing algorithm to try to stay in the same data center if at least one server is not unavailable.

The Directory Proxy Server does both proactive and reactive health checking. With proactive health checking, the Directory Proxy Server will periodically (by default, every 30 seconds), run a full set of tests against each backend server. The result of these tests will be used to determine the overall health check state (available, degraded, or unavailable) and score (and integer value from 10 to 0). With reactive health checking, the Directory Proxy Server may kick off a lesser set of health checks against a server if an operation forwarded to that server did not complete successfully.

Proactive health checking can be used to promote and demote the health of a server, but reactive health checking can only be used to demote the health of a server. As a result, if a server is determined to be

unavailable, then it will remain that way until a subsequent proactive health check determines that it has recovered. If a server is determined to be degraded, it may not become available until the next proactive health check, but it could be downgraded to unavailable by a reactive check if other failures are encountered against that server.

Both proactive and reactive health check assignments take effect immediately and will be considered for all subsequent requests routed to the load-balancing algorithm. If a server is considered degraded, then it will immediately be considered less desirable than available servers in the same data center, and possibly less desirable than available servers in more remote data centers. If a server is considered unavailable, then it will not be eligible to be selected until it is reclassified as available or degraded.

Configuring HTTP Connection Handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire Directory Proxy Server from starting. The Directory Proxy Server's `start-server` tool will output any errors to the error log. This allows the Directory Proxy Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include:

- **listen-address.** Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.
- **listen-port.** Specifies the port on which the connection handler will listen for requests from clients. Required.
- **use-ssl.** Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.
- **http-servlet-extension.** Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.
- **http-operation-log-publisher.** Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.
- **key-manager-provider.** Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.
- **trust-manager-provider.** Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.
- **num-request-handlers.** Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.
- **web-application-extension.** Specifies the Web applications to be hosted by the server.

To Configure an HTTP Connection Handler

About this task

An HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, an HTTP log publisher. The HTTP servlet extension and log publisher must be configured prior to configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the `ExampleHTTPServletExtension` in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like `listen-port`, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
  --handler-name "Hello World HTTP Connection Handler" \
  --type http \
  --set enabled:true \
  --set listen-port:8443 \
  --set use-ssl:true \
  --set "http-servlet-extension:Hello World Servlet" \
  --set "http-operation-log-publisher:HTTP Common Access Logger" \
  --set "http-operation-log-publisher:HTTP Detailed Access Logger" \
  --set "key-manager-provider:JKS" \
  --set "trust-manager-provider:JKS"
```

4. By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to `TRUE` by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP Correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which may be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be

challenging, as log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID may also be passed to the LDAP subsystem. For the SCIM 1, Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest`'s `com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configure HTTP Correlation ID Support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:false
```

Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to "X-Request-Id."

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set correlation-id-response-header:X-Request-Id
```

Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that may be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
  --set correlation-id-request-header:X-Request-Id \
  --set correlation-id-request-header:X-Correlation-Id \
  --set correlation-id-request-header:Correlation-Id \
```

```
--set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP Correlation ID Example Use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a Correlation-Id header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

{
  "_dn": "uid=user.86,ou=People,dc=example,dc=com",
  "_links": {
    "schemas": [
      {
        "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
      }
    ],
    "self": {
      "href": "https://localhost:1443/directory/v1/
uid=user.86,ou=People,dc=example,dc=com"
    }
  },
  "mail": [
    "user.86@example.com"
  ]
}
```

This correlation ID can be used to search the HTTP trace log for matching log records, as follows:

```
$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

Configuring Proxy Transformations

The PingDirectoryProxy Server provides proxy transformations to alter the contents of client requests as they are sent from the client to the LDAP external server. Proxy transformations can also be used to alter the responses sent back from the server to the client, including altering or omitting search result entries. The Directory Proxy Server provides the following types of data transformations:

- **Attribute mapping.** This transformation rewrites client requests so that references to one attribute type may be replaced with an alternate attribute type. The Directory Proxy Server can perform extensive replacements, including attribute names used in DNs and attribute names encoded in the values of a number of different controls and extended operations. For example, a client requests a `userid` attribute, which is replaced with `uid` before being forwarded on to the backend server. This mapping applies in reverse for the response returned to the client.
- **Default value.** This transformation instructs the Directory Proxy Server to include a static attribute value in search results being sent back to the client, in ADD requests being forwarded to an external server, or both. For example, a value of "marketing" for `businessCategory` could be returned for all search results under the base DN `ou=marketing,dc=example,dc=com`.
- **DN mapping.** This transformation rewrites client requests so that references to entries below a specified DN will be mapped to appear below another DN. For example, references to entries below `o=example.com` could be rewritten so that they are below `dc=example,dc=com` instead. The mapping applies in reverse for the response returned to the client.
- **Groovy scripted.** This custom transformation is written in Groovy and does not need to be compiled, though they use the Server SDK. These scripts make it possible to alter requests and responses in ways not available using the transformations provided with the Directory Proxy Server.
- **Suppress attribute.** This proxy transformation allows you to exclude a specified attribute from search result entries. It also provides the ability to reject add, compare, modify, modify DN, or search requests if they attempt to reference the target attribute.
- **Suppress entry.** This proxy transformation allows you to exclude any entries that match a specified filter from a set of search results. Search requests are transformed so that the original filter will be ANDed with a NOT filter containing the exclude filter. For example, if the suppression filter is `"(objectClass=secretEntry)"`, then a search request with a filter of `"(uid=john.doe)"` will be transformed so that it has a filter of `"(&(uid=john.doe)!(objectClass=secretEntry))"`.
- **Simple to external bind.** This proxy transformation may be used to intercept a simple bind request and instead process the bind as a SASL EXTERNAL bind. If the SASL EXTERNAL bind fails, then the original simple bind request may or may not be processed, depending on how you configure the server.
- **Third-party scripted.** This custom transformation is created using the Server SDK, making it possible to alter requests and responses in ways not available using the transformations provided with the Directory Proxy Server.

To Configure Proxy Transformations Using dsconfig

Steps

1. Use the `dsconfig` tool to create and configure a proxy transformation.

```
$ bin/dsconfig
```

2. Enter the connection parameters (for example, host name, port, bind DN and bind DN password).
3. In the Directory Proxy Server main menu, enter the number associated with proxy transformations. On the Proxy Transformation menu, enter the number to create a new proxy transformation.
4. Select the type of proxy transformation you want to create. In this example, we create an attribute mapping transformation. Then, enter a name for the new transformation.

```
>>>> Enter a name for the Attribute Mapping Proxy Transformation that you
want to create: userid-to-uid
```

5. Indicate whether you want the transformation to be enabled by default.

```
Select a value for the 'enabled' property:
```

```
1) true
2) false

?) help
c) cancel
```

```
q) quit
```

```
Enter choice [c]: 1
```

- Specify the name of the client attribute that you want to remap to a target attribute. Note that this attribute must not be equal to the target attribute.

```
Enter a value for the 'source-attribute' property: userid
```

- Specify the name of the target attribute to which the client attribute should be mapped.

```
Enter a value for the 'target-attribute' property: uid
```

- The properties of your new proxy transformation are displayed. If you want to make any further modifications, enter the number corresponding to the property. Enter `f` to finish the creation of the proxy transformation.

```
Enter choice [b]: f
```

The transformation now needs to be assigned to a request processor. To create an initial request processor, see the next section.

Configuring Request Processors

A request processor is responsible for handling client requests by passing the request through a load-balancing algorithm or one or more subordinate request processors. The request processor is also the Directory Proxy Server component that performs proxy transformations. You can create one of the following types of request processors:

- **Proxying request processor.** This request processor is responsible for passing allowed operations through a load balancing algorithm. Proxy transformations can be applied to requests and responses that are processed. Multiple servers may be configured to provide high availability and load balancing, and various transformations may be applied to the requests and responses that are processed.
- **Entry-balancing request processor.** This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. This request processor uses multiple, subordinate proxying request processors to process operations and maintains in-memory indexes to speed the processing of specific search and modify operations.
- **Failover request processor.** This request processor performs ordered failover between subordinate proxying processors, sometimes with different behavior for different types of operations.

To Configure Request Processors Using `dsconfig`

Steps

- Use the `dsconfig` tool to create and configure a request processor.

```
$ bin/dsconfig
```

- Specify the host name, connection method, port number, and bind DN as described in previous procedures.
- In the Directory Proxy Server main menu, enter the number associated with Request Processor configuration and select the option to create a new Request Processor.
- Select an existing request processor to use as a template for creating a new one or enter `n` to create one from scratch. In this example, we create a new proxying request processor from scratch. You will be required to choose an existing load balancing algorithm or create a new one to complete the create of the request processor. Below is the configuration of the proxying request processor after selection of the load balancing algorithm.

```
Property                               Value(s)
```

```
-----
```

```

1) description -
2) enabled true
3) allowed-operation abandon, add, bind, compare, delete,
extended, modify, modify-dn, search
4) load-balancing-algorithm dc_example_dc_com-fewest-operations
5) transformation -
6) referral-behavior pass-through

8) supported-control-oid -

?) help
f) finish - create the new Proxying Request Processor
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit

```

5. Review the configuration properties of the new request processor. If you are satisfied, enter `f` to finish. For the request processor to be used, it must be associated with a subtree view.

To Pass LDAP Controls with the Proxying Request Processor

About this task

If your deployment does not use entry balancing and requires the use of LDAP controls not defined in the request processor's `supported-control` property, configure the Directory Proxy Server to forward these controls correctly. This is done by configuring the `supported-control-oid` property to define the request OID of the LDAP control. The Directory Proxy Server updates the root DSE `supportedControl` attribute with the values entered for the `supported-control-oid` property.

Configuring Server Affinity

The Directory Proxy Server supports the ability to forward a sequence of requests to the same external server if specific conditions are met. This feature, called server affinity, is applied by the load balancing algorithms. The following server affinity methods are available in the Directory Proxy Server:

- **Client Connection.** Requests from the same Directory Proxy Server client connection are consistently routed to the same external server.
- **Client IP.** Directory Proxy Server client requests coming from the same client IP address are routed to the same external server.
- **Bind DN.** Requests from all client connections authenticated as the same bind DN are routed to the same external server.

For each algorithm, you can specify the set of operations for which an affinity will be established, as well as the set of operations for which affinity will be used. Affinity assignments have a time-out value so that they are in effect for some period of time after the last operation that may cause the affinity to be set or updated.

To Configure Server Affinity

About this task

In this example, we create a bind DN server affinity provider for any client requesting write operations to have subsequent requests, whether read or write, forwarded to the same external server. The affinity period will last for 30 seconds after the last write request.

Steps

1. Use the `dsconfig` tool to configure server affinity. Specify the host name, connection method, port number, and bind DN as described in previous procedures.

```
$ bin/dsconfig
```

2. In the Directory Proxy Server main menu, enter the number associated with server affinity provider configuration
3. On the Server Affinity menu, enter the number corresponding to creating a new server affinity provider.
4. Enter a name for your new server affinity provider.

```
>>>> Enter a name for the Bind DN Server Affinity Provider
that you want to create: Affinity for Writing Applications
```

5. Indicate whether you want the server affinity provider to be enabled for use by the Directory Proxy Server. In this example, enter 1 to enable to the server affinity provider.
6. Next, configure the properties of the server affinity provider. For example, you can customize the types of operations for which affinity may be set and the types of operations for which affinity may be used, as well as the length of time for which the affinity should persist. This example illustrates the properties of the bind DN server affinity provider.

```
>>>> >>>> Configure the properties of the Bind DN Server Affinity Provider
```

Property	Value(s)
1) description	-
2) enable	true
3) affinity-duration	30 s
4) set-affinity-operation	add, delete, modify, modify-dn
5) use-affinity-operation	add, bind, compare, delete, modify, modify-dn, search
?) help	
f) finish - create the new Bind DN Server Affinity Provider	
d) display the equivalent dsconfig arguments to create this object	
b) back	
q) quit	

```
Enter choice [b]:
```

7. Review the properties of the server affinity provider. If you are satisfied, enter `f` to finish. Once defined, the affinity provider can now be assigned to a load balancing algorithm.

Configuring Subtree Views

You provide clients access to a specific portion of the DIT creating a subtree view and assigning it to a client connection policy. You can configure subtree views from the command line or using the Administrative Console.

When you create a subtree view, you provide the following information to configure its properties:

- Subtree view name
- Base DN managed by the subtree view

- Request processor used by the subtree view to route requests. If one does not exist already, you will create a new one.

To Configure Subtree View

Steps

1. Use `dsconfig` to configure a subtree view.
2. In the Directory Proxy Server main menu, enter the number associated with subtree view configuration
3. In the Subtree View menu, enter the number corresponding to creating a new subtree view.
4. Enter a name for the subtree view.
5. Enter the base DN of the subtree managed by this subtree view.

```
Enter a value for the 'base-dn' property:dc=example,dc=com
```

6. Select a request processor for this subtree view to route requests or make the appropriate selection to create a new one.

```
Select a Request Processor for the 'request-processor' property:
```

```
1) dc_example_dc_com-req-processor
2) Create a new Request Processor

?) help
c) cancel
q) quit
```

```
Enter choice [c]: 1
```

7. Review the properties of the subtree view. If you are satisfied, enter `f` to finish.

```
>>>> Configure the properties of the Subtree View
>>>> via creating 'example.com' Subtree View
```

	Property	Value(s)
1)	description	-
2)	base-dn	"dc=example,dc=com"
3)	request-processor	dc_example_dc_com-req-processor
?)	help	
f)	finish - create the new Subtree View	
d)	display the equivalent dsconfig arguments to create this object	
b)	back	
q)	quit	

Once configured, you can assign one or more subtree views to any client connection policies.

Configuring Client Connection Policies

Client connection policies help distinguish what portions of the DIT the client can access. They also enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use will be reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you

make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

Once a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are also associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

Understanding the Client Connection Policy

Client connection policies are based on two things:

- **Connection criteria.** The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.
- **Evaluation order index.** If multiple client connection policies are defined in the server, then each of them must have a unique value for the **evaluation-order-index** property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

When a Client Connection Policy is Assigned

A client connection policy can be associated with a client connection at the following times:

- When the connection is initially established. This association occurs exactly once for each client connection.
- After completing processing for a StartTLS operation. This association occurs at most once for a client connection, because StartTLS cannot be used more than once on a particular connection. You also may not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection, because the bind request can be processed many times on a given connection.

StartTLS and bind requests will be subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. Once they have completed, then subsequent operations will be subject to the constraints of the new client connection policy assigned to that client connection. This policy may or may not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and will be applicable when the client reconnects.

All other types of operations will be subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. So, the server will not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy will never be re-evaluated for a search operation.

Restricting the Type of Search Filter Used by Clients

You can restrict the types of search filters that a given client may be allowed to use to prevent the use of potentially expensive filters, like range or substring searches. You can use the `allowed-filter-type`

property to provide a list of filter types that may be included in the search requests from clients associated with the client connection policy. This setting will only be used if search is included in the set of allowed operation types. This restriction will only be applied to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

The `minimum-substring-length` property can be used to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes will be rejected. For example, the server can be configured to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting will only be used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing very short substrings can require the server to perform more expensive processing. The search requires a lot more server effort to assemble a candidate entry list for short substrings because the server has to examine a lot more index keys.
- Allowing very short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server (a process known as "trawling"). If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

Defining Request Criteria

The client connection policy provides several properties that allow you to define the kinds of requests that it can issue. The `required-operation-request-criteria` property causes the server to reject any requests that do not match the referenced request criteria. The `prohibited-operation-request-criteria` property causes the server to reject any request that matches the referenced request criteria.

Setting Resource Limits

A client connection policy can specify resource limits, helping to ensure that no single client monopolizes server resources. The resource limits are applied in addition to any global configuration resource limits. In other words, a client connection policy cannot grant additional resources beyond what is set in the global configuration. If a client connection exceeds either a globally-defined limit or a policy limit, then it is terminated.

Note: The Directory Proxy Server's global configuration can enforce limits on the number of concurrent connections that can be established in the following ways:

- Limit the total number of concurrent connections to the server.
- Limit the total number of concurrent connections from the same IP address.
- Limit the total number of concurrent connections authenticated as the same bind DN.

Defining the Operation Rate

You can configure the maximum operation rate for individual client connections as well as collectively for all connections associated with a client connection policy. If the operation rate limit is exceeded, the Directory Proxy Server may either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of less than twelve operations per second, but with bursts of up to one thousand operations per second.

Rate limit strings should be specified as a maximum count followed by a slash and a duration. The count portion must contain an integer, and may be followed by a multiplier of `k` (to indicate that the integer should be interpreted as thousands), `m` (to indicate that the integer should be interpreted as millions), or `g` (to indicate that the integer should be interpreted as billions). The duration portion must contain a time unit of

milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), and may be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client Connection Policy Deployment Example

In this example scenario, we assume the following:

- Two external LDAP clients are allowed to bind to the Directory Proxy Server.
- Client 1 should be allowed to open only 1 connection to the server.
- Client 2 should be allowed to open up to 5 connections to the server.

Defining the Connection Policies

We need to set a per-client connection policy limit on the number of connections that may be associated with a particular client connection policy. We have to define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, we must create a third client connection policy that applies to unauthenticated clients, because client connections are always unauthenticated as soon as they are established and before they have sent a bind request. Plus, clients are not required to send a bind request as their first operation.

Therefore, we define the following three client connection policies:

- **Client 1 Connection Policy**, which only allows client 1, with an evaluation order index of 1.
- **Client 2 Connection Policy**, which only allows client 2, with an evaluation order index of 2.
- **Unauthenticated Connection Policy**, which allows unauthenticated clients, with an evaluation order index of 3.

We define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none, so that it will only apply to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This DN may be full DN for the target user, or it may be the base DN for a branch that contains a number of users that you want treated in the same way.

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the Policy is Evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy. The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value will be examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection will be associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection will be terminated.

So, in our example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy, because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies will be re-evaluated. If client 2 performs the bind, then the Client 1 Connection Policy will not match but the Client 2 Connection Policy will, so the connection will be re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server will check to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection will be terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy, because it is the client connection policy already assigned to the client connection. Once the bind has completed, then the server will reevaluate the client connection policy against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. Once the bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria do not match, so the client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy, because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed, because this is the client connection policy assigned to the client connection for client 1. The connection is not reevaluated, before or after processing the search operation.

To Configure a Client Connection Policy Using dsconfig

Steps

1. Use the `dsconfig` tool to create and configure a client connection policy.

```
$ bin/dsconfig
```

2. Enter the connection parameters to the server (for example, host name, connection method, port, bind DN and bind DN password).
3. In the Directory Proxy Server main menu, enter the number associated with client connection policy configuration. Then enter the number to create a new client connection policy.

```
>>>> Client connection policy menu
```

```
What would you like to do?
```

```

1) List existing client connection policies
2) Create a new client connection policy
3) View and edit an existing client connection policy
4) Delete an existing client connection policy

b) back
q) quit
```

```
Enter choice [b]: 2
```

4. Enter `n` to create a new client connection policy from scratch.

```
>>>> Select an existing Client Connection Policy to use as a
template for the new Client Connection Policy configuration or
'n' to create one from scratch:
```

```
1) default

n) new Client Connection Policy created from scratch
c) cancel
q) quit
```

5. Enter a name for the new client connection policy.

```
Enter the 'policy-id' for the Client Connection Policy that you
want to create: new_policy
```

6. Indicate whether you want the policy to be enabled by default.

```
Select a value for the 'enabled' property:
```

```
1) true
2) false

?) help
c) cancel
q) quit
```

```
Enter choice [c]: 1
```

7. Provide a value for the `evaluation-order-index` property. Client connection policies with a lower index will be evaluated before those with a higher index.

```
Enter a value for the 'evaluation-order-index' property: 2
```

8. The properties of your new client connection policy are displayed. If you want to make any further modifications, enter the number corresponding to the property. Enter `f` to finish the creation of the client connection policy.

Any changes that you make to the client connection policy do not apply to existing connections. They will only apply to new connections.

Configuring Globally Unique Attributes

The PingDirectoryProxy Server supports a Globally Unique Attributes feature that ensures uniqueness for any value defined for a set of attributes within a subtree view. You can also configure when the server checks for attribute conflicts, either prior to any add, modify, or modify DN change request (pre-commit) or after the successful completion of a change request (post-commit).

About the Globally Unique Attribute plugin

The Directory Proxy Server supports a Globally Unique Attribute plugin that prevents any value within a defined set of attributes to appear more than once in any entry for one or more subtree views. Administrators can also configure whether conflict validation should be checked before an add, modify, or modify DN request to one or more backend servers or after the change has successfully completed.

For example, if the `pre-commit-validation` property is enabled, the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change (i.e., add, modify, or modify DN). If a conflict is detected, then the change request will be rejected. If the `post-commit-validation` property is enabled, after the change has been processed, the server performs one

or more searches to determine if a conflict was created in multiple servers at the same time. If a conflict is detected in this manner, then an administrative alert will be generated to notify administrators of the problem so that they can take any manual corrective action.

Note: The Globally Unique Attribute plugin will attempt to detect and/or prevent unique attribute conflicts for changes processed through this Directory Proxy Server, but it cannot detect conflicts introduced by changes applied by clients communicating *directly* with backend servers.

We recommend that the Unique Attribute plugin be enabled for all backend servers with the same configuration, so that conflicts can be detected within individual backend server instances. However, the Unique Attribute plugin alone may not be sufficient for cases in which the content is split across multiple sets of servers (e.g., in an entry-balanced environment or in proxy configurations with different branches on different servers).

The LDAP SDK uniqueness request control can be used for enforcing uniqueness on a per-request basis. See the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control. See the ASN.1 specification to implement support for it in other APIs.

In general, note the following points about pre-commit validation versus post-commit validation:

- Pre-commit validation is the only mechanism that can try to prevent conflicts. It will increase the processing time for add, modify, and modify DN operations because the necessary searches to look for conflicts happen before the update request is forwarded to any backend servers.
- Post-commit validation will only let you know (via administrative alert) about conflicts that already exist in the data. It can't prevent conflicts, but can allow you to deal with them in a timely manner. It also operates during the post-response phase, so it won't affect the processing time for the associated write operation.
- In most cases, pre-commit validation should be sufficient to prevent conflicts, although we recommend that you periodically run the `identify-unique-attribute-conflicts` tool to find any conflicts that may have arisen. If you want to mitigate any risks due to conflicts being generated by concurrent operations in different servers, then using both `pre-commit-validation` and `post-commit-validation` properties provides the best combination of preventing most conflicts in advance, and detecting and alerting about conflicts that arise from concurrent writes.

For more detailed information about the plugin, see the *Directory Proxy Server Reference (HTML)*

To Configure the Globally Unique Attribute plugin

About this task

The following example shows how to configure the Globally Unique Attribute plugin. The example defines an attribute set consisting of the `telephoneNumber` and `mobile` attributes within the "test-view" subtree view. The `multiple-attribute-behavior` property determines the scope of how attributes may differ among entries and is the same property for the Directory Server plugin. The property is set to `unique-across-all-attributes-including-in-same-entry`, which indicates that the `telephone` and `mobile` attributes must be unique throughout the subtree view, even within an entry. The `pre-commit-validation` property ensures that the Globally Unique Attribute Plugin performs one or more searches to determine whether any entries conflict with the change (i.e., add, modify, or modify DN). If a conflict is detected, then the change request will be rejected.

Note that all configured attributes should be indexed for equality in all backend servers.

Steps

- Run `dsconfig` to create the Globally Unique Attribute plugin. The server checks that any add, modify, or modify DN request does not conflict with any attribute values in the entries. If a conflict exists, the change request is rejected.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Globally-Unique telephone and mobile" \
  --type globally-unique-attribute \
  --set enabled:true \
  --set type:telephoneNumber \
  --set type:mobile \
  --set subtree-view:test-view \
  --set multiple-attribute-behavior:unique-across-all-attributes-including-
in-same-entry \
  --set pre-commit-validation:all-available-backend-servers
```

Configuring the Global Referential Integrity plugin

The PingDirectoryProxy Server supports a global referential integrity plugin mechanism that maintains DN references from a specified set of attributes to entries that exist in the server (e.g., between the members values of a static group and the corresponding user entries). The plugin intercepts delete and modify DN operations and updates any references to the target entry. For a delete operation, any references to the target entry are removed. For modify DN operations, any references to the target entry are updated to reflect the new DN of the entry.

The plugin is similar to the Directory Server Referential Integrity plugin but does not have an asynchronous mode. When enabled on the Directory Proxy Server, the client response will be delayed until the referential integrity processing is complete. For Directory Proxy Server deployments not using entry balancing and using Directory Server external servers, it is best to instead use the Referential Integrity plugin on the Directory Server.

An equality index must be defined on all attributes referenced within the Global Referential Integrity plugin across all external servers.

Sample Global Referential Integrity plugin

Steps

- Use `dsconfig` to configure the Global Referential Integrity plugin. The plugin ensures that the `member`, `uniqueMember`, and `manager` attributes maintain their DN references in the defined subtree views. Note that any attributes for which referential integrity should be maintained should have values which are DNs and should be indexed for equality in all backend servers.

```
$ bin/dsconfig create-plugin \
  --plugin-name "Global Referential Integrity" \
  --type global-referential-integrity \
  --set "enabled:true" \
  --set "attribute-type:member" \
  --set "attribute-type:uniqueMember" \
  --set "attribute-type:manager" \
  --set "subtree-view:employee-view" \
  --set "subtree-view:groups-view"
```

Configuring an Active Directory Server Back-end

Configuring an Active Directory server back-end requires a `dsconfig` script. The following settings are required for an Active Directory server:

- **verify-credentials-method:bind-on-existing-connections**, and **authorization-method:rebind**

Active Directory does not support **proxy-as**. Existing connections must be reused.

- **set max-connection-age:5m**, and **health-check-pooled-connections:true**

Active Directory drops idle connections after 15 minutes. The proxy needs to refresh the connection pool in a shorter interval.

The following example **dsconfig** script configures two Active Directory servers (AD-SRV1 and AD-SRV2).

```
dsconfig set-ldap-health-check-prop --check-name "Consume Admin Alerts" \
  --reset use-for-all-servers

dsconfig set-trust-manager-provider-prop \
  --provider-name "Blind Trust" \
  --set enabled:true

dsconfig create-external-server --server-name AD-SRV1 --type active-directory \
  --set server-host-name:example.server \
  --set server-port:636 \
  --set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
  --set password:password --set connection-security:ssl \
  --set key-manager-provider:Null --set trust-manager-provider:"Blind Trust" \
  --set authorization-method:rebind \
  --set verify-credentials-method:bind-on-existing-connections \
  --set max-connection-age:5m \
  --set health-check-pooled-connections:true

dsconfig create-external-server --server-name AD-SRV2 --type active-directory \
  --set server-host-name:example.server \
  --set server-port:636 \
  --set bind-dn:cn=ProxyUser,dc=dom-ad2,dc=local \
  --set password:password \
  --set connection-security:ssl \
  --set key-manager-provider:Null \
  --set trust-manager-provider:"Blind Trust" \
  --set authorization-method:rebind \
  --set verify-credentials-method:bind-on-existing-connections \
  --set max-connection-age:5m \
  --set health-check-pooled-connections:true

dsconfig create-load-balancing-algorithm --algorithm-name AD-LBA \
  --type fewest-operations \
  --set enabled:true \
  --set backend-server:AD-SRV1 \
  --set backend-server:AD-SRV2 \
  --set use-location:false

dsconfig create-request-processor --processor-name AD-Proxy --type proxying \
  --set load-balancing-algorithm:AD-LBA

dsconfig create-subtree-view --view-name AD-View \
  --set base-dn:dc=dom-ad2,dc=local \
  --set request-processor:AD-Proxy

dsconfig set-client-connection-policy-prop --policy-name default \
  --set subtree-view:AD-View
```

Managing Access Control

The PingDirectoryProxy Server provides a fine-grained access control model to ensure that users are able to access the information they need, but are prevented from accessing information that they should not be allowed to see. It also includes a privilege subsystem that provides even greater flexibility and protection in many key areas.

This chapter presents the access control model and how it applies to the Directory Proxy Server.

Overview of Access Control

The access control model uses access control instructions (ACIs), which are stored in the `aci` operational attribute, to determine what a user or a group of users can do with a set of entries, down to the attribute level. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specifies four items:

- **Resources.** *Resources* are the targeted items or objects that specifies the set of entries and/or operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.
- **Name.** *Name* is the descriptive label for each access control instruction. Typically, you will have multiple access control instructions for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an access control instructions labelled "ACI to grant full access to administrators."
- **Clients.** *Clients* are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com."`
- **Rights.** *Rights* are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

Key Access Control Features

The PingDirectoryProxy Server provides important access control features that provide added security for the Directory Proxy Server's entries.

Improved Validation and Security

The Directory Proxy Server provides an access control model with strong validation to help ensure that invalid ACIs are not allowed into the server. For example, the Directory Proxy Server ensures that all access control rules added over LDAP are valid and can be fully parsed. Any operation that attempts to store one or more invalid ACIs are rejected. The same validation is applied to ACIs contained in data imported from an LDIF file. Any entry containing a malformed `aci` value will be rejected.

As an additional level of security, the Directory Proxy Server examines and validates all ACIs stored in the data whenever a backend is brought online. If any malformed ACIs are found in the backend, then the server generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed due to an access control instruction not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

Global ACIs

Global ACIs are a set of ACIs that can apply to entries anywhere in the server (although they can also be scoped so that they only apply to a specific set of entries). They work in conjunction with access control rules stored in user data and provide a convenient way to define ACIs that span disparate portions of the DIT.

In the PingDirectoryProxy Server, global ACIs are defined within the server configuration, in the `global-aci` property of configuration object for the access control handler. They can be viewed and managed using configuration tools like `dsconfig` and the Administrative Console.

The global ACIs available by default in the PingDirectoryProxy Server include:

- Allow anyone (including unauthenticated users) to access key attributes of the root DSE, including: `namingContexts`, `subschemaSubentry`, `supportedAuthPasswordSchemes`, `supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedLDAPVersion`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`.
- Allow anyone (including unauthenticated users) to access key attributes of the subschema subentry, including: `attributeTypes`, `dITContentRules`, `dITStructureRules`, `ldapSyntaxes`, `matchingRules`, `matchingRuleUse`, `nameForms`, and `objectClasses`.
- Allow anyone (including unauthenticated users) to include the following controls in requests made to the server: authorization identity request, manage DSA IT, password policy, real attributes only, and virtual attributes only.
- Allow anyone (including unauthenticated users) to request the following extended operations: get symmetric key, password modify request, password policy state, StartTLS, and Who Am I?

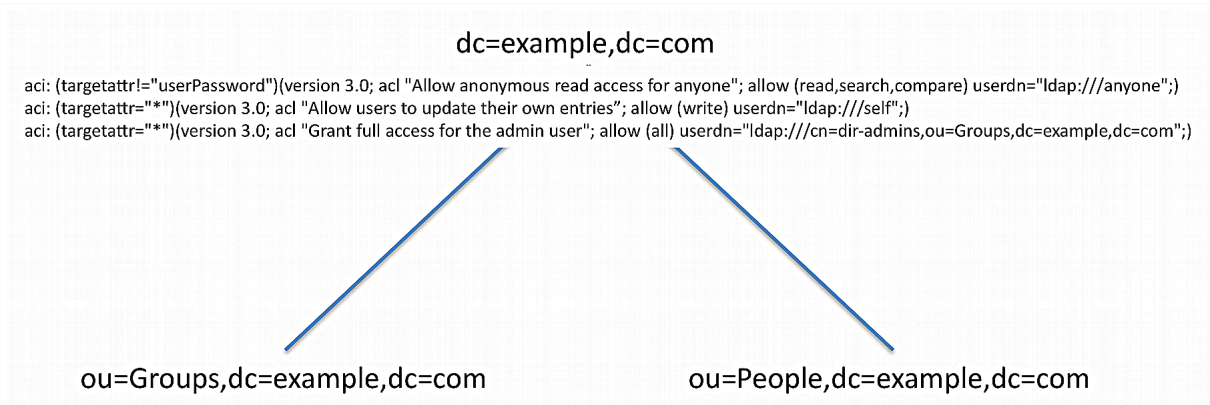

Access Controls for Public or Private Backends

The PingDirectoryProxy Server classifies backends as either public or private, depending on their intended purpose. A private backend is one whose content is generated by the Directory Proxy Server itself (for example, the root DSE, monitor, and backup backends), is used in the operation of the server (for example, the configuration, schema, task, and trust store backends), or whose content is maintained by the server (for example, the LDAP changelog backend). A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The PingDirectoryProxy Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, any access control instruction intended to permit or restrict access to information in private backends should be defined as global ACIs, rather than attempting to add those instructions to the data for that private backend.

General Format of the Access Control Rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the Directory Information Tree (DIT). Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Proxy Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the Directory Proxy Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied, so that a user who may have an ACI at an entry, may also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.

MY TITLE ACI

An access control rule has a basic syntax as follows:

```

aci : (targets) (version 3.0; acl "name";
permissions
bind rules
;)

```

Access Control Components

Access Control Component	Description
targets	Specifies the set of entries and/or attributes to which an access control rule applies. Syntax: <i>(target keyword = != expression)</i>
name	Specifies the name of the ACI.
permissions	Specifies the type of operations to which an access control rule might apply. Syntax: <i>allow deny (permission)</i>
bind rules	Specifies the criteria that indicate whether an access control rule should apply to a given requestor. Syntax: <i>bind rule keyword = != expression;. The bind rule syntax requires that it be terminated with a ";"</i> .

Summary of Access Control Keywords

This section provides an overview of the keywords supported for use in the PingDirectoryProxy Server access control implementation.

Targets

A target expression specifies the set of entries and/or attributes to which an access control rule applies. The *keyword* specifies the type of target element. The *expression* specifies the items that is targeted by the access control rule. The operator is either the equal ("=") or not-equal ("!="). Note that the "!=" operator cannot be used with `targattrfilters` and `targetscope` keywords. For specific examples on each target keyword, see the section [Working with Targets](#).

```
(keyword [= || !=] expression)
```

The following keywords are supported for use in the target portion of ACIs:

Summary of Access Control Target Keywords

Target Keyword	Description	Wildcards
extop	Specifies the OIDs for any extended operations to which the access control rule should apply.	No
target	Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.	Yes
targattrfilters	Identifies specific attribute values based on filters that may be added to or removed from entries to which the access control rule applies.	Yes
targetattr	Specifies the set of attributes to which the access control rule should apply.	Yes
targetcontrol	Specifies the OIDs for any request controls to which the access control rule should apply.	No
targetfilter	Specifies one or more search filters that may be used to indicate the set of entries to which the access control should apply.	Yes
targetscope	Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply.	No

Permissions

Permissions indicate the types of operations to which an access control rule might apply. You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you would grant read access to a targeted entry or entries using "allow (read)" permission. Or you can specifically deny access to the target entries and/or attributes using the "deny (read)" permission. You can list out multiple permissions as required in the ACI.

```
allow (permission1 ...,
      permission2
      , ...permissionN)
```

```
deny (permission1 ...,
      permission2
      , ...permissionN)
```

The following keywords are supported for use in the permissions portion of ACIs:

Summary of Access Control Permissions

Permission	Description
add	Indicates that the access control should apply to add operations.
compare	Indicates that the access control should apply to compare operations, as well as to search operations with a base-level scope that targets a single entry.
delete	Indicates that the access control should apply to delete operations.

Permission	Description
export	Indicates that the access control should only apply to modify DN operations in which an entry is moved below a different parent by specifying a new superior DN in the modify DN request. The requestor must have the <code>export</code> permission for operations against the entry's original DN. The requestor must have the <code>import</code> permission for operations against the entry's new superior DN. For modify DN operations that merely alter the RDN of an entry but keeps it below the same parent (i.e., renames the entry), only the <code>write</code> permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries.
import	See the description for the <code>export</code> permission.
proxy	Indicates that the access control rule should apply to operations that attempt to use an alternate authorization identity (for example, operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a SASL mechanism that allows an alternate authorization identify to be specified).
read	Indicates that the access control rule should apply to search result entries returned by the server.
search	Indicates that the access control rule should apply to search operations with a non-base scope.
selfwrite	Indicates that the access control rule should apply to operations in which a user attempts to add or remove his or her own DN to the values for an attribute (for example, whether users may add or remove themselves from groups).
write	Indicates that the access control rule should apply to modify and modify DN operations.
all	An aggregate permission that includes all other permissions except "proxy." This is equivalent to providing a permission of "add, compare, delete, read, search, selfwrite, write, export, and import."

Bind Rules

The Bind Rules indicate whether an access control rule should apply to a given requester. The syntax for the target keyword is shown below. The *keyword* specifies the type of target element. The expression specifies the items that is targeted by the access control rule. The operator is either equals ("=") or not-equals ("!="). The semi-colon delimiter symbol (";") is required after the end of the final bind rule.

```
keyword [=|!= ] expression;
```

Multiple bind rules can be combined using Boolean operations (AND, OR, NOT) for more access control precision. The standard Boolean rules for evaluation apply: innermost to outer parentheses first, left to right expressions, NOT before AND or OR. For example, an ACI that includes the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets the `uid=admin,dc=example,dc=com` and authenticates using SASL EXTERNAL or accesses the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

The following keywords are supported for use in the bind rule portion of ACIs:

Summary of Bind Rule Keywords

Bind Rule Keyword	Description
authmethod	<p>Indicates that the requester's authentication method should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. The keyword's syntax is as follows:</p> <pre style="text-align: center;">authmethod = <i>method</i></pre> <p>where <i>method</i> is one of the following representations:</p> <ul style="list-style-type: none"> ▪ none ▪ simple. Indicates that the client is authenticated to the server using a bind DN and password. ▪ ssl. Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server. ▪ sasl {sasl_mechanism}. Indicates that the client is authenticated to the server using a specified SASL Mechanism. <p>The following example allows users who authenticate with an SSL/TLS certificate (for example., via SASL EXTERNAL) to update their own entries:</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (userdn="ldap:///self" and authmethod="ssl");)</pre>
dayofweek	<p>Indicates that the day of the week should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. Multiple day of week values may be separated by commas. The keyword's syntax is as follows:</p> <pre style="text-align: center;">dayofweek = <i>day1, day2, ...</i></pre> <p>where <i>day</i> is one of the following representations:</p> <ul style="list-style-type: none"> ▪ sun ▪ mon ▪ tues ▪ wed ▪ thu ▪ fri ▪ sat <p>The following example allows users who authenticate with an SSL/TLS certificate (for example., via SASL EXTERNAL) on weekdays to update their own entries:</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dayofweek!="sun,sat" and userdn="ldap:///self" and authmethod="ssl");)</pre>

Bind Rule Keyword	Description
dns	<p>Indicates that the requester's DNS-resolvable host name should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are allowed in this expression. Multiple DNS patterns may be separated by commas. The keyword's syntax is as follows:</p> <pre style="text-align: center;">dns = dns-host-name</pre> <p>The following example allows users on host name <code>server.example.com</code> to update their own entries:</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (dns="server.example.com" and userdn="ldap:///self");)</pre>
groupdn	<p>Indicates that the requester's group membership should be taken into account when determining whether the access control rule should apply to any operation. Wildcards are not allowed in this expression.</p> <pre style="text-align: center;">groupdn [= !=] "ldap:///groupdn [ldap:///groupdn] ..."</pre> <p>The following example allows users in the managers group to update their own entries:</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (groupdn="ldap:///cn=managers,ou=groups,dc=example,dc=com");)</pre>

Bind Rule Keyword	Description
ip	<p>Indicates that the requester's IP address should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are allowed in this expression. Multiple IP address patterns may be separated by commas. The keyword's syntax is as follows:</p> <pre data-bbox="971 426 1409 457">ip [= !=] ipAddressList</pre> <p>where <i>ipAddressList</i> is one of the following representations:</p> <ul data-bbox="444 554 1435 726" style="list-style-type: none"> ▪ A specific IPv4 address: 127.0.0.1 ▪ An IPv4 address with wildcards to specify a subnetwork: 127.0.0.* ▪ An IPv4 address or subnetwork with subnetwork mask: 123.4.5.0+255.255.255.0 ▪ An IPv4 address range using CIDR notation: 123.4.5.0/24 ▪ An IPv6 address as defined by RFC 2373. <p>The following example allows users on 10.130.10.2 and localhost to update their own entries:</p> <pre data-bbox="444 842 1435 953">aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) (ip="10.130.10.2,127.0.0.1" and userdn="ldap:///self");)</pre>
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre data-bbox="444 1108 1081 1140">oauthscope [= !=] "scopeIdentifier"</pre> <p>where <i>scopeIdentifier</i> is one of the following:</p> <ul data-bbox="444 1205 1435 1310" style="list-style-type: none"> ▪ The name of a single scope to match. The name will be treated as case-sensitive. ▪ A substring assertion that contains one or more asterisks as wildcards. ▪ A single asterisk by itself, which will match any scope. <p>The following example will grant all rights to any client that presented an OAuth 2.0 token that is associated with the "scim_admin" scope:</p> <pre data-bbox="444 1423 1435 1539">aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin");)</pre>

Bind Rule Keyword	Description
timeofday	<p>Indicates that the time of day should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. The keyword's syntax is as follows:</p> <pre data-bbox="444 363 1211 394">timeofday [= != >= > <= <] time</pre> <p>where <i>time</i> is one of the following representations:</p> <ul data-bbox="444 464 1430 558" style="list-style-type: none"> ▪ 4-digit 24-hour time format (0000 to 2359, where the first two digits represent the hour of the day and the last two represent the minute of the hour) ▪ Wildcards are not allowed in this expression <p>The following example allows users to update their own entries if the request is received before 12 noon.</p> <pre data-bbox="444 674 1419 814">aci: (targetattr="*") (version 3.0; acl "Allow users who authenticate before noon to update their own entries"; allow (write) (timeofday<1200 and userdn="ldap:///self" and authmethod="simple");)</pre>
oauthscope	<p>Indicates that the scopes associated with any OAuth 2.0 access token presented by a SCIMv2 client should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre data-bbox="444 972 1081 1003">oauthscope [= !=] "scopeIdentifier"</pre> <p>where <i>scopeIdentifier</i> is one of the following:</p> <ul data-bbox="444 1073 1442 1167" style="list-style-type: none"> ▪ The name of a single scope to match. The name will be treated as case-sensitive. ▪ A substring assertion that contains one or more asterisks as wildcards. ▪ A single asterisk by itself, which will match any scope. <p>The following example will grant all rights to any client that presented an OAuth 2.0 token that is associated with the "scim_admin" scope:</p> <pre data-bbox="444 1283 1433 1392">aci: (targetattr="*") (version 3.0; acl "Full rights for users with the scim_admin OAuth 2.0 scope"; allow (all) oauthscope="scim_admin");)</pre>

Bind Rule Keyword	Description
userattr	<p>Indicates that the requester's relation to the value of the specified attribute should be taken into account when determining whether the access control rule should apply to an operation. A bindType value of <code>USERDN</code> indicates that the target attribute should have a value which matches the DN of the authenticated user. A bindType value of <code>GROUPDN</code> indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A bindType value of <code>LDAPURL</code> indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user. Any value other than <code>USERDN</code>, <code>GROUPDN</code>, or <code>LDAPURL</code> is expected to be present in the target attribute of the authenticated user's entry. The keyword's syntax is as follows:</p> <pre data-bbox="448 590 1175 617">userattr = attrName# [bindType attrValue]</pre> <p>where:</p> <ul data-bbox="448 688 1446 821" style="list-style-type: none"> ▪ <i>attrName</i> = name of the attribute for matching ▪ <i>bindType</i> = <code>USERDN</code>, <code>GROUPDN</code>, <code>LDAPURL</code> ▪ <i>attrValue</i> = an attribute value. Note that the <i>attrVALUE</i> of the attribute must match on both the bind entry and the target of the ACI. <p>The following example allows a manager to change employee's entries. If the bind DN is specified in the <i>manager</i> attribute of the targeted entry, the bind rule is evaluated to TRUE.</p> <pre data-bbox="448 963 1321 1075">aci: (targetattr="*") (version 3.0; acl "Allow a manager to change employee entries"; allow (write) userattr="manager#USERDN");</pre> <p>The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the <i>allowEditors</i> attribute of the targeted entry, the bind rule is evaluated to TRUE.</p> <pre data-bbox="448 1226 1370 1337">aci: (targetattr="*") (version 3.0; acl "Allow allowEditors to change employee entries"; allow (write) userattr="allowEditors#GROUPDN");</pre> <p>The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (0, 1, 2, 3, 4) below the targeted entry, with zero (0) indicating the targeted entry.</p> <pre data-bbox="448 1488 1451 1600">aci: (targetattr="*") (version 3.0; acl "Allow managers to change employees entries two levels below"; allow (write) userattr="parent[0,1,2].manager#USERDN");</pre> <p>The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.</p> <pre data-bbox="448 1715 1451 1852">aci: (targetattr="*") (version 3.0; acl "Allow any member of Eng Dept to update any other member of the engineering department at or below the ACI"; allow (write) userattr="department#ENGINEERING");</pre> <p>The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the <i>allowedEditorCriteria</i> attribute of the target entry.</p> <pre data-bbox="448 2003 1403 2100">aci: (targetattr="*") (version 3.0; acl "Allow a user that matches the filter to change entries"; allow (write) userattr="allowedEditorCriteria#LDAPURL");</pre>

Bind Rule Keyword	Description
userdn	<p>Indicates that the user's DN should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre>userdn [= !=] "ldap:///value ["ldap:///value ..."]</pre> <p>where <i>value</i> is one of the following representations:</p> <ul style="list-style-type: none"> ▪ The DN of the target user ▪ A value of <code>anyone</code> to match any client, including unauthenticated clients. ▪ A value of <code>all</code> to match any authenticated client. ▪ A value of <code>parent</code> to match the client authenticated as the user defined in the immediate parent of the target entry. ▪ A value of <code>self</code> to match the client authenticated as the user defined in the target entry. <p>If the value provided is a DN, then that DN may include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks may be used to match zero or more DN components.</p> <p>The following example allows users to update their own entries:</p> <pre>aci: (targetattr="*") (version 3.0; acl "Allow users to update their own entries"; allow (write) userdn="ldap:///self");</pre>

Working with Targets

The following section presents a detailed look and examples of the target ACI keywords: `target`, `targetattr`, `targetfilter`, `targetattrfilters`, `targetscope`, `targetcontrol`, and `extop`.

target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN). The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com` within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where DN is the distinguished name of the entry or branch:

```
(target = ldap:///
      DN
    )
```

For example, to target a specific entry, you would use a clause such as the following:

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

Note that, in general, specifying a target DN is not recommended. It is better to have the ACI defined in that entry and omit the `target` element altogether. For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, it is better for it to be defined in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the "not equal" (!=) operator to indicate that all entries within the scope of the given branch that do NOT match the expression be targeted for the ACI. Thus, the following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (*) characters as wildcards to match elements within the distinguished name. The following target expression matches all entries that contains and begins with "john.d," so that entries like "john.doe,ou=People,dc=example,dc=com," and "john.davies,ou=People,dc=example,dc=com" would match.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

The following target expression matches all entries whose DN begins with "john.d," and matches the `ou` attribute. Entries like "john.doe,ou=People,dc=example,dc=com," and "john.davies,ou=asia-branch,dc=example,dc=com" would match.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it, and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci: (target="ldap:///ou=People,dc=example,dc=com")
  (targetattr="*")
  (version 3.0; acl "Allow all the ou=People branch to modify their own
  entries";
  allow (write) userdn="ldap:///self";)
```

targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply. There are four general forms that it can take in the PingDirectoryProxy Server:

- **(targetattr="*")**. Indicates that the access control rule applies to all user attributes. Operational attributes will not automatically be included in this set.
- **(targetattr="+")**. Indicates that the access control rule applies to all operational attributes. User attributes will not automatically be included in this set.
- **(targetattr="attr1|attr2|attr3|...|attrN")**. Indicates that the access control rule applies only to the named set of attributes.
- **(targetattr!="attr1|attr2|attr3|...|attrN")**. Indicates that the access control rule applies to all user attributes except the named set of attributes. It will not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry, while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overridden default constraints like size limit, time limit, or look-through limit for that user.

The PingDirectoryProxy Server distinguishes between these two types of attributes in its access control implementation. The Directory Proxy Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes:

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (cn), surname (sn) and state (st) attribute:

```
(targetattr="cn|sn|st")
```

You can use the "+" symbol to indicate that the rule should apply to all operational attributes, as follows:

```
(targetattr="+")
```

To include all user and all operational attributes, you use both symbols, as follows:

```
(targetattr="*||+")
```

If there is a need to target a specific operational attribute rather than all operational attributes, then it can be specifically included in the values of the `targetattr` clause, as follows:

```
(targetattr="ds-rlim-size-limit")
```

Or if you want to target all user attributes and a specific operational attribute, then you can use them in the `targetattr` clause, as follows:

```
(targetattr="*||ds-rlim-size-limit")
```

The following ACIs are placed on the `dc=example,dc=com` tree and allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword") (version 3.0; acl "Allow anonymous
  read access for anyone"; allow (read,search,compare) userdn="ldap:///
  anyone");
aci: (targetattr="telephonenumber||street||homePhone||l||st")
  (version 3.0; acl "Allow users to update their own contact info";
  allow (write) userdn="ldap:///self");
aci: (targetattr="*") (version 3.0; acl "Grant full access for the admin
  user";
  allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

An important note must be made when assigning access to user and operational attributes, which can be outlined in an example to show the implications of the Directory Proxy Server not distinguishing between these attributes. It can be easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. Consider the following example:

```
aci: (targetattr!="uid||employeeNumber")
  (version 3.0; acl "Allow users to update their own entries";
  allow (write) userdn="ldap:///self");
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a very common type of rule and seems relatively harmless on the surface, but it has very serious consequences for a Directory Proxy Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users including administrators granted full rights by access control rules, but excluding users with the `bypass-acl` privilege, allow them to edit any other attributes in their own entry including those excluded by rules like `uid` and `employeeNumber` in the example above, or add, modify, or delete any entries below his or her own entry.

Because the PingDirectoryProxy Server does not automatically include operational attributes in the target attribute list, these kinds of ACIs do not present a security risk for it. Also note that users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword`, and the second allows `cn` and `sn`.

targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter. The `targetfilter` clause has the following syntax:

```
(targetfilter =
    ldap_filter
)
```

For example, the following clause targets all entries that contain "ou=engineering" attribute:

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the OR operator. The following clause targets all entries that contain "ou=engineering," "ou=accounting," and "ou=marketing."

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
  (targetattr="departmentNumber|cn|sn")
  (version 3.0; acl "example"; allow (write)
    userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

targattrfilters

The `targattrfilters` keyword targets specific attribute *values* that match a filtered search criteria. This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following formats:

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrn:FilterN" )
```

where

- **add** represents the operation of adding an attribute value to the entry
- **del** represents the operation of removing an attribute value from the entry
- **attr1, attr2... attrN** represents the targeted attributes
- **filter1, filter2 ... filterN** represents filters that identify matching attribute values

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters, and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci: (targetattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read) ")
  (version 3.0; acl "Allow members of the directory server admins group to grant the soft-delete-read privilege"; allow (write) groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

targetscope

The `targetscope` keyword is used to restrict the scope of an access control rule. By default, ACIs use a subtree scope, which means that they are applied to the target entry (either as defined by the target clause of the ACI, or the entry in which the ACI is defined if it does not include a target), and all entries below it. However, adding the `targetscope` element into an access control rule can restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

- **base**. Indicates that the access control rule should apply only to the target entry and not to any of its subordinates.
- **onelevel**. Indicates that the access control rule should apply only to entries that are the immediate children of the target entry and not to the target entry itself, nor to any subordinates of the immediate children of the target entry.
- **subtree**. Indicates that the access control rule should apply to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.
- **subordinate**. Indicates that the access control rule should apply to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes (`supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`) present in the root DSE entry. The `targetscope` is `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///") (targetscope="base")
  (targetattr="supportedControl||supportedExtension||supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
  (version 3.0; acl "Allow users to view Root DSE Operational Attributes"; allow (read,search,compare) userdn="ldap:///anyone")
```

targetcontrol

The `targetcontrol` keyword is used to indicate whether a given request control can be used by those users targeted in the ACI. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying control OIDs.

The following ACI example shows the controls required to allow an administrator to use and manage the Soft-Delete feature. The Soft Delete Request Control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The Hard Delete Request Control allows the user to permanently remove an entry or soft-deleted entry. The Undelete Request Control allows the user to undelete a currently soft-deleted entry. The Soft-Deleted Entry Access Request Control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
  (version 3.0; acl "Allow admins to use the Soft Delete Request Control, Hard Delete Request Control, Undelete Request Control, and Soft-deleted entry access request control"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

extOp

The `extop` keyword can be used to indicate whether a given extended request operation can be used. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying extended request OIDs.

The following ACI allows the `uid=user-mgr` to use the Password Modify Request (i.e., `OID=1.3.6.1.4.1.4203.1.11.1`) and the StartTLS (i.e., `OID=1.3.6.1.4.1.1466.20037`) extended request OIDs.

```
aci: (extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
  (version 3.0; acl "Allows the mgr to use the Password Modify Request and
  StartTLS;
  allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

Examples of Common Access Control Rules

This section provides a set of examples that demonstrate access controls that are commonly used in your environment. Note that to be able to alter access control definitions in the server, a user must have the `modify-acl` privilege as discussed later in this chapter.

Administrator Access

The following ACI can be used to grant any member of the `"cn=admins,ou=groups,dc=example,dc=com"` group to add, modify and delete entries, reset passwords and read operational attributes such as `isMemberOf` and password policy state:

```
aci: (targetattr="+") (version 3.0; acl "Administrators can read, search or
  compare operational attributes";
  allow (read,search,compare) groupdn="ldap:///
  cn=admins,ou=groups,dc=example,dc=com";)
aci: (targetattr="*") (version 3.0; acl "Administrators can add, modify and
  delete entries";
  allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
```

Anonymous and Authenticated Access

The following ACI allow anonymous read, search and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. The authenticated user will inherit the privileges of the anonymous ACI. In addition, the authenticated user can change `userPassword`:

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Anyone can access names and email addresses of entries
  representing people";
  allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="departmentNumber || manager || isMemberOf")
  (targetfilter="(objectClass=inetorgperson)")
  (version 3.0; acl "Authenticated users can access these fields for entries
  representing people";
  allow (read,search,compare) userdn="ldap:///all";)
aci: (targetattr="userPassword") (version 3.0; acl "Authenticated users can
  change password";
  allow (write) userdn="ldap:///all";)
```

If no unauthenticated access should be allowed to the Directory Server, the preferred method for preventing unauthenticated, or anonymous access is to set the Global Configuration property `reject-unauthenticated-requests` to `true`.

Delegated Access to a Manager

The following ACI can be used to allow an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which

indicates that the target entry's manager attribute must have a value equal to the DN of the authenticated user:

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct
reports";
allow (read,search,compare,write) userattr="manager#USERDN";)
```

Proxy Authorization

The following ACIs can be used to allow the application "cn=OnBehalf,ou=applications,dc=example,dc=com" to use the proxied authorization v2 control to request that operations be performed using an alternate authorization identity. The application user is also required to have the `proxied-auth` privilege as discussed later in this chapter:

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///cn=OnBehalf,ou=applications,dc=example,dc=com";)
```

Validating ACIs Before Migrating Data

Many directory servers allow for less restrictive application of their access control instructions, so that they accept invalid ACIs. For example, if Sun/Oracle encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, the PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server.

To validate an access control instruction, the PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified. Each entry in the output will contain only a single ACI, so if an entry in the input contains multiple ACIs, then it may be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values, and all other attributes will be ignored.

To Validate ACIs from a File

About this task

The `validate-acis` tool can process data contained in an LDIF file. It will ignore all attributes except `aci`, and will ignore all entries that do not contain the `aci` attribute, so any existing LDIF file that contains access control rules may be used.

Steps

1. Run the `bin/validate-acis` tool (UNIX or Linux systems) or `bat\validate-acis` (Windows systems) by specifying the input file and output file. If the output file already exists, the existing contents will be re-written. If no output file is specified, then the results will be written to standard output.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif
```

```
# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

- Review the results by opening the output file. For example, the `validated-acis.ldif` file that was generated in the previous step reads as follows:

```
# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Allow users to update their own entries";
      allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Grant full access for the admin user";
      allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

- If the input file has any malformed ACIs, then the generated output file will show what was incorrectly entered. For example, remove the quotation marks around `userPassword` in the original `test-acis.ldif` file, and re-run the command. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif \
  --onlyReportErrors
```

```
# Processing complete
# Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

The output file shows the following message:

```
# The following access control rule is malformed or contains an unsupported
# syntax: The provided string '(targetattr!=userPassword)(version 3.0; acl
# "Allow anonymous read access for anyone"; allow (read,search,compare)
# userdn="ldap:///anyone";)' could not be parsed as a valid Access Control
# Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
    (version 3.0; acl "Allow anonymous read access for anyone";
      allow (read,search,compare) userdn="ldap:///anyone";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Allow users to update their own entries";
      allow (write) userdn="ldap:///self";)

# The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
    (version 3.0; acl "Grant full access for the admin user";
      allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

To Validate ACIs in Another Directory Proxy Server

About this task

The `validate-acis` tool also provides the ability to examine ACIs in data that exists in another Directory Proxy Server that you are planning to migrate to the PingDirectoryProxy Server. The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- To use it in this manner, provide arguments that specify the address and port of the target Directory Proxy Server, credentials to use to bind, and the base DN of the subtree containing the ACIs to validate.

```
$ bin/validate-acis

# Processing complete # Total entries examined: 1
# Entries found with ACIs: 1
# Total ACI values found: 3
# Malformed ACI values found: 0
# Other processing errors encountered: 0
```

Migrating ACIs from Sun/Oracle to PingDirectory Server

This section describes the most important differences in access control evaluation between Sun/Oracle and the PingDirectory Server.

Support for Macro ACIs

Sun/Oracle provides support for macros ACIs, making it possible to define a single ACI that can be used to apply the same access restrictions to multiple branches in the same basic structure. Macros ACIs are infrequently used and can cause severe performance degradation, so support for macros ACIs is not included in the PingDirectory Server. However, you can achieve the same result by simply creating the same ACIs in each branch.

Support for the roleDN Bind Rule

Sun/Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms. The PingDirectory Server does not support DSEE roles and does not support the use of the `roleDN` ACI bind rule. However, the same behavior can be achieved by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

Targeting Operational Attributes

The Sun/Oracle access control model does not differentiate between user attributes and operational attributes. With Sun/Oracle, using `targetattr="*"` will automatically target both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` will automatically target all operational attributes in addition to all user attributes except `userPassword`. This behavior is responsible for several significant security holes in which users are unintentionally given access to operational attributes. In some cases, it allows users to do things like exempt themselves from password policy restrictions.

In the PingDirectory Server, operational attributes are treated differently from user attributes and operational attributes are never automatically included. As such, `targetattr="*"` will target all user attributes but no operational attributes, and `targetattr!="userPassword"` will target all users attributes except `userPassword`, but no operational attributes. Specific operational attributes can be targeted by including the names in the list, like `targetattr="creatorsName|modifiersName"`. All operational attributes can be targeted using the `+` character. So, `targetattr="+"` targets all operational attributes but no user attributes and `targetattr="*|+"` targets all user and operational attributes.

Specification of Global ACIs

Both DSEE and PingDirectory Server support global ACIs, which can be used to define ACIs that apply throughout the server. In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI, rather than needing to maintain an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSE entry to add values of the `aci` attribute. In the PingDirectory Server, global ACIs are managed with `dsconfig` referenced in the `global-aci` property of the Access Control Handler.

Defining ACIs for Non-User Content

In DSEE, you can write to the configuration, monitor, changelog, and tasks backends to define ACIs. In the PingDirectory Server, access control for private backends, like configuration, monitor, schema, changelog, tasks, encryption settings, backups, and alerts, should be defined as global ACIs.

Limiting Access to Controls and Extended Operations

DSEE offers limited support for restricting access to controls and extended operations. To the extent that it is possible to control such access with ACIs, DSEE defines entries with a DN such as `"oid={oid},cn=features,cn=config"` where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control: `"oid=2.16.840.1.113730.3.4.3,cn=features,cn=config"`.

In the PingDirectory Server, the `"targetcontrol"` keyword can be used to define ACIs that grant or deny access to controls. The `"extop"` keyword can be used to define ACIs that grant or deny access to extended operation requests.

Tolerance for Malformed ACI Values

In DSEE, if the server encounters a malformed access control rule, it simply ignores that rule without any warning. If this occurs, then the server will be running with less than the intended set of ACIs, which may prevent access to data that should have been allowed or, worse yet, may grant access to data that should have been restricted.

The PingDirectory Server is much more strict about the access control rules that it will accept. When performing an LDIF import, any entry containing a malformed or unsupported access control rule will be rejected. Similarly, any add or modify request that attempts to create an invalid ACI will be rejected. In the unlikely event that a malformed ACI does make it into the data, then the server immediately places itself in lockdown mode, in which the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

 **Note:** Consider running the `import-ldif` tool with the `--rejectFile` option so that you can review any rejected ACIs.

About the Privilege Subsystem

In DSEE, only the root user is exempt from access control evaluation. While administrators can create ACIs that give "normal" users full access to any content, they can also create ACIs that would make some portion of the data inaccessible even to those users. In addition, some tasks can only be accomplished by the root user and you cannot restrict the capabilities assigned to that root user.

The PingDirectory Server offers a privilege subsystem that makes it possible to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. In addition, certain particularly risky actions (such as the ability to interact with the server configuration, change another user's password, impersonate another user, or shutdown and restart the server) require that the requester have certain privileges in addition to sufficient access control rights to process the operation.

Identifying Unsupported ACIs

The PingDirectory Server provides a `validate-acis` tool that can be used to examine content in an LDIF file or data in another directory server (such as a DSEE instance) to determine whether the access control rules contained in that data are suitable for use in the PingDirectory Server instance. When migrating data from a DSEE deployment into a PingDirectory Server instance, the `validate-acis` tool should first be used to determine whether ACIs contained in the data are acceptable. If any problems are identified, then the data should be updated to correct or redefine the ACIs so that they are suitable for use in the PingDirectory Server.

For more information about using this tool, see [Validating ACIs Before Migrating Data](#).

Working with Privileges

In addition to the access control implementation, the PingDirectoryProxy Server includes a privilege subsystem that can also be used to control what users are allowed to do. The privilege subsystem works in conjunction with the access control subsystem so that privileged operations are only allowed if they are allowed by the access control configuration and the user has all of the necessary privileges.

Privileges can be used to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. In fact, the capabilities extended to root users in the PingDirectoryProxy Server are all granted through privileges, so you can create a normal user account with the ability to perform some or all of the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. Multiple root users can be defined in the server with different sets of privileges so that the capabilities that they have are restricted to only the tasks that they need to be able to perform.

Available Privileges

The following privileges are defined in the PingDirectoryProxy Server.

Summary of Privileges

Privilege	Description
audit-data-security	This privilege is required to initiate a data security audit on the server, which is invoked by the <code>audit-data-security</code> tool.
backend-backup	This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
backend-restore	This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
bypass-acl	This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed. Note, however, that this does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation (for example, a user with the <code>bypass-acl</code> privilege but without the <code>config-read</code> privilege is not allowed to access the server configuration).
bypass-pw-policy	This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is not evaluated for bind operations so that password policy evaluation will still occur when binding as a user with this privilege.

Privilege	Description
bypass-read-acl	This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.
config-read	This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.
config-write	This privilege is required for a user to alter the server configuration. The user is also required to have the <code>config-read</code> privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.
disconnect-client	This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.
jmx-notify	This privilege is required for a user to subscribe to JMX notifications generated by the Directory Proxy Server. The user is also required to have the <code>jmx-read</code> privilege.
jmx-read	This privilege is required for a user to access any information provided by the Directory Proxy Server via the Java Management Extensions (JMX).
jmx-write	This privilege is required for a user to update any information exposed by the Directory Proxy Server via the Java Management Extensions (JMX). The user is also required to have the <code>jmx-read</code> privilege. Note that currently all of the information exposed by the server over JMX is read-only.
ldif-export	This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global ACI that allows access to members of an Administrators group.
ldif-import	This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as shown in the previous description of the <code>ldif-export</code> privilege.
lockdown-mode	This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.
modify-acl	This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the <code>aci</code> operational attribute.
password-reset	This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the <code>userPassword</code> attribute to the target entry.

Privilege	Description
privilege-change	This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the <code>ds-privilege-name</code> operational attribute.
proxied-auth	This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege applies to operations that include the proxied authorization v1 or v2 control operations that include the intermediate client request control with a value set for the client identity field, or for SASL bind requests that can include an authorization identity different from the authentication identity.
server-restart	This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
server-shutdown	This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.
soft-delete-read	This privilege is required for a user to access a soft-deleted-entry.
stream-values	This privilege is required for a user to perform a stream values extended operation, which obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
unindexed-search	This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.
update-schema	This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.

Privileges Automatically Granted to Root Users

The special abilities that root users have are granted through privileges. Privileges can be assigned to root users in two ways:

- By default, root users may be granted a specified set of privileges. Note that it is possible to create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.
- Individual root users can have additional privileges granted to them, and/or some automatically-granted privileges may be removed from that user.

The set of privileges that are automatically granted to root users is controlled by the `default-root-privilege-name` property of the Root DN configuration object. By default, this set of privileges includes:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`

- lockdown-mode
- manage-topology
- metrics-read
- modify-acl
- password-reset
- permit-get-password-policy-state-issues
- privilege-change
- server-restart
- server-shutdown
- soft-delete-read
- stream-values
- unindexed-search
- update-schema

The privileges not granted to root users by default includes:

- bypass-pw-policy
- bypass-read-acl
- jmx-read
- jmx-write
- jmx-notify
- permit-externally-processed-authentication
- permit-proxied-mschapv2-details
- proxied-auth

The set of default root privileges can be altered to add or remove values as necessary. Doing so will require the `config-read`, `config-write`, and `privilege-change` privileges, as well as either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to make the change to the server's configuration.

Assigning Additional Privileges for Administrators

To allow access to the Tasks backend, set up a global ACI that allows access to members of an Administrators group as follows:

```
$ dsconfig set-access-control-handler-prop \
  --add 'global-aci:(target="ldap:///cn=tasks") (targetattr="*|+")(
    version 5.0; acl "Access to the tasks backend for administrators";
    allow (all) groupdn="ldap:///
      cn=admin,ou=groups,dc=example,dc=com";) '
```

Assigning Privileges to Normal Users and Individual Root Users

Privileges can be granted to normal users on an individual basis. This can be accomplished by adding the `ds-privilege-name` operational attribute to that user's entry with the names of the desired privileges. For example, the following change will grant the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account:

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change will be required to have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

This same method can be used to grant privileges to root users that they would not otherwise have through the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges, and removes the `server-restart` and `server-shutdown` privileges:

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

Note that because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

Disabling Privileges

Although the privilege subsystem in the PingDirectoryProxy Server is a very powerful feature, it might break some applications if they expect to perform some operation that requires a privilege that they do not have. In the vast majority of these cases, you can work around the problem by simply assigning the necessary privilege manually to the account used by that application. However, if this workaround is not sufficient, or if you need to remove a particular privilege (for example, to allow anyone to access information via JMX without requiring the `jmx-read` privilege), then privileges can be disabled on an individual basis.

The set of disabled privileges is controlled by the `disabled-privilege` property in the global configuration object. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

Deploying a Standard Directory Proxy Server

You can deploy PingDirectoryProxy Server in a variety of ways, depending upon the needs of your enterprise. This chapter describes and illustrates a standard deployment scenario.

Creating a Standard Multi-Location Deployment

In this example deployment, PingDirectoryProxy Server will be deployed in the data centers of two geographic locations: east and west. All LDAP external servers in this deployment are PingDirectory Servers. The directory servers in the eastern city are assigned to the location named east, and the directory servers in the western city are assigned to the location named west.

Note: Password policies should be kept synchronized across all PingDirectory Server and Directory Proxy Server instances. See the *PingDirectory Server Administration Guide* for details about configuring password policies.

This example refers to four PingDirectory Server instances in two locations with replication of the `dc=example,dc=com` base DN enabled:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-01.example.com`

We will configure four Directory Proxy Server instances:

- `proxy-east-01.example.com`
- `proxy-east-02.example.com`

- proxy-west-01.example.com
- proxy-west-02.example.com

Overview of the Deployment Steps

In this deployment scenario, we will take the following steps:

- Install the first Directory Proxy Server in east location using the `setup` or `setup.bat` file included in the zip installation file.
- Use the `create-initial-proxy-config` tool to provide a proxy user bind DN and password, define locations for each of our data centers, and configure the LDAP external servers in these data centers.
- Test external server communications after initial setup is complete and test a simulated external server failure.
- Install the second proxy server in the east location using the `setup` or `setup.bat` file included in the zip installation file and copy the configuration of the first Directory Proxy Server using the configuration cloning feature.
- Install two Directory Proxy Server instances in the west location, which includes using the `setup` file and manually setting the location to west using the `dsconfig` command, as well as copying the configuration of the Directory Proxy Server using the configuration cloning feature.

After the proxy server has been configured and tested, we then provide a tour of the configuration of each of the proxy server components. These properties can be modified later as needed using the `dsconfig` tool.

Installing the First Directory Proxy Server

To begin with, we have the PingDirectoryProxy Server installation zip file. In this example, we plan to use SSL security, so we also have a keystore certificate database and a pin file that contains the private key password for the keystore. The keystore files are only necessary when using SSL or StartTLS.

In this deployment scenario, the keystore database is assumed to be a Java Keystore (JKS), which can be created by the `keytool` program. For more information about using the `keytool`, see the "Security Chapter" in the *PingDirectory Server Administration Guide*.

The PingDirectoryProxy directory contains the following:

```
root@proxy-east-01: ls
ExampleKeystore.jks  ExampleTruststore.jks  ExampleKeystore.pin
PingDirectoryProxy-8.0.0.0-with-je.zip
```

The `ExampleKeystore.jks` keystore file contains the private key entry for the `proxy-east-01.example.com` server certificate with the alias `server-cert`. The server certificate, CA, and intermediate signing certificates are all contained in the `ExampleTruststore.jks` file. The password for `ExampleKeystore.jks` is defined in clear text in the corresponding pin file, though the name of the file need not match as it does in our example. The private key password in our example is the same as the password defined for the `ExampleKeystore.jks` keystore.

To Install the First Directory Proxy Server

Steps

1. Unzip the compressed archive file into the PingDirectoryProxy directory and move to this directory.

```
root@proxy-east-01: unzip -q PingDirectoryProxy-<version>-with-je.zip
root@proxy-east-01: cd PingDirectoryProxy
```

2. Because we are configuring SSL security, copy the keystore and pin files into the `config` directory.

```
root@proxy-east01: cp ../Keystore* config/
root@proxy-east01: cp ../Truststore* config/
```

- Next, we install the first proxy server by running the `setup` tool on `proxy-east-01.example.com` as follows:

```
root@proxy-east01: ./setup --no-prompt --acceptLicense \  
--ldapPort 389 --rootUserPassword pass \  
--aggressiveJVMtuning --maxHeapSize 1g \  
--enableStartTLS --ldapsPort 636 \  
--useJavaKeystore config/ExampleKeystore.jks \  
--keyStorePasswordFile config/ExampleKeystore.pin \  
--certNickname server-cert \  
--useJavaTrustStore config/ExampleTruststore.jks
```

New keystore password files are created in `config/keystore.pin`. The original file, `config/ExampleKeystore.pin`, is no longer needed.

- If you are not using SSL or StartTLS, then the SSL arguments are not necessary as follows:

```
root@proxy-east01: ./setup --no-prompt --acceptLicense \  
--ldapPort 389 --rootUserPassword pass \  
--aggressiveJVMtuning --maxHeapSize 1g
```

Once you have installed the Directory Proxy Server, you can configure it using the `create-initial-proxy-config` tool as presented in the next section.

Configuring the First Directory Proxy Server

Once the Directory Proxy Server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool. This tool can only be used once for this initial configuration, after which we will have to use `dsconfig` to make any changes to our proxy server configuration.

Configuring the Directory Proxy Server with the `create-initial-proxy-config` tool involves the following steps:

- Providing a Directory Proxy Server base DN and password.
- Defining locations for each of our data centers, east and west.
- Configuring the LDAP external server in the east location.
- Configuring the LDAP external servers in the west location.
- Applying the changes to the Directory Proxy Server.

To Configure the First Directory Proxy Server

Steps

- Once we have completed setup, we run the `create-initial-proxy-config` tool as follows:

```
root@proxy-east01: bin/create-initial-proxy-config
```

- Provide the bind DN and password that the Directory Proxy Server will use to authenticate to the backend PingDirectory Server instances. The `create-initial-proxy-config` tool requires that the same bind DN and password be used to authenticate to all of the backend servers. All Directory Proxy Server instances have identical proxy user accounts and passwords. If necessary, the proxy user account password can be defined differently for each external server using `dsconfig` after the `create-initial-proxy-config` tool has been executed.
- Specify the type of external server communication security that will be used to communicate with the PingDirectory Server instances. For this example, enter the option for 'None'.
- Specify the base DN of the PingDirectory Server instances that the Directory Proxy Server will access. For this example, use `dc=example,dc=com`.
- Enter any other base DN of the PingDirectory Server instances that will be accessed through the proxy server. Because we are only using one proxy base DN, press **Enter** to finished.

Defining Locations

Next, we define our first location, `east`, to accommodate the servers in our deployment located on the East Coast of the United States.

To Define Proxy Locations

Steps

1. Continuing from the same `create-initial-proxy-config` session, enter a location name for the Directory Proxy Server. In this example, enter `east`, and then press **Enter**.
2. Define a location named `west` for the servers in our deployment located on the West Coast. Press **Enter** when finished.
3. Select the location that contains the Directory Proxy Server itself. The Directory Proxy Server is located in the `east`.

Configuring the External Servers in the East Location

Once the locations have been defined, we need to identify the directory servers. First, we define one of the servers in the `east` location.

To Configure the External Servers in the East Location

Steps

1. Define one of the servers in the `east` location by entering the host name and port of the server. For this example, enter `ds-east-01.example.com:389`.

```
>>>> External Servers

External Servers identify directory server instances including
host, port, and authentication information.

Enter the host and port (host:port) of the first directory server
in 'east'

    b)  back
    q)  quit

Enter a host:port or choose a menu item [localhost:389]: ds-
east-01.example.com:389
```

2. Enter the option to prepare the server and all subsequent servers. Preparing the servers involves testing the connections to these servers and sets up the `cn=Proxy User` account on the Directory Proxy Server.
3. Enter the DN of the account with which to manage the `cn=Proxy User`, `cn=Root DNs`, `cn=config` account. For this example, use the default, `cn=Directory Manager`.
4. Repeat the previous steps to prepare the other server in the `east` location, `ds-east-02.example.com`.
5. Press **Enter** to complete preparing the servers.

To Configure the External Servers in the West Location

About this task

The same process used for the `east` location is used to define the LDAP external servers for the `west` location.

Steps

1. Define the first external server, `ds-west-01.example.com`.

2. Define the second server in the west location, ds-west-02.example.com.
3. Press **Enter** when finished.

Apply the Configuration to the Directory Proxy Server

Next, we review the configuration summary. Once we have confirmed that the changes are correct, we press **Enter** to write the configuration.

To Apply the Changes to the Directory Proxy Server

Steps

1. During the configuration process, the `create-initial-proxy-config` tool writes the configuration settings to a `dsconfig` batch file, which will then be applied to the Directory Proxy Server. The batch file can be reused to configure other servers. On the final step, the `create-initial-proxy-config` tool presents a configuration summary. Review the configuration and then apply the changes to the Directory Proxy Server. Press **Enter** to write the configuration to the server.
2. On the final confirmation prompt, press **Enter** to apply the changes to the proxy server, and then enter the LDAP connection parameters to the server. Once the changes have been applied, the `create-initial-proxy-config` tool cannot be used to configure this proxy server again.

Configuring Additional Directory Proxy Server Instances

We install and configure the second Directory Proxy Server by running the `setup` tool on proxy-east-02.example.com.

To Configure Additional Directory Proxy Server Instances

Steps

1. Copy the keystore and pin files into the `config` directory for the proxy-east-02.example.com server.

```
root@proxy-east-02: cp ../Keystore* config/
root@proxy-east-02: cp ../Truststore* config/
```

2. Install the second Directory Proxy Server by running the `setup` tool on proxy-east-02.example.com as follows:

```
root@proxy-east-02: ./setup --no-prompt \
--listenAddress proxy-east-02.example.com \
--ldapPort 389 --enableStartTLS --ldapsPort 636 \
--useJavaKeystore config/ExampleKeystore.jks \
--keyStorePasswordFile config/ExampleKeystore.pin \
--certNickName server-cert \
--useJavaTrustStore config/ExampleTruststore.jks \
--rootUserPassword pass --acceptLicense \
--aggressiveJVMTuning --maxHeapSize 1g \
--localHostName proxy-east-02.example.com \
--peerHostName proxy-east-01.example.com \
--peerPort 389 --location east
```

3. Configure the third Directory Proxy Server, proxy-west-01.example.com in the same way as shown in the previous step. First, copy the keystore and pin files into the `config` directory.

```
root@proxy-west-01: cp ../Keystore* config/
root@proxy-west-01: cp ../Truststore* config/
```

4. Run the `setup` tool on proxy-west-01.example.com as follows:

```
root@proxy-west-01: ./setup --no-prompt \
--listenAddress proxy-west-01.example.com \
--ldapPort 389 --enableStartTLS --ldapsPort 636 \
--useJavaKeystore config/ExampleKeystore.jks \
```

```
--keyStorePasswordFile config/ExampleKeystore.pin \
--certNickName server-cert \
--useJavaTrustStore config/ExampleTruststore.jks \
--rootUserPassword pass --acceptLicense \
--aggressiveJVMTuning --maxHeapSize 1g \
--localHostName proxy-west-01.example.com \
--peerHostName proxy-east-01.example.com \
--peerPort 389 --location west
```

5. Finally, repeat steps 3 and 4 to install the last Directory Proxy Server by first copying the keystore and pin files to the `config` directory and then running the `setup` command.

At this point, all proxies have the same Admin Data backend and have the `all-servers` group defined as their configuration-server-group in the Directory Proxy Server Global Configuration object. When making a change to a Directory Proxy Server using the `dsconfig` command-line tool or the Administrative Console, you will have the choice to apply the changes locally only or to all proxies in the `all-servers` group.

Testing External Server Communications After Initial Setup

After setting up the basic deployment scenario, the communication between the proxies and the LDAP external servers can be tested using a feature in the proxy server in combination with an LDAP search.

To Test the External Communications After Initial Setup

About this task

After initial setup, the Directory Proxy Server exposes a special search base DN for testing external server connectivity, called the `backend server pass-through subtree` view. While disabled by default, you can enable this feature using `dsconfig` in the Client Connection Policy menu. Set the value of the `backend-server-passthrough-subtree-views` property to `TRUE`.

Steps

1. Run `dsconfig` to set the `include-backend-server-passthrough-subtree-views` property to `TRUE`.

```
root@proxy-east-01: dsconfig set-client-connection-policy-prop \
--policy-name default \
--set include-backend-server-passthrough-subtree-views:true
```

Once set to true, an LDAP search against the Directory Proxy Server with the base DN `dc=example,dc=com,ds-backend-server=ds-east-02.example.com:389` instructs the Directory Proxy Server to perform the search against the `ds-east-02.example.com:389` external server with the base DN set to `dc=example,dc=com`. The value of `ds-backend-server` should be the name of the configuration object representing the external server. Depending on your naming scheme, this name may not be a `host:port` combination.

2. Run `ldapsearch` to fetch the `dc=example,dc=com` entry from the `ds-east-01.example.com` server. Perform this search on each external server to determine if external server communication has been configured correctly on the Directory Proxy Server.

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password \
--baseDN "dc=example,dc=com,ds-backend-server=ds-east-01.example.com:389" \
--searchScope base --useStartTLS "(objectclass=*)" "
```

3. You can also use this special subtree view to track the operations performed on each external server to help determine load balancing requirements. This LDAP search can be run with the base DN values for the `ds-east-01` and `ds-east-02` servers to track the distribution of search and bind requests over

time. These statistics are reset to zero when the server restarts. The following example searches an external server's monitor entry to display operation statistics:

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=directory manager" \
--bindPassword password \
--baseDN "cn=monitor,ds-backend-server=ds-east-02.example.com:389" \
--searchScope sub --useStartTLS "(cn=ldap*statistics)"

Testing a Simulated External Server Failure

Once you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the Directory Proxy Server redirects LDAP requests appropriately. In this procedure, we stop the ds-east-01.example.com:389 server instance and test searches through proxy-east-01.example.com.

To Test a Simulated External Server Failure

Steps

1. First, perform several searches against the Directory Proxy Server. Verify activity in each of the servers in the east location, ds-east-01 and ds-east-02, by looking at the access logs. Because we used the

default load balancing algorithm of fewest operations, it is likely that all of the searches will go to only one of the proxies. The following simple search can be repeated as needed:

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)" "
```

2. Next, stop the Directory Server instance on ds-east-01.example.com using the **stop-server** command and immediately retry the above searches. There should be no errors or noticeable delay in processing the search.

```
root@ds-east-01: bin/stop-server

root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)" "
```

3. Restart the Directory Proxy Server instance on ds-east-01.example.com. Check the access log to confirm that the Directory Proxy Server started to include the ds-east-01 server in load-balancing within 30 seconds. The default time is 30 seconds, though you can change this default if desired.

Automatic Server Discovery

Version 8.0.0.0 supports the use of information in the topology registry to automatically discover the backend Directory Server instances to which requests may be forwarded. This is an alternative to explicitly configuring the PingDirectoryProxy Server with the backend servers that should be used. This option is only available if all of the backend servers are Directory Server instances, and only if the following are true:

- The PingDirectoryProxy Server must be a member of the same topology as the Directory Server instances to which requests will be forwarded.
- The PingDirectoryProxy Server must be configured with an LDAP external server template that provides the settings to use when communicating with dynamically discovered backend Directory Server instances.
- The PingDirectoryProxy Server's load-balancing algorithms must be configured to use the desired LDAP external server template.
- The topology registry entries for each Directory Server instance must be updated to indicate which of the PingDirectoryProxy Server's load-balancing algorithms can forward requests to the server.

Joining a PingDirectoryProxy Server to an Existing PingDirectory Server topology

PingDirectory Server Version 8.0.0.0 supports the addition of PingDirectoryProxy Server instances to the same topology as Directory Server instances. This can be done when the PingDirectoryProxy Server instance is initially configured, using either the setup utility (in either interactive or non-interactive mode) or the manage-profile setup command. This can also be done later using the manage-topology add-server command.

Joining a Topology with Interactive Setup

If you run **setup** without any arguments, it starts in interactive mode and prompts you for all of the necessary information. After you accept the license, the next prompt asks if you want to add the server to an existing PingDirectoryProxy Server topology. If you have at least one PingDirectoryProxy Server instance that is already in the desired topology, you can enter “yes” at this prompt and it will walk you through the process of creating a new instance that is a copy of the existing instance (with all of the same configuration). You are then asked for the information needed to connect and authenticate to the existing PingDirectoryProxy Server instance. For example:

```
Do you accept the terms of this license agreement? Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []:
yes
```

```
Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: yes
```

```
Enter the host name of the peer Directory Proxy Server from which you would
like to copy configuration settings. [proxy2.example.com]:
proxy1.example.com
```

```
Enter the LDAP port of the peer Directory Proxy Server [389]: 636
```

```
How would you like to connect to the peer Directory Proxy Server?
```

- 1) None
- 2) SSL
- 3) StartTLS

```
Enter option [1]: 2
```

```
Enter the manager account DN for the peer Directory Proxy Server
[cn=Directory
Manager]: cn=Directory Manager
```

```
Enter the password for cn=Directory Manager:
The server presented the following certificate chain:
```

```

```

```
Initializing ..... Done
Reading Peer Configuration ..... Done
Connecting to 'proxy1' ..... Done
```

However, cloning an existing installation isn't possible when setting up the first PingDirectoryProxy Server instance. In this case, if you enter “no” at the prompt to join an existing PingDirectoryProxy Server topology, setup asks if you want to join a Directory Server topology instead. If you enter “yes”, the process is basically the same as joining an existing PingDirectoryProxy Server topology and you are prompted for the information needed to connect and authenticate to a Directory Server instance in the topology. The primary difference is that you have to define the PingDirectoryProxy Server configuration yourself. For example:

```
Do you accept the terms of this license agreement? Enter 'yes' to accept,
'no' to reject, or press ENTER to display the next page of the agreement []:
yes
```

```
Would you like to add this server to an existing Directory Proxy Server
```

Successfully connected to the existing PingDirectory server topology

```

Joining a Topology with Non-Interactive Setup

Interactive mode is a convenient method to get the server up and running, especially when you are just getting started, but the installation process for production deployments is generally scripted. For this process, non-interactive mode is a better choice and setup offers a number of useful arguments.

When creating the initial Directory Proxy Server instance, you can use the following arguments to join an existing Directory Server topology:

- `--existingDSTopologyHostName {address}` - The address of a Directory Server instance in the topology to be joined.
- `--existingDSTopologyPort {port}` - The port for communication with the Directory Server to retrieve information about the topology.
- `--existingDSTopologyUseSSL` - Indicates that the communication with the Directory Server to retrieve information about the topology should be encrypted with SSL.

- `--existingDSTopologyUseStartTLS` - Indicates that the communication with the Directory Server to retrieve information about the topology should be encrypted with the StartTLS extended operation.
- `--existingDSTopologyUseNoSecurity` - Indicates that the communication with the Directory Server to retrieve information about the topology should be not be encrypted.
- `--existingDSTopologyUseJavaTruststore {path}` - The path to a JKS trust store that has the information needed to trust the certificate presented by the Directory Server when using SSL or StartTLS.
- `--existingDSTopologyUsePkcs12Truststore {path}` - The path to a PKCS #12 trust store that has the information needed to trust the certificate presented by the Directory Server when using SSL or StartTLS.
- `--existingDSTopologyTrustStorePassword {password}` - The password needed to access the contents of the JKS or PKCS #12 trust store. A password is typically required when using a PKCS #12 trust store but is optional when using a JKS trust store.
- `--existingDSTopologyTrustStorePasswordFile {path}` - The path to a file containing the password needed to access the contents of the JKS or PKCS #12 trust store.
- `--existingDSTopologyBindDN {path}` - The DN of the account to use to authenticate to the Directory Server. This account must have full read and write access to the configuration and to manage the topology.
- `--existingDSTopologyBindPassword {password}` - The password for the account to use to authenticate to the Directory Server.
- `--existingDSTopologyBindPasswordFile {path}` - The path to a file containing the password to use to authenticate to the Directory Server.

For example, you can use a command similar to the following to set up a PingDirectoryProxy Server instance in the same topology as a Directory Server instance:

```
$ ./setup --acceptLicense \  
  --licenseKeyFile PingDirectory.lic \  
  --maxHeapSize 2g \  
  --localHostName proxy1.example.com \  
  --skipHostnameCheck \  
  --instanceName proxy1 \  
  --location Austin \  
  --rootUserDN "cn=Directory Manager" \  
  --rootUserPasswordFile directory-manager-password.txt \  
  --ldapPort 389 \  
  --ldapsPort 636 \  
  --httpsPort 443 \  
  --enableStartTLS \  
  --useJavaKeyStore config/keystore \  
  --keyStorePasswordFile config/keystore.pin \  
  --certNickname server-cert \  
  --useJavaTrustStore config/truststore \  
  --trustStorePasswordFile config/truststore.pin \  
  --encryptDataWithPassphraseFromFile encryption-passphrase.txt \  
  --existingDSTopologyHostName dsl.example.com \  
  --existingDSTopologyPort 636 \  
  --existingDSTopologyBindDN "cn=Directory Manager" \  
  --existingDSTopologyBindPasswordFile directory-manager-password.txt \  
  --existingDSTopologyUseSSL \  
  --existingDSTopologyUseJavaTrustStore config/truststore \  
  --no-prompt
```

As with interactive mode, it is possible to use non-interactive mode to clone the configuration of an existing PingDirectoryProxy Server instance, including joining the same topology as the existing instance. You can use the following arguments to do this rather than the arguments listed above:

- `--peerHostName {address}` - The address of a PingDirectoryProxy Server instance whose configuration should be cloned and whose topology should be joined.

- `--peerPort {port}` - The port communication with the PingDirectoryProxy Server to retrieve the configuration and topology information.
- `--peerUseSSL` - Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should be encrypted with SSL.
- `--peerUseStartTLS` - Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should be encrypted with the StartTLS extended operation.
- `--peerUseNoSecurity` - Indicates that communication with the PingDirectoryProxy Server to retrieve configuration and topology information should not be encrypted.

Note: When using SSL or StartTLS to encrypt the communication, you also need to use one of the `--useJavaTruststore` or `--usePkcs12Truststore` arguments to specify the path to a trust store with the information needed to trust the certificate that is presented by the PingDirectoryProxy Server.

The following is an example of a sample command to set up a new PingDirectoryProxy Server as a clone of an existing PingDirectoryProxy Server instance:

```
$ ./setup --acceptLicense \  
  --licenseKeyFile PingDirectory.lic \  
  --maxHeapSize 2g \  
  --localHostName proxy2.example.com \  
  --skipHostnameCheck \  
  --instanceName proxy2 \  
  --location Austin \  
  --rootUserDN "cn=Directory Manager" \  
  --rootUserPasswordFile directory-manager-password.txt \  
  --ldapPort 389 \  
  --ldapsPort 636 \  
  --httpsPort 443 \  
  --enableStartTLS \  
  --useJavaKeyStore config/keystore \  
  --keyStorePasswordFile config/keystore.pin \  
  --certNickname server-cert \  
  --useJavaTrustStore config/truststore \  
  --trustStorePasswordFile config/truststore.pin \  
  --encryptDataWithPassphraseFromFile encryption-passphrase.txt \  
  --peerHostName proxy1.example.com \  
  --peerPort 636 \  
  --peerUseSSL \  
  --no-prompt
```

Joining a Topology with manage-profile setup

The **manage-profile** tool can be used to set up an instance of the server from information contained in a server profile. This is like an enhanced version of the **setup** utility in non-interactive mode because not only does it invoke **setup**, but it can also perform other tasks like applying configuration changes, installing schema and extensions, and adding files to the server root.

Since **manage-profile setup** uses the **setup** tool in non-interactive mode, you should use the arguments listed in the previous section, including the following:

- `--existingDSTopologyHostName {address}`
- `--existingDSTopologyPort {port}`
- `--existingDSTopologyUseSSL`
- `--existingDSTopologyUseStartTLS`
- `--existingDSTopologyUseNoSecurity`
- `--existingDSTopologyUseJavaTruststore {path}`
- `--existingDSTopologyUsePkcs12Truststore {path}`
- `--existingDSTopologyTrustStorePassword {password}`
- `--existingDSTopologyTrustStorePasswordFile {path}`

- `--existingDSTopologyBindDN {path}`
- `--existingDSTopologyBindPassword {password}`
- `--existingDSTopologyBindPasswordFile {path}`

An appropriate set of arguments should be placed in the `setup-arguments.txt` file in the root directory of the profile, along with all of the other arguments that should be used when invoking `setup`.

If you have already set up an instance of the server, you can run `manage-profile generate-profile` to generate a profile from the information contained in that instance. If the server was added to the topology during the setup process, the generated profile will include an appropriate set of arguments for joining the same topology.

Note that unlike the `setup` utility, `manage-profile setup` does not support cloning an existing PingDirectoryProxy Server instance, so the `--peerHostName`, `--peerPort`, and other related arguments cannot be included in the `setup-arguments.txt` file.

Joining a Topology with `manage-topology add-server`

You can use the `manage-topology add-server` command to add a PingDirectoryProxy Server instance to a topology after it has been installed. You can only do this if the PingDirectoryProxy Server instance is not already part of any other topology, since it is not possible to join two topologies together.

This tool supports all of the normal arguments for connecting and authenticating to the local server instance, including the following:

- `--hostname {address}`
- `--port {port}`
- `--useSSL`
- `--useStartTLS`
- `--trustStorePath {path}`
- `--trustStorePassword {password}`
- `--trustStorePasswordFile {path}`
- `--bindDN {dn}`
- `--bindPassword {password}`
- `--bindPasswordFile {path}`

The `manage-topology add-server` command also allows the following arguments to provide information about a server in the topology to be joined:

- `--remoteServerHostname {address}` - The address of a server in the topology to be joined.
- `--remoteServerPort {port}` - The port for communication with the remote server.
- `--remoteServerConnectionSecurity {noSecurity|useSSL|useStartTLS}` - The type of security to use when communicating with the remote server. This value must be one of `useSSL` (to indicate that the communication should be encrypted with SSL), `useStartTLS` (to indicate that the communication should be encrypted with the StartTLS extended operation), or `noSecurity` (to indicate that the communication should not be encrypted).
- `--remoteServerBindDN {dn}` - The DN of the account to use to authenticate to the remote server.
- `--remoteServerBindPassword {password}` - The password for the account to use to authenticate to the remote server.
- `--remoteServerBindPasswordFile {path}` - The path to a file containing the password for the account to use to authenticate to the remote server.

For example, a command similar to the following could be used to add a PingDirectoryProxy Server to an existing Directory Server topology:

```
$ bin/manage-topology add-server \
  --hostname proxy1.example.com \
  --port 636 \
  --useSSL \
  --trustStorePath config/truststore \
```

```

--bindDN "cn=Directory Manager" \
--bindPasswordFile directory-manager-password.txt \
--remoteServerHostname dsl.example.com \
--remoteServerPort 636 \
--remoteServerConnectionSecurity useSSL \
--remoteServerBindDN "cn=Directory Manager" \
--remoteServerBindPasswordFile directory-manager-password.txt

```

Creating an LDAP External Server Template

An LDAP external server template is a configuration object that can be used to provide a load-balancing algorithm with many of the settings that it should use when communicating with a backend server that has been discovered from the topology registry. An LDAP external server template configuration object has most of the same properties as an LDAP external server configuration object, but omits those related to information that it obtains from the topology registry. The omitted properties include:

- server-host-name
- server-port
- location
- connection-security

In addition, the health-check-state property is also not available for LDAP external server templates since it primarily applies to individual servers rather than all of the servers associated with a load-balancing algorithm.

Because the only LDAP servers which can be in the topology registry are Directory Servers, most of the remaining properties in LDAP external server templates have the same default values as the corresponding properties in the Directory Server external server type. However, there are a couple of exceptions, including the following:

- The authentication-method property has a default value of inter-server in LDAP external server templates, while it has a default value of simple in Directory Server external servers. The inter-server authentication type indicates that the PingDirectoryProxy Server should authenticate to the Directory Server with a proprietary authentication method that uses inter-server certificates stored in the topology registry.

Note: This option is only supported if all of the Directory Server instances are version 8.0.0.0 or later.

- The key-manager-provider property has a default value of Null in LDAP external server templates, while it has no default value in Directory Server external servers. When using the inter-server authentication type, the topology registry is used to obtain the inter-server certificates, so no additional key manager provider is required.
- The trust-manager-provider property has a default value of JVM-Default in LDAP external server templates, while it has no default value in Directory Server external servers. When using the inter-server authentication type, the topology registry is used to obtain information about the listener certificates that the servers are expected to present.

In many cases the PingDirectoryProxy Server's default settings for an LDAP external server template are acceptable for most properties. However, you may wish to add custom health checks that will be invoked against servers created from the template. The PingDirectoryProxy Server will automatically check to see whether the server reports any degraded or unavailable alert types, and will also verify that the backend server's root DSE is accessible in a timely manner, but you may wish to add additional health checks, including the following:

- A search health check that verifies that the base entry from the associated subtree view can be retrieved in a timely manner.
- A replication backlog health check that verifies that replication is working and that none of the servers is too far out of sync.

The following example demonstrates the process for creating these health checks and then creating an LDAP external server template that uses them:

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-retrieve-base-entry \
  --type search \
  --set enabled:true \
  --set base-dn:dc=example,dc=com \
  --set allow-no-entries-returned:false \
  --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-replication-backlog \
  --type replication-backlog \
  --set enabled:true \
  --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
  --template-name dc_example_dc_com \
  --set health-check:dc_example_dc_com-retrieve-base-entry \
  --set health-check:dc_example_dc_com-replication-backlog
```

Defining the Load-Balancing Algorithm Configuration

In versions prior to 8.0.0.0, each load-balancing algorithm had to be explicitly configured with a set of backend servers. This is still supported, and may be the preferred configuration in some cases. For example, this is required if any backend server is not a Directory Server, or if it is a Directory Server prior to version 8.0.0.0. It may also be preferable if you wish to have more direct control over the configuration that the PingDirectoryProxy Server uses for each backend server.

Beginning with version 8.0.0.0, it is possible to configure the fewest operations and failover load-balancing algorithms so that they can automatically discover the appropriate set of backend servers from information in the topology registry. To do this, the load-balancing algorithm should be configured with a value for the `ldap-external-server-template` property rather than with one or more values for the `backend-server` property.

For example, the following configuration change can be used to create a fewest operations load-balancing algorithm that uses an LDAP external server template named `dc_example_dc_com`:

```
dsconfig create-load-balancing-algorithm \
  --algorithm-name fewest-operations-load-balancer \
  --type fewest-operations \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com
```

You can use a similar change to create an instance of a failover load-balancing algorithm that will automatically discover its backend servers:

```
dsconfig create-load-balancing-algorithm \
  --algorithm-name failover-load-balancer \
  --type failover \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com
```

Note that with the failover load-balancing algorithm, the backend servers will be ordered lexicographically by instance name. This ensures that all PingDirectoryProxy Server instances will have a consistent

ordering, but it is not as easy to control the ordering when automatically discovering backend servers as when they are explicitly configured. This is acceptable in many cases, as the primary use of failover load-balancing is often to avoid replication and unique attribute conflicts for write operations, and potentially to avoid read-after-write issues. However, if you wish to direct all traffic to a specific instance as long as it is available, then it may be better to explicitly configure the set of backend servers rather than use automatic discovery.

Although you can use just the fewest operations load-balancing algorithm or the failover load-balancing algorithm, it is recommended that you use both of these together, with failover load-balancing for writes and fewest operations for reads. When combined with the Directory Server's default use of assured replication (for all add, delete, and modify DN operations, as well as for modify operations that target passwords or password-related attributes), this provides an excellent balance that minimizes the chance for replication and unique attribute conflicts, minimizes the chance for read-after-write issues that result from propagation delay, and maximizes performance and minimizes response time for read operations. You can do this by using criteria-based load balancing, which involves the following:

- Creating a failover load-balancing algorithm instance for write operations
- Creating a fewest operations load-balancing algorithm instance for read operations
- Creating a criteria-based load-balancing algorithm instance that uses failover load-balancing for write operations
- Configuring the proxying request processor to use the above criteria-based load balancing algorithm for writes and the fewest operations load-balancing algorithm for everything else

The following is an example of this configuration::

```
# Create a health check to verify that the dc=example,dc=com entry can be
# retrieved in a timely manner.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-retrieve-base-entry \
  --type search \
  --set enabled:true \
  --set base-dn:dc=example,dc=com \
  --set allow-no-entries-returned:false \
  --set allow-multiple-entries-returned:false

# Create a health check to verify that replication is working without a
# significant backlog.
dsconfig create-ldap-health-check \
  --check-name dc_example_dc_com-replication-backlog \
  --type replication-backlog \
  --set enabled:true \
  --set base-dn:dc=example,dc=com

# Create an LDAP external server template with the above
dsconfig create-ldap-external-server-template \
  --template-name dc_example_dc_com \
  --set health-check:dc_example_dc_com-retrieve-base-entry \
  --set health-check:dc_example_dc_com-replication-backlog

# Create a fewest operations failover load-balancing algorithm instance that
# uses the default LDAP external server template for backend servers that it
# discovers from the topology registry.
dsconfig create-load-balancing-algorithm \
  --algorithm-name dc_example_dc_com-fewest-operations \
  --type fewest-operations \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com

# Create a failover load-balancing algorithm instance that also uses the
# default LDAP external server template for backend servers that it
# discovers from the topology registry.
```

```

dsconfig create-load-balancing-algorithm \
  --algorithm-name dc_example_dc_com-failover \
  --type failover \
  --set enabled:true \
  --set ldap-external-server-template:dc_example_dc_com

# Create a criteria-based load-balancing algorithm instance that will use
# failover load-balancing for writes.
dsconfig create-criteria-based-load-balancing-algorithm \
  --algorithm-name failover-for-writes \
  --set load-balancing-algorithm:dc_example_dc_com-failover \
  --set "request-criteria:Write Requests"

# Create a proxying request processor instance that uses criteria-based load
# balancing to ensure that writes use a failover strategy, and the remaining
# read operations use a default fewest operations strategy.
dsconfig create-request-processor \
  --processor-name dc_example_dc_com \
  --type proxying \
  --set load-balancing-algorithm:dc_example_dc_com-fewest-operations \
  --set criteria-based-load-balancing-algorithm:failover-for-writes

# Create a subtree view to ensure that operations below "dc=example,dc=com"
# will use the above proxying request processor.
dsconfig create-subtree-view \
  --view-name dc_example_dc_com \
  --set "base-dn:dc=example,dc=com" \
  --set request-processor:dc_example_dc_com

# Update the default client connection policy to include the above subtree
# view.
dsconfig set-client-connection-policy-prop \
  --policy-name default \
  --add subtree-view:dc_example_dc_com

```

Associating PingDirectory Server Instances with the Appropriate Load-Balancing Algorithms

When configured with an LDAP external server template, either the fewest operations algorithm or the failover load-balancing algorithm will use the topology registry to determine which Directory Server instances should be accessible through the server. To accomplish this, the load-balancing algorithm searches for directory-server-instance objects with a load-balancing-algorithm-name property that matches the name of the load-balancing algorithm. For example, in the following sample configuration, the load-balancing algorithms are named `dc_example_dc_com-fewest-operations` and `dc_example_dc_com-failover`, so if you want a Directory Server instance to be accessible through those load-balancing algorithms, add those values to the load-balancing-algorithm-name property in the topology registry's entry for that instance. You can do this with a configuration change similar to the following:

```

dsconfig set-server-instance-prop \
  --instance-name dsl.example.com:636 \
  --add load-balancing-algorithm-name:dc_example_dc_com-fewest-operations \
  --add load-balancing-algorithm-name:dc_example_dc_com-failover

```

The PingDirectoryProxy Server automatically detects and reacts to applicable changes in the topology registry. This includes the following:

- Adding a new Directory Server instance to the topology. If this instance has any load-balancing-algorithm-name values that match the names of any load-balancing algorithms that are configured for automatic backend server discovery, the new instance is immediately eligible to process client requests (as soon as the instance satisfies all of the configured health checks).

- Removing an existing Directory Server instance. If this instance had been associated with any load-balancing algorithms, then it is no longer eligible to receive requests through these load-balancing algorithms.
- Modifying an existing Directory Server instance to add one or more values to the load-balancing-algorithm-name property. If any of the new values matches the name of any of the configured load-balancing algorithms, the instance is immediately eligible to process client requests.
- Modifying an existing Directory Server instance to remove one or more values from the load-balancing-algorithm-name property. If any of the removed values matches the name of any of the configured load-balancing algorithms, then the instance is no longer eligible to receive requests through these load-balancing algorithms.

Automatic Backend Server Discovery with Entry Balancing

Entry balancing allows directory data to be split across multiple mutually exclusive sets of backend servers. This can provide better scalability by allowing a data set to be fully cached even if it is too large to fit in the memory of any single system. It can also provide better write performance by spreading entries into multiple independent replication sets.

Entry balancing breaks the data into backend sets. Each backend set has its own proxying request processor, which has its own load-balancing configuration (which may optionally include criteria-based load balancing). Each of these load-balancing algorithms may be configured to use automatic backend set discovery in exactly the same way as in a non-entry-balanced configuration. The backend sets must be explicitly configured, but the servers within each set may be automatically determined from the information in the topology registry.

Expanding the Deployment

In the following example deployment, the PingDirectory Server is deployed in a third, centrally-located data center. The directory servers in the central city is assigned to a new location named central. The proxies will use StartTLS to communicate with the directory servers in the central region.

 **Note:** Other than the ability to add to the Directory Proxy Server's truststore, the `prepare-external-server` tool does not alter the Directory Proxy Server configuration in any way.

The Directory Proxy Server itself, installed on `proxy-east-01.example.com`, remains in the East location. This example will reconfigure load balancing between the six directory servers in three locations:

- `ds-east-01.example.com`
- `ds-east-02.example.com`
- `ds-west-01.example.com`
- `ds-west-02.example.com`
- `ds-central-01.example.com`
- `ds-central-02.example.com`

Overview of Deployment Steps

In this deployment scenario, we will take the following steps:

- Prepare the new external servers using the `prepare-external-server` tool.
- Use the `dsconfig` tool to configure the new LDAP external servers in the central data center and reconfigure the load-balancing algorithm to take these servers into account.
- Test external server communications after the servers have been configured and test a simulated external server failure.

Preparing Two New External Servers Using the `prepare-external-server` Tool

First, we prepare the external directory servers, `ds-central-01` and `ds-central-02`, by creating the proxy user account and the supporting access rules. In this example, we will connect to the `ds-central-01`

PingDirectory Server using StartTLS. Because we are using StartTLS, we need to capture the ds-central-01 server's certificate and put it in the trust store on our Directory Proxy Server instance.

The `prepare-external-server` tool is located in the `bin` or `bat` directory of the server root directory, PingDirectoryProxy. In this example, we run the tool on the ds-east-01 instance of the Directory Proxy Server.

To Prepare Two New External Servers Using the prepare-external-server Tool

Steps

1. Run the `prepare-external-server` tool to prepare the two new servers. On the first attempted bind to the server, the tool will report a "failed to bind" message as it cannot bind to the `cn=Proxy User` entry due to its not being created yet. The tool sets up the `cn=Proxy User` entry so that the Directory Proxy Server can access it and tests the communication settings to the server.

```
root@proxy-east-01: ./prepare-external-server \
--hostname ds-central-01.example.com --port 389 \
--baseDN dc=example,dc=com \
--proxyBindPassword password \
--useStartTLS \
--proxyTrustStorePath ../config/ExampleTruststore.jks

Failed to bind as 'cn=Proxy User'

Would you like to create or modify root user 'cn=Proxy User' so that it is
available for this Directory Proxy Server? (yes / no)[yes]:

Enter the DN of an account on ds-central-01:389 with which to create or
manage the 'cn=Proxy User'
account [cn=Directory Manager]:

Enter the password for 'cn=Directory Manager':

Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User' privileges ....Done
```

2. Repeat the process on the other new server in the central location, ds-central-02.

 **Note:** For entry-balancing deployments, the global base DN is required when using `prepare-external-server`.

Adding the New PingDirectory Servers to the Directory Proxy Server

After preparing the external PingDirectory Servers to communicate with the Directory Proxy Server, we can now add the two servers in the central location to the proxy server instance. Because we have run the `prepare-external-server` tool, the two servers have the `cn=Proxy User` entry configured.

To Add the New PingDirectory Servers to the Directory Proxy Server

Steps

- Run the `dsconfig` tool, which is located in the `bin` or `bat` directory of the server root directory, PingDirectoryProxy.

```
root@proxy-east-01:./dsconfig

>>>> Specify LDAP connection parameters

Directory Proxy Server host name or IP address [localhost]:

How do you want to connect to the Directory Proxy Server at
```

```
localhost?
    1)  LDAP
    2)  LDAP with SSL
    3)  LDAP with StartTLS

Enter choice [1]: 1

Directory Proxy Server at localhost port number [389]:
Administrator user bind DN [cn=Directory Manager]:
Password for user 'cn=Directory Manager':
```

Adding New Locations

First, we add a new central location, to which our new PingDirectory Servers will be added.

To Add a New Location

About this task

The following steps show how to add the new servers to a new location using `dsconfig` interactive.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.

```
$ bin/dsconfig
```

2. On the main menu, enter the number corresponding to **Location**.
3. On the Location menu, enter the number corresponding to creating a new location.
4. Enter the option to create a new location from scratch.
5. Configure the `preferred-failover-location` property of the new location so that this location fails over first to the east location and then to the west location, should all of the servers in the central location become unavailable.
6. Add the east and west locations as values of the property, specifying them in the order that they will be used for failover.
7. Confirm that these are the correct values and finish configuring the location.

Editing the Existing Locations

Next, we edit the existing east and west locations to include the new central location in their failover logic. The new failover logic will be based on geographic distance, so that the east location will first fail over to central and then the west location.

To Edit Existing Locations

About this task

The following example procedure uses `dsconfig` interactive mode to edit the east location.

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. On the Directory Proxy Server console configuration menu, enter the number corresponding to Location.
3. On the Location menu, enter the number corresponding to viewing and editing an existing location. Then, enter the number corresponding to the Location to be changed.
4. Remove the west location from the `preferred-failover-location` property. It will be added later.
5. Add a new value to the `preferred-failover-location` property.
6. Select the values of the new failover locations for the east.

7. Confirm the new configuration information and save the changes.
8. Repeat steps 2-7 to reconfigure the failover logic for the west location to include the new central location.
9. List the locations to confirm that the new location was added correctly.

Adding New Health Checks for the Central Servers

Next, we must add new health checks for the two new servers.

To Add New Health Checks for the Central Servers

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Select the number corresponding to creating a new health check.
3. Enter the option to use an existing health check as a template.
4. Enter the number corresponding to the `ds-east-01` health check to use it as a template for the new health check.
5. Name the new health check using the same naming strategy established for the other servers in the deployment. As this health check is for the `ds-central-01` server, the name takes the following format:

```
>>>> Enter a name for the Search LDAP Health Check that you want to create:
ds-central-01.example.com:389_dc_example_dc_com-search-health-check
```

6. Review the configuration properties and then enter `f` to finish configuring the new health check and save changes.
7. Repeat steps 2-6 to create another new health check for the `ds-central-02` server.

Adding New External Servers

Add new external servers by selecting "External Server" from the main menu.

To Add New External Servers

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. On the External Server menu, enter the number corresponding to "Create a new External Server".
3. Base the configuration of the new external server on the existing configuration of the `ds-east-01` server. Enter `t` to use an existing External Server as a template.
4. Enter the number to base the configuration of the new server on the configuration of the `ds-east-01` server.
5. Enter a name for the new `ds-central-01` server that complies with the naming strategy.

```
>>>> Enter a name for the Ping Identity DS External Server that you
want to create: ds-central-01.example.com:389
```

6. Enter the value of the `server-host-name` property.
7. Review and modify the configuration properties of the external server.
8. On the External Server menu, change the `server-host-name` property to reflect the name of the `ds-central-01` server.
9. On the External Server menu, change the `location` property to reflect the central location.
10. Change the `health-check` property to reflect the new health check created for the `ds-central-01` server in the previous section.
11. On the 'health-check' Property menu, enter the number to remove one or more values.
12. Add the health-check created in the previous section.

13. Select the health check associated with the ds-central-01 server.
14. Press **Enter** to use the value associated with ds-central-01 health check.
15. Review the configuration of the new external server and enter **f** to create the server.
16. Repeat these steps to add the new ds-central-02 external server.

Modifying the Load Balancing Algorithm

To modify the existing load-balancing algorithm to include the newly created servers, select "Load-Balancing Algorithm" from the main menu.

To Modify the Load-Balancing Algorithm

Steps

1. Run `dsconfig` and enter the LDAP connection parameters when prompted.
2. Choose the option for Load-Balancing Algorithm.
3. On the Load-Balancing Algorithm menu, enter the number corresponding to "View and edit an existing Load-Balancing Algorithm".
4. Add the ds-central-01 and ds-central-02 servers to the `backend-server` configuration property.
5. On the backend-server property menu, enter the number corresponding to adding one or more values.
6. Select the external servers to add. In this example, select ds-central-01.example.com and ds-central-02.example.com.
7. Review the changes made to the load-balancing algorithm's configuration properties, and enter **f** to save changes.

The change has been saved and applied to the Directory Proxy Server. The load-balancing algorithm is referenced in the load-balancing-algorithm property of the request processor used by this Directory Proxy Server.

8. To view this property, go to the main menu and select the Request Processor option.
9. On the Request Processor menu, enter the number corresponding to view and edit an existing request processor.
10. Select the request process used by the Directory Proxy Server, and review the configuration properties.

This request processor is used by the subtree view serviced by the Directory Proxy Server, which is in turn referenced by the client connection policy.

 **Note:** The changes made in this procedure are already in effect. The Directory Proxy Server does not have to be restarted.

Testing External Server Communication

After adding and configuring the new external servers, test the communication between the Directory Proxy Server and the LDAP external servers using the `include-backend-server-passthrough-subtree-views` property of the Directory Proxy Server in combination with an LDAP search. For more information about this option, see [Testing External Server Communications](#) on page 190.

To Test External Server Communication

Steps

- Run the `ldapsearch` command to test communications on the ds-central-01 serverTask.

```
root@proxy-east-01: bin/ldapsearch --port 389 --bindDN "cn=directory
manager" \
--bindPassword password \
--baseDN "dc=example,dc=com,ds-backend-server=ds-central-01.example.com:389"
\
```

```
--searchScope base "(objectclass=*)" "
```

You can repeat this search on the ds-central-02 server, to confirm that the server returns the entry as expected.

Testing a Simulated External Server Failure

Once you have tested connectivity, run a simulated failure of a load-balanced external server to verify that the Directory Proxy Server redirects LDAP requests appropriately. We stop the ds-east-01.example.com:389 and ds-east-02.example.com:389 server instances and test searches through proxy-east-01.example.com.

To Test a Simulated External Server Failure

Steps

1. We stop the ds-east-01.example.com:389 and ds-east-02.example.com:389 server instances and test searches through proxy-east-01.example.com.
2. Perform several searches against the Directory Proxy Server. Verify activity in each of the servers in the east location, ds-east-01 and ds-east-02, by looking at the access logs. The following simple search can be repeated as needed:

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=Directory Manager" \
--bindPassword password --baseDN "dc=example,dc=com" \
--searchScope base --useStartTLS "(objectclass=*)" "
```

3. Next, stop the Directory Server instance on ds-east-01.example.com and ds-east-02.example.com using the stop-server command and immediately retry the above searches. There should be no errors or noticeable delay in processing the search.

```
root@proxy-east-01: bin/stop-server
```

```
root@proxy-east-01: bin/ldapsearch \
--bindDN "cn=Directory Manager" --bindPassword password \
--baseDN "dc=example,dc=com" --searchScope base --useStartTLS \
"(objectclass=*)" "
```

4. Check the access log to confirm that requests made to these servers are routed to the central servers, as these servers are the first failover location in the failover list for the ds-east-01 and ds-east-02 servers.
5. Restart the Directory Server instance on ds-east-01.example.com and ds-east-02.example.com. Check their access logs to ensure that traffic is redirected back from the failover servers.

Merging Two Data Sets Using Proxy Transformations

In the following example, the Example.com company acquires Sample Corporation. During the merger, Example.com migrates data from Sample's `o=sample` rooted directory, converting Sample's `sampleAccount` auxiliary object class usage to Example.com's `exampleAccount` object class for entries rooted under `dc=example,dc=com`. Knowing that it can take considerable time for Sample's directory clients to become aware of the new DIT and schema, proxy data transformations are created to give the Sample clients as consistent a view of the data as possible during the migratory period. These transformations allow the clients to search and modify entries under `o=sample` using the Sample Corp. schema.

Overview of the Attribute and DN Mapping

To achieve the merger of the two data sets, we create proxy transformations that map the Sample source attributes to Example.com target attributes as described in Table 9-1, "Attribute Mapping". The Example.com schema already defines an attribute to contain the RDN of user entries, called `uid`. However, Example.com chooses to create two new attributes within its `exampleAccount` object class

to accommodate two attributes in the Sample schema for representing the region and the DN of linked accounts.

During the merger, Example.com decides to re-parent Sample's customer entries, which are defined under two different subtrees, `ou=east,o=sample` and `ou=west,o=sample`, placing them under Example.com's `ou=people,dc=example,dc=com` subtree. Associated proxy transformations are described in Table 9-2, "DN Mappings". In this process, Example.com collapses the Sample tree, moving entries from the east and west region under a single DN, `dc=example,dc=com`. The DN proxy transformations assume that all Sample users have been co-located under this single Example.com subtree.

Attribute Mapping

Sample Attribute	Example.com Attribute	Description
sampleID	uid	RDN of user entries
sampleRegion	exSampleRegion	String value representing the region
sampleLinkedAccounts	exSampleLinkedAccounts	DN value

Legacy Sample LDAP applications searching for entries in either the Sample base DN `ou=east,o=sample` or `ou=west,o=sample` will be successfully serviced, though there will be one or more differences in the user entries seen by the Sample legacy applications. Since the Example.com Directory Server has no knowledge of the Sample user's former `ou=east` or `ou=west` association, search results for client searching under `o=sample` will return a DN that may differ from the original search base. For instance, a search for `sampleID=abc123` under `ou=west,o=sample` may return the user entry for `abc123` with the DN of `sampleID=abc123,ou=east,o=sample`. The following table illustrates the mapping DNs.

DN Mapping

Sample DN	Example.com DN
<code>ou=east,o=sample</code>	<code>dc=example,dc=com</code>
<code>ou=west,o=sample</code>	<code>dc=example,dc=com</code>
<code>o=sample</code>	<code>dc=example,dc=com</code>

About Mapping Multiple Source DNs to the Same Target DN

Some complications exist when defining multiple DN mappings that are used for the same request processor and the same source or target DN (or that have source or target DNs that are hierarchically related). The client request may not include enough information to disambiguate and determine the proper rule to follow.

Several solutions exist to avoid problems of disambiguation. If the client does not need to be able to see all mappings at the same time, then a new client connection policy can be created to use connection criteria that select the set of mappings applied to the client based on information such as the IP address or bind DN. Each client connection policy would have separated subtree views with separate proxying request processors that reference the appropriate transformation for that client.

Alternatively, if it is unnecessary to search under the `o=sample` base DN, then separate subtree views can be created in the same client connection policy. For example, one subtree view would be created for `ou=east,o=sample` and one for `ou=west,o=sample`. Each subtree view is then associated with its own proxying request processor, one for `ou=east` requests and one for `ou=west` requests.

An Example of a Migrated Sample Customer Entry

The following example is an example of a Sample customer entry that has been migrated to the Example.com database. The user entry is defined in the Example.com Directory Server's database as follows. The attributes that have undergone a proxy transformation are marked in bold. Note that this view is how the entry appears to search requests under the `dc=example,dc=com` base DN.

```
dn: uid=scase,ou=People,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: uid=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

The following examples shows what the Directory Proxy Server returns to LDAP clients who have requested the entry when searching under the `o=sample` base DN. Note that the DN returned includes `ou=east`, even though this branch does not exist in the Example.com DIT. It also returns the attribute names as they are defined in the Sample schema.

```
dn: sampleID=scase,ou=east,o=sample
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
exAccountNumber: 234098
exSampleRegion: east
exSampleLinkedAccounts: sampleID=jcase,ou=people,dc=example,dc=com
userPassword: password
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
l: Arlington
mail: sterlingcase@maildomain.com st: VA
```

Overview of Deployment Steps

In this deployment scenario, we will take the following steps:

- Install any necessary schema on the Directory Proxy Server.
- Create three attribute mapping proxy transformations and three DN mapping proxy transformations
- Create a new proxying request processor, using the existing `dc_example_dc_com` request processor as a template.
- Assign the six proxy transformations to the new proxying request processor.
- Create a new subtree view for `o=sample` that references the new proxying request processor.

- Add the new subtree view to the existing client connection policy.
- Test our configuration by performing some searches on the Sample DIT.

About the Schema

The Directory Proxy Server inherits user-defined schema from all external servers by comparing `cn=schema` on these servers at Directory Proxy Server startup and at five minute intervals. As a result, `example.com` schema does not need to be added manually to the Directory Proxy Server's `config/schema` directory. We assume that the schema for Sample entries has been defined on the external servers with the `example.com` DIT, requiring no direct schema management on the Directory Proxy Server. The following schema definitions are assumed to exist on the external Directory Server:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.1
  NAME 'exAccountNumber'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.3
  NAME 'sampleLinkedAccounts'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.2
  NAME 'sampleRegion'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.1.1.1
  NAME 'sampleID'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.3
  NAME 'exSampleLinkedAccounts'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.12 )
attributeTypes: ( 1.3.6.1.4.1.32473.2.1.2
  NAME 'exSampleRegion'
  SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
  SINGLE-VALUE )
objectClasses: ( 1.3.6.1.4.1.32473.2.2.1
  NAME 'exampleAccount'
  SUP top
  AUXILIARY
  MAY ( exAccountNumber $
    exSampleRegion $
    exSampleLinkedAccounts $
    sampleID $
    sampleRegion $
    sampleLinkedAccounts ) )
```

The schema file defines some `Example.com` schema, such as `exAccountNumber` and `exSampleRegion`, and some `Sample` schema, such as `sampleRegion` and `sampleID`.

Creating Proxy Transformations

We create three attribute mapping proxy transformations and three DN mapping proxy transformations. We run the `dsconfig` tool, which is located in the `bin` or `bat` directory of the server root directory, `PingDirectoryProxy`.

To Create Proxy Transformations

Steps

1. In the main server root directory, PingDirectoryProxy, run the `start-server` command.

```
$ bin/start-server
```

2. Run `dsconfig` in interactive mode and enter the LDAP connection parameters.
3. On the Configuration main menu, enter the number corresponding to **Proxy Transformation**.

Creating the Attribute Mapping Proxy Transformations

Next, we create the attribute mapping proxy transformations using `dsconfig` interactive. We assume for this example that we are continuing from the previous `dsconfig` session. In the following example, this transformation maps `ou=east,o=sample` in the Sample schema `dc=example,dc=com` in the Example.com schema.

To Creating the Attribute Mapping Proxy Transformations

Steps

1. On the Proxy Transformation menu, enter the number corresponding to "Create a New Proxy Transformation".
2. Create a mapping from the `sampleRegion` attribute to the `exSampleRegion` attribute, enter the number corresponding to "Attribute Mapping Proxy Transformation".

```
>>>> Select the type of Proxy Transformation that you want to create:
```

- ```

1) Attribute Mapping Proxy Transformation
2) Default Value Proxy Transformation
3) DN Mapping Proxy Transformation
4) Groovy Scripted Proxy Transformation
5) Simple To External Bind Proxy Transformation
6) Suppress Attribute Proxy Transformation
7) Suppress Entry Proxy Transformation
8) Third Party Proxy Transformation
```

3. Enter a descriptive name for the new proxy transformation that illustrates the attribute mapping that it performs.
4. Press **Enter** to enable the proxy transformation.
5. Provide the name of the source attribute in the Sample schema to map to the Example.com schema, which is `sampleRegion`.
6. Review the configuration properties, and enter `f` to create the new attribute mapping proxy transformation.
7. Repeat the previous steps to create another attribute mapping proxy transformation. This time, map between the Sample Corporation's `sampleID` attribute and the Example.com `uid` attribute.
8. Repeat the previous steps again to create a last attribute mapping proxy transformation, mapping between the Sample `sampleLinkedAccounts` attribute and the Example.com `exSampleLinkedAccounts` attribute.

### Creating the DN Mapping Proxy Transformations

Now we create the DN mapping proxy transformations.

## To Create the DN Mapping Proxy Transformations

### Steps

1. On the Proxy Transformation menu, enter the number corresponding to Create a new Proxy Transformation.
2. Enter the option to create a new Proxy Transformation from scratch.
3. Enter the option for "DN Mapping Proxy Transformation."
4. Enter a name for the DN Mapping Proxy Transformation. This transformation maps `ou=east,o=sample` in the Sample schema `dc=example,dc=com` in the Example.com schema.
5. Select `TRUE` to enable the transformation by default.
6. Specify the source DN as it appears in client requests.

```
>>>> Configuring the 'source-dn' property
```

```
Specifies the source DN that may appear in client
requests which should be remapped to the target DN.
Note that the source DN must not be equal to the target DN.
```

```
Syntax: DN
```

```
Enter a value for the 'source-dn' property:
ou=east,o=sample
```

7. Specify the target DN, where requests for the source DN should be routed.

```
>>>> Configuring the 'target-dn' property
```

```
Specifies the DN to which the source DN should be mapped.
Note that the target DN must not be equal to the source
DN.
```

```
Syntax: DN
```

```
Enter a value for the 'target-dn' property: dc=example,dc=com
```

8. Review the configuration properties, and then enter `f` to create the new DN mapping proxy transformation.
9. using the previous steps, create a new DN mapping proxy transformation that maps `ou=west,o=sample` in the Sample schema to `dc=example,dc=com` in the Example.com schema, and name it `sample_west-to-example`.
10. Finally, create a DN mapping proxy transformation for the base DN of the Sample database.

## Creating a Request Processor to Manage the Proxy Transformations

Next, we need to create a new proxying request processor that includes our new attribute and DN mapping proxy transformations. We will use the existing `dc_example_dc_com` request processor as a template.

### To Create a Request Processor to Manage Proxy Transformations

#### Steps

1. On the Configuration main menu, enter the number corresponding to Request Processor.
2. On the Request Processor menu, enter the number corresponding to "Create a new Request Processor."
3. Choose the option to use the current request processor as a template.
4. Provide a name for the new proxying request processor, such as `o_sample-req-processor`.

5. Review the properties. The load-balancing algorithm is the same as for the previous request processor, though the transformation property must be changed. Enter the number corresponding to the `Transformation` property.
6. Enter the number corresponding to the proxy transformations that we created in the previous sections.
7. Select the attribute mapping proxy transformations first. Next, select the DN mapping proxy transformations. The order of the selection is important because we have related DNs. Begin with the DNs that are lower in the tree first, and finish with the base DN transformation.

```
Select the Proxy Transformations you wish to add:
```

```

1) sample-to-example 5) sampleLinkedAccounts-to-
 sampleLinkedAccounts
2) sample_east-to-example 6) sampleRegion-to-
 exSampleRegion
3) sample_west-to-example 7) Create a new Proxy
 Transformation
4) sampleID-to-uid 8) Add all Proxy Transformations

?) help
b) back
q) quit

```

```
Enter one or more choices separated by commas [b]: 4,5,6,2,3,1
```

8. Confirm that the proxy transformations are listed in the correct order and press **Enter** to accept and use the values.
9. Review the request processor properties, and enter `f` to save changes.

### Creating Subtree Views

At this stage, we need to configure subtree views for the Directory Proxy Server.

#### To Create Subtree Views

##### Steps

1. On the Configuration main menu, enter the number corresponding to Subtree View.
2. On the Subtree View menu, enter the number corresponding to "Create a new Subtree View."
3. Enter the option to create the new subtree view from an existing one.
4. Select the `dc_example_dc_com-view` subtree view.
5. Enter a descriptive name for the subtree view configuration.
6. Configure the base DN property of the Sample dataset.
7. Enter the request processor created in the previous section.
8. Review the configuration properties, and enter `f` to save changes.

```
>>>> Configure the properties of the Subtree View
```

```

Property Value(s)

1) description -
2) base-dn "o=sample"
3) request-processor o_sample-req-processor

?) help
f) finish - create the new Subtree View
d) display the equivalent dsconfig arguments to create this
 object
b) back
q) quit

```

## Editing the Client Connection Policy

Finally, we edit the client connection policy to add our new `o=sample` subtree view.

### To Edit the Client Connection Policy

#### Steps

1. On the Configuration main menu, enter the number corresponding to Client Connection Policy.
2. On the Client Connection menu, enter the number corresponding to "Create a new Client Connection."
3. In the configuration properties, select the `subtree-view` property. Enter the number corresponding to "Add one or more values" to add the new subtree view created for the previous example.
4. Select the subtree view that was created in the previous section.

```
Select the Subtree Views you wish to add:
```

- ```
1) o_sample-view
2) Create a new Subtree View
```

5. Review the subtree views now referenced by the property and press **Enter** to use these values.
6. Review the configuration properties of the client connection policy and enter `f` to save changes.

Testing Proxy Transformations

After setting up the deployment scenario, the Directory Proxy Server will now respond to requests to the `dc=example,dc=com` and `o=sample` base DNS. We now test the service by imitating example client requests to search and modify users.

Testing Proxy Transformations

About this task

The following example fetches the user with `sampleID=scase` under the `ou=east,o=sample` base DN.

Steps

1. Run `ldapsearch` to view a Sample entry.

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
--bindPassword password --baseDN "ou=east,o=sample" "(sampleID=scase) "
```

```
dn: sampleID=scase,ou=People,ou=east,o=sample
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: exampleAccount
objectClass: top
description: A customer account migrated from Sample merger
sampleID: scase
userPassword: {SSHA}A5O4RrQHWXc2Ii3btD4exGdP0TVW9VL3CR3ZXA==
exAccountNumber: 234098
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
mail: sterlingcase@maildomain.com
l: Arlington
st: VA
sampleRegion: east
sampleLinkedAccounts: sampleID=jcase,ou=People,ou=east,o=sample
```

2. Modify the `sampleRegion` value, changing it to `west`. To do this, we first create a `ldapmodify` input file, called `scase-mod.ldif`, with the following contents:

```
dn: sampleID=scase,ou=People,ou=east,o=sample
changetype: modify
replace: sampleRegion
sampleRegion: west
```

3. Use the file as an argument in the `ldapmodify` command as follows.

```
root@proxy-east-01: bin/ldapmodify --bindDN "cn=Directory Manager" \
--bindPassword password --filename scase-mod.ldif
```

```
Processing MODIFY request for sampleID=scase,ou=People, ou=east,o=sample
MODIFY operation successful for DN sampleID=scase,ou=People,
ou=east,o=sample
```

4. Search for `scase`'s `sampleRegion` value under `o=sample`, we should see `west`:

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
--bindPassword password --baseDN "o=sample" "(sampleID=scase)" \
sampleRegion
```

```
dn: sampleID=scase,ou=People,ou=east,o=sample
sampleRegion: west
```

5. Search for `scase` by `uid` rather than `sampleID`, under the `dc=example,dc=com` base DN. We see the `Example.com` schema version of the entry:

```
root@proxy-east-01: bin/ldapsearch --bindDN "cn=directory manager" \
--bindPassword password --baseDN "dc=example,dc=com" "(uid=scase)"
```

```
dn: uid=scase,ou=People,dc=example,dc=com
objectClass: person
objectClass: exampleAccount
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
description: A customer account migrated from Sample merger
uid: scase
userPassword: {SSHA}A5O4RrQHwXc2Ii3btD4exGdP0TVW9VL3CR3ZXa==
exAccountNumber: 234098
givenName: Sterling
cn: Sterling Case
sn: Case
telephoneNumber: +1 804 094 3356
street: 00468 Second Street
mail: sterlingcase@maildomain.com
l: Arlington
st: VA
exSampleRegion: west
exSampleLinkedAccounts: uid=jcase,ou=People,dc=example,dc=com
```

Deploying an Entry-Balancing Directory Proxy Server

You can deploy PingDirectoryProxy Server in a variety of ways, depending upon the needs of your enterprise. This chapter describes and illustrates an entry-balancing deployment scenario.

Deploying an Entry-Balancing Proxy Configuration

Entry-balancing is a Directory Proxy Server configuration that allows the entries within a portion of the Directory Information Tree (DIT) to reside on multiple external servers. This configuration is typically useful

when the DIT contains many millions of entries, which can be difficult to bring completely into memory for optimal performance. Entry-balancing allows entries under a balancing point base DN to be divided among any number of separate directory servers, making the Directory Proxy Server responsible for intelligently routing requests based on the division.

In this example scenario, the entries in the DIT outside of the balancing point are replicated across all external servers known to the Directory Proxy Server. Replication on the external directory servers must be properly configured before proceeding through this example. The directory servers are expected to contain two replication domains: the global domain, `dc=example,dc=com`, and the balancing point, `ou=people,dc=example,dc=com`.

In this deployment scenario, an `austin-proxy1` instance of the Directory Proxy Server communicates with four external directory servers. The Directory Proxy Server is configured to use entry balancing for the `ou=people,dc=example,dc=com` base DN, with two sets of user entries split beneath it. The first set of user entries is defined in the replicated pair of external servers, `austin-set1.example.com` and `newyork-set1.example.com`. The second set of entries is defined in `austin-set2.example.com` and `newyork-set2.example.com`. The entries in the `dc=example,dc=com` DIT outside of the balancing point base DN are replicated among the four external servers.

The following `dsreplication status` output from the PingDirectory Server external servers describes the replication configuration that exists before creating the Directory Proxy Server configuration.

```
--- Replication Status for dc=example,dc=com: Enabled ---
Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----
austin-set1.example.com:389 : 10003 : 0 : N/A : 722087263
austin-set2.example.com:389 : 10003 : 0 : N/A : 722087263
newyork-set1.example.com:389 : 10003 : 0 : N/A : 722087263
newyork-set2.example.com:389 : 10003 : 0 : N/A : 722087263

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset1):
Enabled ---
Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----
austin-set1.example.com:389 : 100001 : 0 : N/A : 178892712
newyork-set1.example.com:389 : 100001 : 0 : N/A : 178892712

--- Replication Status for ou=people,dc=example,dc=com (Set: dataset2):
Enabled ---
Server : Entries : Backlog : Oldest Backlog Change Age : Generation ID
-----:-----:-----:-----:-----:-----
austin-set2.example.com:389 : 100001 : 0 : N/A : 1057593890
newyork-set2.example.com:389 : 100001 : 0 : N/A : 1057593890
```

Determining How to Balance Your Data

If a single Directory Server instance can hold all of your data, then we recommend storing your data on a single server and replicating for high availability, as this simplifies your deployment. If a single server cannot hold all of your data, then you can spread it across multiple servers in several ways:

- If the data is already broken up by hierarchy and all of the clients understand how to access it that way, the number of top-level branches is small and a single Directory Server instance can hold all of the information within one or more branches. Configure the Directory Proxy Server with multiple base DN's and use simple load-balancing rather than entry balancing to simplify your deployment.
- If simply breaking up the data using the existing hierarchy is not an option, for example if a large number of top-level branches must be configured, then consider using entry balancing. The contents of

any single branch still must fit on a given server, because only entries that are immediate subordinates of the entry-balancing base DN may be spread across multiple servers. Any entries that are further subordinates have to be placed in the same directory server instance as their parent.

- If one or more branches are so large that any single Directory Server instance cannot hold all of the data, you need to use entry balancing within that branch to divide the entries among two or more sets of Directory Servers. You may also need to change the way that the data is arranged in the server so that it uses as flat a DIT as possible, which is easier to use in an entry-balancing deployment.

In an entry-balancing deployment, there can be data that is common to all external directory servers outside the balancing point. This data is referred to as the global domain. The Directory Proxy Server entry-balancing configuration will contain at least two subtree views and associated request processors, one for the global domain and one for the entry-balancing domain. In our examples, the global domain is `dc=example,dc=com` and the entry-balancing domain is `ou=people, dc=example,dc=com`. The entry-balancing base DN, `ou=people,dc=example,dc=com`, is also the balancing point.

Entry Balancing and ACIs

In an entry-balancing deployment, access control instructions (ACIs) are still configured in the backend Directory Server data. When defining access controls in an entry-balancing deployment, you need to ensure that the data used by the access control rule is available for evaluation on all datasets.

If you use groups for access control and a group contains users from different data sets, then that group must exist on each dataset. For a single ACI to be applicable to entries in all datasets, it must be specified above the entry-balancing point. For example, if an ACI allows access to modify users that are part of group 1, then two things must exist on both data sets:

- Group 1 must exist in the `ou=groups` branch of both datasets.
- The ACI referencing group 1 must exist in the `ou=people` branch or above. The `ou=people` branch entry itself is part of the common data.

The Directory Proxy Server ensures that any changes to entries within the scope of the entry-balancing request processor, but outside the balancing point, are applied to all backend server sets. Any ACI stored at the entry-balancing point will be kept in sync if changes are made through the Directory Proxy Server.

Overview of Deployment Steps

In this deployment scenario, we will take the following steps:

- Install the Directory Proxy Server on `austin-proxy1`.
- Use the `create-initial-proxy-config` tool to provide our initial setup for entry balancing. The initial setup includes defining multiple subtree views and global indexes in support of entry balancing.
- Change the placement algorithm of the `austin-proxy-01` server to use an entry-count placement algorithm. This algorithm is used to select the backend set to which to forward an add request. It looks at the number of entries in the backend sets and forwards the add request to the backend with either the fewest or the most entries, depending on the configuration. You can also configure the placement algorithm to make the decision based on the on-disk database size rather than the number of entries.

Installing the Directory Proxy Server

We start by configuring the Directory Proxy Server. The four external servers, `austin-set1.example.com`, `newyork-set1.example.com`, `austin-set2.example.com`, and `newyork-set2.example.com`, are running.

To Install the Directory Proxy Server

Steps

- Run the `setup` program in non-interactive mode.

```
root@austin-proxy1: ./setup --acceptLicense \  
--listenAddress austin-proxy1.example.com \  
--listenAddress newyork-proxy1.example.com \  
--listenAddress austin-proxy2.example.com \  
--listenAddress newyork-proxy2.example.com
```

```
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --entryBalancing \
--aggressiveJVMTuning --maxHeapSize 2g --no-prompt
```

Configuring the Entry-Balancing Directory Proxy Server

Once the Directory Proxy Server has been installed, it can be automatically configured using the `create-initial-proxy-config` tool. This tool can only be used once for this initial configuration, after which we will have to use `dsconfig` to make any changes to our Directory Proxy Server configuration.

To Configure the Entry-Balancing Directory Proxy Server

Steps

1. Run the `create-initial-proxy-config` tool.

```
root@austin-proxy1: ./bin/create-initial-proxy-config
```

2. Our topology meets the requirements, press **Enter** to continue:

```
Some assumptions are made about the topology to keep
this tool simple:
```

- 1) all servers will be accessible via a single user account
- 2) all servers support the same communication security type
- 3) all servers are PingDirectoryProxy Servers

```
If your topology does not have these characteristics you can
use this tool to define a basic configuration and then use the
'dsconfig' tool or the Administrative Console to fine tune the
configuration.
```

```
Would you like to continue? (yes / no) [yes]:
```

3. Provide the external server access credentials. All of our proxies have identical proxy user accounts and passwords.

```
Enter the DN of the proxy user account [cn=Proxy User,cn=Root
DNs,cn=config]:
```

```
Enter the password for 'cn=Proxy User,cn=Root DNs,cn=config':
Confirm the password for 'cn=Proxy User,cn=Root DNs,cn=config':
```

4. Specify the type of security that the Directory Proxy Server will use to communicate with Directory Servers.
5. Enter a base DN of the Directory Server instances that will be accessed by the Directory Proxy Server.
6. Define the balancing point as a separate base DN, which is entry balanced:

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:
```

- 1) Remove dc=example,dc=com
- b) back
- q) quit

```
Enter a DN or choose a menu item [Press ENTER when finished
entering base DNs]: ou=people,dc=example,dc=com
```

```
Are entries within 'ou=people,dc=example,dc=com' split across
multiple servers so that each server stores only a subset of
the entries (i.e. is this base DN 'entry balanced')? (yes / no)
[no]: yes
```

7. In this example, the data in `ou=people,dc=example,dc=com` will be split across two backend sets. Enter 2 to specify that the data will be balanced across two sets of servers.

```
Across how many sets of servers is the data balanced?
```

```
  c) cancel creating ou=people,dc=example,dc=com
  q) quit
```

```
Enter a number greater than one or choose a menu item: 2
```

8. The balancing point is the same as our base DN, `ou=people,dc=example,dc=com.`, so we use it as the entry balancing base.

```
>>>> Entry Balancing Base
```

```
The entry balancing base DN specifies the entry below which the
data is balanced. Entries not below this entry must be duplicated
in all the server sets. If all the entries in the base DN are
distributed the entry balancing base DN is the same as the base DN.
```

```
  c) cancel creating ou=people,dc=example,dc=com
  b) back
  q) quit
```

```
Enter the entry balancing base DN or choose a menu item
```

```
[ou=people,dc=example,dc=com]: ou=people,dc=example,dc=com
```

9. To improve the performance for equality search filters referencing the `uid` attribute, create a `uid` global index. Enter `yes` to add a new attribute to the global index.

10. Specify the `uid` attribute.

```
Enter attributes that you would like to add to the global index:
```

```
  c)cancel creating ou=people,dc=example,dc=com
  b)back
  q)quit
```

```
Enter an attribute name or choose a menu item [Press ENTER when
finished entering index attributes]: uid
```

11. To optimize Directory Proxy Server performance from the moment it starts accepting connections, enter the number corresponding to "Yes, and all subsequent attributes."

12. Press **Enter** to finish specifying index attributes.

13. Press **Enter** to enable RDN index priming.

```
Would you like to enable RDN index priming for
'ou=people,dc=example,dc=com'? (yes / no) [yes]:
```

14. Press **Enter** to finish specifying base DN's.

```
Enter another base DN of the directory server instances that
will be accessed through the Directory Proxy Server:
```

```
  1) Remove dc=example,dc=com
  2) Remove ou=people,dc=example,dc=com (distributed)

  b) back
  q) quit
```

```
Enter a DN or choose a menu item [Press ENTER when finished
entering base DN's]:
```

- 15.** The external servers are spread among two locations, New York and Austin. This Directory Proxy Server instance is located in the austin location.

```
A good rule of thumb when naming locations is to use the
name of your data centers or the cities containing them.
```

- ```
b) back
q) quit
```

```
Enter a location name or choose a menu item: austin
```

- ```
1) Remove austin
b) back
q) quit
```

- 16.** Define the newyork location:

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]: newyork
```

- ```
1) Remove austin
2) Remove newyork
b) back
q) quit
```

```
Enter another location name or choose a menu item [Press ENTER
when finished entering locations]:
```

- 17.** Select the austin location for this Directory Proxy Server instance:

```
Choose the location for this Directory Proxy Server
```

- ```
1) austin
2) newyork
b) back
q) quit
```

```
Enter choice [1]:
```

- 18.** Specify the LDAP external server instances associated with this location.

```
Enter the host and port (host:port) of the first directory server
in 'austin'
```

- ```
b) back
q) quit
```

```
Enter a host:port or choose a menu item [localhost:389]:
austin-set1.example.com:389
```

- 19.** Specify that the austin-set1 server can handle requests from the global domain and from set 1 restricted domain.

```
Assign server austin-set1.example.com:389 to handle requests for
one or more of the defined sets of data:
```

- ```
1) dc=example,dc=com
2) ou=people,dc=example,dc=com; Server Set 1
3) ou=people,dc=example,dc=com; Server Set 2
```

```
Enter one or more choices separated by commas: 1,2
```

- 20.** Enter the number corresponding to "Yes, and all subsequent servers" to prepare the server for access by the Directory Proxy Server.

```
Would you like to prepare austin-set1.example.com:389 for access
by the Directory Proxy Server?
```

- ```
1) Yes
2) No
3) Yes, and all subsequent servers
4) No, and all subsequent servers
```

```
Enter choice [3]:
```

- 21.** Select the entry-balanced data set that the austin-set1 server replicates with other servers.

```
You may choose a single entry-balanced data set with which
austin-set1.example.com:389 will replicate data with other servers
```

- ```
1) ou=people,dc=example,dc=com; Server Set 1
2) None, data will not be replicated
```

```
Enter choice: 1
```

```
Testing connection to austin-set1.example.com:389 ..... Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access ....Denied
```

- 22.** Modify the root user for use by the Directory Proxy Server, specifying the directory manager password for the initial creation of the proxy user.

```
Would you like to create or modify root user 'cn=Proxy User,
cn=Root DNs,cn=config' so that it is available for this
Directory Proxy Server? (yes / no) [yes]:
```

```
Enter the DN of an account on austin-set1.example.com:389
with which to create or manage the 'cn=Proxy User,cn=Root DNs,
cn=config' account and configuration [cn=Directory Manager]:
```

```
Enter the password for 'cn=Directory Manager':
Created 'cn=Proxy User,cn=Root DNs,cn=config'
Testing 'cn=Proxy User,cn=Root DNs,cn=config'privileges...Done
Setting replication set name .....
```

- 23.** Since the replication set name has already been configured, we do not need to use the name created automatically by the Directory Proxy Server.

```
This server is currently configured for replication set 'dataset1'.
Would you like to reconfigure this server for replication set
'set-1'? (yes / no) [no]:
```

```
Setting replication set name ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
Verifying backend 'ou=people,dc=example,dc=com' ..... Done
Testing 'cn=Proxy User' privileges ..... Done
Verifying backend 'dc=example,dc=com' ..... Done
```

- 24.** Define the other Austin and New York servers using the same procedure as in the previous example:

```
Enter another server in 'austin'
```

- ```
1) Remove austin-set1.example.com:389
b) back
q) quit
```

```
Enter a host:port or choose a menu item [Press ENTER when
finished entering servers]: austin-set2.example.com:389
```

Assign server austin-set2.example.com:389 to handle requests for one or more of the defined sets of data

- 1) dc=example,dc=com
- 2) ou=people,dc=example,dc=com; Server Set 1
- 3) ou=people,dc=example,dc=com; Server Set 2

Enter one or more choices separated by commas: 1,3

You may choose a single entry-balanced data set with which austin-set2.example.com:389 will replicate data with other servers

- 1) ou=people,dc=example,dc=com; Server Set 2
- 2) None, data will not be replicated

Enter choice: 1

Testing connection to austin-set2.example.com:389 ....Done

## Configuring the Placement Algorithm Using a Batch File

Now, we configure the placement algorithm using a batch file. We want to place new entries added through the proxy via LDAP ADD operations into the least used dataset. We do this using an entry-count placement algorithm. To change the placement algorithm from round-robin to entry-count, we first create and enable an entry-count placement algorithm configuration object and then disable the existing round-robin placement algorithm. Our batch file, `dsconfig.post-setup`, contains the `dsconfig` commands required to create the entry-count placement algorithm and disable the old round-robin algorithm.

## To Configure the Placement Algorithm Using a Batch File

### About this task

The batch file contains comments to explain each `dsconfig` command. Note that in this example, line wrapping is used for clarity. The `dsconfig` command requires that the full command be provided on a single line.

The batch file itself looks like the following:

```
root@austin-proxyl:more ../dsconfig.post-setup

This dsconfig operation creates the entry-count placement
algorithm with the default behavior of adding entries to the
smallest backend dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true

Note that once the entry-count placement algorithm is created
and enabled, we can disable the round-robin algorithm.
Since an entry-balancing proxy must always have a placement
algorithm, we add a second algorithm and then disable the
original round-robin algorithm created during the setup
procedure.

dsconfig set-placement-algorithm-prop
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false

At this point, LDAP ADD operations will be forwarded to an external
server representing the dataset with the least number of entries.
```

### Steps

- Run the `dsconfig` command using the batch file. Once the batch file has executed, a new entry-count placement algorithm, called `entry-count`, has been created, and the old round-robin placement algorithm, `round-robin`, has been disabled.

```
root@austin-proxyl: bin/dsconfig --no-prompt \
--bindDN "cn=directory manager" --bindPassword password \
--port 389 --batch-file ../dsconfig.post-setup
```

```
Batch file '../dsconfig.post-setup' contains 2 commands
```

```
Executing: create-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name entry-count --type entry-counter --set enabled:true
```

```
Executing: delete-placement-algorithm --no-prompt
--bindDN "cn=directory manager" --bindPassword pass
--port 1389
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin --set enabled:false
```

## Rebalancing Your Entries

If your deployment distributes entries using an entry counter placement algorithm or 3rd party algorithm, you may need to redistribute your entries. For example, imagine that you have an environment that

distributes entries across three backends using an entry counter placement algorithm. This algorithm distributes entries to the backend that has the most space. Imagine that the backends all reach their maximum capacity and you decide to add a new backend to the deployment. You need to move the entries from the full backends and distribute them evenly across all the backends, including the new backend.

You might also want to deliberately rebalance your entries to meet the needs of your organization. For example, you can direct entry balancing based on attributes on the entries themselves. You can write a custom algorithm that looks at the value of an attribute that is being modified on the entry. Based on the attribute, you can then put this entry somewhere specific. You might use this feature if you want to have certain entries closer geographically to the client application using them. The geographical information could be included in the entry. Rebalancing would be used to move these entries to the server in the correct geographical location.

You can redistribute entry-balanced entries in two ways:

- **Using dynamic rebalancing.** With dynamic rebalancing, as existing entries get modified, they get moved. You configure dynamic rebalancing in the entry counter placement algorithm.
- **Using the `move-subtree` tool.** This tool can be used to move either small subtrees through a transactional method or to move large subtrees, potentially taking them offline for a short period.

The remainder of this section describes each of these method of entry rebalancing in more detail.

### About Dynamic Rebalancing

During dynamic rebalancing entries get moved as they are modified. You configure dynamic rebalancing on the entry counter placement algorithm or a third-party placement algorithm that supports rebalancing. This algorithm keeps a count of the number of entries or the size of the backend set. You configure dynamic rebalancing using the following parameters:

- **`rebalancing-enabled`** . Determines whether entry rebalancing is enabled. When rebalancing is enabled, the placement algorithm is consulted after modify and add operations, to determine whether the target entry should be moved to a different backend set.
- **`rebalancing-scope`** . Indicates which modified entries are candidates for rebalancing. A value of `top-level` indicates that only entries immediately below the entry-balancing base can be rebalanced. A value of `any` indicates that entries at any level below the entry-balancing base may be rebalanced.
- **`rebalancing-minimum-percentage`** . Specifies the minimum threshold for entries to be migrated from one backend set to a preferred backend set with a smaller size. Entries are not migrated unless the percentage difference between the value of the current backend set and the value of the preferred backend set exceeds this threshold. This parameter prevents unnecessarily migrating entries back and forth between backend sets of similar sizes.
- **`rebalancing-subtree-size-limit`** . Specifies the maximum size of a subtree that can be rebalanced.
- **`poll-interval`** . Specifies how long to wait between polling the size of the backends to determine how to rebalance; works in conjunction with the `rebalancing-minimum-percentage` property.
- **`placement-criteria`** . Determines which approach to use to select a destination backend for rebalancing. Possible values are: `entry-count`, `backend-size`, or `custom`.

The following figure illustrates an entry-balancing base DN and three subtrees, A, B, and C. If the rebalancing scope is set to `any`, any child entries under the base DN can be rebalanced. For example, if a change is made to entry A1, the entire subtree A might be rebalanced, depending upon how you have configured rebalancing. If the rebalancing scope is set to `top-level`, rebalancing is only triggered when entries at the top level, such as A, are modified. Changes made to subtrees, such as A1 or A2, do not trigger rebalancing. Rebalancing is also triggered upon the addition of entries such as A1, A2, provided the scope is `any`.

## MY TITLE Rebalancing at the Top Level

If you are writing your own 3rd party algorithm, you program dynamic rebalancing using the `SelectRebalancingBackendSet` method on the placement algorithm. For more information, see the Server SDK documentation.

## To Configure Dynamic Rebalancing

About this task

This procedure describes how to configure dynamic rebalancing on an existing entry balancing configuration.

### Steps

1. To configure entry rebalancing, you may create an entry counter placement algorithm, if the current placement algorithm does not support rebalancing. You can either do this using `dsconfig` in interactive mode, or using the `dsconfig` command line as follows:

```
$ dsconfig create-placement-algorithm \
 --processor-name dc_example_dc_com-eb-req-processor \
 --algorithm-name rebalancing --type entry-counter \
 --set enabled:true --set rebalancing-enabled:true
```

2. Remove any placement algorithm previously configured on this entry-balancing request processor.
3. You can throttle how many entries are being moved by the proxy, so that the backend servers do not have too heavy a load. To do this, set the `rebalancing-queue-maximum-size` property of the request processor created in the previous step. By default, it is set to 1000. If the load is too high, reduce this value as follows:

```
$ dsconfig set-request-processor-prop \
 --processor-name dc_example_dc_com-eb-req-processor \
 --set rebalancing-queue-maximum-size:50
```

4. Verify that the access logs are configured to display the subtrees being moved by dynamic rebalancing. The access logs provide a good way to monitor progress. So, if the write load on the backend servers is high and you see lots of rebalancing activity in the access log, lower the queue size to lower the rebalancing activity. You can configure the access log to display entry rebalancing processing information as follows:

```
$ dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Access Logger" \
 --set log-entry-rebalancing-requests:true
```

## About the `move-subtree` Tool

The `move-subtree` tool allows you to specify subtrees for rebalancing. You specify the source server, the target server, and one or more base DNs identifying the subtrees you want to move. You can move small

subtrees using the transactional method or move large subtrees, which does not use this method. Instead, the large subtree is not fully accessible during the move, so clients may get an "insufficient access rights error" if they try to access the subtree. As entries are moved, clients can read but not write to them. Once the transfer is complete, the entries are fully available to client requests.

This tool accepts a file containing a list of the base DN's of the subtrees you want to move.

**Note:** The `move-subtree` tool requires users to have access to the extended operations and controls needed to run the tool. Make sure to apply the following ACIs to your data.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.5 ||
1.3.6.1.4.1.30221.2.5.24 || 1.3.6.1.4.1.30221.2.5.13")
(version 3.0; acl "Allow admin to submit move-subtree controls";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
aci: (extop="1.3.6.1.4.1.30221.2.6.19")
(version 3.0; acl "Allow admin to request move-subtree extended
operation"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

### About the subtree-accessibility Tool

The `subtree-accessibility` tool helps you determine if a subtree has restricted access and helps you fix any problems. If, during rebalancing, the Directory Server issues an alert that a subtree has been unavailable for too long, then you can use this tool to evaluate the problem. For example, if the `move-subtree` tool is interrupted by a host machine going down unexpectedly, the subtree might not be successfully moved. You can use the `subtree-accessibility` tool to evaluate and correct any problems with the subtrees, and then re-run the `move-subtree` tool.

## Managing the Global Indexes in Entry-Balancing Configurations

In an entry-balancing configuration, the Directory Proxy Server maintains the default RDN index as well as one or more in-memory global attribute indexes. The global indexes allow the Directory Proxy Server to select the correct backend server set for incoming operations, which avoids broadcasting operations to all backend sets.

The indexes may be preloaded from peer proxies or the backend directory servers when the server starts up, and are updated by certain operations that come through the Directory Proxy Server. For instance, when a new entry is added, the DN of the new entry is added to the DN index of the Directory Proxy Server performing the operation. The indexes are also fault-tolerant and can adapt to changes made in the backend servers without going through the Directory Proxy Server. For example, operations will be processed directly through the backend server.

This section describes when to create a global attribute index, how to reload the global index, how to monitor its growth, and how to prime the global index from a peer at start-up.

### When to Create a Global Attribute Index

The RDN index is referenced whenever a modify, delete, or base search is requested. In other words, the RDN index is needed when the LDAP request contains the complete DN of the targeted entry. If the entry-balancing request processor is not configured to prime the rdn index at startup, then the index is populated over time as LDAP requests are processed.

A global attribute index is an optional index and is referenced when the Directory Proxy Server is handling a search request with an equality filter involving the attribute, such as the `telephoneNumber` attribute with the filter (`telephoneNumber=+11234567890`). Since the Directory Proxy Server does not know what the data within the subtree views looks like or how it will be searched, it cannot create or recommend default global attribute index definitions. The creation of a global attribute index is based on the range of equality-filtered search requests that the Directory Proxy Server will handle. The Directory Server must also have an equality or ordering index type for the associated attribute Local DB Index."

The common candidates for global attribute indexing are the uniquely-valued equality-indexed attributes on the external servers. Examples of these attributes are `uid`, `mail` and `telephoneNumber`. Though the values of the attribute need not be unique to be used as a global attribute index by the entry-balancing request processor.

Consider a Directory Proxy Server deployment that expects to handle frequent searches of the form `"(&(mail=user@example.com)(objectclass=person))"`. Since the filter is constructed with an equality match and `&`-clause, we can use a global attribute index on the `mail` attribute to avoid forwarding the search request to each entry balanced dataset.

The following `dsconfig` command creates the global attribute index. Note that the `mail` attribute must be indexed for equality searches on each of the external servers behind the Directory Proxy Server.

```
$ bin/dsconfig create-global-attribute-index \
 --processor-name ou_people_dc_example_dc_com-eb-req-processor \
 --index-name mail --set prime-index:true \
```

After creating the index with `dsconfig`, the index will begin to be populated as search requests involving the `mail` attribute are made to the Directory Proxy Server. At this point, you can also use the `reload-index` tool to fully populate the index for optimal performance as described in the following section.

### Reloading the Global Indexes

The Directory Proxy Server provides a tool, `reload-index`, which allows you to manually reload the Directory Proxy Server global indexes. You might need to reload the index when:

- The Directory Proxy Server fails to successfully load its global indexes on startup.
- Changes are made to the set of indexed attributes.
- Significant changes are made to the content in backend servers.
- The integrity of the index is in question.

You can use the tool to reload all configured indexes in the global index, including the RDN index and all attribute indexes, or to reload only those indexes you specify.

The tool schedules an operation to run within the Directory Proxy Server's process. You must supply LDAP connection information so that the tool can communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later scheduled time. Once scheduled, you can manage the tasks using the `manage-tasks` tool.

#### To Reload All of the Index

##### Steps

- Run the `reload-index` tool to reload all of the indexes within the scope of the `dc=example,dc=com` base DN. The task is performed as `cn=Directory Manager` on port 389 of the localhost server. The existing index contents are erased before reloading.

```
$ bin/reload-index --task --bindPassword password --baseDN
"dc=example,dc=com"
```

#### To Reload the RDN and UID Index

##### Steps

- To reload the RDN and UID index in the background so that the existing contents of these indexes can continue to be used, run the command as follows:

```
$ bin/reload-index --task --bindPassword password \
 --baseDN "dc=example,dc=com" --index rdn --index uid --background
```

## To Prime the Backend Server Using the `--fromDS` Option

### About this task

You can force the Directory Proxy Server to prime from the backend directory server only using the `--fromDS` option, overriding the configuration of the `prime-index-source` property. You can do this on a one off basis if the global index appears to be growing too large. For example, run the command as follows:

### Steps

- Run the `reload-index` command with the `--fromDS` option to prime the backend server.

```
$ bin/reload-index --bindPassword password --baseDN "dc=example,dc=com" --fromDS
```

## Monitoring the Size of the Global Indexes

Over time, stale entries can build up in the global indexes because proxies do not communicate changes to the indexes with one another. The Directory Proxy Server continues to operate normally in this situation since the global indexes are only ever used as a hint at where to find entries.

The rate of this growth is typically very slow since in most environments the key attributes change infrequently. The global indexes themselves are also very compact. However, if the global indexes start to fill up the allocated memory, you may need to flush and reload them. The size of the global indexes can be monitored over LDAP using the following command:

```
$ bin/ldapsearch -b "cn=monitor" -D "uid=admin,dc=example,dc=com" -w password \
 "(objectClass=ds-entry-balancing-request-processor-monitor-entry)" \
 global-index-current-memory-percent
```

If the global indexes fill up, the Directory Proxy Server will continue to operate normally, but it will need to start evicting entries from the indexes, which will lead to more broadcast searches, reducing the overall throughput of the Directory Proxy Server.

To reload the indexes so that they no longer hold stale information, run the `reload-index` command with the `--fromDS` option so that data is loaded from backend directory servers. We recommend that you reload the indexes during off-peak hours because it may have an impact on performance while the reload is in progress.

## Sizing the Global Indexes

The Directory Proxy Server includes a tool, `global-index-size`, to help you estimate the size in memory of your global indexes. You can estimate the size of more than one index in a single invocation by providing multiple sets of options. The tool creates its estimate using the following information:

- Number of keys in the index.** For example, for the built-in RDN index, the number of keys is the total number of entries in the Directory Server that are immediately below the balancing point. Entries more than one level below the balancing point, as well as entries that are not subordinate to the balancing point, will not be contained in the RDN index. For attribute indexes, the number of keys will be the number of unique values for that attribute in the entry-balanced portion of the data.
- Average size of each key, in bytes.** For attributes indexes, the key is simply the attribute value. For the built-in RDN index, the key is the RDN directly below the balancing base DN. For example, for the DN `uid=user.0,dc=example,dc=com` under the balancing base DN of `dc=example,dc=com`, the key size is 10 bytes (the number of bytes in the RDN `uid=user.0`).
- Estimated number of keys.** This value corresponds to the maximum number of keys you expect in your Directory Server. The number of keys is provided in the `index-size` configuration property of the `global-attribute-index` object when you configure an attribute index. For the built-in RDN index,

the configured number of keys is provided in the `rdn-index-size` property. If you do not provide a value, the tool assumes that the configured number of keys is the same as the actual number of keys.

### To Size the Global Index

#### Steps

- Run the `global-index-size` to estimate the size of two separate indexes, both with 10,000,000 keys but with differing average key sizes. The configured number of keys is assumed to be equal to the actual number of keys:

```
$ bin/global-index-size --numKeys 10000000 \
 --averageKeySize 11 --numKeys 10000000 \
 --averageKeySize 15
```

| Num Keys | Cfg. Num Keys | Avg. Key Size | Est. Memory Size |
|----------|---------------|---------------|------------------|
| 10000000 | 10000000      | 11            | 159 mb           |
| 10000000 | 10000000      | 15            | 197 mb           |

### Priming the Global Indexes on Start Up

The Directory Proxy Server can prime the global indexes on startup from the backend directory server or from a peer proxy server, preferably one that resides on the same LAN or subnet. When priming occurs locally, you can avoid WAN bandwidth consumption and reduce the processing load on the directory servers in the topology. You can specify the data sources for the index priming and the order in which priming from these sources occurs.

Use the `prime-index-source` property to specify the sources of data, either `ds`, `file` or some combination of the two. The order you specify is the order in which priming from these sources will be attempted. For example, if you specify `prime-index-source:file,ds`, priming will be performed from the `global-index` data file created from the previous run of the directory servers. With the `file,ds` configuration, the contents of the global index are written to disk periodically if, and only if, the entire global index has been primed previously from a directory servers source either from startup or `reloaded-index`. Priming is most efficient if the source server is on the same local network as the Directory Proxy Server.

### To Configure All Indexes at Startup

#### About this task

The following example configures the entry-balancing request processor so that it primes the global index from the persisted file, if present, or from an external directory servers source if necessary.

#### Steps

- Run the `dsconfig` tool to prime all indexes at startup.

```
$ bin/dsconfig set-request-processor-prop \
 --processor-name dc_example_dc_com-eb-req-processor \
 --set prime-all-indexes:true --set prime-index-source:file \
 --set prime-index-source:ds
```

### To Configure the Global Indexes Manually

#### About this task

If you do not want to configure priming during setup, you can configure index priming manually by creating an external server, creating a global attribute index, and then changing the entry-balancing request processor to load indexes from this external server.

## Steps

1. Use the **dsconfig** tool to create an external server of the type PingDirectoryProxy Server to represent a peer of the Directory Proxy Server.

```
$ bin/dsconfig create-external-server \
 --server-name intra-proxy-host.example.com:3389 \
 --type PingDirectoryProxy-server \
 --set server-host-name:intra-proxy-host \
 --set server-port:338 \
 --set "bind-dn:cn=Directory Manager" \
 --set "password:secret123"
```

2. Create a global attribute index on the `uid` attribute as follows:

```
$ bin/dsconfig create-global-attribute-index \
 --processor-name dc_example+dc+com-eb-req-processor \
 --index-name uid \
```

3. Change the entry-balancing request processor to load the indexes at startup from the peer Directory Proxy Server using **dsconfig set-request-processor-prop** as described above.

### To Persist the Global Index from a File

#### About this task

The PingDirectoryProxy Server supports periodically persisting the global index to a file and priming the global index from the persisted file when the server is restarted.

An Entry Balancing Request Processor can be configured to periodically persist the global index to disk, so that when the Entry Balancing Request Processor is reinitialized (on startup), it can prime the values from disk instead of putting load on the remote servers. Being able to read the index from disk eliminates the load on backend Directory Server instances if many PingDirectoryProxy Server instances were to come up at once.

An entry-balancing request processor can be configured to persist the global index to disk by including **file** as one of the prime index sources (with the **prime-index-source** property). The frequency at which the file is written is controlled by the **persist-global-index-frequency** property.

The global index needs to be fully primed before it will be persisted. It can be initially primed using a peer PingDirectoryProxy Server or from a backend Directory Server. On a running PingDirectoryProxy Server, when new global attribute indexes are added, the global index can be primed with those attribute indexes by running the **rebuild-index** tool. The **rebuild-index** tool always uses a remote server for priming the global index even if **file** is configured as a source). On subsequent restarts of the PingDirectoryProxy Server, the global index will be primed from the persisted file instead of going over the network to a remote server, which allows it to be primed much faster than if it were using a remote priming source. Also, during server startup, the global index priming works by using each configured **prime-index-source** property in the specified order until it is fully primed to take advantage of what is available locally before contacting one or more remote servers.

## Steps

- The following **dsconfig** command prime all indexes at startup from a file.

```
dsconfig -n set-request-processor-prop \
 --processor-name entry-balancing \
 --set prime-index-source:file \
 --set prime-index-source:ds \
 --set persist-global-index-frequency:10s \
 --set persist-global-index-directory:/servers/proxy-1/index-files \
 --set prime-all-indexes:true
```

## Priming or Reloading the Global Indexes from Sun Directory Servers

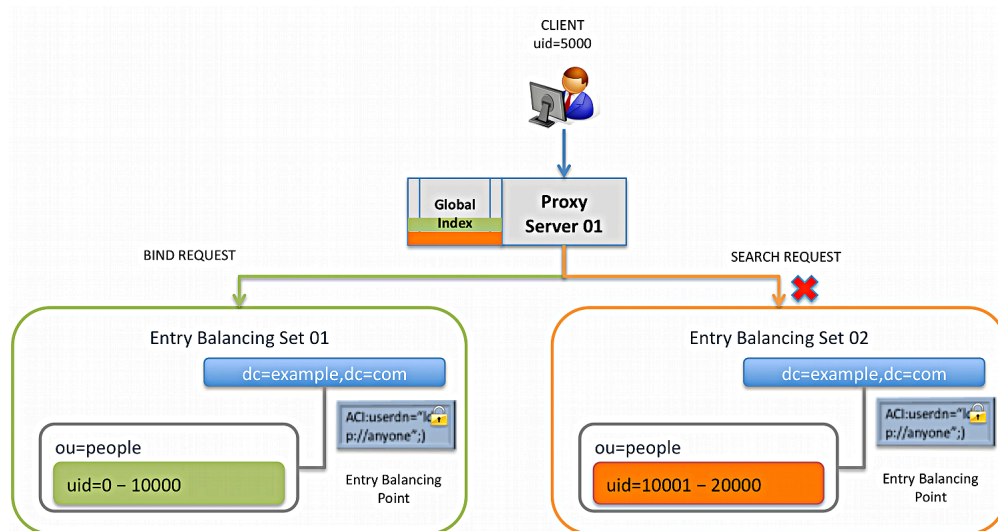

When priming or reloading a global index based on a Sun Directory Server environment, the Sun servers may become overwhelmed and unresponsive because of their method of streaming data. To reduce the impact of priming on these server, you can use the `prime-search-entry-per-second` property. To reduce the impact of reloading these indexes, use the `--searchEntryPerSecond` property of the `reload-index` command. These properties control the rate at which the Directory Proxy Server accepts search result entries from the backend directory servers.

To find the optimum rate, start low and specify a few thousand search entries per second. Then increase as necessary.

## Working with Alternate Authorization Identities

Access control rules in an entry-balanced deployment are configured in the Directory Server backend servers and require access to the entry contents of the user *issuing* the request. This can introduce a possible issue when clients to the Directory Proxy Server authenticate as users whose entries are among the entry-balanced sets. If the server which is processing a request does not contain the issuing user's entry, then the access control cannot be evaluated.

For example, consider a deployment that has two entry-balancing sets, set-01 and set-02. Set-01 has entries in the range `uid=0-10000`, while set-02 has entries for `uid=10001-20000`. The client with `uid=5000` binds to the Directory Proxy Server, which sends a BIND request to entry-balancing set-01. Next, the client sends a SEARCH request with filter "`(uid=15000)`". The Directory Proxy Server determines that `uid=15000` lives on entry-balancing set-02. The Directory Proxy Server then determines that the entry for the authenticated user with `uid=5000` does not exist in set-02 and that the access control handler would reject the SEARCH request issued by an unknown user.

### MY TITLE Entry-Balancing Issue with Clients Not Present in the Underlying Data Set

One solution to this problem is to make use of an *alternate authorization identity* for the user, which references an entry that exists in all Directory Servers in all backend sets and has an equivalent set of access control rights as the authenticated user. The alternate authorization identity is used when the Directory Proxy Server observes that the Directory Server processing a request does not contain the entry of the user issuing the request.

The following sections cover the procedures to configure the alternate authorization identities for the Directory Proxy Server.

## About Alternate Authorization Identities

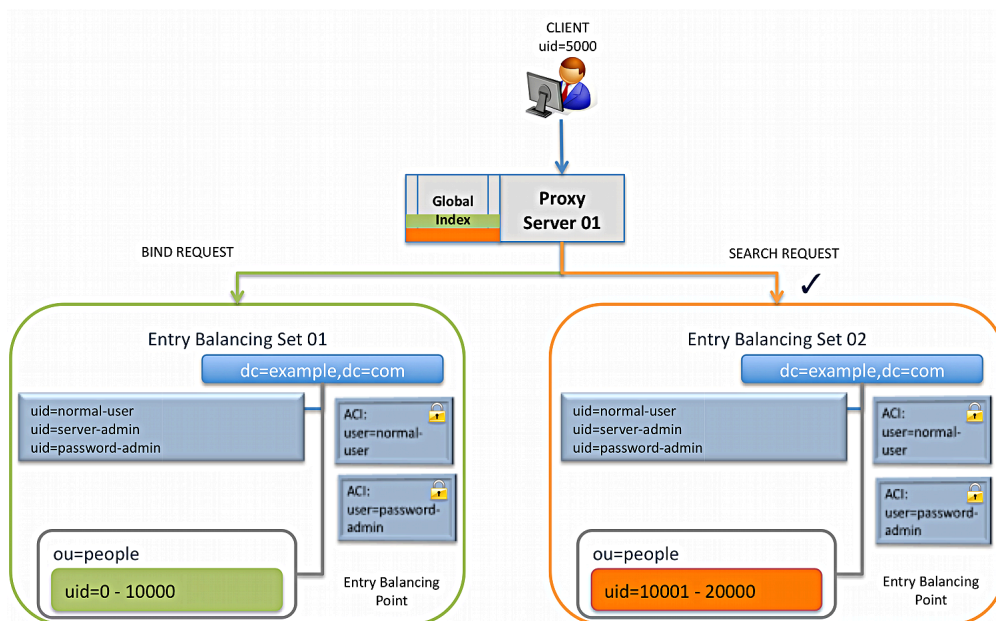

Whenever the Directory Proxy Server forwards a request to the backend set containing the user's entry, it forwards the request with an authorization identity that reflects the user's actual identity, since servers in that set already know about that user. However, when forwarding a request to a backend set that does *not* contain the user's entry, the Directory Proxy Server uses an *alternate authorization identity* that reflects the generic user with the same set of rights as the actual user issuing the request. Alternate authorization identities allow for the proper evaluation of access control rules for users whose entries are not present within an entry-balanced dataset.

There are typically only a few different generic class of users from an access control perspective, which can be placed in a portion of the DIT that is not below the entry-balancing base DN and is replicated to all servers in the topology. For example, assume that you have three classes of users: full administrators, password administrators, and normal users. You could create the following entries in the topology and assign them the appropriate access rights:

- uid=normal user,dc=example,dc=com
- uid=server-admin,dc=example,dc=com
- uid=password-admin,dc=example,dc=com

Returning to the example scenario, the client with uid=5000 binds to the Directory Proxy Server, which sends a BIND request to entry-balancing set-01. Next, the client sends a SEARCH request for uid=15000. The Directory Proxy Server determines that uid=15000 lives on entry-balancing set-02. Next, the Directory Proxy Server then determines that the client uid=5000 does not have an entry on entry-balancing set-02. The Directory Proxy Server uses an *alternate authorization identity* that reflects the generic user, uid=normal user, which has the same set of rights as the client uid=5000 who is issuing the request. The access control is accepted and the SEARCH request returns a response for uid=5000.

Whenever a user authenticates to the Directory Proxy Server, the server can keep track of which backend set holds that user's entry and determine whether an alternate authorization identity is required. The server can also determine which of these generic accounts best describes the rights that the user should have.

## MY TITLE Alternate Authorization Identity Solves Access Control Issues in Entry-Balancing Deployments

When an alternate authorization identity is invoked, you will see `authzID='dn:uid=normal user,dc=example,dc=com'` in the server log, indicating that the alternate authorization identity was used. For example, if the user .15000 is in a different backend set from user .5000, the log will show the following:

```
% bin/ldapsearch -D "uid=user.5000,ou=people,dc=example,dc=com" -w password \
 -b uid=user15000,ou=people,dc=example,dc=com "(objectclass=*)"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2
via="app='Directory-Proxy address='127.0.0.1'
authzID='dn:uid=normal user,dc=example,dc=com' sessionID='conn=2'
requestID='op=1'" base="uid=user.150000,ou=people,dc=example,dc=com"scope=2
filter="(objectclass=*)" attrs="ALL"

[18/Aug/2013:11:54:35 -0500] SEARCH REQUEST conn=153 op=1 msgID=2 resultCode=0
etime=2.038
entriesReturned=1 authzDN="uid=normal-user,dc=example,dc=com"
```

## Configuring Alternate Authorization Identities

Alternate authorization identities are specified by the `authz-attribute` property of the entry-balancing request processor configuration object. By default, the `authz-attribute` property has the default value of `ds-authz-map-to-dn`, which is an attribute reserved for this purpose.

### To Configure Alternate Authorization Identity DNs

#### About this task

If a user entry has a value for `ds-authz-map-to-dn` whether it's explicitly contained in the entry or only present via a virtual attribute, then that will be used to specify the alternate authorization identity for the user. Otherwise, the default authorization identity (as indicated via the `authz-dn` configuration property) will be used to determine the alternate authorization identity.

#### Steps

1. Use `dsconfig` to set the `authz-dn` property of the entry-balancing request processor configuration. If any user among the balanced entries does not have an alternate authorization identity defined, the Directory Proxy Server will use the value of the `authz-dn` property of the entry-balancing request processor configuration.

```
$ bin/dsconfig set-request-processor-prop \
 --processor-name dc_example_dc_com-eb-req-processor \
 --set "authz-dn:uid=normal user,dc=example,dc=com"
```

2. Create an auxiliary object class containing `ds-authz-map-to-dn` as an allowed attribute.
3. Add the auxiliary object class value to all user entries of interest.
4. Then, add the following attribute value to a `server-admin` user.

```
ds-authz-map-to-dn: uid=server-admin,dc=example,dc=com
```

## Managing Entry-Balancing Replication

Replication in the PingDirectoryProxy Server synchronizes directory data between all servers in the topology. In a deployment using the entry-balancing feature, however, directory data under the entry-balancing point is split into multiple data sets. Each data set is replicated to ensure high availability between a subset of the servers in the topology. Other directory data, such as the schema or data above the entry-balancing point, is replicated between all servers in the topology.

This chapter presents the following information about replication in an entry-balancing environment:

### Overview of Replication in an Entry-Balancing Environment

In an entry-balanced deployment, some data is replicated everywhere, such as the schema, the server registry, and other shared data, and some data is replicated only on certain servers. A replication domain

contains all of the servers in a replicated topology and shares a schema. The replication domain is associated with the base DN and must be a base DN of a backend.

By default, replication propagates updates to all replication servers in the topology. Updates to data under the entry-balancing point, however, must be replicated only among server instances in the same data set. Replication requires that, in such deployments, the Directory Server is configured with a replication set name global configuration property, and two backends. One backend has a base DN that is replicated globally (such as `dc=example,dc=com`) and the second backend has a base DN associated with the entry-balancing point (such as `ou=people,dc=example,dc=com`).

### MY TITLE Global and Restricted Backends

If a data set name is not defined when you set up the Directory Proxy Server, one will be provided by default. The proper configuration of an entry-balancing environment requires coordination between the Directory Server and Directory Proxy Server. Once replication is enabled, the replication domain may be designated as the domain participating in entry balancing.

Review the *Directory Server Administration Guide* for more details about replication, managing the replication topology, and working with multiple backends.

## Replication Prerequisites in an Entry-Balancing Deployment

Replication in an entry-balanced deployment requires the following:

- **Multiple local DB backends.** When you set up the Directory Server instances, you need two backends, a global backend for globally replicated data, such as `userRoot`, and a backend for the balancing point base DN, `dataSet`. Both backends need to be enabled for replication and initialized separately.
- **Replication set name.** Every Directory Server in your replicated topology must have a replication set name. This replication set name coordinates the Directory Proxy Server and the Directory Server. The restricted domain is only replicated within instances using the same replication set name.
- **Multiple Directory Proxy Server subtree views.** The entry-balanced proxy configuration relies on multiple subtree views, one for the globally replicated base DN and one for the entry-balancing point base DN. The globally replicated base DN will have a proxying request processor associated with it. The restricted base DN will have an entry-balancing request processor associated with it. This configuration is best achieved using the `create-initial-proxy-config` tool after running `setup`.

## About the `--restricted` Argument of the `dsreplication` Command-Line Tool

When enabling replication for a server that takes part in an entry balanced environment, it is recommended that the multiple domains involved are enabled at the same time. There is a global domain, and a restricted domain, where the restricted domain represents the entry-balancing point. Each base DN is defined in a separate Local DB Backend. The `dsreplication` CLI tool has a `--restricted` argument that is used to specify which base DN is considered an entry-balancing point.

## To Use the `--restricted` Argument of the `dsreplication` Command-Line Tool

### Steps

- Run `dsreplication` to enable replication between two servers with entry balancing.
  - You can run the command in non-interactive mode as follows:

```
$ bin/dsreplication enable --host1 host1.example.com \
--port1 1389 --bindDN1 "cn=Directory Manager" \
--bindPassword1 secret --replicationPort1 8989 \
--host2 host2.example.com --port2 2389 \
--bindDN2 "cn=Directory Manager" --bindPassword2 secret \
--replicationPort2 8989 --baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com
```

- Alternatively, you can enable replication using the interactive command line, making sure to specify that an entry balancing is being used and specifying the base DN of the entry-balancing point. After entering `dsreplication` and entering the LDAP connection parameters, follow the prompts presented.

```
You must choose at least one base DN to be replicated.
Replicate base DN dc=example,dc=com? (yes / no) [yes]: yes
Replicate base DN ou=people,dc=example,dc=com? (yes / no) [yes]: yes
Do you plan to configure entry balancing using the Directory Proxy Server?
(yes / no) [no]: yes
Is dc=example,dc=com an entry-balancing point? (yes / no) [no]: no
Is ou=people,dc=example,dc=com an entry-balancing point? (yes / no) [no]:
yes
```

## Checking the Status of Replication in an Entry-Balancing Deployment

You can use the `dsreplication` status tool to check the status of an entry-balancing deployment. In this example, the `ou=people,dc=example,dc=com` subtree is entry-balanced. The data is split into two sets, `set1` and `set2`. The servers `host1` and `host2` are in replication set `set1` and servers `host3` and `host4` are in replication set `set2`.

### To Check the Status of Replication in an Entry-Balancing Deployment

#### Steps

- Run the `dsreplication` command to get a status of replication in the entry-balancing deployment. To view a specific set, use the `--setName` option to see only the specific replication set; otherwise, all of the sets will be displayed by default.

```
$ bin/dsreplication status --hostname host1.example.com \
```

```
--port 1389 --adminUID admin --adminPassword secret
```

```

--- Replication Status for dc=example,dc=com: Enabled ---
Server : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----;-----;-----;-----;-----;-----
austin1.example.com:1389 : 1000 : 0 : N/A : 8989 : Enabled
austin2.example.com:2389 : 1000 : 0 : N/A : 8989 : Enabled
newyork1.example.com:3389 : 1000 : 0 : N/A : 8989 : Enabled
newyork2.example.com:4389 : 1000 : 0 : N/A : 8989 : Enabled

-- Replication Status for ou=people,dc= example,dc=com (Set: set1): Enabled --
Server : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----;-----;-----;-----;-----;-----
austin1.example.com:1389 : 1000000 : 0 : N/A : 8989 : Enabled
austin2.example.com:2389 : 1000000 : 0 : N/A : 8989 : Enabled

---Replication Status for ou=people,dc= example,dc=com (Set: set2): Enabled ---
Server : Entries: Replication Backlog: Oldest Backlog Change Age : Port :Security
-----;-----;-----;-----;-----;-----
newyork1.example.com:3389 : 1000000 : 0 : N/A : 8989 : Enabled
newyork2.example.com:4389 : 1000000 : 0 : N/A : 8989 : Enabled

```

## Example of Configuring Entry-Balancing Replication

This section describes how to set up a four-server replication topology that uses entry balancing to distribute entries across the servers. The procedure assumes that none of the servers have participated in any previous replication topology. This is supported for one or multiple entry balancing domains.

### Assumptions

The example uses the LDAP (389) and replication (8989) ports respectively. It configures the following hosts:

- austin1.example.com
- newyork1.example.com
- austin2.example.com
- newyork2.example.com

In this example, we have a global domain of `dc=example,dc=com`, which is replicated across all servers. The data below the entry-balancing point of `ou=people,dc=example,dc=com` is distributed across two data sets, `dataSet1` and `dataSet2`. Each data set is replicated between two directory servers. Each of these servers is associated with one of two locations, Austin and New York.

### Configuration Summary

To configure replication in an entry-balanced deployment, you must do the following:

- Install two directory servers in an Austin location and two directory servers in a New York location.
- Create a new backend, called `dataset`, to store the entry-balancing data set.
- Define entry-balancing set names `dataSet1` and `dataSet2` for assignment to the `replication-set-name` Global Configuration Property of the Directory Server instances.
- Import the data representing the global domain, stored in `userRoot`, into a server. Choose a server for each of the entry-balancing data sets, both stored in the backend named `dataset`.
- Enable replication and initialize remaining servers.
- Configure the proxies.
- Check the status of replication.

## To Install the Directory Server

### About this task

First, install the Directory Server instances. In this example, we install the following four servers, two in the Austin location and two in the New York location:

- austin1.example.com
- austin2.example.com
- newyork1.example.com
- newyork2.example.com

### Steps

1. We install the first server, austin1, as follows:

```
root@austin1# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense
```

2. Install the second Austin server, austin2, in the same way:

```
root@austin2 # ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense
```

3. Next, install the two New York servers, newyork1 and newyork2, as follows:

```
root@newyork1# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense
```

```
root@newyork# ./setup --cli --baseDN dc=example,dc=com \
--ldapPort 389 --rootUserDN "cn=Directory Manager" \
--rootUserPassword pass --no-prompt --acceptLicense
```

## To Create the Database Backends and Define the Replication Set Name

### Steps

1. On all servers, create the dataset backend as follows:

```
./bin/dsconfig --no-prompt create-backend \
--backend-name dataset --type local-db --set enabled:true \
--set base-dn:ou=people,dc=example,dc=com
```

2. Set the replication set name for austin1.example.com and newyork1.example.com to dataset1:

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset1
```

3. Set the replication set name for austin2.example.com and newyork2.example.com to dataset2:

```
./bin/dsconfig --no-prompt \
set-global-configuration-prop \
--set replication-set-name:dataset2
```

## To Create and Set the Locations

### Steps

1. On the Austin servers, create the two locations, newyork and austin, and set the location of this instance to austin:

```
./bin/dsconfig --no-prompt create-location --location-name austin

./bin/dsconfig --no-prompt create-location --location-name newyork \
--set preferred-failover-location:austin

./bin/dsconfig --no-prompt set-location-prop --location-name austin \
--add preferred-failover-location:newyork

./bin/dsconfig --no-prompt set-global-configuration-prop \
--set location:austin
```

2. For the New York servers, set the location to newyork:

```
./bin/dsconfig --no-prompt create-location \
--location-name austin

./bin/dsconfig --no-prompt create-location \
--location-name newyork \
--set preferred-failover-location:austin

./bin/dsconfig --no-prompt set-location-prop \
--location-name austin \
--add preferred-failover-location:newyork

./bin/dsconfig --no-prompt set-global-configuration-prop \
--set location:newyork
```

## To Import the Entries

### About this task

We import the userRoot data, based on data defined in the `userRoot.ldif` file, into one server. This file does not contain entries at or within the entry-balancing point, `ou=people,dc=example,dc=com`.

### Steps

1. Use the `import-ldif` command to import the userRoot data.

```
root@austin1# ./bin/import-ldif --backendID userRoot \
--ldifFile /data/userRoot.ldif \
--includeBranch dc=example,dc=com \
--rejectFile /data/austin1-import-rejects \
--port 389
--hostname austin1.example.com
```

2. Import the dataSet1 data on one server into the dataset backend, which is assigned the `dataSet1 replication-set-name`.

```
root@austin1# ./bin/import-ldif --backendID dataset \
--ldifFile /data/dataset1.ldif \
--includeBranch ou=people,dc=example,dc=com \
--rejectFile /data/austin1-dataset-import-rejects \
--hostname austin1.example.com --port 389
```

3. Import the `dataSet2` data on one server into the dataset backend, which is assigned the `dataSet2 replication-set-name`.

```
root@austin2# ./bin/import-ldif --backendID dataset \
--ldifFile /data/dataset2.ldif \
--includeBranch ou=people,dc=example,dc=com \
--rejectFile /data/austin2-dataset-import-rejects \
--hostname austin2.example.com --port 389
```

### To Enable Replication in an Entry-Balancing Deployment

About this task

Now we can enable replication between the servers and initialize the remaining servers without data. Notice that we specify the `--restricted domain` in the `dsreplication` command.

Steps

1. Run `dsreplication enable` to enable the servers in the topology. The first invocation of this command creates the admin account.

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 austin2.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

2. Enable replication between `austin1` and `newyork1`. This procedure automatically enables replication between `austin2` and `newyork1` as well.

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 newyork1.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

3. Enable replication between `austin1` and `newyork2`. This will complete the entry-balancing replication setup.

```
root@austin1# ./bin/dsreplication enable \
--host1 austin1.example.com \
--port1 389 --bindDN1 "cn=directory manager" \
--bindPassword1 pass --host2 newyork2.example.com \
--port2 389 --bindDN2 "cn=directory manager" \
--bindPassword2 pass \
--replicationPort1 8989 \
--replicationPort2 8989 \
```

```
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--restricted ou=people,dc=example,dc=com \
--adminUID admin --adminPassword pass --trustAll \
--no-prompt
```

4. Initialize the remaining servers without data. The global domain, **dc=example,dc=com** needs to be initialized on austin2, newyork1 and newyork2. The **ou=people,dc=example,dc=com** entry-balancing domain needs to be initialized from austin1 to newyork2, and then again from austin2 to newyork2. We will combine these steps by initializing both domains with one invocation once austin2 is initialized with the global domain.

```
root@austin1# ./bin/dsreplication initialize \
--hostSource austin1.example.com --portSource 389 \
--hostDestination austin2.example.com \
--portDestination 389 --adminUID admin \
--adminPassword password \
--baseDN dc=example,dc=com \
--no-prompt

root@austin1# ./bin/dsreplication initialize \
--hostSource austin1.example.com --portSource 389 \
--hostDestination newyork1.example.com \
--portDestination 389 --adminUID admin \
--adminPassword password \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--no-prompt

root@austin2# ./bin/dsreplication initialize \
--hostSource austin2.example.com --portSource 389 \
--hostDestination newyork2.example.com \
--portDestination 389 --adminUID admin \
--adminPassword password \
--baseDN dc=example,dc=com \
--baseDN ou=people,dc=example,dc=com \
--no-prompt
```

### To Check the Status of Replication

About this task

Once replication has been configured, check the status of the replication topology using the **dsreplication status** command.

Steps

- Run the **dsreplication status** command to check its status.

```
root@austin1# ./bin/dsreplication status \
--adminPassword pass --no-prompt --port 389
```

## Managing the Directory Proxy Server

Once you have configured the PingDirectoryProxy Server, you can manage the day-to-day operations of your deployment using the monitoring and logging features. This chapter provides procedures to help you configure logging and monitor your deployment.

This chapter includes the following sections:

## Managing Logs

The Directory Proxy Server provides a number of different types of log publishers that can be used to provide information about how the server is processing.

### About the Default Logs

You can view all logs in the `PingDirectoryProxy/logs` directory. This section provides information about the following default logs:

- Error Log
- server.out Log
- Debug Log
- Config Audit Log and the Configuration Archive
- Access Log
- Setup Log
- Tool Log
- LDAP SDK Debug Log

### Error Log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include:

ACCESS\_CONTROL, ADMIN, ADMIN\_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME\_INFORMATION, TASK, THIRD\_PARTY, TOOLS, USER\_DEFINED, UTIL, VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- **DEBUG** – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, as the Directory Proxy Server provides a separate debug logging facility as described below.
- **INFORMATION** – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.
- **MILD\_WARNING** – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- **MILD\_ERROR** – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action.
- **NOTICE** – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- **SEVERE\_WARNING** – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- **SEVERE\_ERROR** – Used for significant problems that have prevented the server from successfully completing processing and are considered important.

- **FATAL\_ERROR** – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log may be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which may be used to specify the severity of messages logged regardless of their category. By default, this includes the NOTICE, SEVERE\_WARNING, SEVERE\_ERROR, and FATAL\_ERROR severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the PROTOCOL category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-
warning,severe-error,fatal-error
```

Note that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the DEBUG severity for a category will not automatically enable logging at the INFORMATION, MILD\_WARNING, or MILD\_ERROR severities.

The error log configuration may be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger may be activated with a different set of default severities to debug a short-term problem, and then that logger may be removed once the problem is resolved, so that the normal error log does not contain any of the more verbose information.

### server.out Log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill -QUIT" as described in a later section, then output is written to this file.

### Debug Log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- **enabled** – Indicates whether debug logging is enabled. By default, it is disabled.
- **log-file** – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.
- **default-debug-level** – Specifies the minimum log level for debug messages that should be written. The default value is "error," which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- **default-debug-category** – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

**Note:** Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

### Audit log

The audit log is a specialized version of the access log, used for troubleshooting problems that may occur in the course of processing. The log records all changes to directory data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. The audit log is disabled by default because it does adversely impact the server's write performance.

By default, if you enable the audit log on the Directory Proxy Server, the `userPassword` and `authPassword` attribute values are obscured. Each value of an obscured attribute is replaced in the audit log with a string of the form `"***** OBSCURED VALUE *****"`. You can unobscure these attributes by deleting them from the `obscure-attribute` property.

### Config Audit Log and the Configuration Archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that may be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the Directory Proxy Server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

### Access and Audit Log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages may also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1"
to="127.0.0.1"
 protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
 dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
 authDN="cn=Directory Manager,cn=Root DNs,cn=config"
 clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
 base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
 resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- **origin=replication** – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- **message** – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- **additionalInfo** – Additional information about the operation that was not included in the response sent back to the client.
- **authDN** – DN of the user that authenticated to the server (typically only included in bind result messages).
- **authzDN** – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- **authFailureID** – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- **authFailureReason** – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- **responseOID** – OID included in an extended response returned to the client.
- **entriesReturned** – Number of matching entries returned to the client for a search operation.
- **unindexed=true** – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here may also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they may contain.

The Directory Proxy Server provides a second access log implementation called the *audit log*, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The PingDirectoryProxy Server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

## Setup Log

The **setup** tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the **setup** tool has already been run. The full path to the setup log file is provided when the **setup** tool has completed.

## Tool Log

Many of the administrative tools provided with the Directory Proxy Server (for example, **import-ldif**, **export-ldif**, **backup**, **restore**, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, **logs/tools/import-ldif.log**). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running via the server tasks interface, log messages generated while the task is running may alternately be written to the server error log file.

## LDAP SDK Debug Log

This log can be used to help examine the communication between the Directory Server and the Directory Proxy Server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

## Types of Log Publishers

The PingDirectoryProxy Server provides a number of differently types of loggers that can be used to get processing information about the server. There are three primary types of loggers:

- **Access loggers** provide information about operations processed within the server. They can be used for understanding the operations performed by clients and debugging problems with directory-enabled applications, and they can also be used for collecting usage information for performance and capacity planning purposes.
- **Error loggers** provide information about warnings, errors, or significant events that occur within the server.
- **Debug loggers** can provide detailed information about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.

By default, the following log publishers are enabled on the system:

- File-based access logger
- File-based error logger
- Failed-operations access logger

The PingDirectoryProxy Server also provides the follow log publishers that are disabled by default:

- File-based debug logger
- File-based audit logger
- Expensive operations access logger
- Successful searches with no entries returned access logger

## Creating New Log Publishers

The PingDirectory Server provides customization options to help you create your own log publishers with the **dsconfig** command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher. For more information, see [Configuring Log Rotation](#) and [Configuring Log Retention](#).

## To Create a New Log Publisher

### Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher. This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
--type file-based-access --publisher-name "Disconnect Logger" \
--set enabled:true \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set log-connects:false \
--set log-requests:false --set log-results:false \
--set log-file:logs/disconnect.log
```

**Note:** To configure compression on the logger, add the option to the previous command:

```
--set compression-mechanism: gzip
```

Compression cannot be disabled or turned off once configured for the logger. Therefore, careful planning is required to determine your logging requirements including log rotation and retention with regards to compressed logs.

2. If needed, view log publishers with the following command:

```
$ bin/dsconfig list-log-publishers
```

## To Create a Log Publisher Using dsconfig Interactive Command-Line Mode

### Steps

1. On the command line, type `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. On the main menu, select the option to configure the log publisher.
4. On the **Log Publisher** menu, select the option to create a new log publisher.
5. Select the Log Publisher type. In this case, select **File-Based Access Log Publisher**.
6. Type a name for the log publisher.
7. Enable it.
8. Type the path to the log file, relative to the Directory Proxy Server root. For example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.
11. On the Log Publisher Properties menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.
12. Type `f` to apply the changes.

## About Log Compression

The Directory Proxy Server supports the ability to compress log files as they are written. This feature can significantly increase the amount of data that can be stored in a given amount of space, so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off once the logger is

configured. Further, because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it will rotate that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily-available tools. The `summarize-access-log` tool can also work directly on compressed log files, rather than requiring them to be uncompressed first. However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging may wish to have a second logger defined that does not use compression and has rotation and retention policies that will minimize the amount of space consumed by those logs, while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

You can configure compression by setting the `compression-mechanism` property to have the value of "gzip" when creating a new logger.

## About Log Signing

The Directory Proxy Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way. For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are therefore needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by unscrupulous employees. You can use the `dsconfig` tool to enable the `sign-log` property on a Log Publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file will not be completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled will be considered completely valid. For the same reason, if a log file is still open for writing, then signature validation will not indicate that the log is completely valid because the log will not include the necessary "end signed content" indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server (or the `bat` directory for Windows systems).

Once you have enabled this property, you must disable and then re-enable the Log Publisher for the changes to take effect.

## About Encrypting Log Files

The Directory Proxy Server supports the ability to encrypt log files as they are written. The `encrypt-log` configuration property controls whether encryption will be enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension (and if both encryption and compression are enabled, the extension will be `.gz.encrypted`). Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off once the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This will also reduce the overall size of the log file. The `encrypt-file` tool (or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`) is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption will be performed with the server's preferred encryption settings definition. To explicitly specify which definition should be used for the encryption, the `encryption-settings-definition-id` property can be set with the ID of that definition. It is recommended that the encryption settings definition is created from a passphrase so that the file can be decrypted by providing that passphrase, even if the original encryption settings definition is no longer available. A randomly generated

encryption settings definition can also be created, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data may remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written. To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

## To Configure Log Signing

### Steps

1. Use `dsconfig` to enable log signing for a Log Publisher. In this example, set the `sign-log` property on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
--set sign-log:true
```

2. Disable and then re-enable the Log Publisher for the change to take effect.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
--set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
--set enabled:true
```

## To Validate a Signed File

### About this task

The Directory Proxy Server provides a tool, `validate-file-signature`, that checks if a file has not been tampered with in any way.

### Steps

- Run the `validate-file-signature` tool to check if a signed file has been tampered with. For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

```
All signature information in file 'logs/audit' is valid
```

**Note:** If any validation errors occur, you will see a message similar to the one as follows:

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
* The end of the input stream was encountered without
 encountering the end of an active signature block.
 The contents of this signed block cannot be trusted
 because the signature cannot be verified
```

## To Configure Log File Encryption

### Steps

1. Use `dsconfig` to enable encryption for a Log Publisher. In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access" \
\
 --type file-based-access \
 --set enabled:true \
 --set compression-mechanism:gzip \
 --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
 --set encrypt-log:true \
 --set log-file:logs/encrypted-access \
 --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --set "rotation-policy:Size Limit Rotation Policy" \
 --set "retention-policy:File Count Retention Policy" \
 --set "retention-policy:Free Disk Space Retention Policy" \
 --set "retention-policy:Size Limit Retention Policy"
```

2. To decrypt and decompress the file:

```
$ bin/encrypt-file --decrypt \
 --decompress-input \
 --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
 --output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/PingDirectoryProxy/decrypted-access'
using a
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

## Configuring Log Rotation

The Directory Server allows you to configure the log rotation policy for the server. When any rotation limit is reached, the Directory Server rotates the current log and starts a new log. If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

- **Time Limit Rotation Policy.** Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.
- **Fixed Time Rotation Policy.** Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.
- **Size Limit Rotation Policy.** Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.
- **Never Rotate Policy.** Used in a rare event that does not require log rotation.

### To Configure the Log Rotation Policy

#### Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Access Logger" \
 --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

## Configuring Log Rotation Listeners

The Directory Proxy Server provides two log file rotation listeners: the copy log file rotation listener and the summarize log file rotation listener, which can be enabled with a log publisher. Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file will be subject to deletion by a log file retention policy, but the copy will not be automatically removed. Use the following command to create a new copy log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
 --listener-name "Copy on Rotate" \
 --type copy \
 --set enabled:true \
 --set copy-to-directory:/path/to/archive/directory \
 --set compress-on-copy:true
```

The path specified by the **copy-to-directory** property must exist, and the file system containing that directory must have enough space to hold all of the log files that will be written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

The summarize log file rotation listener invokes the **summarize-access-log** tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the **summarize-access-log** tool, including the **file-based-access** and **operation-timing-access** logger types. Use the following command to create a new summarize log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
 --listener-name "Summarize on Rotate" \
 --type summarize \
 --set enabled:true \
 --set output-directory:/path/to/summary/directory
```

The summary output files have the same name as the rotated log file, with an extension of **.summary**. If the **output-directory** property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

## Configuring Log Retention

The Directory Proxy Server allows you to configure the log retention policy for each log on the server. When any retention limit is reached, the Directory Proxy Server removes the oldest archived log prior to creating a new log. Log retention is only effective if you have a log rotation policy in place. If you create a new log publisher, you must configure at least one log retention policy.

- **File Count Retention Policy.** Sets the number of log files you want the Directory Proxy Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log will continue to grow indefinitely without being rotated.
- **Free Disk Space Retention Policy.** Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.
- **Size Limit Retention Policy.** Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.

- **Time Limit Retention Policy.** Sets the maximum length of time that rotated log files should be retained.
- **Custom Retention Policy.** Create a new retention policy that meets your Directory Proxy Server's requirements. This will require developing custom code to implement the desired log retention policy.
- **Never Delete Retention Policy.** Used in a rare event that does not require log deletion.

## To Configure the Log Retention Policy

About this task

Steps

- Use `dsconfig` to modify the log retention policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Access Logger" \
 --set "retention-policy:Free Disk Space Retention Policy"
```

## Setting Resource Limits

You can set resource limits for the Directory Proxy Server using several global configuration properties as well as setting resource limits on specific client connection policies. If you configure both global and client connection policy resource limits, the first limit reached will always be honored. For example, if the server-wide maximum concurrent connections limit is reached, then all subsequent connection will be rejected until existing connections are closed, regardless of whether a client connection policy limit has been reached.

### Setting Global Resource Limits

You can specify the following types of global resource limits:

- Specify the maximum number of client connections that can be established at any given time using the `maximum-concurrent-connections` property. If the server already has the maximum number of connections established, then any new connection attempts from any clients will be rejected until an existing connection is closed. The default value of zero indicates that no limit is enforced.
- Specify the maximum number of client connections that can be established at any give time from the same client system using the `maximum-concurrent-connections-per-ip-address` property. If the server already has the maximum number of connections established from a given client, then any new connection attempts from that client will be rejected until an existing connection from that client is closed. The server may continue to accept connections from other clients that have not yet reached this limit. The default value of zero indicates that no limit is enforced.
- Specify the maximum number of client connections that can be established at any given time while authenticated as a particular user with the `maximum-concurrent-connections-per-bind-dn` property. This property applies after the connection is established, because the bind operation to authenticate the user happens after the connection is established rather than during the course of establishing the connection itself. If the maximum number of connections are authenticated as a given user, then any new attempt to authenticate as that user will cause the connection performing the bind to be terminated. Note that this limit applies only to authenticated connections, and will not be enforced for clients that have not authenticated or for clients that have authenticated as the anonymous user. The default value of zero indicates that no limit is enforced.

Any changes to the `maximum-concurrent-connections` and `maximum-concurrent-connections-per-ip-address` properties will take effect only for new connections established after the change is made. Any change to the `maximum-concurrent-connections-per-bind-dn` property will apply only to connections (including existing connections) which perform authentication after the change is made. Existing connections will be allowed to remain established even if that would cause the new limit to be exceeded.

## Setting Client Connection Policy Resource Limits

You can also configure resource limits in a client connection policy using the following properties of the client connection policy:

- **maximum-concurrent-connections.** This property specifies the maximum number of client connections that may be associated with a specific client connection policy at any given time. Once this limit has been reached, any further attempts to associate a connection with this client connection policy will result in the termination of the connection.
- **maximum-connection-duration.** This property specifies the maximum length of time that a connection associated with a particular client connection policy may be established. When the connection has been established longer than this period, it will be terminated.
- **maximum-idle-connection-duration.** This property specifies the maximum time that a connection associated with a particular client connection policy may remain established after the completion of the last operation processed on that connection. Any new operation requested on the connection resets the timer. Connections that are idle for longer than the specified time will be terminated.
- **maximum-operation-count-per-connection.** This property specifies the maximum number of operations that may be requested by any client connection associated with this client connection policy. If an attempt is made to process more than this number of operations on the connection, then the connection will be terminated.
- **maximum-concurrent-operations-per-connection.** This property specifies the maximum number of concurrent operations that can be in progress for any connection. This property can be used to prevent a single client connection from monopolizing server processing resources by sending a large number of concurrent asynchronous requests.
- **maximum-connection-operation-rate.** This property specifies the maximum rate at which a client associated with a specific client connection policy may issue requests to the Directory Proxy Server. If a client attempts to request operations at a rate higher than this limit, then the server will behave as described by the `connection-operation-rate-exceeded-behavior` property.
- **connection-operation-rate-exceeded-behavior.** This property describes how the server should behave if a client connection attempts to exceed a rate defined in the `maximum-connection-operation-rate` property.
- **maximum-policy-operation-rate.** This property specifies the maximum rate at which all clients associated with a particular client connection policy may issue requests to the Directory Proxy Server. If this limit is exceeded, then the server will exhibit the behavior described in the `policy-operation-rate-exceeded-behavior` property.
- **policy-operation-rate-exceeded-behavior.** This property specifies the behavior of the Directory Proxy Server if a client connection attempts to exceed the rate defined in the `maximum-policy-operation-rate` property.

## Monitoring the Directory Proxy Server

While the Directory Proxy Server is running, it generates a significant amount of information available through monitor entries. This section contains information about the following:

- Monitoring Server Status Using the status Tool
- About the Monitor Entries
- Using the Monitoring Interfaces
- Monitoring with JMX

### Monitoring System Data Using the PingDataMetrics Server

The PingDataMetrics Server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics Server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics Server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics Server documentation.

## To Monitor Server Using the Status Tool

About this task

The PingDirectoryProxy Server provides a `status` tool that provides basic server status information, including version, connection handlers, a table of LDAP external servers, and the percent of the global index that is used.

### Steps

1. Run the `status` tool to view the current state of the server.

```
$ bin/status
```

2. Enter the LDAP connection parameters.

```
>>>> Specify LDAP connection parameters
```

```
Administrator user bind DN [cn=Directory Manager]:
```

```
Password for user 'cn=Directory Manager':
```

```

### About the Monitor Entries

While the Directory Proxy Server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- **General Monitor Entry (cn=monitor)** – Provides a basic set of general information about the server.
- **Active Operations Monitor Entry (cn=Active Operations,cn=monitor)** – Provides information about all operations currently in progress in the server.
- **Backend Monitor Entries (cn={id} Backend,cn=monitor)** – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- **Client Connections Monitor Entry (cn=Client Connections,cn=monitor)** – Provides information about all connections currently established to the server.
- **Connection Handler Monitor Entry (cn={name},cn=monitor)** – Provides information about the configuration of each connection handler and the client connections established to it.
- **Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor)** – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- **Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor)** – Provides information about the amount of usable disk space available to server components.

- **JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor)** – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- **JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor)** – Provides a stack trace of all threads in the JVM.
- **LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor)** – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- **Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor)** – Provides information about the number of percent of operations that completed in various response time categories.
- **SSL Context Monitor Entry (cn=SSL Context,cn=monitor)** – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- **System Information Monitor Entry (cn=System Information,cn=monitor)** – Provides information about the underlying JVM and system.
- **Version Monitor Entry (cn=Version,cn=monitor)** – Provides information about the Directory Proxy Server version.
- **Work Queue Monitor Entry (cn=Work Queue,cn=monitor)** – Provides information about the state of the Directory Proxy Server work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

## Working with Alarms, Alerts, and Gauges

An alarm represents a stateful condition of the server or a resource that may indicate a problem, such as low disk space or external server unavailability. A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state. Gauges are used for monitoring continuous values like CPU load or free disk space (Numeric Gauge), or an enumerated set of values such as 'server unavailable' or 'server unavailable' (Indicator Gauge). Gauges generate alarms, when the gauge's severity changes due to changes in the monitored value. Like alerts, alarms have severity (NORMAL, WARNING, MINOR, MAJOR, CRITICAL), name, and message. Alarms will always have a Condition property, and may have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. Alarms can be configured to generate alerts when the alarm's severity changes. The Alarm Manager, which governs the actions performed when an alarm state is entered, is configurable through the `dsconfig` tool and Administrative Console. A complete listing of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

There are two alert types supported by the server - standard and alarm-specific. The server constantly monitors for conditions that may need attention by administrators, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`. The server can be configured to generate alarm-specific alerts instead of, or in addition to, standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

The Directory Proxy Server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. Existing gauges can be tailored to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered. The Stats Logger can be used to view historical information about the value and severity of all system gauges.

The Directory Proxy Server is compliant with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state can result in one or more alerts. An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. Alarms can be viewed with the `status` tool. As with other alert types, alert handlers can be configured to manage the alerts generated by alarms.

## To Test Alarms and Alerts

### Steps

1. Configure a gauge with `dsconfig` and set the `override-severity` property to critical. The following example uses the CPU Usage (Percent) gauge.

```
$ dsconfig set-gauge-prop \
 --gauge-name "CPU Usage (Percent)" \
 --set override-severity:critical
```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms. The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status

 --- Administrative Alerts ---
Severity : Time : Message

Shown are alarms of severity [Warning,Minor,Major,Critical]
Use the --alarmSeverity option to filter this list

```

## Indeterminate Alarms

Indeterminate alarms are raised for a server condition for which a severity cannot be determined. In most cases these alarms are benign and do not issue alerts nor appear in the output of the `status` tool or Administrative Console by default. These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication may produce indeterminate alarms if a Directory Server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There may be messages that can help determine the issue. The following is sample output from the `status` tool run with the `-alarmSeverity=indeterminate` option:

```

--- Alarms ---
Severity : Severity Start : Condition : Resource : Details
 : Time : : :

Normal : 26/Aug/2014 : Startup Begun : cn=config : The Directory
 Server
 : 14:16:29 -0500 : : : is starting.
 : : : :
Indeterminate: 26/Aug/2014 : Replication : not : The value of
 gauge
 Latency : 14:16:40 -0500 : Latency : available : Replication
 could not : : (Milliseconds) : : (Milliseconds)
 The : : : : be determined.
 INDETERMINATE,
 this : : : : severity is
 26 : : : : having assumed
 2014. : : : : severity Tue Aug
 : : : : 26 15:42:40 CDT
 : : : : 2014.

```

The following is an indeterminate alarm for the Replication Latency (Milliseconds) gauge. The following is a sample search of the monitor backend for this gauge's entry. The result is an error message may explain the indeterminate severity:

```

ldapsearch -w password --baseDN "cn=monitor" \
-D"cn=directory manager" gauge-name="Replication Latency (Milliseconds)"

dn: cn=Gauge Replication Latency (Milliseconds),cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-numeric-gauge-monitor-entry
objectClass: ds-gauge-monitor-entry
objectClass: extensibleObject
cn: Gauge Replication Latency (Milliseconds)
gauge-name: Replication Latency (Milliseconds)
resource:
severity: indeterminate
summary: The value of gauge Replication Latency (Milliseconds) could not
 be determined. The severity is INDETERMINATE, having assumed
 this severity Tue Aug 26 15:42:40 CDT 2014
error-message: No entries were found under cn=monitor having object
 class ds-replica-monitor-entry
...

```

## Working with Administrative Alert Handlers

The PingDirectory Server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The Directory Server provides a number of alert handler implementations, including:

- **Error Log Alert Handler.** Sends administrative alerts to the configured server error logger(s).
- **Exec Alert Handler.** Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the Directory Server. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- **Groovy Scripted Alert Handler.** Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- **JMX Alert Handler.** Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- **SMTP Alert Handler.** Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- **SNMP Alert Handler.** Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- **SNMP Subagent Alert Handler.** Sends SNMP traps to a master agent in response to administrative alerts generated within the server.
- **Third Party Alert Handler.** Provides alert handler implementations created in third-party code using the Server SDK.

### Configuring the JMX Connection Handler and Alert Handler

You can configure the JMX connection handler and alert handler respectively using the `dsconfig` tool. Any user allowed to receive JMX notifications must have the `jmx-read` and `jmx-notify` privileges. By default, these privileges are not granted to any users (including root users or global administrators). For security reasons, we recommend that you create a separate user account that does not have any other privileges but these. Although not shown in this section, you can configure the JMX connection handler and alert handler using `dsconfig` in interactive command-line mode, which is visible on the "Standard" object menu.

#### To Configure the JMX Connection Handler

##### Steps

1. Use `dsconfig` to enable the JMX Connection Handler.

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "JMX Connection Handler" \
 --set enabled:true \
 --set listen-port:1689
```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges. This account can be added using the `ldapmodify` tool using an LDIF representation like:

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
```

```

userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify

```

## To Configure the JMX Alert Handler

### Steps

- Use `dsconfig` to configure the JMX Alert Handler.

```

$ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
 --set enabled:true

```

## Configuring the SMTP Alert Handler

By default, there is no configuration entry for an SMTP alert handler. To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

### Configuring the SMTP Alert Handler

#### Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

```

$ bin/dsconfig create-alert-handler \
 --handler-name "SMTP Alert Handler" \
 --type smtp \
 --set enabled:true \
 --set "sender-address:alerts@example.com" \
 --set "recipient-address:administrators@example.com" \
 --set "message-subject:Directory Admin Alert %%alert-type%%" \
 --set "message-body:Administrative alert:\n%%alert-message%%"

```

## Configuring the SNMP Subagent Alert Handler

You can configure the SNMP Subagent alert handler using the `dsconfig` tool, which is visible at the "Standard" object menu. Before you begin, you need an SNMP Subagent capable of communicating via SNMP2c. For more information on SNMP, see [Monitoring Using SNMP](#).

### To Configure the SNMP Subagent Alert Handler

#### Steps

- Use `dsconfig` to configure the SNMP subagent alert handler. The `server-host-name` is the address of the system running the SNMP subagent. The `server-port` is the port number on which the subagent is running. The `community-name` is the name of the SNMP community that is used for the traps.

The Directory Proxy Server also supports a SNMP Alert Handler, which is used in deployments that do not enable an SNMP subagent.

```

$ bin/dsconfig set-alert-handler-prop \
 --handler-name "SNMP Subagent Alert Handler" \
 --set enabled:true \
 --set server-host-name:host2 \
 --set server-port:162 \
 --set community-name:public

```

## Working with Virtual Attributes

The PingDirectoryProxy Server provides dynamically generated attributes called virtual attributes for local Directory Proxy Server data. The proxy virtual attributes apply to a local proxy backend, such as `cn=config` or the Root DSE. If you want to have virtual attributes in entries for proxied requests, then they must be configured in the backend servers. Alternately, attributes may be inserted into those entries using proxy transformations. For more information about configuring proxy transformations, see “Configuring Proxy Transformations”.

For example, you can define a virtual attribute and assign it to the Root DSE as follows:

```
$ bin/dsconfig create-virtual-attribute \
 --name defineDescriptionOnRootDSE --type user-defined \
 --set enabled:true --set attribute-type:description \
 --set filter:objectclass=ds-root-dse --set value:PrimaryProxy
```

If you search the Root DSE using the following LDAP search, you see that the description attribute now has the value `PrimaryProxy`.

```
$ bin/ldapsearch --baseDN "" --searchScope base --bindDN "" \
 --bindPassword "" --port 5389 --hostname localhost \
 "objectclass=*" description

dn:
description:PrimaryProxy
```

## Managing Monitoring

The PingDirectoryProxy Server also provides a flexible monitoring framework that exposes its monitoring information under the `cn=monitor` entry and provides interfaces via the PingDataMetrics™ Server, the Administrative Console, SNMP, JMX, and over LDAP. The Directory Proxy Server also provides a tool, the Periodic Stats Logger, to profile server performance.

This chapter presents the following information:

### The Monitor Backend

The Directory Proxy Server exposes its monitoring information under the `cn=monitor` entry. Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger. Use the `bin/status` tool to display server component activity and state.

The list of all monitor entries can be seen using `ldapsearch` as follows:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries:

#### Directory Proxy Server Monitoring Components

| Component         | Description                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active Operations | Provides information about the operations currently being processed by the Directory Proxy Server. Shows the number of operations, information on each operation, and the number of active persistent searches. |

| Component                                | Description                                                                                                                                                                                                                                                                                   |
|------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Backends                                 | Provides general information about the state of an a Directory Proxy Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.                             |
| Client Connections                       | Provides information about all client connections to the Directory Proxy Server. The client connection information contains a name followed by an equal sign and a quoted value (e.g., connID="15", connectTime="20100308223038Z", etc.)                                                      |
| Connection Handlers                      | Provides information about the available connection handlers on the Directory Proxy Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.                              |
| Disk Space Usage                         | Provides information about the disk space available to various components of the Directory Proxy Server.                                                                                                                                                                                      |
| General                                  | Provides general information about the state of the Directory Proxy Server, including product name, vendor name, server version, etc.                                                                                                                                                         |
| Index                                    | Provides on each index. The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.                                                                   |
| HTTP/HTTPS Connection Handler Statistics | Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code. |
| JVM Stack Trace                          | Provides a stack trace of all threads processing within the JVM.                                                                                                                                                                                                                              |
| LDAP Connection Handler Statistics       | Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.      |
| Processing Time Histogram                | Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time (ms), number of processing times between 0ms and 1ms, etc.                                                     |
| System Information                       | Provides general information about the system and the JVM on which the Directory Proxy Server is running, including system host name, operation system, JVM architecture, Java home, Java version, etc.                                                                                       |
| Version                                  | Provides information about the Directory Proxy Server version, including build ID, version, revision number, etc.                                                                                                                                                                             |

| Component  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Work Queue | <p>Provides information about the state of the Directory Proxy Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the <code>ldapsearch</code> command for example, use the <code>--useAdministrativeSession</code> option. The requester must have the <code>use-admin-session</code> privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p> |

## Monitoring Disk Space Usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Proxy Server components. The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations may still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the location of every log file, all JE backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the `DiskSpaceConsumer` interface.

The disk space usage monitor provides the ability to generate administrative alerts, as well as take additional action if the amount of usable space drops below the defined thresholds.

Three thresholds can be configured for this monitor:

- Low space warning threshold.** This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Proxy Server will generate an administrative alert but will remain fully functional. It will generate alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Proxy Server will also generate additional alerts as the amount of usable space is further reduced (e.g., each time the amount of usable space drops below a value 10% closer to the low space error threshold). If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.
- Low space error threshold.** This threshold is also defined as either a percentage or absolute size. Once the amount of usable space drops below this threshold, then the server will generate an alert notification and will begin rejecting all operations requested by non-root users with "UNAVAILABLE" results. The server should continue to generate alerts during this time. Once the server enters this mode, then an administrator will have to take some kind of action (e.g., running a command to invoke a task or removing a signal file) before the server will resume normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server will begin rejecting requests from non-root users immediately upon detecting low usable disk space.
- Out of space error threshold.** This threshold may also be defined as a percentage or absolute size. Once the amount of usable space drops below this threshold, then the PingDirectoryProxy Server will generate a final administrative alert and will shut itself down. This threshold must be less than or equal

to the low space error threshold. If they are equal, the server will shut itself down rather than rejecting requests from non-root users.

- **Disk space monitoring for tools.** The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files may be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which will cause problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values may not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database may become, how much space log files may consume, and how many backups will be stored.

The threshold values may be specified either as absolute sizes or as percentages of the total available disk space. All values must be specified as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server will not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database will preserve its integrity but may enter a state in which it rejects all operations with an error and requires the server (or at least the affected backends) to be restarted. If the low space error threshold is also set to zero, then the server will generate periodic warnings about low available disk space but will remain fully functional for as long as possible. If all three threshold values are set to zero, then the server will not attempt to warn about or otherwise react to a lack of usable disk space.

## Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment. The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics, which it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available via a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your Ping Identity Platform system. For more information, refer to the *PingDataMetrics Server Administration Guide*.

### Monitoring Key Performance Indicators by Application

The PingDirectoryProxy Server can be configured to track many key performance metrics (for example, throughput and response-time) by the client applications requesting them. This feature is invaluable for measuring whether the Ping Identity identify infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data can be accessed in the `cn=monitor` backend, the Periodic Stats Logger, and made available for collection by the Metrics Server. See the “Profiling Server Performance Using the Periodic Stats Logger” for more information on using that component. Also, see the Directory Proxy Server Configuration section of the *PingDataMetrics Server Administration Guide* for details on configuring the server to expose metrics that interest you. Tracked application information is exposed in the PingDataMetrics Server by metrics having the 'application-name' dimension. See the documentation under `docs/metrics` of the PingDataMetrics Server for information on which metrics are available with the 'application-name' dimension.

## Configuring the External Servers

Before you install the PingDataMetrics Server, you need to configure the servers you will be monitoring: PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. The PingDataMetrics Server requires all servers to be version 3.5.0 or later. See the administration guides for each product for installation instructions.

Once you have installed the Directory Proxy Server, you can use the `dsconfig` tool to make configuration changes for the PingDataMetrics Server. When using the `dsconfig` tool interactively, set the complexity level to Advanced, so that you can make all the necessary configuration changes.

### Preparing the Servers Monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies. The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. The Directory Proxy Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000, and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
 --policy-name StatsCollectorRetentionPolicy \
 --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
 --backend-name metrics --set sample-flush-interval:30s \
 --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

The flush interval can be set between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Proxy Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a good estimate.

### Configuring the Processing Time Histogram Plugin

The Processing Time Histogram plugin is configured on each Directory Proxy Server and Directory Proxy Server as a set of histogram bucket ranges. When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the processing time histogram plugin to true. This property must be set to expose per-application

monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to `true`, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector Plugin and vice versa.

For example, the following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
 --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
 --set per-application-ldap-stats:per-application-only
```

### Setting the Connection Criteria to Collect SLA Statistics by Application

If you want to collect data about your SLAs, you need to configure connection criteria for each Service Level Agreement that you want to track. The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact your authorized support provider.

For example, imagine that we are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager. We need to create connection criteria on the Directory Proxy Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the `application-name` dimension value that clients will specify when accessing the data via the API. When you define the Connection Criteria, change the `included-user-base-dn` property to include the Directory Manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the Directory Manager:

```
$ bin/dsconfig create-connection-criteria \
 --criteria-name "Directory Manager" \
 --type simple \
 --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

### Updating the Global Configuration

You also need to create Global Configuration-tracked applications for each app (connection criteria) you intend to track. The `tracked-application` property allows individual applications to be identified in the server by connection criteria. The name of the tracked application is the same as the name you defined for the connection criteria.

For example, the following `dsconfig` command line adds the connection criteria we created in the previous step to the list of tracked applications:

```
$ bin/dsconfig set-global-configuration-prop \
 --set "tracked-application:Directory Manager"
```

The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients will specify when accessing the data via the API.

### Proxy Considerations for Tracked Applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server since the Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control. If a client of the Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control will be used as the application name regardless of the criteria listed in the `tracked-application` property.

## Monitoring Using SNMP

The PingDirectory Server supports real-time monitoring using the Simple Network Management Protocol (SNMP). The Directory Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a master agent based on the AgentX protocol.

### SNMP Implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices. The NMS communicates with a master agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device (for example, Directory Proxy Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent). The master agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

The PingDirectoryProxy Server contains an SNMP subagent plugin that connects to a Net-SNMP master agent over TCP. The main configuration properties of the plugin are the address and port of the master agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server, and then registers as a MIB server with the Directory Proxy Server instance. Once the plugin's startup method is called, it starts a session thread with the master agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the master agent. The Directory Proxy Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. (Set and inform operations are not supported). SNMP management applications cannot perform actions on the server on their own or by means of an NMS system.

### MY TITLE Example SNMP Deployment

One important note is that the PingDirectoryProxy Server was designed to interface with a Net-SNMP (version 5.3.2.2 or later) master agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, SMA disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP master agent that only enables UNIX Domain Sockets, you must download and install a separate Net-SNMP binary from its web site.

### Configuring SNMP

Because all server instances provide information for a common set of MIBs, each server instance provides its information under a unique SNMPv3 context name, equal to the server instance name. The server instance name is defined in the Global Configuration, and is constructed from the host name and the server LDAP port by default. Consequently, information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance. This context name is limited to 30 characters

or less. Any context name longer than 30 characters will result in an error message. Since the default context name is limited to 30 characters or less, and defaults to the server instance name and the LDAP port number, pay special attention to the length of the fully-qualified (DNS) host name.

**Note:** The Directory Proxy Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

## To Configure SNMP

### Steps

1. Enable the Directory Proxy Server's SNMP plugin by using the `dsconfig` tool. Make sure to specify the address and port of the SNMP master agent. On each Directory Proxy Server instance, enable the SNMP subagent. Note that the SNMPv3 context name is limited to 30 bytes maximum. If the default dynamically-constructed instance name is greater than 30 bytes, there will be an error when attempting to enable the plugin. Enable the SNMP Subagent Alert Handler so that the sub-agent will send traps for administrative alerts generated by the server.

```
$ bin/dsconfig set-alert-handler-prop \
 --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log. You will see a message that the master agent is not connected, because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent configuration file, `snmpd.conf`, which is often located in `/etc/snmp/snmpd.conf`. Add the directive to run the agent as an AgentX master agent:

```
master agentx agentXSocket tcp:localhost:705
```

Note that the use of `localhost` means that only sub-agents running on the same host can connect to the master agent. This requirement is necessary since there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, `public` (or whatever SNMP community has been configured for your environment) and the port.

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. Run the following command to create the SNMPv3 user.

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the `snmpd` daemon and after a few seconds you should see the following message in the Directory Proxy Server error log:

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. Set up a trap client to see the alerts that are generated by the Directory Proxy Server. Create a config file in `/tmp/snmptrapd.conf` and add the directive below to it. The directive specifies that the trap client can process traps using the `public` community string, and can log and trigger executable actions.

```
authcommunity log, execute public
```

9. Install the MIB definitions for the Net-SNMP client tools, usually located in the `/usr/share/snmp/mibs` directory.

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. Then, run the trap client using the `snmptrapd` command. The following example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), do not read any configuration files (`-C`) except the one specified with the `-c` option, print to standard output (`-Lo`), and then specify that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (i.e., `server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
-m all -M +/usr/share/snmp/mibs
```

11. Run the Net-SNMP client tools to test the feature. The following options are required: `-v` <SNMP version>, `-u` <user name>, `-A` <user password>, `-l` <security level>, `-n` <context name (instance name)>. The `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
-m all localhost localDBBackendCount.0

$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
host.example.com:389 \
-m all localhost systemStatus
```

## MIBS

The Directory Proxy Server provides SMIv2-compliant MIB definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definitions are to be found in text files under `resource/mib` directory under the server root directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

- **LDAP Remote Server MIB.** Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to, and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.
- **LDAP Statistics MIB.** Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Proxy Server. A server typically contain only one connection handler and therefore supplies only one table entry.
- **Local DB Backend MIB.** Provides key metrics related to the state of the local database backends contained in the server.
- **Processing Time MIB.** Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.
- **Replication MIB.** Provides key metrics related to the current state of replication, which can help diagnose how much outstanding work replication may have to do.
- **System Status MIB.** Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on the Directory Server and the Directory Proxy Server, see the text files provided in the `resource/mib` directory below the server installation.

The Directory Proxy Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDID-ALERT-MIB.txt` file.

## Monitoring with the Administrative Console

Ping Identity has an Administrative Console for administrators to configure the directory server. The console also provides a status option that accesses the server's monitor content.

### To View the Monitor Dashboard

Steps

1. Ensure that the Directory Proxy Server is running.
2. Open a browser to `http://server-name:8443/console`.
3. Type the root user DN and password, and then click **Login**.
4. Use the top level navigation dropdown and select 'Status.'
5. On the Administrative Console's Status page, select the Monitors tab.

## Accessing the Processing Time Histogram

The PingDirectoryProxy Server provides a processing time histogram that classifies operation response time into user-defined buckets. The histogram tracks the processing on a per operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type (add, bind, compare, delete, modify, modify DN, search).

### To Access the Processing Time Histogram

Steps

1. On the Administrative Console, click **Configuration > Status > Monitors tab**.
2. Select **Processing Time Histogram**. Other monitor entries can be accessed in similar ways.

## Monitoring with JMX

The PingDirectoryProxy Server supports monitoring the JVM™ through a Java Management Extensions (JMX™) management agent, which can be accessed using JConsole or any other kind of JMX client. The JMX interface provides JVM performance and resource utilization information for applications running Java. You can monitor generic metrics exposed by the JVM itself, including memory pools, threads, loaded classes, and MBeans, as well as all the monitor information that the Directory Proxy Server provides. You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

### Running JConsole

Before you can access JConsole, you must configure and enable the JMX Connection Handler for the Directory Proxy Server using the `dsconfig` tool. See Configuring the JMX Connection Handler and Alert Handler.

To invoke the JConsole executable, type `jconsole` on the command line. If `JDK_HOME` is not set in your path, you can access JConsole in the `bin` directory of the `JDK_HOME` path.

## To Run JConsole

### Steps

1. Use **JConsole** to open the Java Monitoring and Management Console. You can also run JConsole to monitor a specific process ID for your application: `jconsole PID`. Or you can run JConsole remotely using: `jconsole hostname:port`.

```
$ jconsole
```

**Note:** If SSL is configured on the JMX Connection Handler, you must specify the Directory Proxy Server jar file in the class path when running `jconsole` over SSL. For example, run the following `jconsole` command:

```
$ jconsole \
-J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \
-J-Djavax.net.ssl.trustStorePassword=secret \
-J-Djava.class.path=$SERVER_ROOT/lib/PingDirectoryProxy.jar:/Library/Java/
JavaVirtualMachines/jdk-version.jdk/Contents/Home/lib/jconsole.jar
```

2. On the **Java Monitoring & Administrative Console**, click **Local Process**, and then click the **PID** corresponding to the directory server.

3. Review the resource monitoring information.

## Monitoring the Directory Proxy Server Using JConsole

You can set up JConsole to monitor the Directory Proxy Server using a remote process. Make sure to enable the JMX Connection Handler and to assign at least the `jmx-read` privilege to a regular user

account (the `jmx-notify` privilege is required to subscribe to receive JMX notifications). Do not use a root user account, as this would pose a security risk.

### To Monitor the Directory Proxy Server using JConsole

#### Steps

1. Start the Directory Proxy Server.

```
$ bin/start-server
```

2. Enable the JMX Connection handler using the `dsconfig` tool. The handler is disabled by default. Remember to include the LDAP connection parameters (host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "JMX Connection Handler" --set enabled:true
```

3. Assign `jmx-read`, `jmx-write`, and `jmx-notify` (if the user receives notifications) to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
 --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

4. On the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Proxy Server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/
com.unboundid.directory.server.protocols.jmx.client-unknown
```

5. In the **Username** and **Password** fields, type the bind DN and password for a user that has at least the `jmx-read` privilege. Click **Connect**.

6. Click `com.unboundid.directory.server`, and expand the `rootDSE` node and the `cn-monitor` sub-node.

7. Click a monitoring entry. In this example, click the **LDAP Connection Handler** entry.

## Monitoring Using the LDAP SDK

You can use the monitoring API to retrieve monitor entries from the Directory Proxy Server as well as to retrieve specific types of monitor entries.

For example, you can retrieve all monitor entries published by the Directory Proxy Server and print the information contained in each using the generic API for accessing monitor entry data as follows:

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
{
 System.out.println("Monitor Name: " + e.getMonitorName());
 System.out.println("Monitor Type: " + e.getMonitorDisplayName());
 System.out.println("Monitor Data:");
 for (MonitorAttribute a : e.getMonitorAttributes().values())
 {
 for (Object value : a.getValues())
 {
 System.out.println(" " + a.getDisplayName() + ": " +
String.valueOf(value));
 }
 }
}
```

```

 }
 System.out.println();
}

```

For more information about the LDAP SDK and the methods in this example, see the *LDAP SDK* documentation.

## Monitoring over LDAP

The PingDirectoryProxy Server exposes a majority of its information under the `cn=monitor` entry. You can access these entries over LDAP using the `ldapsearch` tool.

```

$ bin/ldapsearch --hostname server1.example.com --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --baseDN "cn=monitor" "(objectclass=*)"

```

## Profiling Server Performance Using the Stats Logger

The Directory Server ships with a built-in Stats Logger that is useful for profiling server performance for a given configuration. At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a comma-separated format (.csv), which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a very small value (less than 1 second). The statistics logged and their verbosity can be customized.

The Stats Logger can also be used to view historical information about server statistics including replication, LDAP operations, host information, and gauges. Either update the configuration of the existing Stats Logger Plugin to set the advanced `gauge-info` property to `basic/extended` to include this information, or create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see [To Enable the Stats Logger](#) on page 880.

### To Enable the Stats Logger

About this task

By default, the Directory Server ships with the built-in 'Stats Logger' disabled. To enable it using the `dsconfig` tool or the Administrative Console, go to **Plugins** menu (available on the Advanced object menu), and then, select .

Steps

1. Run `dsconfig` in interactive mode. Enter the LDAP or LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. Enter `o` to change to the Advanced Objects menu.
3. On the main menu, enter the number for Plugins.
4. On the **Plugin** menu, enter the number corresponding to view and edit an existing plugin.
5. On the **Plugin selection** list, enter the number corresponding to the Stats Logger.
6. On the **Stats Logger Plugin** menu, enter the number to set the `enabled` property to `TRUE`. When done, enter `f` to save and apply the configuration. The default logger will log information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing will be logged, but this can be changed by setting the `suppress-if-idle` property to `FALSE` (`suppress-if-idle=false`).

```
>>>> Configure the properties of the Stats Logger Plugin
```

```
Property Value(s)

```

```

1) description Logs performance stats to a log file
 periodically.
2) enabled false
3) local-db-backend-info basic
4) replication-info basic
5) entry-cache-info -
6) host-info -
7) included-ldap-application If per-application LDAP stats is enabled,
 then stats will be included for all
 applications.
8) log-interval 1 s
9) collection-interval 200 ms
10) suppress-if-idle true
11) header-prefix-per-column false
12) empty-instead-of-zero true
13) lines-between-header 50
14) included-ldap-stat active-operations, num-connections,
 op-count-and-latency, work-queue
 memory-utilization
15) included-resource-stat memory-utilization
16) histogram-format count
17) histogram-op-type all
18) per-application-ldap-stats aggregate-only
19) ldap-changelog-info -
20) gauge-info none
21) log-file logs/dsstats.csv
22) log-file-permissions 640
23) append true
24) rotation-policy Fixed Time Rotation Policy, Size Limit
 Rotation Policy
25) retention-policy File Count Retention Policy

?) help
f) finish - apply any changes to the Periodic Stats Logger Plugin
a) hide advanced properties of the Periodic Stats Logger Plugin
d) display the equivalent dsconfig command lines to either re-create this
 object or only to apply pending changes
b) back
q) quit

Enter choice [b]:

```

7. Run the Directory Server. For example, if you are running in a test environment, you can run the **search-and-mod-rate** tool to apply some searches and modifications to the server. You can run **search-and-mod-rate --help** to see an example command.
8. View the Stats log output at `<server-root>/logs/dsstats.csv`. You can open the file in a spreadsheet.

## To Configure Multiple Periodic Stats Loggers

### About this task

Multiple Periodic Stats Loggers can be created to log different statistics, view historical information about gauges, or to create a log at different intervals (such as logging cumulative operations statistics every hour). To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

### Steps

1. Run **dsconfig** by repeating steps 1–3 in [To Enable the Stats Logger](#).
2. From the **Plugin management** menu, enter the number to create a new plugin.

3. From the **Create a New Periodic Stats Logger Plugin** menu, enter `t` to use an existing plugin as a template.
4. Enter the number corresponding to the existing stats logger as a template.
5. Next, enter a descriptive name for the new stats logger. For this example, type `Stats Logger-10s`.
6. Enter the log file path to the file. For this example, type `logs/dsstats2.csv`.
7. On the menu, make any other change to the logger. For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `false`. When finished, enter `f` to save and apply the configuration.
8. You should now see two loggers `dsstats.csv` and `dsstats2.csv` in the `logs` directory.

### Adding Custom Logged Statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` using the Custom Logged Stats object. This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. Newly created Custom Logged Stats will automatically be included in the Periodic Stats Logger output.

Besides allowing a straight pass-through of the values using the 'raw' statistic-type, you can configure attributes to be treated as a counter (where the interval includes the difference in the value since the last interval), an average, a minimum, or a maximum value held by the attribute during the specified interval. The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

**Note:** Custom third-party server extensions that were written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following procedure reproduces the built-in "Consumer Total GB" column that shows up in the output when the `included-resource-stat` property is set to `memory-utilization` on the Periodic Stats Logger. The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage,cn=monitor` entry as follows:

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

### To Configure a Custom Logged Statistic Using `dsconfig` Interactive

#### Steps

1. Run `dsconfig` and enter the LDAP/LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. On the Directory Proxy Server configuration main menu (Advanced Objects menu), enter the number corresponding to Custom Logged Stats.
3. On the Custom Logged Stats menu, enter the number corresponding to Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press **Enter** to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats. For this example, enter `Memory Usage`.

6. From the `monitor-objectclass` property menu, enter the `objectclass` attribute to monitor. For this example, enter `ds-memory-usage-monitor-entry`. You can run `ldapsearch` using the base DN `"cn=JVM Memory Usage,cn=monitor"` entry to view the entry.
7. Next, specify the attributes of the monitor entry that you want to log in the stats logger. In this example, enter `total-bytes-used-by-memory-consumers`, and then press **Enter** again to continue.
8. Next, specify the type of statistics for the monitored attribute that will appear in the log file. In this example, enter the option for raw statistics as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration. At this point, we want to set up a column name that lists the Memory Usage. Enter the option to change the `column-name` property.
10. Next, we want to add a specific label for the column name. Enter the option to add a value, and then enter **Memory Consumer Total (GB)**, and press **Enter** again to continue.
11. Confirm that you want to use the `column-name` value that you entered in the previous step, and then press **Enter** to use the value.
12. Next, we want to scale the Memory Consumer Totals by one gigabyte. On the **Custom Logged Stats** menu, enter the option to change the `divide-value-by` property.
13. On the `divide-value-by` property menu, enter the option to change the value, and then enter `1073741824` (i.e., `1073741824` bytes = 1 gigabytes).
14. On the **Custom Logged Stats** menu, review your configuration. When finished, enter `f` to save and apply the settings.

```
>>>> Configure the properties of the Custom Logged Stats
>>>> via creating 'Memory Usage' Custom Logged Stats

Property Value(s)

1) description -
2) enabled true
3) monitor-objectclass ds-memory-usage-monitor-entry
4) include-filter -
5) attribute-to-log total-bytes-used-by-memory-consumers
6) column-name Memory Consumer Total (GB)
7) statistic-type raw
8) header-prefix -
9) header-prefix-attribute -
10) regex-pattern -
11) regex-replacement -
12) divide-value-by 1073741824
13) divide-value-by-attribute -
14) decimal-format #.##
15) non-zero-implies-not-idle false

?) help
f) finish - create the new Custom Logged Stats
a) hide advanced properties of the Custom Logged Stats
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit
```

```
Enter choice [b]:
```

```
The Custom Logged Stats was created successfully
```

When the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

## To Configure a Custom Stats Logger Using dsconfig Non-Interactive

### Steps

- Use the `dsconfig` non-interactive command-line equivalent to create your custom stats logger. The following one-line command replicates the procedure in the previous section. This command produces a column named "Memory Consumer Total (GB)" that contains the value of the `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
--stats-name "Memory Usage" --type custom \
--set monitor-objectclass:ds-memory-usage-monitor-entry \
--set attribute-to-log:total-bytes-used-by-memory-consumers \
--set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
--set divide-value-by:1073741824
```

## StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD Endpoint type that you can use to transfer metrics data in the StatsD format.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

For a list of available metrics, use the interactive `dsconfig` menu for the Stats Collector Plugin or in the Administrative Console, edit the **Stats Collector** plugin as explained in the second example.

You configure the Monitoring Endpoint using the `dsconfig` command. When you configure Monitoring Endpoint, you include:

- The endpoint's hostname
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

For example, to configure a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`:

```
dsconfig create-monitoring-endpoint \
--type statsd \
--endpoint-name StatsDEndpoint \
--set enabled:true \
--set hostname:localhost \
--set server-port:8125 \
--set connection-type:unencrypted-udp
```

If you are using the Administrative Console:

- Click **Show Advanced Configuration**.
- In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
- Click **New Monitoring Endpoint**.

You can send data to any number of monitoring endpoints.

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint. To send metrics with the StatsD monitoring endpoint, you must enable the Stats Collector Plugin. Also, you must configure the Stats Collector Plugin to indicate the metrics to send.

To enable the Stats Collector Plugin or to configure the type of data sent, use the `dsconfig` command or the Administrative Console. For example, to enable the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using `dsconfig`:

```
dsconfig set-plugin-prop \
 --plugin-name "Stats Collector" \
 --set enabled:true \
 --set host-info:cpu \
 --set host-info:disk \
 --set status-summary-info:basic
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**
3. Edit the **Stats Collector** plugin.

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk as explained in [Sending Metrics to Splunk with StatsD](#) on page 883.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation. Configure the StatsD monitoring endpoint to use the correct host and port. The `dsconfig create-monitoring-endpoint` example above uses a host of localhost and a port of 8125. You can also set these values in the Administrative Console.

## Sending Metrics to Splunk with StatsD

About this task

With the StatsD Endpoint type, you can send metric data to a Splunk installation.

In Splunk, you can use SSL to secure ports that are open for StatsD.

### Note:

StatsD metrics are typically sent over UDP. By using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

You can configure open UDP (or TCP) ports in Splunk to accept only connections from a certain hostname or IP address.

To securely send UDP (or TCP) data to Splunk, you can:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Have the forwarder communicate with the Splunk Indexer over SSL.

## DevOps and infrastructure as code

Derived from the words *development* and *operations*, the term *DevOps* refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- **Pets** — With the *pets service model*, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- **Cattle** — With the *cattle service model*, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-master datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectoryProxy Server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Prior to server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see [Server profiles](#) on page 933.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectoryProxy Servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

## Server profiles

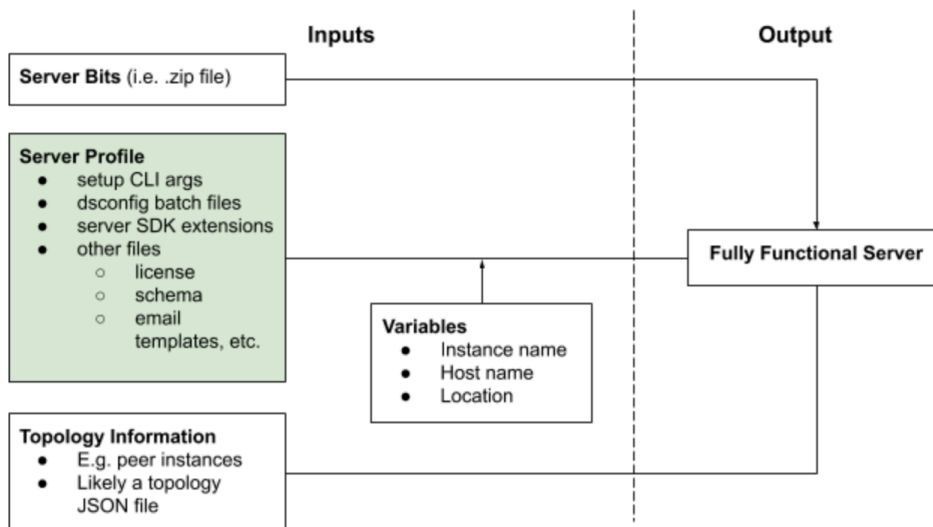

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- `dsconfig`
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectoryProxy Server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 934.
- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the **manage-profile replace-profile** subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, **manage-profile setup** can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the **manage-profile** tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the **manage-profile** tool, see [About the manage-profile tool](#) on page 936.

### Variable substitution

The **manage-profile** tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example profile variables file.

```
MY_VARIABLE=value
MY_OTHER_VARIABLE=anothervalue
```

In this example, the tool provides the `PING_SERVER_ROOT` and `PING_PROFILE_ROOT` variables. The following table describes the built-in variables.

| Built-in variable              | Description                                                    |
|--------------------------------|----------------------------------------------------------------|
| <code>PING_SERVER_ROOT</code>  | Evaluates to the absolute path of the server's root directory. |
| <code>PING_PROFILE_ROOT</code> | Evaluates to the individual profile's root directory.          |

For more information about the tool's usage, run the command `bin/manage-profile --help`.

### Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the `manage-profile generate-profile` subcommand. The `manage-profile` tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
 |-- dsconfig/
 |-- misc-files/
 |-- server-root/
 | |-- post-setup/
 | |-- pre-setup/
 |-- server-sdk-extensions/
 |-- setup-arguments.txt
```

### setup-arguments.txt

When creating a profile, the first step is to add arguments to the file `setup-arguments.txt`. When `manage-profile` setup is run, these arguments are passed to the server's setup tool. To view the arguments that are available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive CLI arguments after any prompts have been completed, run `setup` interactively. The `setup-arguments.txt` file in the profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

### dsconfig/

`dsconfig` batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain `dsconfig` commands to apply to server.

Because the `dsconfig` batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

### server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

### server-sdk-extensions/

Add server SDK extension ZIP files to the `server-sdk-extensions` directory. Use the `manage-extension` tool to install them, and include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

### variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the `manage-profile` tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

### server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

### misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the `manage-profile` tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

### About the manage-profile tool

The `manage-profile` tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the `manage-profile` tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

### manage-profile generate-profile

To create a server profile from a configured server, use the **generate-profile** subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- **dsconfig** commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by **generate-profile**, and must be provided values when other **manage-profile** subcommands use the generated profile.

### manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the **setup** subcommand, which replaces the normal setup tool when using a server profile. Run **manage-profile setup** to complete the following tasks:

- Copies the server root files
- Runs the setup tool
- Runs the **dsconfig** batch files
- Installs the server SDK extensions
- Sets the server's cluster name to a unique value

**Note:** Cluster-wide configuration is automatically mirrored across all servers in the topology with the same cluster name. In a DevOps deployment with immutable servers, configuration mirroring introduces risk. Therefore, in most cases, cluster names should be unique for each server to avoid configuration mirroring.

While **manage-profile setup** is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

### manage-profile replace-profile

Run the **replace-profile** subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While **manage-profile replace-profile** is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run **manage-profile replace-profile** from a second unzipped server install package on the same host as the existing server, similar to the **update** tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent **manage-profile setup** or **manage-profile replace-profile** was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before **manage-profile replace-profile** was run.

**Note:** The **manage-profile replace-profile** tool can update the server version when needed.

**Note:** The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

### Server profiles in a Pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 936.

## Troubleshooting the Directory Proxy Server

---

This chapter provides the common problems and potential solutions that might occur when running PingDirectoryProxy Server. It is primarily targeted at cases in which the Directory Proxy Server is running on Linux® systems, but much of the information can be useful on other platforms as well.

This chapter presents the following information:

### Garbage Collection Diagnostic Information

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the Directory Proxy Server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with " `bin/start-server.java-args`". After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

## Working with the Troubleshooting Tools

If problems arise with the Directory Proxy Server (whether from issues in the Directory Proxy Server itself or a supporting component, like the JVM, operating system, or hardware), then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

### Working with the Collect Support Data Tool

The Directory Server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target Directory Server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

### Available Tool Options

The `collect-support-data` tool has some important options that you should be aware of:

- **--noLdap**. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- **--pid {pid}**. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- **--sequential**. Use this option to diagnose “Out of Memory” errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- **--reportCount {count}**. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- **--reportInterval {interval}**. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it default to 1.
- **--maxJstacks {number}**. Specifies the number of `jstack` samples to collect. If not specified, the default number of samples collected is 10.
- **--collectExpensiveData**. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- **--comment {comment}**. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- **--includeBinaryFiles**. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- **--adminPassword {adminPassword}**. Specifies the global administrator password used to obtain `dsreplication status` information.
- **--adminPasswordFile {adminPasswordFile}**. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.

## To Run the Collect Support Data Tool

### Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
 --bindDN "cn=Directory Manager" --bindPassword secret \
 --serverRoot /opt/PingDirectoryProxy --pid 1234
```

3. Email the zip file to your Authorized Support Provider.

## Directory Proxy Server Troubleshooting Tools

The PingDirectoryProxy Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

### Server Version Information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the Directory Proxy Server software that is in use. If the server is running, then this information can be obtained from the "cn=Version,cn=monitor" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

### LDIF Connection Handler

The Directory Proxy Server provides an LDIF connection handler that provides a way to request operations that do not require any network communication with the server. This can be particularly helpful if a configuration problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files to be placed in the `config/auto-process-ldif` directory. This Directory Proxy Server does not exist by default, but if it is created and an LDIF file is placed in it that contains one or more changes to be processed, then those changes will be applied.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

### Embedded Profiler

If the Directory Proxy Server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- **start** – Indicates that the embedded profiler should start capturing data in the background.
- **stop** – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- **cancel** – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

### To Invoke the Profile Viewer in Text-based Mode

#### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

### To Invoke the Profile Viewer in GUI Mode

#### Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
```

## Troubleshooting Resources for Java Applications

Because the PingDirectoryProxy Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the Directory Proxy Server. In many cases, obtaining the full benefit of these tools requires access to the Directory Proxy Server source code. These Java tools should be used under the advisement of your authorized support provider.

### Java Troubleshooting Tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the PingDirectoryProxy Server.

#### `jps`

The `jps` tool is a Java-specific version of the UNIX `ps` tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the Directory Proxy Server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- **-v** – Includes the arguments passed to the JVM for the processes that are listed.

- **-m** – Includes the arguments passed to the main method for the processes that are listed.
- **-l** – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

### jstack

The **jstack** tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the PingDirectoryProxy Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where {processID} is the process ID of the target JVM as returned by the **jps** command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where {pathToJava} is the path to the java command from which the core file was created, and {pathToCore} is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The **-l** option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The **-m** option can be used to include native frames in the stack trace.

### jmap

The **jmap** tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native **pmmap** tool provided by many operating systems. As with the **jstack** tool, **jmap** can be invoked against a running Java process by providing the process ID, or against a core file, like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- **-dump:live,format=b,file=filename** – Dump the live heap data to a file that can be examined by the **jhat** tool
- **-heap** – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- **-histo:live** – Provides a count of the number of objects of each type contained in the heap. If the **:live** portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

### jhat

The **jhat** (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the Directory Proxy Server encounters an out of memory error (as a result of the **-XX:+HeapDumpOnOutOfMemoryError** JVM option) or from the use of the **jmap** command with the **-dump** option.

The **jhat** tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming

significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The `jhat` tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the `jhat` web server to begin listening on port 7000. It can be accessed in a browser at `http://localhost:7000` (or `http://address:7000` from a remote system). An alternate port number can be specified using the `-port` option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL `http://localhost:7000/oql/` (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at `http://localhost:7000/oqlhelp/`.

### jstat

The `jstat` tool is used to obtain a variety of statistical information from the JVM, much like the `vmstat` utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the Directory Proxy Server, which can be obtained by running `jps` as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- **-class** – Provides information about class loading and unloading.
- **-compile** – Provides information about the activity of the JIT complex.
- **-printcompilation** – Provides information about JIT method compilation.
- **-gc** – Provides information about the activity of the garbage collector.
- **-gccapacity** – Provides information about memory region capacities.

### Java Diagnostic Information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

#### Garbage Collection Diagnostic Information

You can enable the JVM debugging options to track garbage collection data for your system. The options can impact JVM performance, but they provide valuable data to tune your server when troubleshooting garbage collection issues. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to the JVM to use when running the server to provide additional detail.

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

To run the Directory Proxy Server with these options, edit the `config/java.properties` file and add them to the end of the line that begins with `" bin/start-server.java-args"`. After the file has been saved, invoke the following command to make those new arguments take effect the next time the server is started:

```
$ bin/dsjavaproperties
```

## JVM Crash Diagnostic Information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the Directory Proxy Server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

## Troubleshooting Resources in the Operating System

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the Directory Proxy Server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the Directory Proxy Server, and in others system, tools can help narrow down the cause of the problem.

## Identifying Problems with the Underlying System

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

## Monitoring System Data Using the PingDataMetrics Server

The PingDataMetrics Server provides collection and storage of performance data from your server topology. You can use the System Utilization Monitor with the PingDataMetrics Server to collect information about the host system CPU, disk, and network utilization on any platform except Linux. If you are not using the PingDataMetrics Server, you do not need to use the system utilization monitor. When data is being collected, it periodically forks the process and executes commands.

For more information about using the System Utilization Monitor, refer to the data collection chapter of the PingDataMetrics Server documentation.

## Examining CPU Utilization

Observing CPU utilization for the Directory Proxy Server process and the system as a whole provides clues as to the nature of the problem.

### *System-Wide CPU Utilization*

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the Directory Proxy Server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the Directory Proxy Server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

### *Per-CPU Utilization*

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add "-P ALL" to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

### *Per-Process Utilization*

To investigate CPU consumption on a per-process basis, use a command such as the `top` utility on Linux. If a process other than the Java process used to run the Directory Proxy Server is consuming a significant amount of available CPU, it might be interfering with the ability of the Directory Proxy Server to run effectively.

### **Examining Disk Utilization**

If the underlying system has a very high disk utilization, it can adversely impact Directory Proxy Server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool may be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the "-x" argument, like:

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the "%util" column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor Directory Proxy Server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

### **Examining Process Details**

There are a number of tools provided by the operating system that can help examine a process in detail.

`ps`

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

### *pstack*

The **pstack** command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using **jstack**, it includes threads that are not available in a Java stack trace. For example, the command displays those threads used to perform garbage collection and other housekeeping tasks. The general usage for the **pstack** command is:

```
pstack {processID}
```

### *dbx / gdb*

A process debugger provides the ability to examine a process in detail. Like **pstack**, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger **gdb** is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

### *pfiles / lsof*

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as **lsof** on Linux systems, (

```
lsof -p {processID}
```

)

## Tracing Process Execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the **strace** tool on Linux (

```
strace -f -p {processID}
```

).

Consult the **strace** manual page for additional information.

## Problems with SSL Communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
 --publisher-name "File-Based Debug Logger" \
 --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
 --set debug-level:verbose \
 --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Debug Logger" \
```

```
--set enabled:true \
--set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

### Examining Network Communication

Because the PingDirectoryProxy Server is a network-based application, it can be valuable to observe the network communication that it has with clients. The Directory Proxy Server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there may be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the `tcpdump` tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using `"-w {path}"` with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore may require root access.

### Common Problems and Potential Solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

#### General Methodology to Troubleshoot a Problem

When a problem is detected, Ping Identity recommends using the following general methodology to isolate the problem:

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
  - `logs/errors`
  - `logs/failed-ops`
  - `logs/expensive-ops`
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the Ping Identity Platform do not have direct access to the systems where the production

servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

**i Important:** Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

### The Server Will Not Run Setup

If the `setup` tool does not run properly, some of the most common reasons include the following:

#### *A Suitable Java Environment Is Not Available*

The PingDirectoryProxy Server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

#### *Unexpected Arguments Provided to the JVM*

If the `setup` script attempts to launch the `java` command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

#### *The Server Has Already Been Configured or Used*

The `setup` tool is only intended to provide the initial configuration for the Directory Proxy Server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the Directory Proxy Server prior to running the `setup` tool. This protects an existing Directory Proxy Server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the Directory Proxy Server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

## The Server Will Not Start

If the Directory Proxy Server does not start, then there are a number of potential causes.

### *The Server or Other Administrative Tool Is Already Running*

Only a single instance of the Directory Proxy Server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Directory Proxy Server could not acquire an exclusive lock on file
/ds/PingDirectoryProxy/locks/server.lock: The exclusive lock requested for
file
/ds/PingDirectoryProxy/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the Directory Proxy Server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

### *There Is Not Enough Memory Available*

When the Directory Proxy Server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the Directory Proxy Server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the Directory Proxy Server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the Directory Proxy Server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the Directory Proxy Server, or reconfigure the Directory Proxy Server to reduce the amount of memory that it attempts to use.
- The Directory Proxy Server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

### *An Invalid Java Environment or JVM Option Was Used*

If an attempt to start the Directory Proxy Server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value may override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

### *An Invalid Command-Line Option Was Provided*

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

### *The Server Has an Invalid Configuration*

If a change is made to the Directory Proxy Server configuration using an officially-supported tool like `dsconfig` or the Administrative Console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the Directory Proxy Server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started

successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

**i Note:** In addition to manually-editing the config file, you can look at previous achieved configurations to see if the most recent one works. You can also use the `ldif-diff` tool to compare the configurations in the archive to the current configuration to see what is different.

#### *You Do Not Have Sufficient Permissions*

The Directory Proxy Server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the Directory Proxy Server installation, so that they are owned by the user or role under which the server should run. For example, if the Directory Proxy Server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/PingDirectoryProxy
```

#### **The Server Has Crashed or Shut Itself Down**

You can first check the current server state by using the `bin/server-state` command. If the Directory Proxy Server was previously running but is no longer active, then the potential reasons include the following:

- The Directory Proxy Server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The Directory Proxy Server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The Directory Proxy Server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The Directory Proxy Server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then

messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.

- The JVM in which the Directory Proxy Server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

### Conditions for Automatic Server Shutdown

All PingDirectoryProxy Server servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The Directory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
 --set unrecoverable-database-error-mode:initiate-server-shutdown
```

### The Server Will Not Accept Client Connections

You can first check the current server state by using the `bin/server-state` command. If the Directory Proxy Server does not appear to be accepting connections from clients, then potential reasons include the following:

- The Directory Proxy Server is not running.
- The underlying system on which the Directory Proxy Server is installed is not running.
- The Directory Proxy Server is running but is not reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the Directory Proxy Server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the Directory Proxy Server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the Directory Proxy Server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

### The Server is Unresponsive

You can first check the current server state by using the `bin/server-state` command. If the Directory Proxy Server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that

operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

**Note:** If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which may not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the Directory Proxy Server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the Directory Proxy Server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the Directory Proxy Server is running are not receiving TCP acknowledgement.
- If the system on which the Directory Proxy Server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

If it appears that the problem is with the Directory Proxy Server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

### The Server is Slow to Respond to Client Requests

If the Directory Proxy Server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the Directory Proxy Server. The Periodic Stats Logger can save the information in csv format for easy viewing in a spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the Directory Proxy Server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread

configured), or it can be necessary to provision more systems on which to run the Directory Proxy Server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```

 --- Work Queue ---
 : Recent : Average : Maximum
-----:-----:-----:-----
Queue Size : 10 : 1 : 10
% Busy : 17 : 14 : 100

```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see Disk-Bound Deployments.
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the Directory Proxy Server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if `swappiness` is not set to 0 on Linux. For more information, see Disable File System Swapping.
- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the Directory Proxy Server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

### The Server Returns Error Responses to Client Requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.
- If a portion of the Directory Proxy Server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update proxies or load balancers or both to route requests away from the affected server. As of Directory Proxy Server version 3.1 or later, the Directory Proxy Server will indicate that it is in a degraded status and the Directory Proxy Server will route around it.
- If the Directory Proxy Server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.

- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.
- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and reopened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

### The Server Must Disconnect a Client Connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
 --bindDN "cn=directory manager" \
 --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for (`description=expensive`), which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3
msgID=4
 clientIP="10.8.4.21" authDN="cn=appl,ou=applications,dc=example,dc=com"
 base="dc=example,dc=com" scope=wholeSubtree filter="(description=expensive)"
 attrs="A
 LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1
msgID=2
 clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root
 DNs,cn=config" base="cn=monitor" scope=wholeSubtree filter="(cn=active operations)"
 attrs="ALL"
 num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named `disconnect6.ldif`.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name:
 com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to `ds-task-disconnect-connection-id`. The value for `ds-task-id` value does not follow a specific convention. It must be unique among other task entries currently cached by the server.

- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif \
 --defaultAdd --bindDN "cn=directory manager" \
 --bindPassword password
```

### Problems with the Administrative Console

If a problem arises when trying to use the Administrative Console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target Directory Proxy Server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the Directory Proxy Server instance using the Administrative Console, then the access and error logs for that Directory Proxy Server instance might provide additional information about the underlying problem.

### Problems with the Administrative Console: JVM Memory Issues

**Console runs out of memory (PermGen).** An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
error. Please report this problem and include this log file.
OutOfMemoryError: PermGen space
() \ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
(DirectoryServer.java:15783) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1057) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.Thread.dispatchUncaughtException
(Thread.java:1986) \nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

### Global Index Growing Too Large

If the global index appears to be growing too large, you can reload from the backend directory servers. Use the **reload-index** tool with the **--fromDS** option, overriding the configuration of the **prime-index-source** property. You can do this on a one off basis if the global index appears to be growing too large as follows:

```
$ bin/reload-index \
 --bindPassword password \
 --baseDN "dc=example,dc=com" \
 --fromDS
```

### Forgotten Proxy User Password

If you have forgotten the password you set for the **cn=Proxy User** entry, you can work around the problem as follows:

- You can temporarily add a second password to the proxy user entry so that you can transition all of the proxy server instances to the new password. However, you should have multiple passwords on the **cn=Proxy User** entry for the shortest time possible.
- If you do not know the clear-text value, then you can use the encrypted value when configuring the new Directory Proxy Server. The encryption scheme allows reversible passwords that are stored in the server configuration so that they can be decrypted by any server instance.
- You can create a new root user in the directory server instances with the appropriate set of privileges and have the new proxy server instance use that account to authenticate. Since it is not a good idea to

have an account for which you do not know the password, you may want to update all of the other proxy server instances to use the new account.

- You can use a protocol analyzer like **snoop** or **Wireshark**, to capture the password from the network communication.

### Providing Information for Support Cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

## Managing the SCIM 1.1 Servlet Extension

The PingDirectoryProxy Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

### Overview of SCIM 1.1 Fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- **Provision identities.** Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- **Provision groups.** SCIM also allows you to manage groups.
- **Interoperate using a common schema.** SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

**Note:** SCIM 1.1 will be deprecated in a future release.

### Summary of SCIM 1.1 Protocol Support

PingDirectoryProxy Server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

#### SCIM Protocol Support

| SCIM Feature                 | Supported                                                     |
|------------------------------|---------------------------------------------------------------|
| Etags                        | Yes                                                           |
| JSON                         | Yes                                                           |
| XML*                         | Yes                                                           |
| Authentication/Authorization | Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens |

| SCIM Feature                        | Supported                                          |
|-------------------------------------|----------------------------------------------------|
| Service Provider Configuration      | Yes                                                |
| Schema                              | Yes                                                |
| User resources                      | Yes                                                |
| Group resources                     | Yes                                                |
| User-defined resources              | Yes                                                |
| Resource retrieval via GET          | Yes                                                |
| List/query resources                | Yes                                                |
| Query filtering*                    | Yes                                                |
| Query result sorting*               | Yes                                                |
| Query result pagination*            | Yes (Directory Server, not Directory Proxy Server) |
| Resource updates via PUT            | Yes                                                |
| Partial resource updates via PATCH* | Yes                                                |
| Resource deletes via DELETE         | Yes                                                |
| Resource versioning*                | Yes (requires configuration for updated servers)   |
| Bulk*                               | Yes                                                |
| HTTP method overloading             | Yes                                                |
| Raw LDAP Endpoints**                | Yes                                                |

\* denotes an optional feature of the SCIM protocol.

\*\* denotes a PingDirectoryProxy Server extension to the basic SCIM functionality.

### About the Identity Access API

The PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access directory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (e.g., 'Users' and 'Groups'), only LDAP object classes (e.g., `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there may be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top` --> `person` --> `organizationalPerson` --> `inetOrgPerson`, etc.), a client application can access an entry in multiple ways due to the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the PingDirectory Server.

## Creating Your Own SCIM 1.1 Application

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 1.1 SDK is available for download at <https://github.com/pingidentity/scim>.

**Note:** The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

## Configuring SCIM 1.1

This section discusses details about the PingDirectoryProxy Server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

### Before You Begin

To set up your SCIM servlet extension, the Directory Proxy Server provides a `dsconfig` batch file, `scim-config-ds.dsconfig`, that contains the necessary commands to set up a SCIM extension, which is located in the `config` directory. The batch file assumes that the JKS key and trust manager providers are already enabled. Setup examples are presented in later sections.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

### Configuring the SCIM 1.1 Servlet Extension

The Directory Server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (e.g., changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

### To Configure the SCIM Servlet Extension

#### Steps

1. Before you enable the SCIM servlet extension, add access controls on each of the backend Directory Servers to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its `dsconfig` interactive equivalent.

```
$ bin/dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id
||
createTimestamp || modifyTimestamp")
(version 3.0;acl "Authenticated read access to operational attributes \
used by the SCIM servlet extension"; allow (read,search,compare)
userdn="ldap:///all";) '
```

2. On the Directory Proxy Server, enable the SCIM servlet extension by running the `dsconfig` batch file.

```
$ bin/dsconfig --batch-file config/scim-config-proxy.dsconfig
```

3. The `dsconfig` batch file must be edited to use the correct request processor name and base DN name(s) for the `set-request-processor-prop` and `set-root-dse-backend-prop` commands, respectively, as described in the "Configuring LDAP Control Support on All Request Processors" and "SCIM Servlet Extension Authentication" sections later in the chapter.

### To Enable Resource Versioning

#### About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

#### Steps

1. Enable the `ds-entry-checksum` virtual attribute.

```
$ bin/dsconfig set-virtual-attribute-prop \
 --name ds-entry-checksum \
 --set enabled:true
```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

```
$ bin/dsconfig set-access-control-handler-prop \
 --remove 'global-aci:(targetattr="entryUUID ||
entryDN || ds-entry-unique-id || createTimestamp || ds-create-time ||
modifyTimestamp || ds-update-time")(version 3.0;acl "Authenticated read
access to operational attributes used by the SCIM servlet extension"; allow
(read,search,compare) userdn="ldap:///all"'
```

3. On the backend Directory Server, make sure new access controls required by SCIM for read access to operational attributes are enabled with the following command. If this ACI is not present, issues will occur when a SCIM client tries to authenticate with a non-root DN.

```
$ bin/dsconfig set-access-control-handler-prop \
 --add 'global-aci:(targetattr="entryUUID ||
entryDN || ds-entry-unique-id || createTimestamp || ds-create-time ||
modifyTimestamp || ds-update-time || ds-entry-checksum")(version 3.0;acl
"Authenticated read access to operational attributes used by the SCIM
servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
```

### Configuring LDAP Control Support on All Request Processors (Proxy Only)

You need to configure support for the required LDAP controls on all request processors handling LDAP requests that result from SCIM requests. Change the request processor name that was provided as an example and repeat the command for all additional request processors.

#### To Configure LDAP Control Support on All Request Processors

#### Steps

- Use `dsconfig` to change the request processor name that was provided as an example and repeat the command for all additional request processors. Make sure to use your deployment's request processor name.

```
$ bin/dsconfig set-request-processor-prop \
 --processor-name dc_example_dc_com-req-processor \
 --add supported-control-oid:1.2.840.113556.1.4.319 \
 --add supported-control-oid:1.2.840.113556.1.4.473 \
 --add supported-control-oid:2.16.840.1.113730.3.4.9
```

## SCIM 1.1 Servlet Extension Authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the Directory Proxy Server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, PingDirectoryProxy Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

### Enabling HTTPS Communications

If you want the SCIM HTTP connection handler to use SSL, which is mandated by the SCIM specification, you need to enable a Key Manager provider and Trust Manager provider.

To enable SSL during the Directory Proxy Server's initial setup, include the `--ldapsPort` and the `--generateSelfSignedCertificate` arguments with the `setup` command. If your server already has a certificate that you would like to use, set the `key-manager-provider` to the value you set when you enabled SSL in the Directory Proxy Server, or define a new key manager provider (see Configuring HTTP Connection Handlers).

### To Configure Basic Authentication Using an Identity Mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of `cn`.

```
$ bin/dsconfig create-identity-mapper \
 --mapper-name "CN Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:cn
```

2. Configure the SCIM servlet to use the new Identity Mapper.

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name SCIM \
 --set "identity-mapper:CN Identity Mapper"
```

### To Enable OAuth Authentication

About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

## Steps

1. Install your OAuth token handler on the server using **dsconfig**.

```
$ bin/dsconfig create-oauth-token-handler \
 --handler-name ExampleOAuthTokenHandler \
 --type third-party \
 --set extension-
class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
```

2. Configure the SCIM servlet extension to use it as follows:

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name SCIM \
 --set oauth-token-handler:ExampleOAuthTokenHandler
```

## Using HTTP Basic Authentication with Bare UID on the Directory Proxy Server

As discussed above, clients can authenticate to the SCIM extension using HTTP basic authentication and a bare UID value. However, when a SCIM extension is hosted by a Directory Proxy Server, the server needs to be explicitly configured with the names of subordinate base DN's to search. To do this, run the following command on the Directory Proxy Server for every base DN that may be accessed via SCIM. Make sure to specify your deployment's subordinate base DN.

```
$ bin/dsconfig set-root-dse-backend-prop \
 --set subordinate-base-dn:dc=example,dc=com
```

## Verifying the SCIM 1.1 Servlet Extension Configuration

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

### To Verify the SCIM Servlet Extension Configuration

#### About this task

You can verify the configuration of the SCIM extension by navigating to a SCIM resource URL via the command line or through a browser window.

## Steps

- Run **curl** to verify that the SCIM extension is running. The **-k** (or **--insecure**) option is used to turn off curl's verification of the server certificate, since the example Directory Proxy Server is using a self-signed certificate.

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
not considered to be a secure method of user authentication (unless used in
conjunction with some external secure system such as SSL), as the user
name and password are passed over the network as cleartext.","specUrl":
"http://www.ietf.org/rfc/rfc2617","documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
```

- If the user ID is a valid DN (such as **cn=Directory Manager**), the SCIM extension authenticates by binding to the Directory Proxy Server as that user. If the user ID is not a valid DN, the SCIM extension

searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

```
$ curl -u "user.0:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"
```

## Configuring Advanced SCIM 1.1 Extension Features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

### Managing the SCIM 1.1 Schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

#### About SCIM Schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances may be present for each resource. Attributes may be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

#### Mapping LDAP Schema to SCIM Resource Schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the Directory Proxy Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using `"dataType=binary"` in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any

values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

#### *About the <resource> Element*

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

#### *About the <attribute> Element*

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is false.

An attribute element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
  - `simple`: specifies a simple, singular SCIM attribute.
  - `complex`: specifies a complex, singular SCIM attribute.
  - `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
  - `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

#### *About the <simple> Element*

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A simple element contains the following XML element:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

#### *About the <complex> Element*

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

#### *About the <simpleMultiValued> Element*

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

#### *About the <complexMultiValued> Element*

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.
- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

#### *About the <subAttribute> Element*

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.

- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false`.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

#### *About the <canonicalValue> Element*

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, `work` is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

#### *About the <mapping> Element*

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in the [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#) section.

#### *About the <subMapping> Element*

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#).

#### *About the <LDAPSearch> Element*

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DN's to be used when querying for the SCIM resource.
- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

**Note:** The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

### About the `<resourceIDMapping>` Element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or `Directory Proxy Server`, meaning that a value is automatically provided by the Directory Proxy Server (as would be the case if the mapped LDAP attribute is `entryUUID`).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
 <baseDN>ou=people,dc=example,dc=com</baseDN>
 <filter>(objectClass=inetOrgPerson)</filter>
 <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

### About the `<LDAPAdd>` Element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

### About the `<fixedAttribute>` Element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made. The default value is `merge`.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

## Validating Updated SCIM Schema

The PingDirectoryProxy Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

## Mapping SCIM Resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the Directory Proxy Server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute may result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification

regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource may also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID may be stored in the Directory Proxy Server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin may be used by the Directory Proxy Server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the *PingDirectory Server Administration Guide*.

**Note:** Resource IDs may not be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the <resourceIDMapping> Element".

### Using Pre-defined Transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM dateTime data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the \$ character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

### Mapping LDAP Entries to SCIM Using the SCIM-LDAP API

In addition to the SCIM SDK, PingDirectory Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
 <groupId>com.unboundid.product.scim</groupId>
 <artifactId>scim-ldap</artifactId>
 <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory.

**Note:** The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

### SCIM Authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the Directory Server and the Directory Proxy Server using the OAuthTokenHandler API (i.e., via a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

### SCIM Logging

The Directory Proxy Server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use `origin=scim` in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

### SCIM Monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- **HTTPConnectionHandlerStatisticsMonitorProvider** -- Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- **SCMServletMonitorProvider** -- Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, `user-patch-404:26`.

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

## Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- **include-ldap-objectclass**. Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value `""` to allow all object classes. If `""` is used, then the SCIM servlet uses the same case used in the Directory Proxy Server LDAP Schema.
- **exclude-ldap-objectclass**. Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- **include-ldap-base-dn**. Specifies a multi-valued property that lists the base DN's that will be exposed. If specified, only entries under these base DN's will be accessible. No parent-child relationships in the DN's are allowed here.
- **exclude-ldap-base-dn**. Specifies a multi-valued property that lists the base DN's that will not be exposed. If specified, entries under these base DN's will not be accessible. No parent-child relationships in the DN's are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

## To Configure the Identity Access API

### Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the `entryDN` virtual attribute. See the [Configure SCIM](#) section for more information.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name SCIM --set 'include-ldap-objectclass:*' \
 --set include-ldap-base-dn:ou=People,dc=example,dc=com
```

The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

## To Disable Core SCIM Resources

### Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

**Note:** When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using `dsconfig`, the changes take effect immediately without any restart required.

## To Verify the Identity Access API Configuration

### Steps

- Perform a curl request to verify the Identity Access API configuration.

```
$ curl -k -u "cn=directory manager:password" \
 -H "Accept: application/json" \
 "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
 attributes=entryDN,uid,givenName,sn,entryUUID"
 {"schemas":
 [{"urn:scim:schemas:core:1.0","urn:unboundid:schemas:scim:ldap:1.0"},
 {"id":"56c9fd6b-f870-35ef-9959-691c783b7318",
 "meta":{"lastModified":"2013-01-11T23:38:26.489Z",
 "location":"https://example.com:443/v1/top/56c9fd6b-
f870-35ef-9959-691c783b7318"},
 "urn:unboundid:schemas:scim:ldap:1.0":{"givenName":["Rufus"],"uid":
["user.1"],
 "sn":["Firefly"],"entryUUID":["56c9fd6b-f870-35ef-9959-691c783b7318"],
 "entrydn":"uid=user.1,ou=people,dc=example,dc=com"}}
```

## Monitoring the SCIM Servlet Extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the Directory Proxy Server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by

LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

### Testing SCIM Query Performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll \
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

### Monitoring Resources Using the SCIM Extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
--bindPassword password --baseDN cn=monitor \
--searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called `host`.

```
$ bin/ldapsearch --baseDN cn=monitor \
'(objectclass=scim-servlet-monitor-entry)'
dn: cn=SCIM Servlet (SCIM HTTP Connection Handler),cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: scim-servlet-monitor-entry
objectClass: extensibleObject
```

### About the HTTP Log Publishers

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.
- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE\_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "[dd/MM/yyyy:HH:mm:ss Z]"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```

[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063

```

```
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-
d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

## Managing Server SDK Extensions

---

The PingDirectoryProxy Server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

### About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your Directory Proxy Server. Extension bundles are installed from a .zip archive or a file system directory. You can use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

**Note:** The `manage-extension` tool may only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

### Available Types of Extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity Server Products, including the PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. Some of those extensions include:

#### Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

#### PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes

- Password Validators
- Plugins
- Tasks
- Virtual Attribute Providers

### PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

### PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

## Command-Line Tools

---

The PingDirectoryProxy Server provides a full suite of command-line tools necessary to administer the server. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

This chapter presents the following topics:

### Using the Help Option

Each command-line utility provides a description of the subcommands, arguments, and usage examples needed to run the tool. You can view detailed argument options and examples by typing `--help` with the command.

```
bin/dsconfig --help
```

For those utilities that support additional subcommands (for example, `dsconfig`), you can get a list of the subcommands by typing `--help-subcommands`.

```
bin/dsconfig --help-subcommands
```

You can also get more detailed subcommand information by typing `--help` with the specific subcommand.

```
bin/dsconfig list-log-publishers --help
```

**Note:** For detailed information and examples of the command-line tools, see the *Ping Identity Directory Proxy Server Command-Line Tool Reference*.

### Available Command-Line Utilities

The Directory Proxy Server provides the following command-line utilities, which can be run directly in interactive, non-interactive, or script mode.

## Command-Line Utilities

Command-Line Tools	Description
authrate	Perform repeated authentications against an LDAP directory server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.
backup	Run full or incremental backups on one or more Directory Proxy Server backends. This utility also supports the use of a properties file to pass predefined command-line arguments. See <a href="#">Managing the tools.properties File</a> for more information.
base64	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
collect-support-data	Collect and package system information useful in troubleshooting problems. The information is packaged as a ZIP archive that can be sent to a technical support representative.
create-initial-proxy-config	Create an initial Directory Proxy Server configuration.
create-rc-script	Create a Run Control (RC) script that may be used to start, stop, and restart the Directory Proxy Server on UNIX-based systems.
create-recurring-task	Create a recurring task to run on the server. Tasks can be created for backups, LDIF exports, a statically defined task, or a third-party task.
create-recurring-task-chain	Create a chain of recurring tasks to run on the server.
dsconfig	View and edit the Directory Proxy Server configuration.
dsjavaproperties	Configure the JVM arguments used to run the Directory Proxy Server and associated tools. Before launching the command, edit the properties file located in <code>config/java.properties</code> to specify the desired JVM options and <code>JAVA_HOME</code> environment variable.
dump-dns	Obtain a listing of all of the DNSs for all entries below a specified base DN in the Directory Server.
enter-lockdown-mode	Request that the Directory Proxy Server enter lockdown mode, during which it only processes operations requested by users holding the <code>lockdown-mode</code> privilege.
global-index-size	Estimates the size in memory of one or more global indexes from the actual number of keys, the configured number of keys and the average key size.
ldap-diff	Compare the contents of two LDAP directory server servers.
ldap-result-code	Display and query LDAP result codes.
ldapcompare	Perform LDAP compare operations in the Directory Proxy Server.
ldapdelete	Perform LDAP delete operations in the Directory Proxy Server.
ldapmodify	Perform LDAP modify, add, delete, and modify DN operations in the Directory Proxy Server.
ldappasswordmodify	Perform LDAP password modify operations in the Directory Proxy Server.
ldapsearch	Perform LDAP search operations in the Directory Proxy Server.
ldif-diff	Compare the contents of two LDIF files, the output being an LDIF file needed to bring the source file in sync with the target.

Command-Line Tools	Description
ldifmodify	Apply a set of modify, add, and delete operations against data in an LDIF file.
ldifsearch	Perform search operations against data in an LDIF file.
leave-lockdown-mode	Request that the Directory Proxy Server leave lockdown mode and resume normal operation.
list-backends	List the backends and base DN's configured in the Directory Proxy Server.
make-ldif	Generate LDIF data based on a definition in a template file.
manage-extension	Install or update extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectoryProxy Server. Extension bundles are installed from a zip archive or file system directory. The Directory Proxy Server will be restarted if running to activate the extension(s).
manage-tasks	Access information about pending, running, and completed tasks scheduled in the Directory Proxy Server.
modrate	Perform repeated modifications against an LDAP directory server.
move-subtree	Move a subtree entries or a single entry from one server to another.
parallel-update	Perform add, delete, modify, and modify DN operations concurrently using multiple threads.
prepare-external-server	Prepare and a directory server for communication.
profile-viewer	View information in data files captured by the Directory Proxy Server profiler.
reload-index	Reload the contents of the global index.
remove-backup	Safely remove a backup and optionally all of its dependent backups from the specified Directory Proxy Server backend.
remove-defunct-server	Remove a server from this server's topology.
restore	Restore a backup of the Directory Proxy Server backend.
revert-update	Returns a server to the version before the last update was performed.
review-license	Review and/or indicate your acceptance of the product license.
scramble-ldif	Obscure the contents of a specified set of attributes in an LDIF file.
search-and-mod-rate	Perform repeated searches against an LDAP directory server and modify each entry returned.
search-rate	Perform repeated searches against an LDAP directory server.
server-state	View information about the current state of the Directory Proxy Server process.
setup	Perform the initial setup for the Directory Proxy Server instance.
start-server	Start the Directory Proxy Server.
status	Display basic server information.
stop-server	Stop or restart the Directory Proxy Server.
subtree-accessibility	List or update the a set of subtree accessibility restrictions defined in the Directory Server.

Command-Line Tools	Description
sum-file-sizes	Calculate the sum of the sizes for a set of files.
summarize-access-log	Generate a summary of one or more access logs to display a number of metrics about operations processed within the server.
uninstall	Uninstall the Directory Proxy Server.
update	Update the Directory Proxy Server to a newer version by downloading and unzipping the new server install package on the same host as the server you wish to update. Then, use the <code>update</code> tool from the new server package to update the older version of the server. Before upgrading a server, you should ensure that it is capable of starting without severe or fatal errors. During the update process, the server is stopped if running, then the update performed, and a check is made to determine if the newly updated server starts without major errors. If it cannot start cleanly, the update will be backed out and the server returned to its prior state. See the <code>revert-update</code> tool for information on reverting an update.
validate-ldif	Validate the contents of an LDIF file against the server schema.

## Managing the tools.properties File

The PingDirectory Server supports the use of a tools properties file that simplifies command-line invocations by reading in a set of arguments for each tool from a text file. Each property is in the form of name/value pairs that define predetermined values for a tool's arguments. Properties files are convenient when quickly testing the Directory Server in multiple environments.

The Directory Server supports two types of properties file: default properties files that can be applied to all command-line utilities or tool-specific properties file that can be specified using the `--propertiesFilePath` option. You can override all of the Directory Server's command-line utilities with a properties file using the `config/tools.properties` file.

### Creating a Tools Properties File

You can create a properties file with a text editor by specifying each argument, or option, using standard Java properties file format (name=value). For example, you can create a simple properties file that define a set of LDAP connection parameters as follows:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

Next, you can specify the location of the file using the `--propertiesFilePath /path/to/ File` option with the command-line tool. For example, if you save the previous properties file as `bin/mytool.properties`, you can specify the path to the properties file with `ldapsearch` as follows:

```
$ bin/ldapsearch --propertiesFilePath bin/mytools.properties "(objectclass=*)"
```

Properties files do not allow quotation marks of any kind around values. Any spaces or special characters should be escaped. For example,

```
bindDN=cn=QA\ Managers,ou=groups,dc=example,dc=com
```

The following is not allowed as it contains quotation marks:

```
bindDN=cn="QA Managers,ou=groups,dc=example,dc=com"
```

## Tool-Specific Properties

The Directory Proxy Server also supports properties for specific tool options using the format: `tool.option=value`. Tool-specific options have precedence over general options. For example, the following properties file uses `ldapsearch.port=2389` for `ldapsearch` requests by the client. All other tools that use the properties file uses `port=1389`.

```
hostname=server1.example.com
port=1389
ldapsearch.port=2389
bindDN=cn=Directory\ Manager
```

Another example using the `dsconfig` configuration tool is as follows:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
dsconfig.bindPasswordFile=/ds/config/password
```

**Note:** The `.bindPasswordFile` property requires an absolute path. If you were to specify `~/ds/config/password`, where `~` refers to the home directory, the server does not expand the `~` value when read from the properties file.

## Specifying Default Properties Files

The Directory Proxy Server provides default properties files that apply to all command-line utilities used in client requests. A default properties file, `tools.properties`, is located in the `<server-root>/config` directory.

If you place a custom properties file that has a different file name as `tools.properties` in this default location, specify the path by using the `--propertiesFilePath` option. If you make changes to the `tools.properties` file, you do not need the `--propertiesFilePath` option. See the examples in the next section.

## Evaluation Order Summary

The Directory Proxy Server uses the following evaluation ordering to determine options for a given command-line utility:

- All options used with a utility on the command line takes precedence over any options in any properties file.
- If the `--propertiesFilePath` option is used with no other options, the Directory Proxy Server takes its options from the specified properties file.
- If no options are used on the command line including the `--propertiesFilePath` option (and `--noPropertiesFile`), the Directory Proxy Server searches for the `tools.properties` file at `<server-root>`
- If no default properties file is found and a required option is missing, the tool generates an error.
- Tool-specific properties (for example, `ldapsearch.port=3389`) have precedence over general properties (for example, `port=1389`).

## Evaluation Order Example

Given the following properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The Directory Proxy Server locates a command-line option in a specific priority order.

1. All options presented with the tool on the command line take precedence over any options in any properties file. In the following example, the client request is run with the options specified on the command line (port and baseDN). The command uses the `bindDN` and `bindPassword` arguments specified in the properties file.

```
$ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
 --propertiesFilePath bin/tools.properties "(objectclass=*)" "
```

2. Next, if you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the Directory Proxy Server uses the specified properties file as follows:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
 "(objectclass=*)" "
```

3. If no options are presented with the tool on the command line and the `--noPropertiesFile` option is not present, the Directory Proxy Server attempts to locate any default `tools.properties` file in the following location:

```
<server-root>/config/tools.properties
```

Assume that you move your `tools.properties` file from `<server-root>/bin` to the `<server-root>/config` directory. You can then run your tools as follows:

```
$ bin/ldapsearch "(objectclass=*)" "
```

The Directory Proxy Server can be configured so that it does not search for a properties file by using the `--noPropertiesFile` option. This option tells the Directory Proxy Server to use only those options specified on the command line. The `--propertiesFilePath` and `--noPropertiesFile` options are mutually exclusive and cannot be used together.

4. If no default `tools.properties` file is found and no options are specified with the command-line tool, then the tool generates an error for any missing arguments.

## Running Task-based Utilities

The Directory Proxy Server has a Tasks subsystem that allows you to schedule basic operations, such as backup, restore, `bin/start-server`, `bin/stop-server` and others. All task-based utilities require the `--task` option that explicitly indicates the utility is intended to run as a task rather than in offline mode. The following table shows the arguments that can be used for task-based operations:

### Task-based Utilities

Option	Description
<code>--task</code>	Indicates that the tool is invoked as a task. The <code>--task</code> argument is required. If a tool is invoked as a task without this <code>--task</code> argument, then a warning message will be displayed stating that it must be used. If the <code>--task</code> argument is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message will be displayed and the tool will exit with an error.
<code>--start</code>	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation starts when scheduled as a server task. A value of '0' causes the task to be scheduled for immediate execution. When this option is used, the operation is scheduled to start at the specified time, after which this utility will exit immediately.
<code>--dependency</code>	Specifies the ID of a task upon which this task depends. A task will not start execution until all its dependencies have completed execution. This option can be used multiple times in a single command.

Option	Description
--failedDependencyAction	Specifies the action this task will take should one of its dependent tasks fail. The value must be one of the following: <code>PROCESS</code> , <code>CANCEL</code> , <code>DISABLE</code> . If not specified, the default value is <code>CANCEL</code> . This option can be used multiple times in a single command.
--completionNotify	Specifies the email address of a recipient to be notified when the task completes. This option can be used multiple times in a single command.
--errorNotify	Specifies the email address of a recipient to be notified if an error occurs when this task executes. This option can be used multiple times in a single command.

## Introduction to the Consent Service and Consent API

---

Companies gain loyalty and trust when they offer transparency and control to their users and customers regarding the personal data that is collected, processed, or shared. In Europe, the General Data Protection Regulation (GDPR) was designed specifically for allowing companies to collect and use valuable data about its users, while protecting the rights of citizens to control what is collected and used. To support the collection and end-user control of personal data, PingDirectory Server includes schema and REST APIs that provide the ability to collect fine-grained data authorizations (consents), from users and customers.

### Consent Service overview

The Consent Service is an HTTP-based REST API hosted by the PingDirectory Server or PingDirectoryProxy Server. The service enables the collection of consent from application users, the enforcement of consent, a user's management of his or her consent, and auditing of consent actions. Enterprises can integrate these features into their applications to give users transparency and control of their data privacy.

For the purpose of this document, the following terms are used:

### Consent Terms

Term	Meaning
Consent definition	The terms of the fine-grained contract, which describes the data that can be processed or shared, and a purpose for processing or sharing the data. The consent definition is stored in the server configuration.
Consent localization	A child object of a definition that contains versioned, localized text for the consent definition, to be used when prompting an individual. This is stored in the server configuration.
Consent record	A record of a consent interaction with a user. Consent records are stored in the directory tree.
Subject	The individual whose data can be collected, processed, or shared.
Actor	The individual who granted/denied/revoked consent. This is usually the same as the subject.
Audience	The entity, application, or service that is granted or denied access to a subject's data for a specific purpose.

### Consent API overview

The PingDirectory Server and PingDirectoryProxy Server provide a REST API for managing individuals' consent to handle their data. This can be used as a component of a larger solution, such as a GDPR compliance system or the PingDataGovernance Server Open Banking Account Requests API.

The PingDirectory Server Consent API enables authorization services:

- to capture user consent for sharing or processing data
- to confirm that consent to share or process data has been granted
- for individuals to manage the consent that they have granted.

Detailed API documentation can be found on the Ping Identity website.

### How consents are collected

User consent is collected by creating a consent record through the Consent API. In most cases, the Consent API client uses consent localization data to construct an approval prompt to display to the user. This prompt should include text describing what data is collected and for what purpose, allowing the user to make an informed decision about the value of sharing his or her data.

For example, a web application needing to collect consent for a user's browsing behavior would use the Consent API to look up the localizations for the **browsing-behavior** consent definition. It would select the localization appropriate for the user and use data from the localization resource to construct a consent prompt for display to the user. After the user is prompted and makes a decision, the client could store the decision by creating a new consent record through the Consent API.

### How consents are enforced

The Consent Service can be used as a data source for making access control decisions. If a particular data usage scenario requires consent, then the application or service needing to access or process that data must not be able to use the data unless the user has provided consent. The entity that performs this consent check may be the application itself or some other service.

To perform a consent check, the Consent API client must be able to correlate a data access request type with a consent definition. For example, if a web application needs to collect a user's browsing behavior, this data collection scenario might be represented by a consent definition called **browsing-behavior**.

The application would check for an existing consent grant by searching the Consent API for a consent record that matches the user and the **browsing-behavior** consent definition. If a match is found, then the application can proceed. If a match is not found, the application must collect consent from the user.

## How applications use the Consent API

The following example illustrates both consent capture and consent enforcement. This example follows a user's journey on a website during which the company must gather consent to track the user's browsing behavior:

1. A user launches the company's application and authenticates. The application wants to record the page visit, but first it must check if the user has granted consent to do so.
2. The application makes a call to the Consent API to determine if the **browsing-behavior** consent record exists for this user, and whether consent been granted.
3. The API returns a result indicating that no consent record exists. The application must prompt the user for his or her consent. The application calls the Consent API to retrieve the localization for the **browsing-behavior** consent, which includes the language that the application uses to produce a prompt for the user.
4. After the user makes a decision, the application stores the user's decision by creating a new consent record. This is through a call to the Consent API.
5. Later, the user visits another page in the company's site. The application wants to record the page visit, and again checks whether the user has granted consent to do so.
6. The application makes a call to the Consent API to get the **browsing-behavior** consent record for this user.
7. If the user's consent record agrees to have the company track his or her browsing behavior, the application can then make the appropriate calls to track browsing behavior. This is consent enforcement.

## Consent Service configuration

---

This section provides details for installing and configuring the components on which the Consent Service relies. Refer to the PingDirectory Server Administration Guide for detailed configuration information.

### Configuration overview

The Consent Service is not enabled by default. The setup and configuration process varies depending on the following factors:

- Whether client applications will allow an individual to self-manage consents.
- Whether some or all client applications will be privileged, with the ability to manage all consents.
- The HTTP authentication method used by client applications.
- Whether consent records exist in the same directory as user entries.

### Example configuration scenarios

The following client application scenarios are available for determining how the Consent Service should be configured to meet your business needs.

#### Directly managed consents

In this scenario, one or more client applications provide provide an interface for individuals to directly manage their own consent records. These applications can only manage consents for the currently authenticated user. In addition, there is also a client application for consent administrators. An OAuth 2 authorization server grants access tokens that the applications uses to access the Consent API.

**Configuration for this scenario includes:**

1. Configure an OAuth 2 authorization server to issue a `urn:pingdirectory:consent` scope to individuals and a `urn:pingdirectory:consent_admin` scope to consent administrators.
2. Create an identity mapper to map subject identifiers used by the authorization server to LDAP DNs used by the PingDirectory Server.
3. Configure an access token validator to validate tokens issued by the OAuth 2 authorization server.
4. Configure the Consent HTTP Servlet Extension to disable HTTP basic authentication and restart the HTTPS Connection Handler.
5. Configure the Consent Service to use the OAuth scopes and token validator.

### Indirectly managed consents (basic authentication)

In this scenario, an application uses a privileged service account to manage its users' consents. The application's privileged account can access any consent record, which gives the application the ability to perform operations that an individual user cannot. The following include steps the setup needed for the PingDataGovernance Server's Open Banking Account Requests service to use the Consent Service as its backend.

#### Configuration for this scenario includes:

1. Create a service account for the application.
2. Configure the Consent HTTP Servlet Extension to enable HTTP basic authentication and restart the HTTPS Connection Handler.
3. Create an identity mapper to map consent record subject and actor attribute values to LDAP DNs. This is optional.
4. Configure the Consent Service to use the application's service account, and optionally the identity mapper.

## Set up with the configuration scripts

PingDirectory Server includes two configuration scripts that can serve as the starting point for setting up the Consent Service. Both scripts must be carefully reviewed and updated to support your client application scenarios and business needs.

- `consent-service-base-entries.ldif` - This LDIF script can be imported to create the base DN where consent records will be stored.
- `consent-service-cfg.dsconfig` - This script can be imported to configure and enable the Consent Service.

Both are located in the `/resource/consent/` directory of the PingDirectory Server server root.

Basic configuration with the `consent-service-base-entries.ldif` file includes:

1. Edit the LDIF script and change the location of where consent records will be stored.
2. Import the LDIF script using the `ldapmodify` command, such as:

```
$ bin/ldapmodify --defaultAdd \
 --filename consent-service-base-entries.ldif
```

Basic configuration with the `consent-service-cfg.dsconfig` file includes:

1. Search for **CHANGE-ME** and replace values.
2. Review configuration commands and make additional changes to match existing Ping environment parameters, application scenarios, and business needs.
3. Import the script with the `dsconfig` command, such as:

```
$ bin/dsconfig --no-prompt \
 --batch-file consent-service-cfg.dsconfig
```

## Setup in a replicated PingDirectory Server environment

Running the Consent Service setup script requires special consideration in an environment that includes replicated PingDirectory Servers. If possible, setup the Consent Service after replication is enabled for the PingDirectory Servers. See the *PingDirectory Server Administration Guide* for details about server replication.

### Set up Consent Service after replication is enabled

Complete the following steps if replication is already enabled for PingDirectory Servers.

1. If needed, configure the PingDirectory Servers to use a configuration group called "all-servers." This will ensure that configuration changes are applied to all servers in a topology.

```
$ bin/dsconfig set-global-configuration-prop \
 --set configuration-server-group:all-servers
```

2. Run the Consent Service setup script.

```
$ bin/dsconfig --no-prompt \
 --batch-file resource/consent/consent-service-cfg.dsconfig \
 --applyChangeTo server-group
```

### Set up Consent Service before replication is enabled

If you have already set up the Consent Service on a standalone PingDirectory Server, perform the following steps before enabling replication. In this example, "DS1" is the original PingDirectory Server, and "DS2" is the second server that will be added as a replica.

1. Run the **config-diff** command without arguments on DS1 to produce a batch file that contains configuration changes that will be applied to DS2.

```
$ bin/config-diff > config-changes.dsconfig
```

2. Apply the **config-changes.dsconfig** file to DS2.

```
$ bin/dsconfig --no-prompt \
 --batch-file config-changes.dsconfig \
 --applyChangeTo single-server
```

3. Restart DS2.
4. Enable replication between the two servers.

## Configuration reference

There are many configuration options for the Consent Service and application integration. The configuration scripts included with the PingDirectory Server provide a starting point. Additional detailed information about the Consent Service properties and configuration is provided as reference.

### General Consent Service configuration

The Consent Service configuration is used to control authorization behavior and determines where consent records are stored in the PingDirectory Server. The service properties are configured with the **dsconfig set-consent-service-prop** command. The consent service configuration script configures the consent service properties as follows:

```
$ bin/dsconfig set-consent-service-prop \
 --set enabled:true \
```

```
--set base-dn:ou=consents,dc=example,dc=com \
--set "bind-dn:cn=consent service account" \
--set unprivileged-consent-scope:urn:pingdirectory:consent \
--set privileged-consent-scope:urn:pingdirectory:consent_admin \
--set "consent-record-identity-mapper:User ID Identity Mapper"
```

The following are Consent Service properties.

### Consent Service properties

Property	Description	Required to enable service
<b>enabled</b>	If set to true, enables the Consent Service for handling client requests.	Yes
<b>base-dn</b>	Specifies a container DN for consent record entries.	Yes
<b>bind-dn</b>	Specifies an internal service account used by the Consent Service to perform LDAP operations.	Yes
<b>service-account-dn</b>	Specifies one or more DN's of requesters that will be considered privileged when using basic authentication. If not defined, a requester will only be considered privileged if it is mapped to a DN with the <b>bypass-ac1</b> privilege. Optional.	No
<b>unprivileged-consent-scope</b>	Specifies the name of the scope required for bearer tokens representing unprivileged requesters.	Yes
<b>privileged-consent-scope</b>	Specifies the name of the scope required for bearer tokens representing privileged requesters.	Yes
<b>consent-record-identity-mapper</b>	Specifies one or more identity mappers used to map consent record <b>subject</b> and <b>actor</b> values to DN's. By default, these values are inferred from the authentication context, such as the bearer token subject. Optional.	No
<b>audience</b>	Specifies an <b>audience</b> claim value that the Consent Service will require to be present in bearer tokens that it accepts. Optional.	No

For the Consent Service to report itself as available to clients, the following must be true:

- The Consent Service must be enabled.
- The Consent Service base DN must be configured and must exist.
- The internal service account must be configured and must exist.
- The internal service account must have the right to read, add, modify, and delete entries under the Consent Service base DN.

### Create a container entry for consent records

About this task

Each consent record is a distinct entry in the PingDirectory Server, and the Consent Service requires that these entries be stored under a common base DN, defined by the **base-dn** property of the Consent Service configuration. The Consent Service LDIF file sets the base DN. Use these steps to choose a different location to store consent records.

## Steps

1. To create the Consent Service base DN, open a text editor and save the following to the file `consent-service-base-dn.ldif`.

```
dn: ou=consents,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
ou: consents
```

2. Use `ldapmodify` to add the entry.

```
$ bin/ldapmodify --defaultAdd --filename consent-service-base-dn.ldif
```

## Create an internal service account

### About this task

The Consent Service uses an internal LDAP connection to operate against consent records that are stored as LDAP entries. It authenticates this LDAP connection using a service account, which must be created and dedicated solely to the Consent Service.

The Consent Service configuration script configures the internal service account using a topology admin user. If needed, this can be changed to a root DN user or a user DN whose entry is in the user backend. In all cases, the service account should exist in every LDAP server in the topology.

This service account must have full read and write access to the Consent Service base DN, the ability to read users' `isMemberOf` attribute, and the right to use the following LDAP controls:

- IntermediateClientRequestControl (1.3.6.1.4.1.30221.2.5.2)
- NameWithEntryUUIDRequestControl (1.3.6.1.4.1.30221.2.5.44)
- RejectUnindexedSearchRequestControl (1.3.6.1.4.1.30221.2.5.54)
- PermissiveModifyRequestControl (1.2.840.113556.1.4.1413)
- PostReadRequestControl (1.3.6.1.1.13.2)

For more information about configuring access, see the *"Managing Access Control"* chapter of the PingDirectory Server Administration Guide.

## Steps

- To ensure the correct access, create a user with the `bypass-acl` privilege. The following `dsconfig` command creates a topology admin user with the `bypass-acl` privilege. After this is created, set this user as the `bind-dn` for the Consent Service.

```
$ dsconfig create-topology-admin-user \
 --user-name "Consent Service Account" \
 --set "description:Consent API service account" \
 --set "alternate-bind-dn:cn=consent service account" \
 --set first-name:Consent \
 --set inherit-default-root-privileges:false \
 --set last-name:Service \
 --set password:CHANGE-ME \
 --set privilege:bypass-acl
```

- Because the `bypass-acl` privilege grants a broad level of access, you may not want to grant this privilege to the Consent Service account. If desired, add the following ACL to enable a targeted set of functionality for the Consent Service. The following example grants this access to the DN `cn=consent service account` using global ACIs:

```
Grant access to the consent record base DN ou=consents,dc=example,dc=com
dsconfig set-access-control-handler-prop --add 'global-aci:(target="ldap:///ou=consents,dc=example,dc=com") (targetattr="*|+")(version 3.0; acl "Consent
```

```
Service account access to consent record data"; allow(all) userdn="ldap:///
cn=consent service account";) '

Grant access to the LDAP request controls used by the Consent Service.
dsconfig set-access-control-handler-prop --add 'global-aci:
(targetcontrol="1.3.6.1.4.1.30221.2.5.2||1.3.6.1.4.1.30221.2.5.44||
1.3.6.1.4.1.30221.2.5.54||1.2.840.113556.1.4.1413||1.3.6.1.1.13.2") (version
3.0; acl "Consent Service account access to selected controls"; allow
(read) userdn="ldap:///cn=consent service account";) '

```

## Configure an identity mapper

The Consent Service uses identity mappers to map requester identities, subject values, and actor values to DN. An identity mapper takes a user identifier string and correlates the identifier with the DN of a user entry. The PingDirectory Server provides four different types of identity mappers.

### Identity mappers

Identity mapper type	Description
Exact match identity mapper	Maps a user identifier to a DN by searching for an entry with an attribute that exactly matches the identifier.
Regular expression identity mapper	Similar to an exact match identity mapper, but allows a regular expression to be specified for more flexible matching.
Third-party identity mapper	A custom Java identity mapper implementation written using the Server SDK.
Groovy scripted identity mapper	A custom Groovy identity mapper implementation written using the Server SDK.

The Consent Service can be configured to use identity mappers for each of the following scenarios:

- Requesters authenticating using basic authentication - use the Consent HTTP Servlet Extension **identity-mapper** property to configure an identity mapper that takes the HTTP Basic authorization user name string to find the corresponding user's identity in the PingDirectory Server.
- Requesters authenticating using bearer token authentication - use the Access Token Validator **identity-mapper** property to configure an identity mapper that takes the subject (or other claim value from the OAuth token) to find the corresponding user's identity in the PingDirectory Server.
- Consent record actor and subject values - use the Consent Service **consent-record-identity-mapper** property to configure an identity mapper that takes these consent record attribute values and uses them to find the corresponding users' identities in the PingDirectory Server.

### The consent record identity mapper

By default, the Consent Service automatically sets the subject, subjectDN, actor, and actorDN values to the identity of the authenticated requester. If the requester uses basic authentication, then all values will be set to the auth DN determined by the basic authentication identity mapper. If the requester uses bearer token authentication, then the subject and actor values are set to the bearer token's subject claim value, while the subjectDN and actorDN values will be set to the auth DN determined by the access token validator identity mapper.

Privileged clients may manually set a consent record's subject and/or actor values. In those cases, the Consent Service's **consent-record-identity-mapper** property is used to map a consent record's subject and/or actor values to subjectDN and actorDN values, respectively.

## Identity mapper configuration options

The Consent Service configuration script configures a single identity mapper to be used for all three scenarios. The provided identity mapper searches by **uid**, **cn**, or **entryUUID** attributes under the base DNs **cn=config** and **ou=people,dc=example,dc=com**.

The following configuration provides an example of an identity mapper that will match a user identifier to an LDAP entry with the same value in its **uid** attribute:

```
$ bin/dsconfig create-identity-mapper --mapper-name "User ID Exact Match" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid
```

The following configuration shows another typical example, that of an identity mapper that will match a user identifier to an LDAP entry with the same value in its **entryUUID** attribute:

```
$ bin/dsconfig create-identity-mapper --mapper-name "EntryUUID Exact Match" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:entryUUID
```

The last example creates an identity mapper that will match a user identifier to an LDAP entry with the same value in either its **uid**, **cn**, or **entryUUID** attribute. This identity mapper will also constrain its search to the **ou=people,dc=example,dc=com** and **cn=config** base DNs. (The **cn=config** base DN is not searched by default, and must be explicitly listed to be searched.)

```
$ bin/dsconfig create-identity-mapper \
 --mapper-name "User ID Identity Mapper" \
 --type exact-match \
 --set enabled:true \
 --set match-attribute:uid \
 --set match-attribute:cn \
 --set match-attribute:entryUUID \
 --set match-base-dn:cn=config \
 --set match-base-dn:ou=people,dc=example,dc=com
```

## Authentication methods

The Consent Service supports two HTTP authentication methods, which are both enabled by default:

- Basic authentication
- Bearer token authentication

The Consent servlet looks at the request's Authorization header to determine which authentication type is being used by the client.

With basic authentication, the client provides an encoded user name-password pair in the HTTP Authorization request header. When the Consent Service receives a request using basic authentication, it maps the user name credential to a DN using an identity mapper. This DN is designated the **auth DN** and is used to make subsequent authorization decisions. The Consent Service then performs an LDAP bind using the DN and password to determine if the request can be processed.

With bearer token authentication, the client provides an access token in the HTTP Authorization request header. The access token is always obtained by the client from an external OAuth 2 authorization server and encapsulates information ("claims") about a user identity, the client identity, and the requests that the client is authorized to make.

The PingDirectory Server must be configured to accept access tokens using one or both available access token validators:

- **PingFederate access token validator.** Supports access tokens issued by a PingFederate authorization server. This validator verifies an access token and discovers its claims by making a request to the PingFederate server's token introspection endpoint.
- **JWT access token validator.** Supports signed or encrypted JWT access tokens issued by an arbitrary authorization server. This validator checks an access token by cryptographically verifying the token's signature using a trusted public certificate. The token's claims are encoded in the token itself, so discovering the token's claims does not require an outgoing token introspection request.

The token validator uses its identity mapper to map the subject claim to a DN. This DN is designated the **auth DN** and is used along with the token's claims to make subsequent authorization decisions.

If the PingDirectory Server is configured with at least one access token validator, it will be used by the Consent Service. If the PingDirectory Server is configured with more than one access token validator, the validators are consulted in order until one is able to successfully authenticate the request.

If the PingDirectory Server is configured with multiple access token validators, but only one should be used by the Consent Service, the access token validator can be configured by setting the **access-token-validator** property of the Consent HTTP Servlet Extension.

**Note:** Configuring an access token validator for the Consent Service requires information from the authorization server configuration:

- The values that the authorization server sets for **subject** claims must be mappable to a DN in the PingDirectory Server.
- The authorization server must be configured to authorize clients and grant scopes appropriately for privileged or unprivileged Consent API access.
- The authorization server must be configured to issue tokens with scopes corresponding to the Consent Service's **unprivileged-scope-name** and **privileged-scope-name** configuration.

Refer to the authorization server's documentation for guidance.

## Configure basic authentication

About this task

Basic authentication is enabled by default, and the settings are configured in the Consent HTTP Servlet Extension configuration.

Steps

- Use the following command to disable basic authentication.

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Consent \
 --set basic-auth-enabled:false
```

- Use the following command to enable basic authentication.

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Consent \
 --set basic-auth-enabled:true
```

- Use the following command to configure an identity mapper for basic authentication.

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Consent \
 --set "identity-mapper:User ID Exact Match"
```

- All of these configuration changes require the Consent servlet to be reloaded before they can take effect. Use the following commands to restart the connection handler that hosts the Consent servlet.

```
$ bin/dsconfig set-connection-handler-prop \
```

```
--handler-name "HTTPS Connection Handler" \
--set enabled:false
```

```
$ bin/dsconfig set-connection-handler-prop \
--handler-name "HTTPS Connection Handler" \
--set enabled:true
```

## Configure bearer token authentication

### Steps

- The following is an example access token validator configured on the PingDirectory Server for a PingFederate server:

```
$ bin/dsconfig create-external-server \
--server-name PingFederate \
--type http \
--set base-url:https://my-ping-federate-server:1443/
```

```
$ bin/dsconfig create-access-token-validator \
--validator-name "PingFederate Token Validator" \
--type ping-federate \
--set enabled:true \
--set "identity-mapper:User ID Exact Match" \
--set authorization-server:PingFederate \
--set client-id:id \
--set client-secret:secret
```

- If more than one access token validator is configured on the PingDirectory Server, the Consent Service can be configured to use a single validator with the following command:

```
$ bin/dsconfig set-http-servlet-extension-prop \
--extension-name Consent \
--set "access-token-validator:PingFederate Token Validator"
```

## Configure Consent Service scopes

### About this task

The Consent Service checks access tokens for a **subject** claim and uses an identity mapper to map the value to a DN, called the request DN or auth DN. If no request DN can be mapped, the request is rejected. In addition, the Consent Service will only accept an access token with a scope that it is configured to recognize.

- An unprivileged consent scope designates the requester as unprivileged. The scope's name is configured with the Consent Service's **unprivileged-consent-scope** property.
- A privileged consent scope designates the requester as privileged. This is configured using the Consent Service's **privileged-consent-scope** property.

The authorization server must also be configured to issue tokens with these scopes.

### Steps

- The following example configures these scopes for the Consent Service.

```
$ bin/dsconfig set-consent-service-prop \
--set unprivileged-consent-scope:consent \
--set privileged-consent-scope:consent_admin
```

## Authorization

The Consent Service's distinction between privileged and unprivileged requesters determines the type of operations that can be performed by requesters. During the authorization phase, the Consent servlet

performs checks on both the bearer token claims (if present) and the **auth DN** to determine if the requester is privileged or unprivileged. These are summarized in the following table.

#### Available operations per requester type

Requester type	Description	Access determined by	Can create consent records	Can update consent records	Can delete consent records
Unprivileged	Requesters with no authority to operate on consent records other than their own.	A requester is considered unprivileged if it does not meet any of the criteria for a privileged requester. If using bearer token authentication, the access token must include a scope named by the <b>unprivileged-consent-scope</b> property of the Consent Service configuration. Also, an unprivileged requester can only perform actions on consent records where the subject DN matches the requester DN.	Yes. The subject/subjectDN and actor/actorDN values will be set based on the requester.	Yes, if the requester DN matches the subject DN.	No.
Privileged	A requester with the authority to perform any operation on any consent record.	When using basic authentication, a requester is considered privileged if the requester DN either has the <b>bypass-ac1</b> privilege or is listed in the <b>service-account-dn</b> property of the Consent Service configuration. If using bearer token authentication, the access token must include a scope named by the <b>privileged-consent-scope</b> property of the Consent Service configuration.	Yes.	Yes.	Yes.

#### Bearer token check

If a bearer token was used, the following checks are performed:

- If the Consent Service's **audience** property is configured, the bearer token's audience claim must match the configured value.

- If the bearer token contains a scope matching the Consent Service's `privileged-scope-name` property, then the requester is considered privileged.
- If not, the bearer token must have a scope matching the Consent Service's `unprivileged-scope-name` property, and the requester is considered unprivileged.

#### Basic authentication check

If basic authentication is used, the following checks are performed:

- If the `auth DN` has the LDAP privilege `bypass-ac1`, the requester is privileged.
- If the `auth DN` is listed in the Consent Service's `service-account-dn` property, the requester is privileged.
- If not, the requester is considered unprivileged.

## Manage consents

---

This section describes the tasks required to support the collection and end-user control of personal data, and manage users' consents.

### Overview of consent management

The full lifecycle of consent management goes beyond collecting the user's consent. First, the terms of each consent contract must be centrally managed. After collecting consent, the user will want to review previously granted consents and potentially revoke some. Finally, companies will need to be able to trace the history of updates to any consent in order to resolve a dispute or respond to audit.

### Consent definitions and localizations

Companies will want to centrally manage the language used when prompting a user to give consent. This is key to ensuring a consistent user experience across multiple applications, such as mobile and web. The Consent Service requires one or more consent definitions to be defined in the PingDirectory Server configuration. Each consent definition represents the combination of:

- The data to be collected or shared.
- The purpose for collecting or sharing this data.

For example, a consent definition could represent user email addresses, used to deliver a third party's email newsletter. A consent definition could also represent access to a user's network-connected IoT device, which would be used for a home automation task controlled by a third party.

Each consent definition must have one or more localization. A localization is a versioned object consisting of the data that a Consent API client needs to prompt a user for consent. When a consent record is accepted or denied by a Consent Service client, it must include a reference to a consent definition, locale, and version.

#### Create consent definition and localization

##### Steps

- The following creates a consent definition and a localization for it.

```
$ bin/dsconfig create-consent-definition \
 --definition-name email_newsletter \
 --set "display-name:Email newsletter"
```

```
$ bin/dsconfig create-consent-definition-localization \
 --definition-name email_newsletter \
 --localization-name en-US \
 --set version:1.0 \
```

```
--set "data-text:Your email address" \
--set "purpose-text:To receive newsletter updates"
```

- The following example updates a localization and its version.

```
$ bin/dsconfig set-consent-definition-localization-prop \
--definition-name email_newsletter \
--localization-name en-US \
--set version:1.1 \
--set "data-text:Your preferred email address"
```

## Perform an audit on consents

Changes to Consent Service resources are tracked by one of two types of audit logs. For examples of configuring either type of log, see the `<server-root>/resource/consent-service-cfg.dsconfig` script bundled with the server or *Logging*. This example uses the Consent Trace Logger. It represents Consent Service change events using the same field names used by the Consent API.

### Log Publishers

Log publisher	Log publisher type	Description
Consent Trace Logger	file-based-trace	Records Consent Service events at the Consent API level. Change events are recorded using messages of type <code>audit</code> .
Consent LDAP Audit Logger	file-based-audit	Records data changes at the LDAP level. In combination with a Request Criteria configuration object, an LDAP audit logger can be configured to record changes to Consent Service resources only.

Trace logger keys for auditing

Trace logger audit messages consist of a timestamp, the message type (`CONSENT AUDIT`), and a set of key/value pairs. A subset of important keys are described in the following table.

**Note:** The keys used in trace log audit messages vary depending on the type of resource.

### Log Publishers

Trace logger key	Description
<code>requestID</code>	A server-specific HTTP request ID. This value can be correlated with messages produced by other loggers.
<code>resourceType</code>	The type of Consent Service resource that was changed. Possible values are <code>definition</code> , <code>localization</code> , or <code>consent</code> .
<code>changeType</code>	The type of change recorded by this message. Possible values are <code>create</code> , <code>update</code> , or <code>delete</code> .
<code>attrsAdded</code>	A comma-delimited list of the attributes that were added to the resource.
<code>attrsUpdated</code>	A comma-delimited list of the attributes that were modified on the resource.
<code>attrsDeleted</code>	A comma-delimited list of the attributes that were removed from the resource.

Trace logger key	Description
<b>requestDN</b>	The DN of the requester, which is available only when the resource type is <b>consent</b> .
<b>definitionID</b>	The consent definition ID. If the resource type is <b>definition</b> , this identifies the definition that was changed. If the resource type is <b>localization</b> , this identifies the parent definition. If the resource type is <b>consent</b> , this identifies the consent record's related definition.
<b>locale</b>	The locale. If the resource type is <b>localization</b> , this identifies the localization (in combination with the definition ID). If the resource type is <b>consent</b> , this identifies the related localization (combined with the definition ID).
<b>consentID</b>	The consent record ID, available only when the resource type is <b>consent</b> .
<b>subject</b>	The subject value, available only when the resource type is <b>consent</b> .
<b>subjectDN</b>	The subject's mapped LDAP DN, available only when the resource type is <b>consent</b> .
<b>actor</b>	The actor value, available only when the resource type is <b>consent</b> .
<b>actorDN</b>	The actor's mapped LDAP DN, available only when the resource type is <b>consent</b> .
<b>audience</b>	The audience value, available only when the resource type is <b>consent</b> .
<b>status</b>	The consent status. Possible values are <b>pending</b> , <b>accepted</b> , <b>denied</b> , <b>revoked</b> , and <b>restricted</b> . Only available when the resource type is <b>consent</b> .
<b>previousStatus</b>	The previous consent status, if applicable. Only available when the resource type is <b>consent</b> .
<b>msg</b>	A multiline value that includes the complete body of the changed resource. If the action is an update or a delete, the resource's body before the change will be included.

### Perform an audit

Consent resource changes for particular entities (such as a specific user, or a specific consent definition) can be audited by searching the trace log using a combination of one of the message keys and the desired value. For example, if an individual's LDAP DN is known, then the **subjectDN** key can be used to construct a text search for any audit log messages containing that DN. Any matching log messages would constitute a history of that individual's consent activity.

### Example new consent record

The following is a sample record. this audit log message provides important values in a parseable key/value format, but also includes the entirety of the new consent record.

```
[22/May/2018:18:02:42.584 -0500] CONSENT AUDIT requestID=57
requestDN="uid=user.0,ou=people,
dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24"
subject="user.0" subjectDN="uid=user.0,
ou=People,dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com" audience="client1"
definitionID="cats" locale="en-US" status="accepted"
attrsAdded="actor,audience,createdDate,dataText,subject,
```

```

purposeText,definition,id,updatedAt,actorDN,status,subjectDN"
changeType="create" resourceType="consent" msg="
New Consent Record:
 {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'accepted','subject':'user.0','subjectDN':'uid=user.0,
ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=exampl
'client1','definition':{'id':'cats','version':'1.0','locale':'en-
US'}},'dataText':'Collect data about your
cats','purposeText':'To recommend cat food flavors that will satisfy and
delight your feline companion',

'createdDate':'2018-05-22T23:02:42.553Z','updatedAt':'2018-05-22T23:02:42.553Z'}"

```

### Example updated consent record

This example shows the complete consent record before and after it was updated. With the **attrsUpdated**, **status**, and **previousStatus** keys, one can determine that the **status** changed from accepted to revoked.

```

[22/May/2018:18:05:08.660 -0500] CONSENT AUDIT requestID=59
requestDN="uid=user.0,ou=people,
dc=example,dc=com" consentID="6cff325b-e092-4094-b7f9-5a30864b0d24"
subject="user.0" subjectDN="uid=user.0,
ou=People,dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com"
audience="client1" definitionID="cats" locale="en-US" status="revoked"
previousStatus="accepted"
attrsUpdated="status" changeType="update" resourceType="consent" msg="
Previous Consent Record:
 {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'accepted','subject':'user.0','subjectDN':'uid=user.0,
ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=People,dc=exampl
'audience':'client1','definition':
{'id':'cats','version':'1.0','locale':'en-US'}},'dataText':'Collect
data about your cats','purposeText':'To recommend cat food flavors that
will satisfy and delight your

{'id':'cats','version':'1.0','locale':'en-US'}},'dataText':
'Collect data about your cats','purposeText':'To recommend cat food
flavors that will satisfy and
delight your feline
companion','createdDate':'2018-05-22T23:02:42.553Z','updatedAt':'2018-05-22T23:05:08

```

### Example deleted consent record

This example shows that a consent record has been deleted, and the complete representation of the consent record prior to its deletion is provided.

```

[22/May/2018:18:06:35.071 -0500] CONSENT AUDIT requestID=61
requestDN="cn=directory manager"
consentID="6cff325b-e092-4094-b7f9-5a30864b0d24" subject="user.0"
subjectDN="uid=user.0,ou=People,

```

```

dc=example,dc=com" actor="user.0"
actorDN="uid=user.0,ou=People,dc=example,dc=com" audience="client1"
definitionID="cats" locale="en-US" status="revoked"
previousStatus="revoked" attrsDeleted="actor,audience,

createdDate,dataText,subject,purposeText,definition,id,updatedDate,actorDN,status,subject
changeType="delete"
resourceType="consent" msg="
Deleted Consent Record:
 {'id':'6cff325b-e092-4094-
b7f9-5a30864b0d24','status':'revoked','subject':'user.0','subjectDN':

'uid=user.0,ou=People,dc=example,dc=com','actor':'user.0','actorDN':'uid=user.0,ou=Peop
dc=example,dc=com','audience':'client1','definition':
{'id':'cats','version':'1.0','currentVersion':
'1.0','locale':'en-US'},'dataText':'Collect data about your
cats','purposeText':'To recommend cat food
flavors that will satisfy and delight your feline
companion','createdDate':'2018-05-22T23:02:42.553Z',
'updatedDate':'2018-05-22T23:05:08.655Z'}"

```

## Logging

### About this task

The PingDirectory Server trace log publisher is used for logging events generated by HTTP service operations. The trace logger can be used to observe, debug, and audit consent requests.

**Note:** To create a log of consent audit events only, remove all message types except for `consent-message-type:audit`.

### Steps

- The following example creates a trace logger for all consent events, plus summaries of HTTP requests and responses.

```

$ bin/dsconfig create-log-publisher \
--publisher-name "Consent Trace Logger" \
--type file-based-trace \
--set "description:Records Consent API operations" \
--set enabled:true \
--set consent-message-type:audit \
--set consent-message-type:consent-created \
--set consent-message-type:consent-deleted \
--set consent-message-type:consent-retrieved \
--set consent-message-type:consent-search \
--set consent-message-type:consent-updated \
--set consent-message-type:definition-created \
--set consent-message-type:definition-deleted \
--set consent-message-type:definition-retrieved \
--set consent-message-type:definition-search \
--set consent-message-type:definition-updated \
--set consent-message-type:error \
--set consent-message-type:localization-created \
--set consent-message-type:localization-deleted \
--set consent-message-type:localization-retrieved \
--set consent-message-type:localization-search \
--set consent-message-type:localization-updated \
--set http-message-type:request \
--set http-message-type:response \

```

```

--set 'exclude-path-pattern:/**/*.*css' \
--set 'exclude-path-pattern:/**/*.*eot' \
--set 'exclude-path-pattern:/**/*.*gif' \
--set 'exclude-path-pattern:/**/*.*ico' \
--set 'exclude-path-pattern:/**/*.*jpg' \
--set 'exclude-path-pattern:/**/*.*js' \
--set 'exclude-path-pattern:/**/*.*png' \
--set 'exclude-path-pattern:/**/*.*svg' \
--set 'exclude-path-pattern:/**/*.*ttf' \
--set 'exclude-path-pattern:/**/*.*woff' \
--set 'exclude-path-pattern:/**/*.*woff2' \
--set 'exclude-path-pattern:/console/**' \
--set 'exclude-path-pattern:/console/**/template/**' \
--set log-file:logs/consent-trace \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy" \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy"

```

## Correlating user and consent data

In some cases, the organization that has been granted consent by a group of users may need to perform an LDAP search so that they can act upon consent data in the aggregate. For example, a marketing group has collected consent to send a newsletter by email. A search must be performed that will list all of the consent records where the consent definition is **email** and the status is **accepted**. Those records must be correlated to user entries, and each user's email address must be retrieved.

This task is performed with an LDAP search on the PingDirectory Server. Every consent record has a **subject**, the user whose data is collected and stored. The Consent Service can be configured so that it stores the subject's DN in the **subjectDN** field.

In the LDAP schema:

- A consent record's **subjectDN** field is the **ping-consent-subject-dn** attribute.
- A consent record's status is the **ping-consent-state** attribute.
- A consent record's definition ID is in the **ping-consent-definition.id** JSON attribute field.
- And a user entry's email address is in the **mail** attribute.

The search will need to find all of the consent record entries where **ping-consent-definition.id** is **email** and the **ping-consent-status** is **accepted**. It then needs to correlate those consent record entries to user entries using **ping-consent-subject-dn**, and retrieve each user entry's **mail** attribute value. For example:

```

$ bin/ldapsearch \
 --baseDN "ou=consents,dc=example,dc=com" \
 --searchScope sub \
 --joinRule "dn:ping-consent-subject-dn" \
 --joinBaseDN "ou=people,dc=example,dc=com" \
 --joinScope sub \
 --joinRequestedAttribute mail
 '&(ping-consent-
definition:jsonObjectFilterExtensibleMatch:={ "filterType" : "equals",
"field" : "id", "value" : "email" }) (ping-consent-state=accepted)' \
 1.1

Join Result Control:
OID: 1.3.6.1.4.1.30221.2.5.9
Join Result Code: 0 (success)
Joined With Entry:
dn: uid=user.0,ou=People,dc=example,dc=com
mail: user.0@example.com

```

```
dn: entryUUID=9e481010-8330-425a-
bbf1-6637de053d48,ou=Consents,dc=example,dc=com

Result Code: 0 (success)
Number of Entries Returned: 1
```

The output listed under "Join Result Control" specifies the mail value.

## Troubleshooting

The following are general guidelines for troubleshooting the Consent Service and any connection issues. When evaluating the configuration, make sure these issues are addressed first:

- Is the Consent Service enabled?
- Does the Consent Service base DN exist?
- Does the Consent Service's service account have the correct permissions?
- If the Consent Service should accept bearer tokens:
  - Are one or more Access Token Validators correctly configured?
  - Are the identity mappers for the Access Token Validators configured correctly?
  - Are the authorization servers correctly configured to issue tokens that the Consent Service will accept? Check the **audience**, **privileged-consent-scope**, and **unprivileged-consent-scope** properties of the Consent Service configuration.
- If privileged users are defined, are the members of the LDAP group specified by the Consent Service configuration's **privileged-users-group-dn** property?
- If there are applications that allow individuals to manage their own consents, is the system properly configured to map **actor** and **subject** DN's? Check the Consent Service configuration's **consent-record-identity-mapper** property.

### Error cases

#### Consent Service is unavailable

If the Consent Service is unavailable, check that the service is enabled and that the communication with the service is available. Confirm that the service account for the Consent Service has been properly provisioned. If the Consent Service resides on a PingDirectoryProxy Server, make sure that the service account exists on the PingDirectoryProxy Server and all PingDirectory Server behind the PingDirectoryProxy Server.

#### Requester lacks sufficient rights to perform operation

A request may be rejected with a 403 for the following reasons:

- The bearer token does not contain a required scope. Check the **privileged-consent-scope** and **unprivileged-consent-scope** properties of the Consent Service configuration.
- The bearer token does not contain a required **audience** claim. Check the **audience** property of the Consent Service configuration.
- Authentication was successful, but the requester is unprivileged and attempted to perform an operation that only a privileged requester may perform. For example, it may have attempted to act upon a consent record that it does not own, or it may have attempted to delete a consent record.

When using basic authentication, the requester must be listed in the Consent Service configuration **service-account-dn** property to be considered privileged.

#### Subject and actor do not match

Only a privileged requester can create or modify a consent record whose **subject** and **actor** values do not match.

### Unindexed search

The Consent Service will not allow a client to make an unindexed search. In most cases, a client should be able to fix this by refining the search. For example, if a search by `subject` would be unindexed, perform a search by `subject definition ID`.

### Search size limit exceeded

The Consent Service caps the maximum number of records that can be returned in a search result using its `search-size-limit` configuration property. This limit can be increased, or the client may be able to refine the search to produce fewer results.

## Delegated Admin Application Guide

## Delegated Admin overview

---

Delegated Admin from Ping Identity Corp is an add-on to PingDirectory that enables the delegation of user and group management.

### Introduction

Many organizations spend a disproportionate, and often wasteful, amount of time resetting passwords, updating account data, and completing other simple but recurring tasks. Delegated Admin lets organizations assign these responsibilities, as well as others associated with the management of identities in PingDirectory Server, to a subset of administrators. Such *delegated administrators* can be any user outside the organization's IT department, including a customer.

The following employees typically fulfill roles that involve at least a basic level of identity management:

- Help desk or customer service representatives who unlock and reset passwords
- Managers and Human Resources administrators who update employee profiles

- Application administrators who update identity attributes and manage access to applications
- These employees represent strong candidates for inclusion in a group of delegated administrators.

## Features

Delegated Admin lets delegated administrators complete the following tasks across groups, subtrees, and entire organizations:

- Create, view, and search user profiles
- Update user attributes
- Implement constructed attributes
- Set attributes to `read-only`
- Enable and disable accounts
- Reset locked accounts
- Create and edit groups
- Manage the membership of groups and subgroups
- Manage the roles of users and groups
- Implement custom UI form fields

## Install Delegated Admin

---

Depending on your environment and the location of your installation, different options and procedures are available when you install Delegated Admin. Before attempting to install the application, make certain that you complete the tasks in [Prerequisites](#) on page 1272, and in [Before you install](#) on page 1273.

### Installation locations

Delegated Admin can be installed in any of the following locations:

- PingDirectory Server, including replicated instances
- PingDirectoryProxy Server
- External web server

The location that you choose determines the steps that you must perform to install Delegated Admin.

### Prerequisites

Regardless of the location of your Delegated Admin installation, make certain the following Ping Identity products are installed and configured before attempting to install Delegated Admin.

Product	Description	Minimum Version
PingDirectory Server	Stores user-identity data. The HTTPS port that was configured during PingDirectory Server setup is required to install Delegated Admin. For information about upgrading PingDirectory Server, see <a href="#">Upgrade PingDirectory Server</a> on page 1293. For information about installing and configuring PingDirectory Server, refer to <a href="#">PingDirectory Server Administration Guide</a> .	8.0.0.0
PingFederate Server	Provides identities for authentication and authorization. For information about installing and configuring PingFederate Server, see <a href="#">Configure PingFederate Server</a> on page 1296, or refer to <a href="#">PingFederate Server Guide</a> .	9.0

For more information about the compatibility of Delegated Admin with different versions of PingDirectory Server and PingFederate Server, see [Compatibility matrix](#) on page 1296.

## Obtain the installation files

About this task

To obtain the Delegated Admin installation files, perform the following steps:

Steps

1. Download the Delegated Admin installation package, `pingdirectory-delegator-{version}.zip`, to the server on which you plan to install the application.
2. Extract the contents of the installation package.
3. Copy the folder named `/delegator` and its contents to the appropriate directory, as shown by the following table.

Server	Directory
PingDirectory Server	<code>/webapps</code>
Replicated instance of PingDirectory Server	<code>/webapps</code>
PingDirectoryProxy Server	<code>/webapps</code>
External web server	Directory for web-based apps

## Before you install

If you plan to install Delegated Admin on PingDirectory Server or a replicated instance of PingDirectory Server, complete the relevant tasks in this section before installing the application.

PingDirectory Server

If you are installing Delegated Admin on a PingDirectory Server installation that had "Install with sample data" chosen as the installation option, remove the relevant Access Control Information (ACI) from the PingDirectory Server base entry. For more information, refer to the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

If you are installing Delegated Admin on a PingDirectory Server installation that did not have "Install with sample data" chosen as the installation option, proceed to [Obtain the installation files](#) on page 1273.

Replicated instance of PingDirectory Server

If you plan to install Delegated Admin on a replicated instance of PingDirectory Server, perform the following steps:

1. Make certain that replication is enabled for the PingDirectory Servers.

For information about enabling server replication, refer to *PingDirectory Server Administration Guide*.

2. To ensure that configuration changes are applied to all the servers in your topology, configure the PingDirectory Servers to use a configuration group called `all-servers`, as follows:

```
$ bin/dsconfig set-global-configuration-prop \
 --set configuration-server-group:all-servers
```

3. If you are installing Delegated Admin on a replicated PingDirectory Server that had "Install with sample data" chosen as the installation option, remove the relevant Access Control Information (ACI) from the PingDirectory Server base entry.

Because replicated instances share the same data, perform this step against only one of the servers. For more information, refer to the LDIF file `delegator/remove-sample-directory-data-aci.ldif`.

If you are installing Delegated Admin on a PingDirectory Server installation that did not have "Install with sample data" chosen as the installation option, proceed to [Obtain the installation files](#) on page 1273.

## Install the application

### About this task

The steps for installing Delegated Admin depend on whether you are setting up the application in a Unix/Linux environment or in a Windows environment.

**Note:** Regardless of your setup environment, if port 443 is used but not specified in the PingFederate Base URL, do not assign a value to `window.PF_PORT`.

### Unix or Linux

#### About this task

To begin installing Delegated Admin in a Unix or Linux environment, run the following script in the `/delegator` directory from [Obtain the installation files](#) on page 1273:

```
$./set-up-delegator.sh
```

The system generates a configuration file named `config.js` and a batch file named `delegated-admin.dsconfig`.

### Windows

#### About this task

To begin installing Delegated Admin in a Windows environment, perform the following steps:

#### Steps

1. In the Delegated Admin application directory, copy or rename the file `example.config.js` to `config.js`.  
`config.js` contains comments and placeholders for necessary information. For example, the client ID that is required in this file must be one of the client IDs that has been defined for the PingFederate configuration. This value represents the client intended for token issuance, such as `dadmin`.
2. Open `config.js` in a text editor.
3. Change the variable values to match your setup configuration, as the following table shows.

<code>config.js</code> Variable	Value
<code>window.PF_HOST</code>	Public address of the PingFederate Server to which the application redirects the user's browser when logging on.
<code>window.PF_PORT</code>	PingFederate port number. If port 443 is used but not specified in the PingFederate Base URL, do not assign a value to <code>window.PF_PORT</code> .

<code>config.js</code> Variable	Value
<code>window.DADMIN_CLIENT_ID</code>	PingFederate Client ID for the application.

4. Save your changes to `config.js`.
5. Copy or rename the batch file `delegated-admin-template.dsconfig` to `delegated-admin.dsconfig`.
6. Open `delegated-admin.dsconfig` in a text editor and replace the variables (`${variable}`) with actual values.
7. Save your changes to `delegated-admin.dsconfig`.

### All environments

Regardless of whether you are installing Delegated Admin in a Unix/Linux or Windows environment, perform the relevant steps in this section after you complete the previous OS-specific tasks.

### PingDirectoryProxy Server

About this task

If you are installing Delegated Admin on PingDirectoryProxy Server, perform the following steps on all instances of PingDirectory Server:

#### Steps

1. Open the batch file `delegated-admin.dsconfig` in a text editor.
2. Configure the following elements exactly as they are configured on PingDirectoryProxy Server:
  - Virtual-attribute `Delegated Admin Privilege`
  - Global ACI `Authenticated access to the multi-update extended request for the Delegated Admin API`
  - Global ACI `Authenticated access to the no-op request control for the Delegated Admin API`
3. Remove the following elements and sections:
  - Web-application-extension `Delegator`
  - Access-token-validator `PingFederateValidator`
  - Definition `rest-resource-type`
  - Definition `delegated-admin-rights`
4. Save your changes to `delegated-admin.dsconfig`.

### Replicated instances of PingDirectory Server

About this task

If you are installing Delegated Admin on one or more replicated instances of PingDirectory Server, apply the following commands in `delegated-admin.dsconfig` to each instance:

```
$./bin/dsconfig \
 --bindDN "cn=Directory Manager" \
 --no-prompt \
 --batch-file webapps/delegator/delegated-admin.dsconfig \
 --applyChangeTo server-group
```

### External web server

About this task

If you are installing Delegated Admin on an external web server, perform the following steps:

## Steps

1. Open `config.js` in a text editor.
2. Change the variable values to specify the location of PingDirectory Server, as the following table shows.

<code>config.js</code> Variable	Value
<code>window.DS_HOST</code>	host name of PingDirectory Server
<code>window.DS_PORT</code>	HTTPS port of PingDirectory Server

To view an example outline that features these settings, refer to `example.config.js`.

3. Save your changes to `config.js`.
4. Open `delegated-admin.dsconfig` in a text editor.
5. Comment out the following lines, which are located in the `Configure the delegator web app` section, near the bottom of the file:

```
dsconfig create-web-application-extension --extension-name Delegator --
set base-context-path:/delegator --set document-root-directory:webapps/
delegator/app
dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" --add web-application-extension:Delegator
dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" --set enabled:false
dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" --set enabled:true
```

6. Save your changes to `delegated-admin.dsconfig`.
7. Create a CORS policy for the Delegated Admin HTTP servlet extension, where `<origin>` represents the public name of the host, proxy, or load balancer that presents the Delegated Admin web application:

```
dsconfig create-http-servlet-cross-origin-policy --policy-name "Delegated
Admin Cross-Origin Policy" --set "cors-allowed-methods: GET" --set "cors-
allowed-methods: OPTIONS" --set "cors-allowed-methods: POST" --set "cors-
allowed-methods: DELETE" --set "cors-allowed-methods: PATCH" --set "cors-
allowed-origins: <origin>"
dsconfig set-http-servlet-extension-prop --extension-name "Delegated
Admin" --set "cross-origin-policy:Delegated Admin Cross-Origin Policy"
```

## All locations except replicated PingDirectory Server instances

### About this task

**Note:** The `PingDirectory/webapps/delegator/delegated-admin-account-created.template` template must be copied to the `PingDirectory/config/account-status-notification-email-templates/` directory. This file must be copied before running `delegated-admin.dsconfig` even if email functionality is not needed, since some commands in `dsconfig` require this template. See [Edit and copy the email template to PingDirectory Server](#) for information on setting up email.

To continue installing Delegated Admin on PingDirectory Server, PingDirectoryProxy Server, or an external web server, apply the following commands in `delegated-admin.dsconfig` to the appropriate server:

```
$./bin/dsconfig \
--bindDN "cn=Directory Manager" \
--no-prompt \
--batch-file webapps/delegator/delegated-admin.dsconfig
```

## Next steps

After you finish installing Delegated Admin, visit `https://webserverHost:httpPort/delegator` to view the application's **Sign On** page. At this time, you cannot log on to Delegated Admin because the rights of the delegated administrators have not been configured. For more information about configuring administrative rights, the REST resource type, session timeout values, and other properties, see [Configure Delegated Admin](#) on page 1277.

After you configure Delegated Admin, *verify that the application is installed* and working successfully.

## Configure Delegated Admin

---

This chapter describes the necessary configuration to support Delegated Admin after the application is installed successfully.

At a minimum, you must configure the following properties on PingDirectory Server:

- Delegated administrator rights
- REST resource type
- Attributes and attribute searching

### Configuration overview

Delegated Admin must have a PingDirectory Server and PingFederate Server installed. For installation instructions, refer to the documentation for each product.

The process of configuring support for Delegated Admin on PingDirectory Server includes the following tasks:

- Configure users as Delegated Admin administrators.
- Configure attributes and attribute searching.
- Configure groups whose management requires delegation

The process of configuring PingFederate Server includes the following tasks:

- Configure PingFederate as the identity provider for Delegated Admin.
- Configure PingFederate as the OAuth server for Delegated Admin.
- Register Delegated Admin as a client.
- Register PingDirectory Server as an OAuth token validator client.

### Authentication configuration

The delegated administrator logs on to Delegated Admin through the PingFederate Server, which is configured as the authentication server and OpenID Connect (OIDC) provider. PingFederate validates the user's credentials against PingDirectory Server, encapsulates information **claims** about the user's identity, and issues an access token to Delegated Admin, which presents the token to PingDirectory Server in the HTTP Authorization request header.

#### Interaction with PingDirectory Server

PingDirectory Server is configured to accept access tokens by using Access Token Validators. The values that PingFederate Server sets for the access token **sub** claim must be mappable to a distinguished name (DN) in PingDirectory Server. Setting up an access token validator for use with Delegated Admin requires some coordination with the server configuration. In the suggested default configuration, the access token contains the entryUUID of the administrator user entry in the **sub** claim. This value is mapped back to a PingDirectory Server entry by using an Exact Match Identity Mapper.

## Authorization by PingDirectory Server

After validation, PingDirectory Server checks the Delegated Admin configuration for authorization of the delegated administrator. Users or groups of users are authorized as delegated administrators in the PingDirectory Server Administrator Console, or with the `dsconfig` tool.

## Configure authentication

Before installing and configuring Delegated Admin, configure the following OAuth clients within PingFederate:

- Delegated Admin, which obtains an OIDC token that describes the authenticated user
- PingDirectory Server itself, which calls PingFederate to validate the OIDC token that Delegated Admin passes to it

Specifically, the Delegated Admin OAuth client must be configured as follows:

- The client ID is `dadmin` and requires no client secret key.
- The redirect URL is `https://webserverHost:httpPort/delegator/*`, where `webserverHost:httpPort` represents the public host and port of the web application.

**Note:** If you specify 443 as the `httpPort` number, some web browsers might strip the value from the URL. In this scenario, we recommend using both of the following redirect URLs:

- `https://webserverHost/delegator/*`
- `https://webserverHost:443/delegator/*`

- The grant type is `Implicit`.
- The OIDC policy uses JWT tokens, where the entryUUID of the user is passed through the `sub` claim of the OIDC token.

Configure the PingDirectory Server OAuth client as follows:

- The client ID is `pingdirectory` and requires a secret key.
- The grant type is `Access Token Validation`.

For more information about configuring PingFederate Server, see [Configure PingFederate Server](#) on page 1296.

## Configure delegated administrator rights on PingDirectory Server

About this task

To use Delegated Admin, an administrator must possess more than valid credentials and an access token that PingDirectory Server can validate. He or she must possess rights that are designated through the PingDirectory Server configuration. To delegate users or groups as administrators, use the PingDirectory Server Administrator Console (Delegated Admin rights and resource rights) or the `dsconfig create-delegated-admin-rights` and `create-delegated-admin-resource-rights` commands.

The example commands in this section illustrate the configuration options for delegated administration and are performed on PingDirectory Server.

**Note:** Delegated administrators who manage only users in specified groups cannot create new users, and a new user cannot be assigned to one of the specified groups when created. Further, administrators who manage only specific subtrees cannot create users in an organization that does not reside under, or at the same level as, one of the subtrees.

## Steps

- The following commands restrict an administrator to manage users in specified subtrees:

```
$ bin/dsconfig create-delegated-admin-rights \
 --rights-name admin1 \
 --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
 --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
 --rights-name admin1 \
 --rest-resource-type users \
 --set admin-scope:resources-in-specific-subtrees \
 --set "resource-subtree:ou=org1,dc=example,dc=com" \
 --set admin-permission:create \
 --set admin-permission:read \
 --set admin-permission:update \
 --set admin-permission:delete \
 --set enabled:true
```

- An administrator can be restricted to managing the member users of one or more specified groups. In the following example, we assume the existence of a static or dynamic group entry whose members include the users to be managed:

```
$ bin/dsconfig create-delegated-admin-rights \
 --rights-name admin1 \
 --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com"
 --set enabled:true
$ bin/dsconfig create-delegated-admin-resource-rights \
 --rights-name admin1 \
 --rest-resource-type users \
 --set admin-scope:resources-in-specific-groups \
 --set "resources-in-group:cn=User Group,dc=example,dc=com" \
 --set admin-permission:read \
 --set admin-permission:update \
 --set enabled:true
```

- Rather than delegate a single user as an administrator, you might find it more convenient to delegate an entire group of users as administrators, as follows:

```
$ bin/dsconfig create-delegated-admin-rights \
 --rights-name admin-group1 \
 --set "admin-group-dn:cn=Admin Group,ou=people,dc=example,dc=com"
 --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
 --rights-name admin-group1 \
 --rest-resource-type users \
 --set admin-scope:all-resources-in-base \
 --set admin-permission:create \
 --set admin-permission:read \
 --set admin-permission:update \
 --set admin-permission:delete \
 --set enabled:true
```

In this example, groups can be configured to manage specific subtrees or groups with the **resources-in-specific-subtrees** or **resources-in-group** setting for the **admin-scope**. For more information about PingDirectory Server administrators and configuring dynamic and static groups, refer to the *PingDirectory Server Administration Guide*.

## Configure user self-service

### About this task

PingFederate Server provides end users with the ability to self-service their own profiles. To enable this capability, additional configuration is required on the `user` REST resource type in PingDirectory Server.

Before attempting to configure the REST resource type, ensure that you have already configured profile management by users on PingFederate Server. For more information, refer to "Configure profile management by users" and "Set up PingDirectory for customer identities" in the *PingFederate Administrator's Manual*.

Configure the REST resource type as follows:

```
$ bin/dsconfig set-rest-resource-type-prop --type-name users \
 --add auxiliary-ldap-objectclass:pf-connected-identities \
 --set post-create-constructed-attribute:pf-connected-identity
```

**i Important:** To ensure that you can view users who are already defined in the directory, add the auxiliary object class `pf-connected-identities` to all existing users in your PingDirectory Server.

## Configure attributes and attribute search on PingDirectory Server

### About this task

The file that installs Delegated Admin also specifies the following values:

- Object class of user entries through `structural-ldap-objectclass:inetOrgPerson`
- Number of user attributes to expose

**i Note:** Delegated Admin supports the following attribute types:

- Boolean
- Integer
- String
- DateTime
- Custom attributes
- Constructed attributes

### Steps

1. If necessary, change the attribute that is designated as the primary attribute.

```
$ bin/dsconfig set-rest-resource-type-prop \
 --type-name users \
 --set primary-display-attribute-type:mail
```

2. Configure any additional user attributes to appear in Delegated Admin by specifying the LDAP attribute type to expose and by providing a display name for it.

```
$ bin/dsconfig create-delegated-admin-attribute \
 --type-name users \
 --attribute-type customAttr
 --set "display-name:My custom attribute"
```

- Use the following command to set the search filter, where %% represents the search text entered in the web application:

```
$ bin/dsconfig set-rest-resource-type-prop \
 --type-name users \
 --set 'search-filter-pattern:(|(cn=%%*) (mail=%%*) (uid=%%*))'
```

When search text is entered in Delegated Admin, the property **search-filter-pattern** specifies which attributes to search in PingDirectory Server. To satisfy the query, define the appropriate attribute indexes for PingDirectory Server. For more information, refer to *PingDirectory Server Administration Guide*.

- To manage users whose profiles feature a large number of attributes, place the attributes in logical groupings, called *attribute categories*, and give them a specific display order.

The following commands create attribute categories and specify their display order:

```
$ bin/dsconfig create-delegated-admin-attribute-category \
 --display-name "Basic Information" \
 --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute-category \
 --display-name "Contact Information" \
 --set display-order-index:2

$ bin/dsconfig create-delegated-admin-attribute-category \
 --display-name "Other Attributes" \
 --set display-order-index:3
```

- The following example commands assign attributes to a category and specify the display order of each attribute within its category.

```
$ bin/dsconfig set-delegated-admin-attribute-prop \
 --type-name users \
 --attribute-type cn \
 --set "attribute-category:Basic Information" \
 --set display-order-index:1

$ bin/dsconfig set-delegated-admin-attribute-prop \
 --type-name users \
 --attribute-type sn \
 --set "attribute-category:Basic Information" \
 --set display-order-index:2
```

Unassigned attributes are displayed in a miscellaneous category.

### Constructed attributes

A *constructed attribute* is an attribute whose value is computed from values that are assigned to other attributes. For example, the system might construct a full- or common-name attribute, `cn`, from values that are assigned to the standard `givenName` and `sn` attributes, as follows:

```
dsconfig create-constructed-attribute
 --attribute-name ReqConstructedCN --set attribute-type:cn \
 --set 'value-pattern:{givenName} {sn}'
```

Beginning with Delegated Admin 3.5.0 and PingDirectory Server 7.3.0.1, the value of a constructed attribute can be updated automatically whenever the value of a source attribute is not only created, but also when it is edited.

```
dsconfig set-rest-resource-type-prop \
 --type-name users \
 --set post-create-constructed-attribute:ReqConstructedCN \
```

```
--set update-constructed-attribute:ReqConstructedCN
```

In these examples, a change to the value of `givenName` or `sn` forces a corresponding change to the value of `cn`. Attributes that contribute to a required constructed attribute are identified in the UI as **Required**, even if they were not originally designated as such. Because `cn` is a required attribute in this example, `givenName` and `sn` are also required.

**Note:** The capability of an attribute to be changed after its creation is referred to as its *mutability*.

As with standard attributes, constructed attributes are stored as LDAP attributes in a database like PingDirectory Server.

### Set an attribute to read-only

About this task

Beginning with Delegated Admin 3.5.0 and PingDirectory Server 7.3.0.1, user access to standard and constructed attributes can be set to `read-only` as well as to `read/write`. We recommend that you restrict access to constructed attributes to `read-only`. Read-only attributes do not appear on the UI pages that are associated with the creation of users groups and other objects.

Use the `dsconfig` tool to set a standard or constructed attribute as `read-only`, as the following example shows:

```
dsconfig set-delegated-admin-attribute \
 --type-name users \
 --attribute-type modifyTimestamp \
 --set mutability:read-only
```

The following example resets a standard or constructed attribute from `read-only` to `read/write`:

```
dsconfig set-delegated-admin-attribute \
 --type-name users \
 --attribute-type modifyTimestamp \
 --reset mutability
```

## Users and groups

Delegated administrators can be configured to manage users and groups in PingDirectory Server, as follows:

- Create new entries
- Read, view, and search existing entries
- Edit and update existing entries

The following sections describe users and groups in more detail.

### Enable user creation

Enable the creation of new users and resources by configuring either a parent entry distinguished name (DN) or parent resource type where new users will be located. If you configure a parent DN, the entry that it references must exist in PingDirectory Server. All new users are created in this single location. If necessary, use `ldapmodify` to create the parent entry. For more information about the `ldapmodify` tool or about command-line help, refer to the *PingDirectory Server Administration Guide*. Alternatively, if a parent resource type is configured, the administrator can choose the specific resource where the new user is created.

**Note:** Delegated Admin cannot list organizations in which the delegated administrator is unable to manage user entries. Delegated administrators who manage only users in specified groups cannot create

new users, and a new user cannot be assigned to a specified group when created. Further, administrators who manage only specific subtrees cannot create users in an organization that does not reside under, or at the same level as, one of the subtrees.

The following example specifies a single location for new users on PingDirectory Server:

```
$ bin/dsconfig set-rest-resource-type-prop \
 --type-name users \
 --set "parent-dn:ou=people,dc=example,dc=com" \
 --reset parent-resource-type
```

The setup script creates a resource type named **orgs**, which works with entries that feature the **organization objectClass**.

The following example shows that any organization resource can function as the location for new users on PingDirectory Server:

```
$ bin/dsconfig set-rest-resource-type-prop \
 --type-name users \
 --reset parent-dn \
 --set parent-resource-type:orgs
```

A different resource type can be created for **organizationalUnit objectClass** entries, as follows:

```
$ bin/dsconfig create-rest-resource-type \
 --type-name orgUnits \
 --set "display-name:Organizational Units" \
 --set primary-display-attribute-type:ou \
 --set "search-filter-pattern: (&(objectClass=organizationalUnit) (ou=%%))" \
 --set structural-ldap-objectclass:organizationalUnit \
 --set enabled:false

$ bin/dsconfig create-delegated-admin-attribute \
 --type-name orgUnits \
 --attribute-type ou \
 --set "display-name:Organizational Unit"

$ bin/dsconfig set-rest-resource-type-prop \
 --type-name orgUnits \
 --set enabled:true
```

The new resource type can be referenced as a **parent-resource-type**.

By default, new entries are named by their server-generated **entryUUID** values. To change this behavior, configure the LDAP **RDN** attribute.

**Note:** The **RDN** attribute type must also be configured as a Delegated Admin attribute. For more information, see [Configure attributes and attribute search on PingDirectory Server](#) on page 1280. Do not set read-only attributes as the **RDN** attribute.

In the following example, **uid** names new entries and becomes a required attribute:

```
$ bin/dsconfig set-rest-resource-type-prop \
 --type-name users \
 --set create-rdn-attribute-type:uid
```

New users are always created with their configured structural LDAP **objectclass**. One or more auxiliary LDAP **objectclasses** can be specified, as the following example shows:

```
$ bin/dsconfig set-rest-resource-type-prop \
```

```
--type-name users \
--set auxiliary-ldap-objectclass:ubidPersonAux
```

When existing users without all of the specified auxiliary **objectclasses** are edited, the missing **objectclasses** are updated automatically.

## Manage groups

Use the following commands to delegate a user as a group administrator:

```
$ bin/dsconfig create-delegated-admin-rights \
 --rights-name group-admin1 \
 --set "admin-user-dn:uid=admin1,ou=people,dc=example,dc=com" \
 --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
 --rights-name group-admin1 \
 --rest-resource-type groups \
 --set admin-scope:resources-in-specific-subtrees \
 --set "resource-subtree:ou=Groups,dc=example,dc=com" \
 --set admin-permission:manage-group-membership \
 --set admin-permission:create \
 --set admin-permission:read \
 --set admin-permission:update \
 --set admin-permission:delete \
 --set enabled:true

$ bin/dsconfig create-delegated-admin-resource-rights \
 --rights-name group-admin1 \
 --rest-resource-type users \
 --set admin-scope:resources-in-specific-subtrees \
 --set "resource-subtree:ou=org1,dc=example,dc=com" \
 --set admin-permission:read \
 --set enabled:true
```

The administrative scope for users determines which users are visible to the group administrator. In this example, all users in the subtree **ou=org1,dc=example,dc=com** are visible. An administrator can be configured to edit users as well as to manage group memberships.

The group administrator can view, add, and remove any of the users within their administrative scope to the membership of groups within the groups' administrative scope. Static groups can be nested. Users who belong indirectly to a group through nesting are visible as group members but cannot be removed. Users can be removed only from the group of which they are a member. For example, an Employees group might include a Developers group as a nested member. In such a scenario, a user in the Developers group is a direct member of that group and an indirect member of Employees. This member can be removed only when viewing the Developers group, not when viewing the Employees group.

If a group is configured as a dynamic or virtual static group rather than a static group, then the group and its members are visible, but the group membership cannot be modified.

## Set group attributes

The default settings for group attributes specify **cn** and **description** as group attributes, with **cn** used for the group title in Delegated Admin. To create the default settings, use the following commands with a search DN and parent DN ("**dc=example,dc=com**"):

```
$ bin/dsconfig create-rest-resource-type \
 --type group \
 --type-name groups \
 --set "display-name:Groups" \
 --set enabled:false \
 --set "search-base-dn:dc=example,dc=com" \
```

```

--set primary-display-attribute-type:cn \
--set resource-endpoint:groups \
--set "search-filter-pattern:(cn=%%*)" \
--set structural-ldap-objectclass:groupOfUniqueNames
--set parent-dn:dc=example,dc=com

$ bin/dsconfig create-delegated-admin-attribute \
--type-name groups \
--attribute-type cn \
--set "display-name:Name"

$ bin/dsconfig create-delegated-admin-attribute \
--type-name groups \
--attribute-type description \
--set "display-name:Description"

$ bin/dsconfig set-rest-resource-type-prop \
--type-name groups \
--set enabled:true

```

### Set group search filter

When entering text to search for groups, the groups' **search-filter-pattern** property specifies the attributes to be searched in PingDirectory Server. To satisfy the query, define the appropriate attribute indexes for PingDirectory Server. The default setting searches the attribute **cn** for the search text, which is represented by **%%**. Use the following command to set the group search filter:

```

$ bin/dsconfig set-rest-resource-type-prop \
--type-name groups \
--set 'search-filter-pattern:(cn=%%*)'

```

For more information about managing groups, refer to *PingDirectory Server Administrator Guide*.

### Create a group

Users can be added as members to groups that delegated administrators create and manage. Subgroups can also be added as members to a group.

The configuration for each delegated group type consists of the following elements:

- Group REST resource type – Defines the attributes to locate groups in the directory information tree (DIT).
- Parent DN or Parent resource type – Specifies the location in which to create groups in the DIT.
  - To specify a Parent DN for a resource type, type the value in the **Parent DN** text box in the **Resource Creation** section. The Parent DN is often identical to the Search Base DN, such as `ou=customers,ou=Groups,dc=example,dc=com`.
  - To specify a Parent resource type, select a value from the **Parent Resource Type** list box in the **Resource Creation** section. Delegated administrators are subsequently presented with a list box that lets them select a resource, and the group is created under the selected parent resource. If you specify a Parent resource type, set a value for the **Primary Display Attribute Type** in the **Delegated Admin** section. This setting determines the values that are displayed in the Delegated Admin GUI. For example, a Primary Display attribute type of `ou` displays the `ou` value in the list box for each resource within the Parent resource type.
- Attributes to present to the delegated administrators.

To configure a Group REST resource type, use the **Edit Group REST Resource Type** page in the PingData Administrator Console. The **Search Base DN** value in the **General Configuration** section determines the data structure that is searched in Delegated Admin, and the **Display Name** value in the **Delegated Admin** section specifies the label of the REST resource in the Delegated Admin GUI.

PingData Administrator Console		Delegated Admin
UI Form Field	Page and Section	UI Form Field on Create a New Group Page
Display Name	<b>General Configuration# Delegated Admin</b>	Select a Type label
REST Resource Type	<b>Edit Delegated Admin Rights# Delegated Admin Resource Rights</b>	Select a Type option
Parent Resource Type	<b>General Configuration# Resource Creation</b>	Display name for Parent resource type
Display Name	<b>General Configuration# Delegated Admin Attributes</b>	Additional elements like CN, Description, Business Category, and Organization

### Add a user to a group

Users can be added to groups from the **Manage Users** page as well as from the **Manage Groups** page.

#### Add a user from the Manage Users page

About this task

To add a user from the **Manage Users** page, perform the following steps:

Steps

1. In Delegated Admin, click **Manage Users**.
2. Select or search for the user to add to a group.
3. Expand the user profile.
4. Click **Edit**.
5. Click **Groups**.
6. Select or search for the appropriate group.
7. From the **Nonmember Groups** list, click **+** to the right of the group.  
The group is moved to the **Member Groups** list.

#### Add a user from the Manage Groups page

About this task

To add a user from the **Manage Groups** page, perform the following steps:

Steps

1. In Delegated Admin, click **Manage Groups**.
2. Select or search for the appropriate group.
3. Expand the group profile.
4. Click **Edit**.
5. Select or search for the appropriate user.
6. From the **Nonmembers** list, click **+** to the right of the user.  
The user is moved to the **Members** list.

## Generic resource types

Use *generic resource types* to manage LDAP entries that are neither users nor groups, as follows:

- Create new entries
- Read, view, and search existing entries
- Edit and update existing entries

A generic resource type can represent a device, for example, or can be used for organizational unit branch entries that are parents of other resources.

### Define a generic resource type

About this task

Generic resources can be defined for any structural LDAP object class, and can function as members of a group. The following example enables the management of device entries:

```
$ bin/dsconfig create-rest-resource-type \
 --type-name device \
 --set enabled:true \
 --set resource-endpoint:device \
 --set "display-name:Device" \
 --set structural-ldap-objectclass:device \
 --set search-base-dn:dc=example,dc=com \
 --set parent-dn:dc=example,dc=com \
 --set 'search-filter-pattern:(cn=%%*)' \
 --set primary-display-attribute-type:cn

$ bin/dsconfig create-delegated-admin-attribute \
 --type-name device \
 --attribute-type cn \
 --set "display-name:Device Name" \
 --set display-order-index:1

$ bin/dsconfig create-delegated-admin-attribute \
 --type-name device \
 --attribute-type serialNumber \
 --set "display-name:Serial Number" \
 --set display-order-index:2
```

After you define a generic resource type, create Delegated Admin resource rights for it. For more information, see [Configure delegated administrator rights on PingDirectory Server](#) on page 1278.

## Customize UI form fields

About this task

Delegated Admin provides a way to exercise additional control over the form field for a given attribute. Although the presentation can be customized completely, example files are provided to help give a sense of the capabilities from a functionality standpoint.

**Note:** Because the example files will most likely require modifications to address your specific needs, we recommend a basic level of familiarity with HTML, CSS, and JavaScript when dealing with custom UI form fields.

The example files cover the following scenarios:

- Single-selection lists, which allow users to select one item from multiple options
- Check boxes, which can be customized so that one check box is dependent on the other

- String fields with validation and error messages

To set up Delegated Admin to use the custom HTML files and to display custom UI form fields, perform the following steps:

#### Steps

1. Navigate to `PingDirectory/webapps/delegator/app/customAttributes`.
2. Use an editor to open the relevant example HTML file, as shown by the following table.

UI Form Field	Example File
Single selection list	<code>example-select.html</code>
Dependent check boxes	<code>example-dependent.html</code>
String field	<code>example-basic.html</code>

3. Make the appropriate modifications to the example file.  
For information about resizing and other custom capabilities, refer to the comments in `PingDirectory/webapps/delegator/app/assets/iframe--v1.js`.
4. Save the example file as a new file named `attributeName.html`.  
For example, if you are setting up a custom attribute presentation for `cn`, name the file `cn.html`.
5. *Optional:* For further clarity, create a directory under the `customAttributes` directory with the name of the resource endpoint of the REST resource types.  
For example, because a `users` type exists with the endpoint `usersEndpoint`, you might place `cn.html` under `customAttributes/usersEndpoint/`.  
When locating the appropriate HTML file, Delegated Admin searches for the attribute name under the endpoint folder, if one exists, before searching under the `customAttributes` folder.
6. Within PingDirectory Server, set the `attribute-presentation` field for the Delegated Admin attribute to `custom`, as the following example shows.

```
dsconfig set-delegated-admin-attribute-prop \
 --type-name users \
 --attribute-type cn \
 --set attribute-presentation:custom
```

#### Next steps

Browsers that attempt to aggressively cache HTML files often save and reuse outdated versions of those files. Because such browsers might not display changes that are made to an example HTML file, we recommend that you include the following `<meta>` tag in the head of each custom HTML file:

```
<meta http-equiv="Cache-Control" content="no-cache"/>
```

If your browser still does not display the updated HTML file, try one or more of the following suggestions:

- Clear the browser's cache.
- Use a private browsing window.
- Try a different browser.

## Set up email invitations for a new user

#### About this task

To set up email invitations for a new user, complete the following tasks:

1. Set up PingFederate for local identity profile management. For more information, see [Configure profile management by users](#) on page 1299 and [Configure user self-service](#) on page 1280.

When you complete this task, the PingFederate configuration will have a Local Identity Profile.

2. Configure Delegated Admin profile management by users. For more information, see [Configure profile management by users](#) on page 1299 and [Configure user self-service](#) on page 1280.

When you complete this task, users whom the Delegated Admin creates have the pf-connected-identities auxiliary object class as well as a pf-connected-identity attribute value, providing integration with PingFederate's user self-service.

3. Instruct users to copy the email template to PingDirectory Server. For more information, see [Edit and copy the email template to PingDirectory Server](#) on page 1289.
4. Create request criteria to match Delegated Admin user **ADD** requests. For more information, see [Create request criteria to match Delegated Admin user ADD requests](#) on page 1290.
5. Edit the provided email template and insert the URL to the PingFederate self-service profile management endpoint. For more information, see [Edit and copy the email template to PingDirectory Server](#) on page 1289.
6. Create an SMTP external server. For more information, see [Create an SMTP external server](#) on page 1290.
7. Create a multi-part Email Account Status notification handler for Delegated Admin user **ADD** requests. For more information, see [Create a multi-part Email Account Status notification handler for Delegated Admin user ADD requests](#) on page 1290.

The following sections describe these tasks in more details.

### Edit and copy the email template to PingDirectory Server

#### About this task

An example email template is provided in the Delegated Admin package at the top level in the file `delegated-admin-account-created.template`. This template provides a multi-part text and HTML email to the user with their user name and initial password, along with a self-service link they can use to log on to PingFederate and change their password and profile information.

**Note:** The `PingDirectory/webapps/delegator/delegated-admin-account-created.template` template must be copied to the `PingDirectory/config/account-status-notification-email-templates/` directory. This file must be copied before running `delegated-admin.dsconfig` even if email functionality is not needed, since some commands in `dsconfig` require this template.

#### Steps

1. Edit the template as follows:
  - a. Uncomment the line that sets the value for `profile_management_url`.
  - b. Change the value of `profile_management_url` to the externally accessible URL of the Profile Management Endpoint of your PingFederate Local Identity Profile.
2. Copy the template file to the `config/account-status-notification-email-templates` folder of each instance of PingDirectory Server.

By default, the email is sent to the address that is found within the user's LDAP mail attribute.

**Note:** A mail value must be provided for each user. For more information, refer to `common-header-fields.vm` in the email templates folder.

### Next steps

For more information about the format of the email and further customization, refer to the `README` file in the `templates` folder.

## Create request criteria to match Delegated Admin user ADD requests

### About this task

For each user resource type for which new user email invites need to be sent, create simple request criteria to match the parent DN and object classes for the resource type.

**Note:** The setup script already includes such a request criteria for the user resource type that it creates.

```
$ dsconfig create-request-criteria --criteria-name \
"Delegated Admin User Creation Request Criteria" --type simple \
--set operation-type:add --set \
"included-target-entry-dn:ou=people,dc=example,dc=com" \
--set "any-included-target-entry-filter:(objectClass=inetOrgPerson)" \
--set "included-application-name:PingDirectory Delegated Admin"
```

The `included-application-name` property ensures that the criteria matches users whom the Delegated Admin created, but not users who were created through another interface, such as the Directory REST API. This application name value is visible in the LDAP access log for operations that the Delegated Admin HTTP servlet invokes.

## Create an SMTP external server

### About this task

To send emails, PingDirectory Server must be configured with an SMTP server in the global configuration, as the following example shows.

```
$ dsconfig create-external-server --server-name \
"SMTP Server" --type smtp --set server-host-name:smtp.example.com \
--set user-name:example-smtp-user --set password:example-smtp-password
$ dsconfig set-global-configuration-prop --set \
"smtp-server:SMTP Server"
```

## Create a multi-part Email Account Status notification handler for Delegated Admin user ADD requests

### About this task

An Email Account Status Notification Handler must be set in the password policy in force for new users. This handler is typically the Default Password policy.

**Note:** The setup script creates an example notification handler in a disabled state. This handler cannot be enabled until an SMTP server becomes available in the global configuration.

The notification handler references the email template in the `config/account-status-notification-email-templates` folder.

## Steps

### 1. Create or enable the handler, as appropriate:

- To create the handler from scratch, use the **dsconfig create-account-status-notification-handler** command, as the following example shows.

```
$ dsconfig create-account-status-notification-handler \
--handler-name "Delegated Admin Email Account Status \
Notification Handler" --type multi-part-email --set \
enabled:true --set \
"account-creation-notification-request-criteria:Delegated \
Admin User Creation Request Criteria" --set \
account-created-message-template:config/account-status-\
notification-email-templates/delegated-admin-account-created.template
```

- To enable the handler that is provided with the setup script, use the **dsconfig set-account-status-notification-handler-prop** command, as the following example shows.

```
$ dsconfig set-account-status-notification-handler-prop \
--handler-name "Delegated Admin Email Account Status Notification \
Handler" --set enabled:true
```

### 2. Set the handler in the password policy.

```
$ dsconfig set-password-policy-prop \
--policy-name "Default Password Policy" --set \
"account-status-notification-handler:Delegated Admin Email Account \
Status Notification Handler"
```

## Enable the referential integrity plugin

### About this task

When a REST resource type is set to create new entries using an RDN attribute other than `entryUUID`, referential integrity issues can result when the entry's RDN attribute is edited. To preserve the referential integrity of group memberships in such a scenario, enable the referential integrity plugin, as follows:

```
bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
--set enabled:true
```

After the plugin is enabled, group memberships are preserved.

## Enable log tracing

Log tracing can be enabled for OAuth token processing, HTTP request and response actions, and API debugging.

To view OAuth token processing and full HTTP request/response tracing, enable the debug trace logger, as follows:

```
$ bin/dsconfig set-log-publisher-prop \
--publisher-name 'Debug Trace Logger' \
--set enabled:true
```

To enable **admin** API debug logging, use the following commands:

```
$ bin/dsconfig create-debug-target \
--publisher-name 'File-Based Debug Logger' \
--target-name com.unboundid.directory.server.http \
```

```
--set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
 --publisher-name 'File-Based Debug Logger' \
 --target-name com.unboundid.directory.server.extensions.dadmin \
 --set debug-level:VERBOSE
```

```
$ bin/dsconfig create-debug-target \
 --publisher-name 'File-Based Debug Logger' \
 --target-name com.unboundid.directory.broker.api \
 --set debug-level:VERBOSE
```

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name 'File-Based Debug Logger' \
 --set enabled:true
```

## Change the application logo

To change the Ping logo to your corporate logo, add the following line to the configuration file `config.js`:

```
window.HEADER_BAR_LOGO = '<filename>';
```

Support for corporate logos includes, but is not limited to, the following file types:

- JPG
- PNG
- SVG

Add the logo to the build directory, making certain to use the same file name that you specified earlier. The corporate logo appears in the header, and the Ping logo becomes relegated to the sidebar, in grayscale, with a "Powered by" line above it.

To maintain an appropriate aspect ratio, logo images are resized in Delegated Admin to a height of 22px and a maximum width of 150px.

## Configure the session timeout

By default, Delegated Admin features an idle session timeout value of 30 minutes. To adjust this value, perform the following steps:

1. Open the configuration file `config.js` in a text editor.
2. Add the following line, where `{TimeoutValue}` is an integer that represents, in minutes, the session timeout value:

```
window.TIMEOUT_LENGTH_MINS={TimeoutValue};
```

To view an example outline that features this setting, refer to `example.config.js`.

3. Save your changes to `config.js`.

## Verify the installation

About this task

To verify that Delegated Admin is installed successfully, visit `https://webserverHost:httpPort/delegator` and log on to the application.

If your logon attempt is unsuccessful, see [Enable log tracing](#) on page 1291, and use your browser's debug feature to gain insight into the token-validation process.

## Upgrade Delegated Admin

---

Ping Identity periodically issues software with new features, enhancements, and fixes for improved performance. Administrators can use the PingDirectory Server's `update` tool to upgrade the current code version.

This chapter presents some update scenarios and the related implications to consider when upgrading your version of Delegated Admin.

### Upgrade PingDirectory Server

Before attempting to upgrade Delegated Admin to the current version, ensure that you are running version 8.0.0.0 or later of PingDirectory Server. If you are already running PingDirectory Server 8.0.0.0 or later, proceed to [Upgrade the application](#) on page 1295.

For more information about the compatibility of Delegated Admin with different versions of PingDirectory Server and PingFederate Server, see [Compatibility matrix](#) on page 1296.

#### Overview and considerations

The process of upgrading PingDirectory Server involves downloading and extracting a new version of the PingDirectory Server ZIP file on the server to be updated, and running the `update` utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation to be upgraded.

Consider the following when upgrading replicating servers:

- Upgrade affects only the server being upgraded. The process does not alter the configuration of other servers.
- The `update` tool will verify that the version of Java that is installed meets the new server requirements. To simplify the process, install the version of Java that is supported by the new server before running the tool.
- To be safe, backup the user data (userRoot) before an upgrade. Restoring from a backup could be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` utilities will issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This will result in a temporary increase in disk usage for the replicationChanges database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology
- Enable new features after all replicating servers are upgraded.

#### Update servers in a topology

An update to the current PingDirectory Server release includes significant changes as well as the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts. For the admin backend to be migrated, the `update` tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security option requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to true (such as the `cn=Directory Manager` user) that exists on every server can be used.

After enabling or fixing the configuration of the LDAP connection handler(s) to support the desired connection security mechanism on each server, run the following **dsframework** command on the server being updated so that its admin backend has the most up-to-date information:

```
$ bin/dsframework set-server-properties \
 --serverID serverID \
 --set ldapport:port \
 --set ldapsport:port \
 --set startTLSEnabled:true
```

The **update** tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The **update** tool will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

```
$ bin/dsconfig set-global-configuration-prop \
 --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under **cn=cluster**, **cn=config** (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output. For example:

```
$ bin/config-diff --sourceHost hostName \
 --sourcePort port \
 --sourceBindDN bindDN \
 --sourceBindPassword password \
 --targetHost hostName \
 --targetPort port \
 --targetBindDN bindDN \
 --targetBindPassword password
```

If any of these conditions are not satisfied, the **update** tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

## Upgrade PingDirectory Server

About this task

To upgrade PingDirectory Server, perform the following steps:

Steps

1. Download and extract the new version of PingDirectory Server to a location outside the existing server's installation.

For these steps, assume that the existing server installation resides in `/prod/PingDirectory`, and that the new server version is extracted to `/home/stage/PingDirectory`.

- To upgrade the existing PingDirectory Server, run the **update** tool that is provided with the new server package, as follows:

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

If the tool detects any degree of customization, it might prompt for confirmation on server configuration changes.

## Upgrade the application

In DA 3.3.0 and earlier, the setup script assigned a cross-origin resource sharing (CORS) policy to the Delegated Admin HTTP servlet extension. This policy is potentially insecure because the CORS setting **Allowed-Origin** permits requests that use a wildcard to allow requests from any origin. Unless you have made changes to secure this policy, remove it, as follows:

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin"
--reset "cross-origin-policy"
dsconfig delete-http-servlet-cross-origin-policy --policy-name "Delegated
Admin Cross-Origin Policy"
```

**i Important:** Beginning with Delegated Admin 3.2.0 and PingDirectory Server 7.2.1.0, the following configuration changes were made:

- **delegated-admin-resource-type** was replaced with **rest-resource-type**.
- **delegated-administrator** was replaced with **delegated-admin-rights** and **delegated-admin-resource-rights**.

As a result, Delegated Admin 3.0.2 or earlier requires PingDirectory Server 7.2.0.1 or earlier. Similarly, Delegated Admin 3.2.0 or later requires PingDirectory Server 7.2.1.0 or later.

The **update** tool converts earlier configurations to new configuration definitions. This tool is also used during the process of upgrading PingDirectory Server.

The migrated Delegated Admin configuration features a `group` REST resource type for the structural object classes `groupOfNames` and `groupOfUniqueNames`. If the original user's resource type configuration includes a value for `Org Search Filter`, then the migrated configuration also features a generic `orgs` REST resource type, with the structural object class `organizationalUnit` as the parent resource type of users. If necessary, change the structural object class on the resource type configuration after the Delegated Admin update completes.

**i Note:** If you change the structural object class, you must stop the server to proceed with the update.

**i Note:** The `delegated-admin-template.dsconfig` file has been updated to allow for `generate-password` extended requests and `password validation details` request controls. This change is not applied during an update. You must run the following two **dsconfig** commands when updating PingDirectory Delegated Admin to Version 4.0.0:

```
dsconfig set-access-control-handler-prop --add \
'global-aci:(extop="1.3.6.1.4.1.30221.2.6.62")(version 3.0; \
acl "Authenticated access to the generate-password extended \
request for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

```
dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.40")\
(version 3.0;acl "Authenticated access to the password validation details \
request \
```

```
control for the Delegated Admin API"; allow (read) userdn="ldap:///all");'
```

To upgrade Delegated Admin on PingDirectory Server, perform the following steps:

1. Extract the contents of the Delegated Admin upgrade ZIP file.
2. Rename the original `delegator` folder to retain a backup copy of the earlier version.
3. Copy the extracted folder named `delegator` to the PingDirectory Server folder named `webapps`.
4. Copy the configuration file `config.js` to the new `delegator` folder.

`config.js` is located in `{OriginalDelegatorFolder}/app/config.js`.

5. Restart PingDirectory Server.

For more information, including details about upgrading the RPM package and reverting an update, refer to the *PingDirectory Server Administration Guide*.

## Compatibility matrix

The following matrix identifies the minimum versions of PingDirectory Server that are required to access the full functionality provided by each release of Delegated Admin. For all versions of Delegated Admin, PingFederate Server 9.0.0 or later is required.

Delegated Admin	PingDirectory Server
4.0.0	8.0.0.0
3.5.1	7.3.0.1
3.5.0	7.3.0.1
3.4.0	7.2.1.0
3.3.0	7.2.1.0
3.2.0	7.2.1.0
3.0.2	7.2.0.1*
3.0.1	7.2.0.0*
3.0.0	7.2.0.0*

\*The corresponding version of Delegated Admin is incompatible with version 7.2.1.0 and later.

## Configure PingFederate Server

PingFederate offers many configuration options. This appendix provides an example PingFederate configuration that supports Delegated Admin.

### PingFederate configuration

About this task

The following is a sample PingFederate configuration. Minimal support for Delegated Admin includes configuring PingFederate to use the HTML Form Adapter to authenticate users for Delegated Admin, and configuring PingFederate to identify an authenticated user through the user's entryUUID, which is mapped to the `subject` of the OIDC token.

**Note:** Some of the PingFederate interface terms have changed from version 9.0 to the latest version. The terminology in this sample configuration represents version 9.2.

## Configure PingFederate as the identity provider

About this task

This procedure configures the PingFederate Server as the identity provider for PingDirectory Server.

**Note:** Before starting, download the LDAPS certificate from PingDirectory Server. All other steps are performed on the PingFederate server. For more information, refer to *PingDirectory Server Administration Guide*.

Steps

1. Click **System# Protocol Settings# Roles and Protocols**.
2. Under **Enable OAuth 2.0 Authorization Server (AS) role**, select **OpenID Connect**.
3. Upload the PingDirectory Server LDAPS certificate in **Security > Trusted CAs**.
4. Add an LDAP datastore in **System > Datastores**. Specify:
  - a. The PingDirectory Server host name and LDAPS port.
  - b. Select **Use LDAPS**.
  - c. Under **Advanced**, clear the **Verify LDAPS hostname** option.
  - d. Click **Next**.
  - e. Click **Done**.
  - f. Click **Save**.
5. Create the HTML form **IdP Adapter and Password Credential Validator** that is used to authenticate users against PingDirectory Server:
  - a. Select **Identity Provider > Adapters > Create New Instance**.
  - b. Select the HTML Form type.
  - c. Click **Next**, scroll to the bottom of the page, and click **Manage Password Credential Validators**.
  - d. Select **Create New Instance**.
  - e. Click **Next** and select the LDAP User Name and Password Credential Validator.
  - f. Click **Next** and enter the following search filter to use the email address or user name to log on to the system:
 

```
(|(uid=${username})(mail=${username}))
```
  - g. Click **Next** and extend the contract with **entryUUID** and **cn**.  
These values are used later.
  - h. Click **Next**, **Done**, and **Save** until the Create Adapter Instance screen.
  - i. Add a new row to Password Credential Validators, choose the new LDAP Password Credential Validator, and click **Update**.
  - j. Click **Next** and extend the contract with **entryUUID** and **cn**.  
These values are used later.
  - k. Select **entryUUID** for a pseudonym, and then click **Next**, **Next**, **Done**, and **Save**.
6. Enable session tracking in **Identity Provider > Sessions**, and select the **Track adapter session for logout** and **Enable authentication sessions for all sources** options.
7. Click **Save**.

## Configure the OAuth server

### Steps

1. Click **IdP Adapter Mapping** and add the new IdP adapter for creating OAuth grants.  
An additional attribute source is unnecessary. Fulfill the contract with the `USER_KEY` from adapter `entryUUID` and with the `USER_NAME` from adapter `cn`, and then click **Next**, **Next**, and **Save**.
2. Select an existing instance or click **Access Token Management > Create New Instance**.  
If selecting an existing instance, JSON Web Tokens (JWTs) are configured automatically:
  - a. If creating a new instance, select **JSON Web Tokens**.  
If selecting an existing instance, click **Instance Configuration**.
  - b. Choose one-way encryption for JWT, which only requires a symmetric key (not a certificate and private key).  
This step requires the client to validate the token by hitting the validation endpoint on the server.
  - c. Add a row to symmetric keys and use 32 bytes or 64 chars of hex.
  - d. Choose the JWS Algorithm HMAC using SHA-256.
  - e. Choose your symmetric key for Active Symmetric Key ID and click **Next**.
  - f. Select all options and click **Next**.
  - g. List at least one attribute to be defined in the access token, add `sub`, and click **Save**.
3. Click **Access Token Mapping** and map the access token attributes from the persistent grant, as follows:
  - a. Choose **Default Context** and the new Access Token Manager.
  - b. Click **Contract Fulfillment**.
  - c. In the `sub` row, make the following selections:
    - From the **Source** list box, select `Persistent Grant`.
    - From the **Value** list box, select `USER_KEY`.
  - d. Click **Save**.
4. Click **OpenID Connect Policy Management > Add Policy**.
  - a. Choose the previously created Access Token Manager and click **Next**.
  - b. Delete all extended contract attributes except `sub`.  
Other scopes are defined, if configured.
  - c. Click **Next** to reach Contract Fulfillment.
  - d. Fulfill the OIDC contract `sub` with the Access Token attribute `sub`.
  - e. Click **Next** and then click **Done**.
  - f. If a default OIDC policy is not already defined, set this new policy as the default, and click **Save**.
5. Add scopes for PingDirectory Server APIs.
  - a. Click **Scope Management > Exclusive Scopes**.
  - b. Add a value and description for `urn:pingidentity:directory-delegated-admin`.
  - c. Click **Save**.

## Configure PingDirectory Server as the token validator

### About this task

When creating a PingFederate Access Token Validator in PingDirectory Server, use the `pingdirectory` client ID and secret. PingDirectory Server uses an identity mapper to match the `sub` claim against the `entryUUID` attribute.

To configure PingDirectory Server as the token validator, perform the following steps:

## Steps

1. Click **Create new client**.
2. For both the **Client ID** and **Name**, specify `pingdirectory`.
3. Make the following selections:
  - In the **Client Authentication** section, select `Client Secret`.
  - In the **Client Secret** section, select `Change Secret`.
4. Click **Generate Secret** to generate a new secret key.
5. Copy the secret key.
6. In the **Allowed Grant Types** section, select **Access Token Validation**.
7. Click **Save**.

## Configure Delegated Admin as a new client

### About this task

To configure Delegated Admin as a new client, perform the following steps:

## Steps

1. Click **Create new client**.
2. For both the **Client ID** and **Name**, specify `dadmin`.

 **Note:** Do not configure authentication.

3. Define the redirect URI as "`https://${directoryServer:httpPort}/delegator/*`", using the host name and HTTPS listener port for PingDirectory Server.
4. Make the following selections:
  - Select **Bypass Authorization Approval**.
  - Select **Allow Exclusive Scopes**, and then select `urn:pingidentity:directory-delegated-admin`.
  - For the **Grant Type**, select `Implicit`.
  - Select the default ATM that was created previously for Delegated Admin.
  - Select the OIDC policy that was created previously.
5. Click **Save**.
6. Click **OAuth Server# Authorization Server Settings# Allowed Origin Settings**.
7. Add "`https://${directoryServer:httpPort}`" to the Allowed origins, using the host name and HTTPS listener port for PingDirectory Server.
8. Click **Save**.

## Configure profile management by users

### About this task

Users created by delegated administrators can manage their own profiles through PingFederate. Additional configuration steps must be taken to enable users whom delegated administrators create to manage their own profiles through the PingFederate local identity profile-management feature.

This example assumes PingDirectory Server and PingFederate are configured for local identity profile management, following the PingFederate administrator documentation for Customer IAM. Specifically, the `entryUUID` attribute of the user record must be mapped to the subject of the local identity profile contract in PingFederate's Authentication Policies contract fulfillment.

## Steps

1. On PingFederate Server, copy the LDIF file `local-identity-pingdirectory.ldif` from the following location:
 

```
<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif
```
2. Use the command `scp` to securely copy the LDIF file to your local machine.
3. Update the LDAP schema, as follows:
  - a. Log on to the PingDirectory Server Administrator Console.
  - b. Click **LDAP Schema# Schema Utilities**.
  - c. Click **Import Schema Element**.
  - d. Copy the schema changes from the file `<pf_install>/pingfederate/server/default/conf/local-identity/ldif-scripts/local-identity-pingdirectory.ldif`.
  - e. Paste the schema changes into the text area.
 

If you are creating a new organizational unit as part of the LDIF import, edit the DN information.
  - f. Click **Import**.
4. On PingDirectory Server, create a constructed attribute for `pf-connected-identity` (for example where the `entryUUID` is the PingFederate user ID attribute):

```
$ bin/dsconfig create-constructed-attribute \
 --attribute-name pf-connected-identity \
 --set attribute-type:pf-connected-identity \
 --set value-pattern:auth-source=pf-local-identity:user-id={entryUUID}
```

## Next steps

After you finish installing Delegated Admin, make certain that you configure the REST resource type. For more information, see [Configure user self-service](#) on page 1280.

## Adding Server Roles

### About this task

Perform the following steps to add the **Service Provider** role.

## Steps

1. Select the **System > Protocol settings > Roles and protocols** tab.
2. Check **ENABLE SERVICE PROVIDER (SP) ROLE AND SUPPORT THE FOLLOWING:**
  - Make sure **SAML 2.0** is checked.
  - Check **OpenID Connect** (under the service provider)
3. Click **Save**. On the main screen make sure that the service provider role was saved.

## Adding an Identity Provider

After adding a service provider, you can add an identity provider. There are five steps involved in creating an identity provider:

- [Defining a policy contract](#)
- [Defining the local identity profile](#)
- [Updating the HTML form adapter to use the local identity profile](#)
- [Mapping the HTML login form adapter to the local identity provider](#)
- [Additional setup](#)
- [Testing local identity](#)

## Defining a Policy Contract

### About this task

A policy contract is used to tie the HTML login form adapter to the local identity profile. Perform the following steps to defining a policy contract:

### Steps

1. Add the **Service Provider** role in the **System > Protocol settings > Roles and protocols** tab.
2. Enable **ENABLE SERVICE PROVIDER (SP) ROLE AND SUPPORT THE FOLLOWING:**
3. Make sure that **SAML 2.0** is enabled.
4. Enable **OpenID Connect** (under the service provider).
5. Click **Save**.

## Defining the Local Identity Profile

### About this task

Perform the following steps to define a local identity profile.

### Steps

1. To define the local identity profile (which for this limited use case is really just the LDAP profile attributes mapped to HTML form fields), select **Identity Provider -> Identity Profiles -> Create New Profile**.
  - For **LOCAL IDENTITY PROFILE NAME**, pick the name you created for the contract.
  - For **Authentication policy contract**, select the contract you created above.
  - Click **Enable Profile Management**.
2. Click **Next**. Do not specify an authentication source since you are not doing social login.
3. Click **Next**. In the **Fields** tab, do the following:
  - Configure the fields for the profile management HTML form. Click **Create new field** for each field.
  - Add a field with id `firstName`, label `First Name`, and type of `text`. These are required. Click **Next** and then **Done** to save.
  - Add a field with id `lastName`, label `Last Name`, and type of `text`. These are required.
  - Add a field with id `email`, label `E-mail`, and type of `email`. These are required.
  - The **entryUUID**, label **entryUUID**, type **hidden** (no checkbox checked for **Parameters**), and new fields **Applies to** are enabled by default. Leave these enabled and select one of the fields as the **Unique ID**.
4. Select **Email Verification**. Enable email ownership verification if desired
5. Do not select anything on the **Registration** or **Profile Management** tabs.
6. Go to **Data Store configuration** and click **Configure data store** and do the following
7. Select your PingDirectory data store and click **Next** to go to **LDAP Configuration**, then do the following:
  - Set the base DN to where your users are in PingDirectory (for example, `ou=people,dc=example,dc=com`).
  - Under **Root Object Class** select **Show all attributes** from the dropdown menu.
  - Under **attribute** select the **givenName**, **sn**, **email** (mail? or emailAddress) and **entryUUID** attributes.
8. Click **Add Attribute** to add the next attribute (including after adding the last attribute in order to save your settings). Add all of the attributes in which you will store the form fields (for example, **entry UUID**, **givenName**, **sn**, and **mail**).

9. A new tab, **Identity Creation**, is created. This is a required field if you checked registration above.
10. Click **Next** to go to **Data Store Mapping** and do the following:
  - Map **firstName** to **givenName**, **lastName** to **sn**, **email** to **mail**, and **entryUUID** to **entryUUID**.
11. Click **Next** to go to the **Summary** page for the the **Data Store Config** section.
12. Click **Done** to save your changes.
13. Click **Next** to go to **Summary** in **Local Identity Profile**.
14. Click **Done** to go to **Local Identity**.
15. Click **Save** to finish saving all of your changes. Make sure that you end up on the main page after this step, otherwise your changes may not have been saved.

### Updating the HTML form adapter to use the local identity profile

About this task

To update the HTML form adapter to use the local identity profile, perform the following steps:

Steps

1. Go to **Identity Provider -> Adapters -> (instance) -> IdP Adapter**.
2. For **Local Identity Profile**, select the identity profile you created in [Defining the local identity profile](#).
3. Click **Done**.
4. Click **Save**.

### Mapping the HTML login form adapter to the local identity provider

About this task

To map the HTML login form adapter to the local identity provider, perform the following steps:

Steps

1. Go to **Identity Provider -> Policies -> Add Policy** and do the following;
  - For **Name**, add a name (for example, DS-DA)
  - For **Policy**, select your HTML form adapter listed under **IdP Adapters**. (for example, **PingDirectoryIdp- (Adapter)**).
  - For **Fail**, click **Done**.
  - For **Success**, select **PingDirectoryIdP**. Another **Fail** and **Success** are displayed.
    - For **Fail**, click **Done**
    - For **Success**, click on the arrow. A popup window displays.
2. Click the arrow and find the **Local Identity Profiles** option.
3. Select your local identity profile.
4. Click **Local Identity Mapping** and do the following:
  - For **inbound mapping**, select **pf.local.identity.unique.id**
  - For **source**, select **Adapter** (for example, **PingDirectoryIdP**).
  - For **value**, select **entryUUID**.
5. Click **Add**.
6. Click **Next**. Do not enter anything for **Attribute Sources**.
7. Click **Next**. For contract fulfillment, map the subject (required) to **Adapter** for **Source** and to **entryUUID** for the value.
8. Click **Next**. **Issuance Criteria** is displayed.
9. Click **Next**. **Summary** is displayed.

10. Click **Done** to save the Local Identity mapping.
11. Click **Done** to save your new Authentication Policy entry.
12. Click **Save** to save your Authentication Policies change.

### Additional setup

About this task

To complete the setup of a local identity profile, perform the following steps:

Steps

1. Go to **Identity Provider -> Identity Profiles -> (instance) -> Profile Info**
2. Click **Enable Registration**.
3. Click the **Fields** tab, then click **edit** on the **entryUUID**.
4. On the **Field configuration** tab check the box for registration.
5. Click **Done** to return to the **Fields** tab.
6. Check **Unique ID** for the **entryUUID**.
7. Click **Done** or **Save**.
8. Go to the **Data Store Configuration** tab and click **Configure Data Store**.
9. Go to the **Identity Creation** tab.
10. In the **Relative DN pattern** field enter `entryUUID=${entryUUID}` and `inetOrgPerson` for the class.
11. Click **Save**.
12. Go to **Identity Provider -> Identity Profiles -> (instance) -> Profile Info**.
13. Uncheck **Enable Registration**.
14. Click **Save**.

### Testing Local Identity

About this task

To test the local identity configuration, perform the following steps:

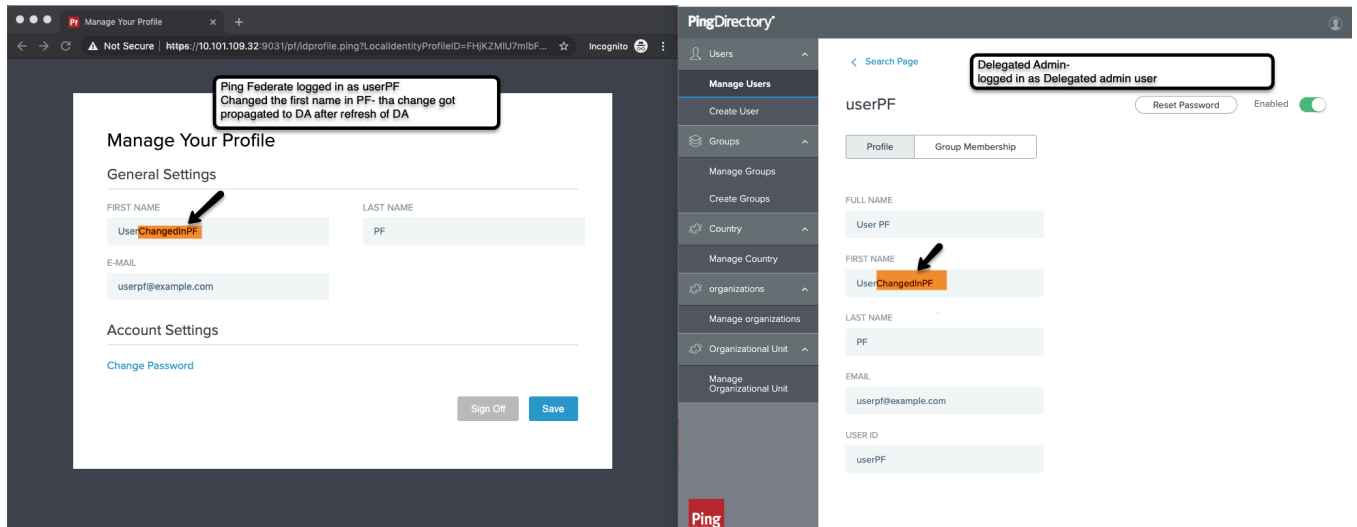

Steps

1. Go to **Identity Provider -> Identity profiles -> Local Identity profile name**.
2. On the **Summary** page, right-click the profile management endpoint URL and view it in a private window.
3. Log in as a user (for example, `user.0` and `password`).

 **Note:** The user you are logging in as needs to have the `pf-connected-identities` object class and a value for the `pf-connected-identity` attribute.

Example

You should be able to see the profile and update the fields.

## Introduction

PingDataSync Server is a high-capacity, high-reliability data synchronization and transfer pipe between source and destination topologies.

This chapter presents a general overview of the PingDataSync Server process and examples for use.

Topics include:

[Overview of PingDataSync Server](#)

[Data synchronization process](#)

[Synchronization modes](#)

[PingDataSync Server operations](#)

[Configuration components](#)

[Synchronization flow examples](#)

[Sample synchronization](#)

## Overview of PingDataSync Server

PingDataSync Server is an efficient, Java-based server that provides high throughput, low latency, and bidirectional real-time synchronization between two endpoint topologies consisting of PingDirectory Servers, PingDirectoryProxy Servers, PingOne, and/or Relational Database Management Systems (RDBMS) systems. PingDataSync Server uses a dataless approach that synchronizes changes directly from the data sources in the background so that applications can continue to update their data sources directly. PingDataSync Server does not store any data from the endpoints themselves, thereby reducing hardware and administration costs. The server's high-availability mechanisms also makes it easy to fail over from the main PingDataSync Server to redundant instances.

Designed to run with little administrative maintenance, PingDataSync Server includes the following features:

- High performance and availability with built-in redundancy.
- Dataless virtual architecture for a small-memory footprint and easy maintenance.
- Hassle-free setup that enables mapping attribute names, values, and DNs between endpoints. For directory server endpoints, this enables making schema and Directory Information Tree (DIT) changes without custom coding and scripting.
- Multi-vendor directory server support including the PingDirectory Server, PingDirectoryProxy Server, Nokia 8661 Directory Server, Nokia 8661 Directory Proxy Server, Oracle/Sun Directory Server Enterprise Edition, Oracle/Sun Directory Server, Oracle Unified Directory, OpenDJ, and Microsoft Active Directory, and generic LDAP directories.
- RDBMS support including Oracle Database, and Microsoft SQL Server systems.
- Proxy Server support including the PingDirectoryProxy Server and the Nokia 8661 Directory Proxy Server.
- Notification support that allows real-time change notifications to be pushed to client applications or services as they occur.

## Data synchronization process

PingDataSync Server performs point-to-point synchronization between a source endpoint and a destination endpoint. An endpoint is defined as any source or destination topology of directory or database servers.

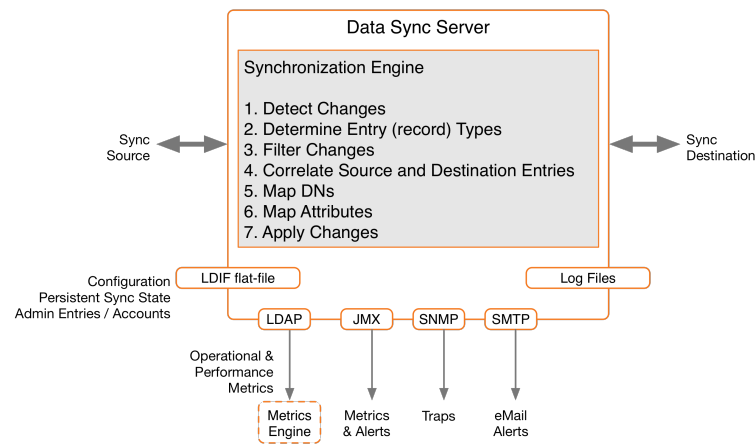

PingDataSync Server synchronizes data in one direction or bidirectionally between endpoints.

For example, in a migration phase from Sun Directory Server to a PingData PingDirectory Server, synchronization can occur in one direction from the source server to a staging server. With one-way synchronization, the source server is the authoritative endpoint for changes in the system. Bidirectional synchronization allows for parallel active installations between the source and the destination endpoints. With bidirectional synchronization, both endpoints are authoritative for the same set of attributes or for different sets of data.

PingDataSync Server also contains no single point of failure, either for detecting changes or for applying changes. PingDataSync Server instances themselves are redundant. There can be multiple instances running at a time, but only the server with the highest priority is actively synchronizing changes. The stand-by servers are constantly polling the active server instance to update their persistent state. This state contains the minimum amount of information needed to begin synchronization where the primary server left off, which logically is the last processed change number for the source server. In the case of a network partition, multiple servers can synchronize simultaneously without causing problems as they each verify the full entry before making changes.

## Synchronization architecture

PingDataSync Server uses a virtualized, dataless approach that does not store directory data locally. The log files, administrator entries, configuration, sync state information are stored as flat files (LDIF format) within the system. No additional database is required.

## Change tracking, monitoring, and logging

PingDataSync Server tracks and manages processes and server health with the following tools:

### Change Tracking

Each directory instance stores a separate entry under `cn=changelog` for every modification made to the directory. PingDataSync Server provides full control over the synchronization process by determining which entries are synchronized, how they are correlated to the entries at the destination endpoint, and how they are transformed into the destination schema.

- For the PingData PingDirectory Server or Nokia 8661 Directory Server topologies, PingDataSync Server uses the server's LDAP Change Log for modification detection.
- For Oracle/Sun Directory Server, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, PingDataSync Server uses the server's Retro Change Log, which provides a detailed summary of each change.
- For Active Directory, PingDataSync Server uses the DirSync control, which polls for object attribute changes.
- For RDBMS systems, PingDataSync Server uses a Ping Identity Server SDK plugin to interface with a customized RDBMS change log table. Database triggers on each table record all INSERT, UPDATE, and DELETE operations to the change log table.

### Monitoring, Alerts, and Alarms

PingDataSync Server supports several industry-standard, administrative protocols for monitoring, alarms, and alerts. System alarms and gauges can be configured to determine healthy performance thresholds and the server actions taken when performance values are outside the threshold.

All administrative alarms are exposed over LDAP as entries under base DN `cn=alarms`.

An administrative alert framework sends warnings, errors, or other server events through log messages, email, or JMX notifications. Administrative alerts are also exposed over LDAP as entries below base DN `cn=alerts`. Typical alert events are startup or shutdown, applied configuration changes, or synchronized resources unavailable.

## Logging

PingDataSync Server provides standard logs (`sync`, `access`, `error`, `failed-operations`, `config-audit.log`, `debug`). The server can also be configured for multiple active sync logs. For example, each detected change, each dropped change, each applied change, or each failed change can be logged.

## Synchronization modes

PingDataSync Server runs as a standalone Java process with two synchronization modes: standard and notification.

### Standard synchronization

In standard synchronization mode, PingDataSync Server polls the directory server change log for create, modify, and delete operations on any entry. The server fetches the full entries from both the source and destination endpoints, and compares them to produce the minimal set of changes required to synchronize the destination with the source.

The following shows the standard synchronization change flow between two servers. The changes are processed in parallel, which increases throughput and offsets network latency.

### Notification synchronization

In notification synchronization mode, PingDataSync Server skips the fetch and compare phases of processing and simply notifies the destination that a change has happened and provides the details of the change. Notification mode is currently available for the PingData and Alcatel-Lucent 8661 directory and proxy servers only.

## PingDataSync Server operations

PingDataSync Server provides seamless integration between disparate systems to transform data using attribute and DN mappings. A bulk resynchronization operation can be run to verify mappings and test synchronization settings.

### Real-time synchronization

Real-time synchronization is performed with the `realtime-sync` utility. The `realtime-sync` utility polls the source server for changes and synchronizes the destination entries immediately. Once the server determines that a change should be synchronized, it fetches the full entry from the source. It then searches for the corresponding entry in the destination endpoint using correlation rules and applies the minimum set of changes to synchronize the attributes. The server fetches and compares the full entries to make sure it does not synchronize any old data from the change log.

After a synchronization topology is configured, run `resync` to synchronize the endpoints, and then run `realtime-sync` to start global synchronization.

The `realtime-sync` tool is used for the following tasks:

- Start or stop synchronization globally or for specific sync pipes only.
- Set a start point at which synchronization should begin such as the beginning or end of the change log, at a specified change number, at a specified change sequence number, or at a specified time frame in the change log.

### Data transformations

Data transformations alter the contents of synchronized entries between the source and destination directory server to handle variances in attribute names, attribute values, or DN structures. When entries are synchronized between a source and a destination server, the contents of these entries can be changed using attribute and DN mappings, so that neither server needs be aware of the transformations.

- Attribute Mapping – Any attribute in the entry can be renamed to fit the schema definitions from the source endpoint to the destination endpoint. This mapping makes it possible to synchronize information stored in one directory's attribute to an attribute with a different name in another directory server, or to construct an attribute using portions of the source attribute values.
- DN Mapping – Any DNs referenced in the entries can be transparently altered. This mapping makes it possible to synchronize data from a topology that uses one DIT structure to a system that uses a different DIT structure.

### Bulk resync

The `resync` tool performs a bulk comparison of entries on source topologies and destination topologies. PingDataSync Server streams entries from the source, and either updates the corresponding destination entries or reports those that are different. The `resync` utility resides in the `/bin` folder (UNIX or LINUX) or `\bat` folder (Windows), and can be used for the following tasks:

- Verify that the two endpoints are synchronized after an initial configuration.
- Initially populate a newly configured target endpoint.
- Validate that the server is behaving as expected. The `resync` tool has a `--dry-run` option that validates that synchronization is operating properly, without updating any entries. This option also can be used to check attribute or DN mappings.
- Perform scheduled synchronization.
- Recover from a failover by resynchronizing entries that were modified since the last backup was taken.

The `resync` tool also enables control over what can be synchronized, such as:

- Include or exclude any source and destination attributes.
- Apply an LDAP filter to only sync entries created since that last time the tool ran.
- Synchronize only creations or only modifications.
- Change the logging verbosity.
- Set a limit on `resync` operations (such as 2000 operations per second) to reduce impact on endpoint servers.

### The sync retry mechanism

PingDataSync Server is designed to quickly synchronize data and attempt a retry should an operation fail for any reason. The retry mechanism involves two possible retry levels, which are configurable on the Sync Pipe configuration using advanced Sync Pipe properties. For detailed information, see the *PingDataSync Server Reference Guide* for the Sync Pipe configuration parameters.

Retry involves two possible levels:

#### First Level Retry

If an operation fails to synchronize, the server will attempt a configurable number of retries. The total number of retry attempts is set in the `max-operation-attempts` property on the Sync Pipe. The property indicates how many times a worker thread should retry the operation before putting the operation into the second level of retry, or failing the operation altogether.

#### Second Level Retry

Once the `max-operation-attempts` property has been exceeded, the retry is sent to the second level, called the delayed-retry queue. The delayed-retry queue uses two advanced Sync Pipe properties to determine the number of times an operation should be retried in the background after a specified delay.

Operations that make it to this level will be retried after the `failed-op-background-retrydelay` property (default: 1 minute). Next, PingDataSync Server checks the `max-failedop-background-retries` property to determine the number of times a failed operation should be retried in the background. By default, this property is set to 0, which indicates that no background retry should be attempted, and that the operation should be logged as failed.

**Note:**

Background operations can hold up processing other changes, since PingDataSync Server will only process up to the next 5000 changes while waiting for a retried operation to complete.

Retry can be controlled by the custom endpoint based on the type of error exception. When throwing an exception, the endpoint code can signal that a change should be aborted, retried a limited number of times, or retried an unlimited number of times. Some errors, such as endpoint server down, should be retried indefinitely.

If the `max-failed-op-background-retries` property has been exceeded, the retry is logged as a failure and appears in the `sync` and the `sync-failed-ops` logs.

## Configuration components

PingDataSync Server supports the following configuration parameters that determine how synchronization takes place between directories or databases:

### Sync Pipe

Defines a single synchronization path between the source and destination topologies. Every Sync Pipe has one or more Sync Classes that control how and what is synchronized. Multiple Sync Pipes can run in a single server instance.

### Sync Source

Defines the directory topology that is the source of the data to be synchronized. A Sync Source can reference one or more supported external servers.

### Sync Destination

Defines the topology of directory servers where changes detected at the Sync Source are applied. A Sync Destination can reference one or more external servers.

### External Server

Defines a single server in a topology of identical, replicated servers to be synchronized. A single external server configuration object can be referenced by multiple Sync Sources and Sync Destinations

### Sync Class

Defines the operation types and attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated. A source entry is in one Sync Class and is determined by a base DN and LDAP filters. A Sync Class can reference zero or more Attribute Maps and DN Maps, respectively. Within a Sync Pipe, a Sync Class is defined for each type of entry that needs to be treated differently. For example, entries that define attribute mappings, or entries that should not be synchronized at all. A Sync Pipe must have at least one Sync Class but can refer to multiple Sync Class objects.

### DN Map

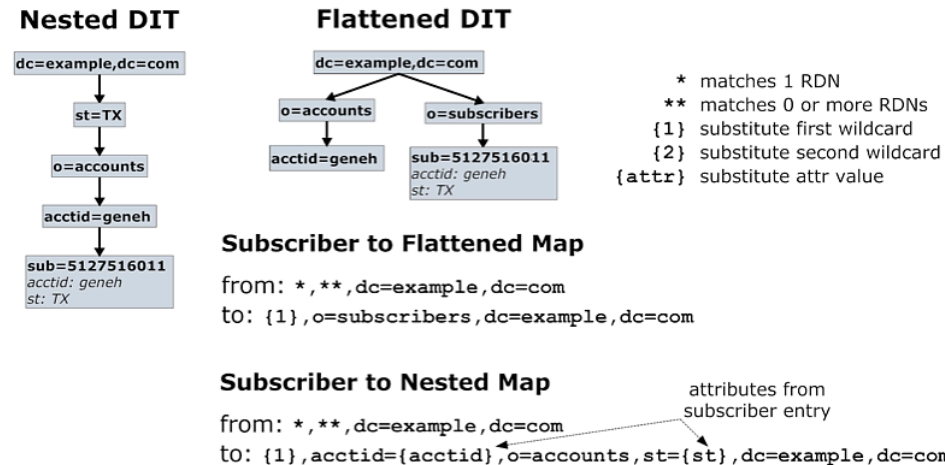

Defines mappings for use when destination DNs differ from source DNs. These mappings allow the use of wild cards for DN transformations. A single wild card ("\*") matches a single RDN component and can be used any number of times. The double wild card ("\*\*") matches zero or more RDN components and can be used only once. The wild card values can be used in the `to-dn-pattern` attribute using `{1}` and their original index position in the pattern, or `{attr}` to match an attribute value. For example:

```
** , dc=myexample, dc=com->{1}, o=example
```

Regular expressions and attributes from the user entry can also be used. For example, the following mapping constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of `givenname` and `sn`) and the employee ID (`eid` attribute).

```
uid={givenname:/^(.) (.*)/$1/s}{sn:/^(.) (.*)/$1/s}{eid},{2},o=example
```

The following illustrates a how a nested DIT can be mapped to a flattened structure.

### Attribute Map and Attribute Mappings

Defines a mapping for use when destination attributes differ from source attributes. A Sync Class can reference multiple attribute maps. Multiple Sync Classes can share the same attribute map. There are three types of attribute mappings:

- Direct Mapping – Attributes are directly mapped to another attribute: For example:

```
employeenumber->employeeid
```

- Constructed Mapping – Destination attribute values are derived from source attribute values and static text. For example:

```
{givenname}.{sn}@example.com->mail
```

- DN Mapping – Attributes are mapped for DN attributes. The same DN mappings that map entry DNs can be referenced. For example:

```
uid=jdoe,ou=People,dc=example,dc=com.
```

### Sync flow examples

PingDataSync Server processes changes by fetching the most up-to-date, full entries from both sides and then compares them. This process flow is called standard synchronization mode. The processing flow differs depending on the type of PingDataSync Server change (ADD, MODIFY, DELETE, MODDN) that is requested. The following examples show the control flow diagrams for the sync operations, especially for those cases when a MODIFY or a DELETE operation is dropped. The sync log records all completed and failed operations.

## Modify operation example

About this task

Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
4. Fetch the entry or table rows from affected tables on the destination.
5. Diff the computed destination entry and actual destination entry.
6. Apply the changes to the destination.

## Add operation example

About this task

Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
4. Fetch the entry or table rows from affected tables on the destination.
5. The entry or table row does not exist on the destination.
6. Create the entry or table row.

## Delete operation example

About this task

Steps

1. Detect delete from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
4. Fetch the entry or table rows from affected tables on the destination.
5. The entry or table row exists on the destination.
6. Apply the delete on the destination.

## Delete after source entry is re-added

About this task

Steps

1. Detect delete from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. The entry or table row exists on the source.
4. Delete request is dropped.

## Standard modify after source entry is deleted

About this task

Steps

1. Detect change from the change log table on the source.
2. Fetch the entry or table rows from affected tables on the source.
3. The entry does not exist.
4. Change request is dropped because the source entry no longer exists.

## Notification add, modify, modifyDN, and delete

About this task

Steps

1. Detect change from the change log table on the source.
2. Perform any mappings and compute the equivalent destination entry by constructing an equivalent LDAP entry or equivalent table row.
3. Reconstruct changed entries.
4. Push notification with change details to the destination.

## Sample synchronization

The following is a synchronization migration example from a Sun Directory Server Enterprise Edition (DSEE) topology to the PingData PingDirectory Server topology, including a change in the DIT structure to a flattened directory structure. The Sync Pipe connects the Sun Directory Server topology as the Sync Source and the PingDirectory Server topology as the Sync Destination. Each endpoint is defined with three external servers in their respective topology. The Sync Pipe destination has its base DN set to `o=example`, which is used when performing LDAP searches for entries.

Two Sync Classes are defined: one for Subscribers, and one for Accounts. Each Sync Class uses a single "Sun DS to PingData Attribute Map" that has four attribute mappings defined. Each Sync Class also defines its own DN maps. For example, the Accounts Sync Class uses a DN map, called PingData

Account Map, that is used to flatten a hierarchical DIT, so that the Account entries appear directly under `ou=accountsas` as follows:

```
* , ** , o=example -> {1} , ou=accounts , o=example
```

With this mapping, if an entry DN has `uid=jsmith, ou=people, o=example`, then `"**"` matches `uid=jsmith`, `"**"` matches `ou=people`, and `{1}` matches `uid=jsmith`. Therefore, `uid=jsmith, ou=people, o=example` gets mapped to `uid=jsmith, ou=accounts, o=example`. A similar map is configured for the Subscribers Sync Class.

## Install PingDataSync Server

This section describes how to install and run PingDataSync Server. It includes pre- installation requirements and considerations.

Topics include:

[System requirements](#) on page 432

[Install the JDK](#) on page 1316

[Optimize the Linux operating system](#) on page 1316

[Ping license keys](#) on page 440

[Administrative accounts](#) on page 1328

## System requirements

PingDataSync Server has qualified the configurations in this section and has certified that they are compatible with the product. Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software is suspected of causing an issue.

### Platforms

- Windows Server 2019
- Windows Server 2016
- Red Hat Enterprise Linux ES 8
- Red Hat Enterprise Linux ES 7.6
- Red Hat Enterprise Linux ES 7.5
- CentOS 7.6
- CentOS 7.5
- SUSE Linux Enterprise 15
- SUSE Linux Enterprise 12 SP3
- Ubuntu 18.04 LTS
- Ubuntu 16.04 LTS
- Amazon Linux 2
- Amazon Linux

**Note:** This product has been tested with the default configurations of all operating system components. If your organization has customized implementations or has installed third-party plugins, the deployment of this product might be affected.

### Docker

Version: Docker 18.09.0

Host operating system: Ubuntu 18.04 LTS

Kernel: 4.4.0-1052-aws 7.3

**Note:** PingDataSync Server accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

### Java Runtime Environment

- Amazon Corretto 8
- OpenJDK 11
- OpenJDK 8
- Oracle Java SE Development Kit 11 LTS
- Oracle Java SE Development Kit 8

**Note:**  
The applies to your Java Runtime Environment.

### Browsers

#### Administration Console

- Chrome
- Firefox

- Internet Explorer 11 and later

#### End users

- Chrome
- Edge
- Firefox
- Internet Explorer 11 and later
- Safari

## Install the JDK

The Java 64-bit JDK is required on the server. Even if Java is already installed, create a separate Java installation for use by the server to ensure that updates to the system-wide Java installation do not inadvertently impact the installation.

## Optimize the Linux operating system

Configure the Linux file system by making the following changes.

### Note:

The server explicitly overrides environment variables like `PATH`, `LD_LIBRARY_PATH`, and `LD_PRELOAD` to ensure that settings used to start the server do not inadvertently impact its behavior. If these variables must be edited, set values by editing the `set_environment_vars` function of the `lib/_script-util.sh` script. Stop and restart the server for the change to take effect.

### Setting the file descriptor limit

About this task

The server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. If needed, increase the file descriptor limit on the operating system with the following procedure.

### Note:

If the operating system relies on `systemd`, refer to the Linux operating system documentation for instructions on setting the file descriptor limit.

### Steps

1. Display the current hard limit of the system. The hard limit is the maximum server limit that can be set without tuning the kernel parameters in the `proc` file system.

```
ulimit -aH
```

2. Edit the `/etc/sysctl.conf` file. If the `fs.file-max` property is defined in the file, make sure its value is set to at least 65535. If the line does not exist, add the following to the end of the file:

```
fs.file-max = 65535
```

3. Edit the `/etc/security/limits.conf` file. If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines to the end of the file (before `#End of file`). Insert a tab between the columns.

```
* soft nofile 65535
```

```
* hard nofile 65535
```

4. Reboot the system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535 with the following command:

```
ulimit -n
```

### Next steps

Once the operating system limit is set, the number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as, `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the default of 65535 is used. This is strictly optional if wanting to ensure that the server shuts down safely prior to reaching the file descriptor limit.

#### Note:

For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits:

```
/etc/security/limits.d/20-nproc.conf
```

Add or edit the following lines if they do not already exist:

```
* soft nproc 65536
* soft nofile 65536
* hard nproc 65536
* hard nofile 65536
root soft nproc unlimited
```

### Set the file system flushes

Linux systems running the ext3 file system only flush data to disk every five seconds. If the server is on a Linux system, edit the mount options to include the following:

```
commit=1
```

This variable changes the flush frequency from five seconds to one. Also, set the flush frequency in the `/etc/fstab` file to make sure the configuration remains after reboot.

### Install sysstat and pstack on Red Hat

The server troubleshooting tool `collect-support-data` relies on the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance statistics, and stack trace information on the server's processes. For Red Hat systems, make sure that these packages are installed, for example:

```
$ sudo yum install sysstat gdb dstat -y
```

### Install the dstat utility

The `dstat` utility is used by the `collect-support-data` tool.

## Disable file system swapping

It is recommended that any performance tuning services like `tuned` be disabled. As root, change the current value in the operating system and by adding a line `vm.swappiness = 0` to `/etc/sysctl.conf` to ensure that the correct setting is applied when the system restarts.

If performance tuning is required, `vm.swappiness` can be set by cloning the existing performance profile then adding `vm.swappiness = 0` to the new profile's `tuned.conf` file in `/usr/lib/tuned/profile-name/tuned.conf`. The updated profile is then selected by running `tuned-adm profile customized_profile`.

## Manage system entropy

Entropy is used to calculate random data that is used by the system in cryptographic operations. Some environments with low entropy may have intermittent performance issues with SSL-based communication. This is more typical on virtual machines, but can occur in physical instances as well. Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

If necessary, update `$JAVA_HOME/jre/lib/security/java.security` to use `file:/dev/./urandom` for the `securerandom.source` property.

## Set file system event monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events (including file creation, deletion, and updates). The Linux system puts a limit on the number of `inotify` watches assigned to each user. To increase the limit, edit `etc/sysctl.conf` to add a line:

```
fs.inotify.max_user_watches =524288
```

Run the command:

```
$ sudo sysctl -wfs.inotify.max_user_watches=524288
```

## Tune IO scheduler

Using the correct IO scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load. For file systems running on an SSD, or in a virtualized environment, the `noop` scheduler is recommended. For all other systems, the `deadline` scheduler is recommended. To determine which scheduler is configured on your system, run this command:

```
$ cat /sys/block/<block-device>/queue/scheduler
```

For example:

```
$ cat /sys/block/sda/queue/scheduler
```

Changing the scheduler on a running system can be done with the following command:

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

The change will take effect after the system is restarted. The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

## Enable the server to listen on privileged ports

Linux provides 'capabilities' used to grant specific commands the ability to do things that are normally only allowed for a root account. Instead of granting the ability to a specific user, capabilities are granted to a specific command. It may be convenient to enable the server to listen on privileged ports while running as a non-root user.

The `setcap` command is used to assign capabilities to an application. The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024). If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), the Java binary can be granted the `cap_net_bind_service` capability with the following command:

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

The `java` binary needs an additional shared library (`libjli.so`) as part of the Java installation. More strict limitations are imposed on where the operating system will look for shared libraries to load for commands that have capabilities assigned. So it is also necessary to tell the operating system where to look for this library. This can be done by creating the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file. For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

Run the following command for the change to take effect:

```
$ sudo ldconfig -v
```

## Ping license keys

License keys are required to install all Ping products. To obtain a license key, contact your account representative or [Ping Identity](#).

- A license is always required for setting up a new single server instance and can be used site-wide for all servers in an environment. When cloning a server instance with a valid license, no new license is needed.
- A new license must be obtained when updating a server to a new major version, for example from 6.2 to 7.0. Licenses with no expiration date are valid until the server is upgraded to the next major version. A prompt for a new license is displayed during the update process.
- A license may expire on particular date. If a license does expire, obtain a new license and install it using `dsconfig` or the Administrative Console. The server will provide a notification as the expiration date approaches. License details are available using the server's `status` tool.

When installing the server, specify the license key file in one of the following ways:

- Copy the license key file to the server root directory before running `setup`. The interactive `setup` tool will discover the file and not require input. If the file is not in the server root, the `setup` tool will prompt for its location.
- If the license key is not in the server root directory, specify the `--licenseKeyFile` option for non-interactive `setup`, and the path to the file.

## Installing PingDataSync Server

About this task

Use the `setup` tool to install the server. The server needs to be started and stopped by the user who installed it.

### Note:

A Windows installation requires that the Visual Studio 2010 runtime patch be installed prior to running the `setup` command.

## Steps

1. Log in as a user, other than root.
2. Obtain the latest zip release bundle from Ping Identity and unpack it in a directory owned by this user.

```
$ unzip PingDataSync-<version>.zip
```

3. Change to the server root directory.

```
$ cd PingDataSync
```

4. Run the `setup` command.

```
$./setup
```

5. Type `yes` to accept the End-User License Agreement and press Enter to continue.
6. If adding this server to an existing PingDataSync Server topology, type `yes`, or press Enter to accept the default (`no`).
7. Enter the fully qualified host name or IP address of the local host.
8. Create the initial root user DN for PingDataSync Server, or press Enter to accept the default (`cn=Directory Manager`).
9. Enter and confirm a password for this account.
10. Press Enter to enable server services and the Administrative Console.
11. Enter the port on which PingDataSync Server will accept connections from HTTPS clients, or press Enter to accept the default.
12. Enter the port on which PingDataSync Server will accept connections from LDAP clients, or press Enter to accept the default.
13. Press Enter to enable LDAPS, or enter `no`.
14. Press Enter to enable StartTLS, or enter `no`.
15. Select the certificate option for this server.
16. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
  - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
  - Encrypt data with a key generated from a passphrase read from a file.
  - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
  - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
  - Do not encrypt server data.
17. Choose the option for the amount of memory that should be allocated to the server.
18. To start the server when the configuration is complete, press Enter for (`yes`).
19. A Setup Summary is displayed. Choose the option to setup the server with the listed parameters, change the parameters, or cancel the setup.

## Next steps

After the server configuration is complete, the `create-sync-pipe-config` tool can be run to configure the synchronization environment.

The PingDataSync Server Administrative Console enables browser-based server management, the `dsconfig` tool enables command line management, and the Configuration API enables management by third-party interfaces.

## Log on to the Administrative Console

After the server is installed, access the Administrative Console, <https://<host>/console/login>, to verify the configuration and manage the server. The root user DN or the common name of a root user DN is required to log into the Administrative Console. For example, if the DN created when the server was installed is `cn=Directory Manager, directory manager` can be used to log into the Administrative Console.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package can be installed according to that container's documentation. Contact Ping Identity Customer Support for the package location and instructions.

## Server folders and files

After the distribution file is unzipped, the following folders and command-line utilities are available:

Directories/Files/Tools	Description
ldif	Stores any LDIF files that you may have created or imported.
import-tmp	Stores temporary imported items.
classes	Stores any external classes for server extensions.
bak	Stores the physical backup files used with the backup command-line tool.
velocity	Stores Velocity templates that define the server's application pages.
update.bat, and update	The update tool for UNIX/Linux systems and Windows systems.
uninstall.bat, and uninstall	The uninstall tool for UNIX/Linux systems and Windows systems.
ping_logo.png	The image file for the Ping Identity logo.
setup.bat, and setup	The setup tool for UNIX/Linux systems and Windows systems.
revert-update.bat, and revert-update	The revert-update tool for UNIX/Linux systems and Windows systems.
README	README file that describes the steps to set up and start the server.
License.txt	Licensing agreement for the product.
legal-notice	Stores any legal notices for dependent software used with the product.
docs	Provides the release notes, Configuration Reference (HTML), API Reference, and all other product documentation.
metrics	Stores the metrics that can be gathered for this server and surfaced in the PingDataMetrics Server.
bin	Stores UNIX/Linux-based command-line tools.
bat	Stores Windows-based command-line tools.
lib	Stores any scripts, jar files, and library files needed for the server and its extensions.
collector	Used by the server to make monitored statistics available to the PingDataMetrics Server.
locks	Stores any lock files in the backends.
tmp	Stores temporary files.

Directories/Files/Tools	Description
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.
config	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.
logs	Stores log files.
AD-Password-Sync-Agent.zip	The Active Directory Sync Agent package.

## Start and stop the server

To start PingDataSync Server, run the `bin/start-sync-server` command on UNIX or Linux systems (the `bat` folder on Microsoft Windows systems).

### Start the server as a background process

Navigate to the server root directory, and run the following command:

```
$ bin/start-server
```

For Windows systems:

```
$ bat/start-server
```

### Start the server at boot time

About this task

By default, the server does not start automatically when the system is booted. To configure the server to start automatically, use the `create-rc-script` tool to create a run control script as follows:

Steps

1. Create the startup script. In this example `ds` is the user.

```
$ bin/create-rc-script \
 --outputFile Ping-Identity-Sync.sh \
 --userName ds
```

2. Log in as root, move the generated `Ping-Identity-Sync.sh` script into the `/etc/init.d` directory, and create symlinks to it from the `/etc/rc3.d` (starting with an "S" to start the server) and `/etc/rc0.d` directory (starting with a "K" to stop the server).

```
mv Ping-Identity-Sync.sh /etc/init.d/
ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc3.d/S50-Ping-
IdentitySync.sh
ln -s /etc/init.d/Ping-Identity-Sync.sh /etc/rc0.d/K50-Ping-
IdentitySync.sh
```

### Stop the server

If PingDataSync Server has been configured to use a large amount of memory, it can take several seconds for the operating system to fully release the memory. Trying to start the server too quickly after shut down can fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by PingDataSync Server is released back to the system.

A configuration option can also be set that specifies the maximum shutdown time a process can take.

To stop the server, navigate to the server root directory and run the following command:

```
$ bin/stop-server
```

### Restart the server

Restart the server using the `bin/stop-server` command with the `--restart` or `-R` option. Running the command is equivalent to shutting down the server, exiting the JVM session, and then starting up again.

```
$ bin/stop-server --restart
```

## Run the server as a Microsoft Windows service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables log out of a machine without the server being stopped.

### Register the service

About this task

Perform the following steps to register the server as a service:

Steps

1. Stop the server with `bin/stop-server`. A server cannot be registered while it is running.
2. Register the server as a service. From a Windows command prompt, run `bat/register-windows-service.bat`.
3. After a server is registered, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

#### Note:

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

### Run multiple service instances

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file. To run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

### Deregister and uninstall

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat/deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

### Log files

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or due to file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

## Uninstall the server

### About this task

Use the `uninstall` command-line utility to uninstall the server using either interactive or non-interactive modes. Interactive mode provides options, progress, and a list of the files and directories that must be manually deleted if necessary.

Non-interactive mode, invoked with the `--no-prompt` option, suppresses progress information, except for fatal errors. All options for the `uninstall` command are listed with the `--help` option.

The `uninstall` command must be run as either the root user or the user account that installed the server.

Perform the following steps to uninstall in interactive mode:

### Steps

1. Navigate to the server root directory.

```
$ cd PingData<server>
```

2. Start the uninstall command:

```
$./uninstall
```

3. Select the components to be removed, or press Enter to remove all components.
4. If the server is running, press Enter to shutdown the server before continuing.
5. Manually remove any remaining files or directories, if required.

## Update servers in a topology

An update to the current release includes significant changes, and the introduction of a topology registry, which will store information previously stored in the admin backend (server instances, instance and secret keys, server groups, and administrator user accounts). For the admin backend to be migrated, the `update` tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security options requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to `true` (such as the `cn=Directory Manager` user) that exists on every server can be used.

After enabling or fixing the configuration of the LDAP connection handler(s) to support the desired connection security mechanism on each server, run the following `dsframework` command on the server being updated so that its admin backend has the most up-to-date information:

```
$ bin/dsframework set-server-properties \
 --serverID serverID \
 --set ldapport:port \
 --set ldapsport:port \
 --set startTLSEnabled:true
```

The `update` tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The `update` tool will connect to the peer servers of the server being updated to obtain

the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.

- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

```
$ bin/dsconfig set-global-configuration-prop \
 --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under `cn=cluster, cn=config`. (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. To synchronize the cluster-wide configuration data across all servers in the topology, run the `config-diff` tool on each pair of servers to determine the differences, and use `dsconfig` to update each instance using the `config-diff` output. For example:

```
$ bin/config-diff --sourceHost hostName \
 --sourcePort port \
 --sourceBindDN bindDN \
 --sourceBindPassword password \
 --targetHost hostName \
 --targetPort port \
 --targetBindDN bindDN \
 --targetBindPassword password
```

If any of these conditions are not satisfied, the `update` tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

## Update the server

### About this task

This procedure assumes that an existing version of the server is stored at `PingData-server-old`. Make sure a complete, readable backup of the existing system is available before upgrading the server. Also, make sure there is a clear backout plan and schedule.

### Steps

1. Download the latest version of the server software and unzip the file. For this example, the new server is located in the `PingData-server-new` directory.
2. Use the `update` tool of the newly unzipped build to update the server. Make sure to specify the server instance that is being upgrading with the `--serverRoot` option. The server must be stopped for the update to be applied.

## Reverting an update

If necessary, a server can be reverted to the previous version using the `revert-update` tool. The tool accesses a log of file actions taken by the `update` tool to put the file system back to its prior state. If multiple updates have been run, the `revert-update` tool can be used multiple times to revert to each prior update sequentially. For example, the `revert-update` command can be run to revert to the server's previous state, then run again to return to its original state. The server is stopped during the `revert-update` process.

### Note:

Reverting an update is not supported for upgrades to version 7.0, due to the topology backend changes.

Use the `revert-update` tool in the server root directory revert back to the most recent version of the server:

```
$ PingData-server-old/revert-update
```

## Revert an update

Once the server has been updated, you can revert to the most recent version (one level back) using the `revert-update` tool. The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the server, you can run the `revert-update` command to revert to its previous state, then run the `revert-update` command again to return to its original state.

### Revert from version 7.x to a version earlier than 7.0

Reverting from version 7.0 or later to a pre-7.0 version can be done using the `revert-update` command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 to 6.2.0.2 or later. These steps are listed when the `update` and `revert-update` tool are run as well. You may need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes may need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the `rebuild-index` tool to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the `logs/config-audit.log` file. If you wish to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following `dsconfig` command:

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
 --bindPassword secret \
 --no-prompt set-global-configuration-prop \
 --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, the `revert-update` command can be used to return to the previous version.

However, if new servers are added, then the restored `admin` backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.

- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the `admin` backend) will need to know that the reverted server was downgraded to the `admin` backend. This is done by running the following `dsconfig` command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
 --instance-name <Reverted server instance name> \
 --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made master with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
 --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you wish to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the `changelogDb/` and `db/changelog/` directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent startups.

### To revert to the most recent server version

Use `revert-update` in the server root directory revert back to the most recent version of the server.

```
$ <PingServer>-old/revert-update
```

## Install a failover server

About this task

PingDataSync Server supports redundant failover servers that automatically become active when the primary server is not available. Multiple servers can be present in the topology in a configurable prioritized order.

Before installing a failover server, have a primary server already installed and configured. When installing the redundant server, the installer will copy the first server's configuration.

The primary and secondary server configuration remain identical. Both servers should be registered to the `allservers` group and all `dsconfig` changes need to be applied to the server group `allservers`.

### Note:

If the primary server has extensions defined, they should also be installed on any cloned or redundant servers. If extensions are missing from a secondary server, the following message is displayed during the installation:

```
Extension class <com.server.directory.sync.MissingSyncExtension> was not
found. Run manage-extension --install to install your extensions. Re-run
setup to continue.
```

To remove a failover server, use the `uninstall` command.

### Steps

1. Unpack the PingDataSync Server zip build. Name the unpacked directory something other than the first server instance directory.

```
$ unzip PingData<server>-<version>.zip -d <server2>
```

2. Navigate to the server root directory.

3. Use the `setup` tool in interactive mode in [Install the Server](#), or in non-interactive mode as follows:

```
$./setup --localHostName <server2>.example.com --ldapPort 7389 \
--masterHostName <server1>.example.com --masterPort 8389 \
--masterUseNoSecurity \
--acceptLicense \
--rootUserPassword password \
--no-prompt
```

The secondary server is now ready to take over as a primary server in the event of a failover. No `realtime-sync` invocations are needed for this server.

4. Verify the configuration by using the `bin/status` tool. Each server instance is given a priority index. The server with the lowest priority index number has the highest priority.

```
$ bin/status --bindPassword secret

...(status output)...

 --- Sync Topology ---
Host:Port :Status :Priority
-----:-----:-----:-----
<server>.example.com:389 (this server) : Active : 1
<server>.example.com:389 : Unavailable : 2
```

5. Obtain the name of a particular server, run the `dsconfig` tool with the `list-external-servers` option.

```
$ bin/dsconfig list-external-servers
```

6. To change the priority index of the server, use the `bin/dsconfig` tool:

```
$ bin/dsconfig set-external-server-prop \
--server-name <server2>.example.com:389 \
--set <server>-priority-index:1
```

## Administrative accounts

Users that authenticate to the Configuration API or the Administrative Console are stored in `cn=RootDNs,cn=config`. The `setup` tool automatically creates one administrative account when performing an installation. Accounts can be added or changed with the `dsconfig` tool.

### Change the administrative password

#### About this task

Root users are governed by the Root Password Policy and by default, their passwords never expire. However, if a root user's password must be changed, use the `ldappasswordmodify` tool.

#### Steps

1. Open a text editor and create a text file containing the new password. In this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

2. Use `ldappasswordmodify` to change the root user's password.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager" \
--bindPassword secret --newPasswordFile rootuser.txt
```

### 3. Remove the text file.

```
$ rm rootuser.txt
```

## Configure PingDataSync Server

---

PingDataSync Server provides a suite of tools to configure a single server instance or server groups. All configuration changes to the server are recorded in the `config-audit.log`. Before configuring PingDataSync Server, review [Sync Configuration Components](#).

Topics include:

[Configuration checklist](#) on page 1329

[Sync user account](#) on page 1331

[Configure PingDataSync Server in Standard mode](#) on page 1332

[Use the Configuration API](#) on page 1336

[Configure failover behavior](#) on page 1384

[Configure traffic through a load balancer](#) on page 1389

[Configure authentication with a SASL external certificate](#) on page 1390

[Configure an LDAPv3 Sync Source](#) on page 1391

[Server SDK extensions](#) on page 1391

### Configuration checklist

Prior to any deployment, determine the configuration parameters necessary for the Synchronization topology. Gather the following:

#### External servers

##### External Server Type

Determine the type of external servers included in the synchronization topology. See [Overview of PingDataSync Server](#) on page 1305 for a list of supported servers.

## LDAP Connection Settings

Determine the host, port, bind DN, and bind password for each external server instance(s) included in the synchronization topology.

## Security and Authentication Settings

Determine the secure connection types for each external server (SSL or StartTLS). Determine authentication methods for external servers such as simple, or external (SASL mechanisms). If synchronizing passwords, encoded or especially for clear-text, the connection should be secure. If synchronizing to or from a Microsoft Active Directory system, establish an SSL or StartTLS connection to PingDataSync Server. [Configure password encryption](#) on page 1401 should also be enabled for synchronization from Active Directory, or when synchronizing clear-text passwords.

## Sync pipes

A Sync Pipe defines a single synchronization path between the source and destination targets. One Sync Pipe is needed for each point-to-point synchronization path defined for a topology.

### Sync Source

Determine which external server is the Sync Source for the synchronization topology. A prioritized list of external servers can be defined for failover purposes.

### Sync Destination

Determine which external server is the Sync Destination for the synchronization topology. A prioritized list of external servers can be defined for failover purposes.

## Sync classes

A Sync Class defines how attributes and DNs are mapped and how Source and Destination entries are correlated. For each Sync Pipe defined, define one or more Sync Classes with the following information:

### Evaluation Order

If defining more than one Sync Class, the evaluation order of each Sync Class must be determined with the `evaluation-order-index` property. If there is an overlap between criteria used to identify a Sync Class, the Sync Class with the most specific criteria is used first.

### Base DNs

Determine which base DNs contain entries needed in the Sync Class.

### Include Filters

Determine the filters to be used to search for entries in the Sync Source.

### Synchronized Entry Operations

Determine the types of operations that should be synchronized: creates, modifications, and/or deletes.

### DNs

Determine the differences between the DNs from the Sync Source topology to the Sync Destination topology. Are there structural differences in each Directory Information Tree (DIT)? For example, does the Sync Source use a nested DIT and the Sync Destination use a flattened DIT?

### Destination Correlation Attributes

Determine the correlation attributes that are used to associate a source entry to a destination entry during the synchronization process. During the configuration setup, one or more comma-separated lists of destination correlation attributes are defined and used to search for corresponding source entries. PingDataSync Server maps all attributes in a detected change from source to destination attributes using the attribute maps defined in the Sync Class.

The correlation attributes are flexible enough so that several destination searches with different combinations of attributes can be performed until an entry matches. For LDAP server endpoints, use the distinguished name (DN) to correlate entries. For example, specify the attribute lists `dn,uid,uid,employeeNumber` and `cn,employeeNumber` to correlate entries in LDAP deployments. PingDataSync Server will search for a corresponding entry that has the same `dn` and `uid` values. If the search fails, it then searches for `uid` and `employeeNumber`.

Again if the search fails, it searches for `cn` and `employeeNumber`. If none of these searches are successful, the synchronization change would be aborted and a message logged.

To prevent incorrect matches, the most restrictive attribute lists (those that will never match the wrong entry) should be first in the list, followed by less restrictive attribute lists, which will be used when the earlier lists fail. For LDAP-to-LDAP deployments, use the DN with a combination of other unique identifiers in the entry to guarantee correlation. For other non-LDAP deployments, determine the attributes that can be synchronized across the network.

## Attributes

Determine the differences between the attributes from the Sync Source to the Sync Destination, including the following:

- **Attribute Mappings** – How are attributes mapped from the Sync Source to the Sync Destination? Are they mapped directly, mapped based on attribute values, or mapped based on attributes that store DN values?
- **Automatically Mapped Source Attributes** – Are there attributes that can be automatically synchronized with the same name at the Sync Source to Sync Destination? For example, can direct mappings be set for `cn,uid,telephoneNumber`, or for all attributes?
- **Non-Auto Mapped Source Attributes** – Are there attributes that should not be automatically mapped? For example, the Sync Source may have an attribute, `employee`, while the Sync Destination may have a corresponding attribute, `employeeNumber`. If an attribute is not automatically mapped, a map must be provided if it is to be synchronized.
- **Conditional Value Mapping** – Should some mappings only be applied some of the time as a function of the source attributes? Conditional value mappings can be used with the `conditional-value-pattern` property, which conditionalizes the attribute mapping based on the subtype of the entry, or on the value of the attribute. For example, this might apply if the `adminName` attribute on the destination should be a copy of the `name` attribute on the source, but only if the `isAdmin` attribute on the source is set to `true`. Conditional mappings are multi-valued. Each value is evaluated until one is matched (the condition is `true`). If none of the conditional mappings are matched, the ordinary mappings is used. If there is not an ordinary mapping, the attribute will not be created on the destination.

## Sync user account

PingDataSync Server creates a Sync User account DN on each external server. The account (by default, `cn=Sync User`) is used exclusively by PingDataSync Server to communicate with external servers. The entry is important in that it contains the credentials (DN and password) used by PingDataSync Server to access the source and target servers. The Sync User account resides in different entries depending on the targeted system:

- For the Ping Identity PingDirectory Server, Ping Identity PingDirectoryProxy Server, Nokia 8661 Directory Server, Nokia 8661 Directory Proxy Server, the Sync User account resides in the configuration entry (`cn=Sync User,cn=Root DNs,cn=config`).
- For Sun Directory Server, Sun DSEE, OpenDJ, Oracle Unified Directory, and generic LDAP directory topologies, the Sync User account resides under the base DN in the `userRoot` backend (`cn=Sync User,dc=example,dc=com`). The Sync User account should not reside in the `cn=config` branch for Sun Directory Server and DSEE machines.
- For Microsoft Active Directory servers, the Sync User account resides in the Users container (`cn=Sync User,cn=Users,DC=adsync,DC=unboundid,DC=com`).

- For Oracle and Microsoft SQL Servers, the Sync User account is a login account (`SyncUser`) with the sufficient privileges to access the tables to be synchronized.

In most cases, modifications to this account are rare. Make sure that the entry is not synchronized by setting up an optional Sync Class if the account resides in the `userRoot` backend (Sun Directory Server or Sun DSEE) or Users container (Microsoft Active Directory). For example, a Sync Class can be configured to have all CREATE, MODIFY, and DELETE operations set to `false`.

## Configure PingDataSync Server in Standard mode

The `create-sync-pipe-config` tool is used to configure Sync Pipes and Sync Classes. For bidirectional deployments, configure two Sync Pipes, one for each directional path.

[Use the `create-sync-pipe` tool to configure synchronization](#) on page 1332 illustrates a bidirectional synchronization deployment in standard mode. The example assumes that two replicated topologies are configured:

- The first endpoint topology consists of two Sun LDAP servers: the main server and one failover. Both servers have Retro change logs enabled and contain the full DIT that will be synchronized to the second endpoint.
- The second endpoint topology consists of two PingDirectory Servers: the main server and one failover. Both servers have change logs enabled and contain entries similar to the first endpoint servers, except that they use a `mail` attribute, instead of an `email` attribute.

A specific `mail` to `email` mapping must also be created to exclude the source attribute on the Sync Pipe going the other direction.

### Note:

If the source attribute is not excluded, PingDataSync Server will attempt to create an `email` attribute on the second endpoint, which could fail if the attribute is not present in the destination server's schema.

Then, two Sync Classes are defined:

- One to handle the customized `email` to `mail` attribute mapping.
- Another to handle all other cases (the default Sync Class).

The `dsconfig` command is used to create the specific attribute mappings. The `resync` command is used to test the mappings. Synchronization can start using the `realtime-sync` command.

## Use the `create-sync-pipe` tool to configure synchronization

About this task

Use the `create-sync-pipe-config` utility to configure a Sync Pipe. Once the configuration is completed, settings can be adjusted using the `dsconfig` tool.

### Note:

If servers have no base entries or data, the `cn=Sync User`, `cn=Root` DN's, `cn=config` account needed to communicate cannot be created. Make sure that base entries are created on the destination servers.

If synchronizing pre-encoded passwords to a Ping PingDirectory Server destination, allow pre-encoded passwords in the default password policy. [Configure password encryption](#) on page 1401 must also be configured on the destination. Be sure that the password encryption algorithm is supported by both source and destination servers with the following command:

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
```

```
--set allow-pre-encoded-passwords:true
```

Encrypted and clear-text passwords can be synchronized by configuring the Sync Destination `password-synchronization-format`, and `require-secure-connection-for-clear-text-passwords` properties.

**Note:**

The `require-secure-connection-for-clear-text-passwords` property can be set to `false` when working in a test environment. If the `password-synchronization-format` property is set to `clear-text`, and `require-secure-connection-for-clear-text-passwords` property is set to `true`, the connection must be secure. If a secure connection is not available, an error is generated and the password is not synchronized.

Perform the following steps to configure PingDataSync Server by using `create-sync-pipe-config`:

### Steps

1. Start PingDataSync Server.

```
$ <server-root>/bin/start-server
```

2. From the `bin` directory, run the `create-sync-pipe-config` tool.

```
$bin/create-sync-pipe-config
```

3. On the Initial Synchronization Configuration Tool menu, press Enter (yes) to continue the configuration.
4. On the Synchronization Mode menu, press Enter to select Standard Mode.
5. On the Synchronization Directory menu, select **oneway(1)** or **bidirectional(2)** for the synchronization topology. This example assumes bidirectional synchronization.
6. On the Source Endpoint Type menu, select the directory or database server for the first endpoint.
7. On the Source Endpoint Name menu, type a name for the endpoint server, or press Enter to accept the default.
8. On the Base DNs menu, type the base DN on the first endpoint topology where the entries will be searched. In this example, `(dc=example,dc=com)` is used.
9. Select an option for the server security.
10. Type the host name and listener port number for the source server, or accept the default. Make sure that the endpoint servers are online and running.
11. Enter another server host and port, or press Enter to continue.
12. Enter the SyncUser account DN for the endpoint servers, or press Enter to accept the default (`cn=SyncUser,cn=RootDNs,cn=config`).
13. Enter and confirm a password for this account.
14. The servers in the destination endpoint topology can now be configured. Repeat steps 6– 13 to configure the second server.
15. Define the maximum age of changelog log entries, or press Enter to accept the default.
16. After the source and destination topologies are configured, PingDataSync Server will "prepare" each external server by testing the connection to each server. This step determines if each account has the necessary privileges (root privileges are required) to communicate with and transfer data to each endpoint during synchronization.
17. Create a name for the Sync Pipe on the Sync Pipe Name menu, or press Enter to accept the default. Because this configuration is bidirectional, the following step is setting up a Sync Pipe path from the source endpoint to the destination endpoint. A later step will define another Sync Pipe from the PingDirectory Server to another server.

18. On the SyncClass Definitions menu, type `Yes` to create a custom Sync Class. A Sync Class defines the operation types (creates, modifies, or deletes), attributes that are synchronized, how attributes and DNs are mapped, and how source and destination entries are correlated.
19. Enter a name for the new Sync Class, such as "server1\_to\_server2."
20. On the Base DNs for Sync Class menu, enter one or more base DNs to synchronize specific subtrees of a DIT. Entries outside of the specified base DNs are excluded from synchronization. Make sure the base DNs do not overlap.
21. On the Filters for Sync Class menu, define one or more LDAP search filters to restrict specific entries for synchronization, or press `Enter` to accept the default (no). Entries that do not match the filters will be excluded from synchronization.
22. On the Synchronized Attributes for Sync Class menu, specify which attributes will be automatically mapped from one system to another. This example will exclude the source attribute (`email`) from being auto-mapped to the target servers.
23. On the Operations for Sync Class menu, select the operations that will be synchronized for the Sync Class, or press `Enter` to accept the default (1, 2, 3).
24. Define a default Sync Class that specifies how the other entries are processed, or press `Enter` to create a Sync Class called "Default Sync Class."
25. On the Default Sync Class Operations menu, specify the operations that the default Sync Class will handle during synchronization, or press `Enter` to accept the default.
26. Define a Sync Pipe going from the PingDirectory Server to the Sun Directory Server and exclude the `mail` attribute from being synchronized to the other endpoint servers.
27. Review the Sync Pipe Configuration Summary, and press `Enter` to accept the default (write configuration), which records the commands in a batch file (`<server-root>/sync-pipe-cfg.txt`). The batch file can be re-used to set up other topologies.

#### Next steps

Apply the configuration changes to the local PingDataSync Server instance by using a `dsconfig` batch file. Any Server SDK extensions, should be saved to the `<server-root>/lib/extensions` directory.

The next step will be to configure the attribute mappings using the `dsconfig` command.

### Configuring attribute mapping

#### About this task

The following procedure defines an attribute map from the `email` attribute in the source servers to a `mail` attribute in the target servers. Both attributes must be valid in the target servers and must be present in their respective schemas.

#### Note:

The following can also be done with `dsconfig` in interactive mode. Attribute mapping options are available from the PingDataSync Server main menu.

#### Steps

1. On PingDataSync Server, run the `dsconfig` command to create an attribute map for the "SunDS>DS" Sync Class for the "Sun DS to Ping Identity DS" Sync Pipe, and then run the second `dsconfig` command to apply the new attribute map to the Sync Pipe and Sync Class.

```
$ bin/dsconfig --no-prompt create-attribute-map \
 --map-name "SunDS>DS Attr Map" \
 --set "description:Attribute Map for SunDS>Ping Identity Sync Class" \
 --port 7389 \
 --bindDN "cn=admin,dc=example,dc=com" \
```

```
--bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
--pipe-name "Sun DS to DS" \
--class-name "SunDS>DS" \
--set "attribute-map:SunDS>DS Attr Map" \
--port 7389 \
--bindDN "cn=admin,dc=example,dc=com" \
--bindPassword secret
```

## 2. Create an attribute mapping (from email to mail) for the new attribute map.

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
--map-name "SunDS>DS Attr Map" \
--mapping-name mail --type direct \
--set "description:Email>Mail Mapping" \
--set from-attribute:email \
--port 7389 \
--bindDN "cn=admin,dc=example,dc=com" \
--bindPassword secret
```

## 3. For a bidirectional deployment, repeat steps 1–2 to create an attribute map for the DS>SunDS Sync Class for the Ping Identity DS to Sun DS Sync Pipe, and create an attribute mapping that maps mail to email.

```
$ bin/dsconfig --no-prompt create-attribute-map \
--map-name "DS>SunDS Attr Map" \
--set "description:Attribute Map for DS>SunDS Sync Class" \
--port 7389 \
--bindDN "cn=admin,dc=example,dc=com" \
--bindPassword secret
```

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
--pipe-name "Ping Identity DS to Sun DS" \
--class-name "DS>SunDS" \
--set "attribute-map:DS>SunDS Attr Map" \
--port 7389 \
--bindDN "cn=admin,dc=example,dc=com" \
--bindPassword secret
```

```
$ bin/dsconfig --no-prompt create-attribute-mapping \
--map-name "DS>SunDS Attr Map" \
--mapping-name email \
--type direct \
--set "description:Mail>Email Mapping" \
--set from-attribute:mail \
--port 7389 \
--bindDN "cn=admin,dc=example,dc=com" \
--bindPassword secret
```

## Configure server locations

### About this task

PingDataSync Server supports endpoint failover, which is configurable using the `location` property on the external servers. By default, the server prefers to connect to, and failover to, endpoints in the same location as itself. If there are no location settings configured, PingDataSync Server will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

**Note:**

Location-based failover is only applicable for LDAP endpoint servers.

**Steps**

1. On PingDataSync Server, run the `dsconfig` command to set the location for each external server in the Sync Source and Sync Destination. For example, the following command sets the location for six servers in two data centers, `austin` and `dallas`.

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:1389 \
 --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:2389 \
 --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:3389 \
 --set location:austin
```

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:4389 \
 --set location:dallas
```

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:5389 \
 --set location:dallas
```

```
$ bin/dsconfig set-external-server-prop \
 --server-name example.com:6389 \
 --set location:dallas
```

2. Run `dsconfig` to set the location on the Global Configuration. This is the location of PingDataSync Server itself. In this example, set the location to "austin."

```
$ bin/dsconfig set-global-configuration-prop \
 --set location:austin
```

**Use the Configuration API**

PingData servers provide a Configuration API, which may be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's `host:port` in the `/config` context. Due to the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used, for hosting the Configuration extension.

### Authentication and authorization

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Configuration \
 --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

### Relationship between the Configuration API and the dsconfig tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes may be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes may be excluded from responses by specifying the `excludedAttributes` parameter. See [Sorting and filtering configuration objects](#) on page 1345 for more information on query parameters.

Operations supported by the API are those typically found in REST APIs:

HTTP Method	Description	Related dsconfig Example
GET	Lists the attributes of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> . Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .	<code>get-backend-prop</code> <code>list-backends</code> <code>get-global-configuration-prop</code>

HTTP Method	Description	Related dsconfig Example
POST	Creates a new instance of an object when used with a relation parent path, such as <code>config/backends</code> .	<code>create-backend</code>
PUT	Replaces the existing attributes of an object. A PUT operation is similar to a PATCH operation, except that the PATCH is determined by determining the difference between an existing target object and a supplied source object. Only those attributes in the source object are modified in the target object. The target object is specified using a path, such as  <code>/config/backends/userRoot</code> .	<code>set-backend-prop</code>  <code>set-global-configuration-prop</code>
PATCH	Updates the attributes of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> . See <a href="#">PATCH Example</a> on page 1341.	<code>set-backend-prop</code>  <code>set-global-configuration-prop</code>
DELETE	Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<code>delete-backend</code>

The OPTIONS method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded in the `path` segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. So the URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

### GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot",
 "meta": {
```

```

 "resourceType": "Local DB Backend",

```

### GET list example

The following is a sample GET request for all local backends:

```

GET /config/backends
Host: example.com:5033
Accept: application/scim+json

```

The response (which has been shortened):

```

{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],
 "totalResults": 24,
 "Resources": [
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:ldif"
],
 "id": "adminRoot",
 "meta": {
 "resourceType": "LDIF Backend",
 "location": "http://localhost:5033/config/backends/adminRoot"
 },
 "backendID": "adminRoot",
 "backupFilePermissions": "700",
 "baseDN": [
 "cn=admin data"
],
 "enabled": "true",
 "isPrivateBackend": "true",
 "javaClass": "com.unboundid.directory.server.backends.LDIFBackend",
 "ldifFile": "config/admin-backend.ldif",
 "returnUnavailableWhenDisabled": "true",
 "setDegradedAlertWhenDisabled": "false",
 "writabilityMode": "enabled"
 },
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:trust-store"
],
 "id": "ads-truststore",
 "meta": {
 "resourceType": "Trust Store Backend",
 "location": "http://localhost:5033/config/backends/ads-truststore"
 },
 }
]
}

```

```

 "backendID": "ads-truststore",
 "backupFilePermissions": "700",
 "baseDN": [
 "cn=ads-truststore"
],
 "enabled": "true",
 "javaClass":
"com.unboundid.directory.server.backends.TrustStoreBackend",

 "setDegradedAlertWhenDisabled": "true",
 "trustStoreFile": "config/server.keystore",
 "trustStorePin": "*****",
 "trustStoreType": "JKS",
 "writabilityMode": "enabled"
 },
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:alarm"
],
 "id": "alarms",
 "meta": {
 "resourceType": "Alarm Backend",
 "location": "http://localhost:5033/config/backends/alarms"
 }
 },
 ...

```

### PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API supports a subset of possible values for the `path` attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

```

{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
}

```

is analogous to:

```

$ dsconfig set-backend-prop --backend-name userRoot \
 --set "description:A new backend"

```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

```

{
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
}

```

is analogous to:

```

$ dsconfig set-backend-prop --backend-name userRoot \
 --add je-property:je.env.backgroundReadLimit=0

```

- An operation to remove a value from a multi-valued property. In this case, `path` specifies a SCIM filter identifying the value to remove:

```
{
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.cleaner.adjustUtilization=false
```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is `value`:

```
{
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.nodeMaxEntries=32
```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --reset id2childrenIndexEntryLimit
```

The following is the full example request. The API responds with the entire modified configuration object, which may include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

Example request:

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
 "schemas" : ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
 "Operations" : [{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
 }, {
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
 }, {
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
 }
]
```

```

}, {
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}, {
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
}]
}

```

**Example response:**

```

{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot2",
 "meta": {
 "resourceType": "Local DB Backend",
 "location": "http://example.com:5033/config/backends/userRoot2"
 },
 "backendID": "userRoot2",
 "backgroundPrime": "false",
 "backupFilePermissions": "700",

"setDegradedAlertForUntrustedIndex": "true",
"setDegradedAlertWhenDisabled": "true",
"subtreeDeleteBatchSize": "5000",
"subtreeDeleteSizeLimit": "5000",
"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled",
"urn:unboundid:schemas:configuration:messages:2.0": {
 "requiredActions": [
 {
 "property": "jeProperty",
 "type": "componentRestart",
 "synopsis": "In order for this modification to take effect,
the component must be restarted, either by disabling and
re-enabling it, or by restarting the server"
 },
 {
 "property": "id2childrenIndexEntryLimit",
 "type": "other",
 "synopsis": "If this limit is increased, then the contents
of the backend must be exported to LDIF and re-imported to
allow the new limit to be used for any id2children keys
that had already hit the previous limit."
 }
]
}
}
}

```

### API paths

The Configuration API is available under the `/config` path. A full listing of root sub-paths can be obtained from the `/config/ResourceTypes` endpoint:

```

GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json

```

Sample response (abbreviated):

```
{
```

```

"schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],
"totalResults": 520,
"Resources": [
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "dsee-compat-access-control-handler",
 "name": "DSEE Compat Access Control Handler",
 "description": "The DSEE Compat Access Control
 Handler provides an implementation that uses syntax
 compatible with the Sun Java System Directory Server
 Enterprise Edition access control handler.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/dsee-
compat-
access-control-handler"
 }
 },
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "access-control-handler",
 "name": "Access Control Handler",
 "description": "Access Control Handlers manage the
 application-wide access control. The server's access
 control handler is defined through an extensible
 interface, so that alternate implementations can be created.
 Only one access control handler may be active in the server
 at any given time.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
 }
 },
 {
 ...
 }
]

```

The response's endpoint elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name like `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

### Sorting and filtering configuration objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the

full set of operations for SCIM filters. Clients may also specify sort parameters, or paging parameters. As previously mentioned, clients may specify attributes to include or exclude in both get and list operations.

### GET Parameters for Sorting and Filtering

GET Parameter	Description
filter	Values can be simple SCIM filters such as <code>id eq "userRoot"</code> or compound filters like <code>meta.resourceType eq "Local DB Backend" and baseDn co"dc=example,dc=com"</code> .
sortBy	Specifies a property value by which to sort.
sortOrder	Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.
startIndex	1-based index of the first result to return.
count	Indicates the number of results per page.

### Update properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
 "description" : "A new description."
}
```

Response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot",
 "meta": {
 "resourceType": "Local DB Backend",
 "location": "http://example.com:5033/config/backends/userRoot"
 },
 "backendID": "userRoot",
 "backgroundPrime": "false",

"subtreeDeleteSizeLimit": "100000",
"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled"
}

```

### Administrative actions

Updating a property may require an administrative action before the change can take effect. If so, the server will return 200 Success, and any actions are returned in the

urn:unboundid:schemas:configuration:messages:2.0 section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
 "requiredActions": [
 {
 "property": "baseContextPath",
 "type": "componentRestart",
 "synopsis": "In order for this modification to
 take effect, the component must be restarted,
 either by disabling and re-enabling it, or by
 restarting the server"
 },
 {
 "property": "id2childrenIndexEntryLimit",
 "type": "other",
 "synopsis": "If this limit is increased, then the
 contents of the backend must be exported to LDIF
 and re-imported to allow the new limit to be used
 for any id2children keys that had already hit the
 previous limit."
 }
]
}
...

```

### Update servers and server groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query parameter. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `singleServer` or `serverGroup` can be specified. For example:

```
https://example.com:5033/config/Backends/userRoot?applyChangeTo=singleServer
```

#### Note:

This does not apply to mirrored subtree objects, which include Topology and Cluster level objects. Changes made to mirrored objects are applied to all objects in the subtree.

### Configuration API responses

Clients of the API should examine the HTTP response code in order to determine the success or failure of a request. The following are response codes and their meanings:

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the urn:unboundid:schemas:configuration:messages:2.0 object.	List of objects, or object properties, administrative actions.

Response Code	Description	Response Body
204 No Content	The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.	None.
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message.
401 Unauthorized	User authentication is required. Some user agents such as browsers may respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.	None.
403 Forbidden	The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint such as an object is edit-only and cannot be deleted.	None.
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message.
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists or an attempt was made to delete an object that is referred to by another object.	Error summary and optional message.
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None.
500 Server Error	The server encountered an unexpected error. Please report server errors to customer support.	Error Summary and optional message.

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages may change, and their presence may depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:Error"
],
 "status": 404,
 "scimType": null,
 "detail": "The Local DB Index does not exist."
}
```

## Configuration with the dsconfig tool

The Ping Identity servers provide several command-line tools for management and administration. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

The `dsconfig` tool is the text-based management tool used to configure the underlying server configuration. The tool has three operational modes:

- Interactive Mode
- Non-interactive mode
- Batch mode

The `dsconfig` tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

Each command-line utility provides a description of the subcommands, arguments, and usage examples needed to run the tool. View detailed argument options and examples by typing `-- help` with the command.

```
$ bin/dsconfig --help
```

To list the subcommands for each command:

```
$ bin/dsconfig --help-subcommands
```

To list more detailed subcommand information:

```
$ bin/dsconfig list-log-publishers --help
```

### Use dsconfig in interactive mode

Running `dsconfig` in interactive command-line mode provides a menu-driven interface for accessing and configuring the PingData server. To start `dsconfig` in interactive mode, run the tool without any arguments:

```
$ bin/dsconfig
```

Running the tool requires server connection and authentication information. After connection information is confirmed, a menu of the available operation types is displayed.

### Use dsconfig in non-interactive mode

Non-interactive command-line mode provides a simple way to make arbitrary changes to the server, and to use administrative scripts to automate configuration changes. To make changes to multiple configuration objects at the same time, use batch mode.

The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` argument specifies non-interactive mode. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on the implementation. The `{subcommand}` specifies which general action to perform. The following uses standard LDAP connections:

```
$ bin/dsconfig --no-prompt list-backends \
--hostname server.example.com \
--port 389 \
--bindDN uid=admin,dc=example,dc=com \
--bindPassword password
```

The following uses SASL GSSAPI (Kerberos) parameters:

```
$ bin/dsconfig --no-prompt list-backends \
--sasloption mech=GSSAPI \
--sasloption authid=admin@example.com \
--sasloption ticketcache=/tmp/krb5cc_1313 \
--sasloption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular task. To always display the advanced properties, use the `--advanced` command-line option.

**Note:**

Global arguments can appear anywhere on the command line. The subcommand-specific arguments can appear anywhere after the subcommand.

### Use dsconfig batch mode

The `dsconfig` tool provides a batching mechanism that reads multiple invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

```
$ bin/dsconfig --no-prompt \
 --hostname host1 \
 --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret \
 --batch-file /path/to/sync-pipe-config.txt
```

If a `dsconfig` command has a missing or incorrect argument, the command will fail and stop the batch process without applying any changes to the server. A `--batch-continue-on-error` option is available, which instructs `dsconfig` to apply all changes and skip any errors.

View the `logs/config-audit.log` file to review the configuration changes made to the server, and use them in the batch file. The batch file can have blank lines for spacing, and lines starting with a pound sign (`#`) for comments. The batch file also supports a `"\"` line continuation character for long commands that require multiple lines.

PingDataSync Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to Ping Identity PingDataSync Server machines.

## Topology configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a master/slave architecture for mirroring shared data across the topology. All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group.

**Note:**

To remove a server from the topology, it must be uninstalled with the `uninstall` tool.

### Topology master requirements and selection

A topology master server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers when they poll the master. The master always sends a digest of its subtree contents on each update. If the node has a different digest than the master, it knows it's not synchronized. The servers will pull the entire subtree from the master if they detect that they are not synchronized. A server may detect it is not synchronized with the master under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its master, then it knows it's not synchronized.

- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The master of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a master, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the master. If a new server can be the master, it will communicate that to the other servers, if no other server has advertised that it should be the master. This ensures that all servers accept the same master at approximately the same time (within a few milliseconds of each other). If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master. (The master server itself is considered while determining this majority.)
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `mirrored-subtree-manager-forced-as-master-error` critical alarm will be raised.

## Topology components

When a server is installed, it can be added to an existing topology, which will clone the server's. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

### Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, `force-as-master-for-mirrored-data`. This should be set to `true` on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a master because a majority of servers is not available. A server with this setting enabled will be assigned the role of master, if no suitable master can be determined. See [Topology master requirements and selection](#) on page 1351 for details about how a master is selected for a topology.

The Config File Handler Backend defines three topology (`mirrored-subtree`) settings:

- `mirrored-subtree-peer-polling-interval` – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that may warrant a new master selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable master is found, the polling frequency is adjusted to 100 milliseconds until a new master is selected.
- `mirrored-subtree-entry-update-timeout` – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the master on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if master selection is in progress at the time the update operation was received.
- `mirrored-subtree-search-timeout` – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

## Topology settings

Topology meta-data is stored under the `cn=topology,cn=config` subtree and cluster data is stored under the `cn=cluster,cn=config` subtree. The only setting that can be changed is the cluster name.

### Monitor data for the topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology.

Topology data includes the following:

- The server ID of the current master, if the master is not known.
- The instance name of the current master, or if a master is not set, a description stating why a master is not set.
- A flag indicating if this server thinks that it should be the master.
- A flag indicating if this server is the current master.
- A flag indicating if this server was forced as master.
- The total number of configured peers in the topology group.
- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its master, or another node in the topology if the master is unknown.
- The amount of time in milliseconds where multiple masters were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as master.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master.
- The number of operations processed by this server as master that were successful.
- The number of operations processed by this server as master that failed to validate.
- The number of operations processed by this server as master that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the master.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the master.

### Certificates

Depending on the circumstances, PingDirectory Server uses one of the following certificates:

- Inter-server certificate – Used for internal purposes, like the following examples:
  - Replication authentication
  - Inter-server authentication in the topology registry
  - Reversible password encryption
  - Encrypted backups and LDIF exports
- Server certificate – Presented by the server when a client uses a protocol like LDAPS or HTTPS to initiate a secure connection. A client must trust the server's certificate to obtain a secure connection to it.

The following sections describe these certificates in more detail.

#### Inter-server certificate

Generated during installation, the inter-server certificate is stored under the alias `ads-certificate` in a file named `ads-truststore`, which resides in the server's `/config` directory. This certificate contains the key pair for the local server as well as for the certificates of all trusted servers, and has a lifetime of 20 years before expiring.

The local server's public key is signed by its own private key, making it a *self-signed certificate*. The alias is hard-coded to `ads-certificate`, and the keystore file is hard-coded to `ads-truststore`. This behavior cannot be modified during setup.

**Warning:**

- Although some customers feel uncomfortable with the self-signed nature of the inter-server certificate, we recommend that you do not replace it with a CA-signed certificate for the following reasons:
  - If the inter-server certificate is replaced incorrectly, serious problems can occur during topology authentication.
  - The inter-server certificate is used for internal purposes only.
- If the server's access logs contain authentication (bind) errors, the inter-server certificate is most likely configured inappropriately. In the topology registry, this certificate is persisted in the **`inter-server-certificate`** property of a server instance.

*Replace the inter-server certificate*

About this task

Because the inter-server certificate is also stored in the topology registry, it can be replaced on one server and mirrored to all other servers in the topology. Changes are mirrored automatically to the other servers in the topology.

**Important:** Before attempting to replace the inter-server certificate, ensure that all servers in the topology are updated to version 7.0 or later.

The inter-server certificate is stored in human-readable, PEM-encoded format and can be updated by using the `dsconfig` tool. While the certificate is being replaced, existing authenticated connections continue to work. If the server is restarted, or if a topology change requires a reset of peer connections, the server continues authenticating with its peers, all of whom trust the new certificate.

To replace the inter-server certificate with no downtime, complete the following tasks:

Steps

1. Prepare a new keystore with the replacement key pair.
2. Import the earlier trusted certificates into the new keystore.
3. Update the server configuration to use the new certificate by adding it to the server's list of certificates in the topology registry.  
After this step is performed, other servers will trust the certificate.
4. Replace the server's `ads-truststore` file with the new one.
5. Retire the previous certificate by removing it from the topology registry.

Next steps

The following sections describe these tasks in more detail.

Prepare a new keystore with the replacement key pair

The self-signed certificate can be replaced with an existing key pair. As an alternative, the certificate that is associated with the original key pair can be used.

Use an existing key pair

If a private key and certificate in PEM-encoded format already exist, both the original private key and the self-signed certificate can be replaced in `ads-truststore` by using the `manage-certificates` tool. Depending on your operating system, the **`manage-certificates`** tool is located in the server's `bin` or `bat` directory.

**i Important:** If the existing key pair is not in PEM-encoded format, convert it to a format that is compatible with the server's `ads-truststore` keystore file format before proceeding.

If you replace the entire key pair instead of only the certificate that is associated with the original private key, your existing backups and LDIF exports might be rendered invalid. To avoid this scenario, perform this step immediately after setup, or at least before the key pair is used. After the first use, change only the certificate associated with the private key to extend its validity period, or to replace it with a certificate that is signed by a different CA.

The following command imports existing certificates into a new keystore file named `ads-truststore.new`:

```
manage-certificates import-certificate \
 --keystore ads-truststore.new \
 --keystore-type JKS \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --private-key-file existing.key \
 --certificate-file existing.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Order the certificates that use the `--certificate-file` option in such a manner that each subsequent certificate functions as the issuer for the previous one. The server certificate is listed first, any intermediate certificates are listed next, and the root CA certificate is listed last. Because some deployments do not feature an intermediate issuer, you might need to import only the server certificate and a single issuer.

Replace the certificate associated with the original key pair

About this task

Alternatively, to replace the certificate that is associated with the original server-generated, `ads-certificate` private key, perform the following steps:

Steps

1. Create a CSR for the `ads-certificate`, as follows:

```
manage-certificates generate-certificate-signing-request \
 --keystore ads-truststore \
 --keystore-type JKS \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --use-existing-key-pair \
 --subject-dn "CN=ldap.example.com,O=Example Corporation,C=US" \
 --output-file ads.csr
```

2. Submit `ads.csr` to a CA for signing.

3. Export the server's private key into `ads.key`, as follows:

```
manage-certificates export-private-key \
 --keystore ads-truststore \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --output-file ads.key
```

4. Import the certificates obtained from the CA – including the CA-signed server certificate, the root CA certificate, and any intermediate certificates – into `ads-truststore.new`, as follows:

```
manage-certificates import-certificate \
```

```
--keystore ads-truststore.new \
--keystore-type JKS \
--keystore-password-file ads-truststore.pin \
--alias ads-certificate \
--private-key-file ads.key \
--certificate-file new-ads.crt \
--certificate-file intermediate.crt \
--certificate-file root-ca.crt
```

## Import earlier trusted certificates into the new keystore

### About this task

The new `ads-truststore` file, `ads-truststore.new`, contains only the server's new key pair. You must import the currently trusted certificates of other servers in the topology.

To export trusted certificates from `ads-truststore` and import them into `ads-truststore.new`, perform the following steps for each trusted certificate:

### Steps

1. Locate the currently trusted certificates, as follows:

```
manage-certificates list-certificates \
--keystore ads-truststore
```

2. For each alias other than `ads-certificate`, or whose fingerprint does not match `ads-certificate`, perform the following steps:

- a. Export the trusted certificate from `ads-truststore`, as follows:

```
manage-certificates export-certificate \
--keystore ads-truststore \
--keystore-password-file ads-truststore.pin \
--alias <trusted-cert-alias> \
--export-certificate-chain \
--output-file <trust-cert-alias>.crt
```

- b. Import the trusted certificate into `ads-truststore.new`, as follows:

```
manage-certificates import-certificate \
--keystore ads-truststore.new \
--keystore-type JKS \
--keystore-password-file ads-truststore.pin \
--alias <trusted-cert-alias> \
--certificate-file <trusted-cert-alias>.crt
```

## Update the server configuration to use the new certificate

### About this task

Before updating the server to use the appropriate key pair, update the `inter-server-certificate` property for the server instance in the topology registry. To support the transition from an existing certificate to a new one, earlier and newer certificates might appear within their own beginning and ending headers in the `inter-server-certificate` property.

To update the server configuration to use the new certificate, perform the following steps:

## Steps

1. Export the server's previous `ads-certificate` into `old-ads.crt`, as follows:

```
manage-certificates export-certificate \
 --keystore ads-truststore \
 --keystore-password-file ads-truststore.pin \
 --alias ads-certificate \
 --output-file old-ads.crt
```

2. Concatenate the previous and new certificate into one file.

On Windows, use a text editor like Notepad. On Unix, use the following command:

```
cat old-ads.crt new-ads.crt > old-new-ads.crt
```

3. Use `dsconfig` to update the `inter-server-certificate` property for the server instance in the topology registry, as follows:

```
$ bin/dsconfig -n set-server-instance-prop \
 --instance-name <instance-name> \
 --set "inter-server-certificate<old-new-ads.crt"
```

Replace the previous `ads-truststore` file with the new one

Because the server still uses the previous `ads-certificate`, you must replace the previous `ads-truststore` file with `ads-truststore.new` in the server's `config` directory when you want the new `ads-certificate` to go into effect:

```
$ mv ads-truststore.new ads-truststore
```

Retire the previous certificate

Retire the previous certificate by removing it from the topology registry after it expires, as follows:

```
$ dsconfig -n set-server-instance-prop \
 --instance-name <instance-name> \
 --set "inter-server-certificate<chain.crt"
```

Existing encrypted backups and LDIF exports remain unaffected. Because the public key is the same in the previous and new server certificates, the private key can decrypt them.

### Server certificate

During setup, administrators have the option of using self-signed certificates or CA-signed certificates for the server certificate. Where possible, we encourage the use of CA-signed certificates. Self-signed certificates are recommended only for demonstration and proof-of-concept environments.

If you specify the option `--generateSelfSignedCertificate` during setup, the server certificate is generated automatically with the alias `server-cert`. The key pair consists of the private key and the self-signed certificate, and is stored in a file named `keystore`, which resides in the server's `/config` directory. The certificates for all the servers that the server trusts are stored in the `truststore` file, which is also located under the server's `/config` directory.

To override the server certificate alias and the files that store the key pair and certificates, use the following arguments during setup:

- `--certNickname`
- `--use*Keystore`
- `--use*Truststore`

For more information about these arguments, refer to the setup tool's Help and the Installation Guide.

**i Important:** If the server's access logs contain authentication (bind) errors, the inter-server certificate is most likely configured inappropriately. In the topology registry, this certificate is persisted in a Server Instance Listener's listener-certificate property.

### *Replace the server certificate*

#### About this task

Regardless of whether the server was set up with self-signed or CA-signed certificates, the steps to replace the server certificate are nearly identical.

This task makes the following assumptions:

- You are replacing the self-signed server certificate.
- The certificate alias is `server-cert`.
- The private key is stored in `keystore`.
- The trusted certificates are stored in `truststore`.
- The `keystore` and `truststore` use the JKS keystore format.

If a PKCS#12 keystore format was used for the `keystore` and `truststore` files during setup, change the `--keystore-type` argument in the `manage-certificate` commands to `PKCS12` in the relevant steps.

**i Important:** Before attempting to replace the inter-server certificate, ensure that all servers in the topology are updated to version 7.0 or later.

While the certificate is being replaced, existing secure connections continue to work. If the server is restarted, or if a topology change requires a reset of peer connections, the server continues authenticating with its peers, all of whom trust the new certificate.

To replace the server certificate with no downtime, complete the following tasks:

#### Steps

1. Prepare a new keystore with the replacement key pair.
2. Import the earlier trusted certificates into the new `truststore` file.
3. Update the server configuration to use the new certificate by adding it to the server's list of listener certificates in the topology registry.  
After this step is performed, other servers will trust the certificate.
4. Replace the server's `keystore` and `truststore` files with the new ones.
5. Retire the previous certificate by removing it from the topology registry.

#### Next steps

The following sections describe these tasks in more detail.

#### Prepare a new keystore with the replacement key pair

The self-signed certificate can be replaced with an existing key pair. As an alternative, the certificate that is associated with the original key pair can be used.

#### Use an existing key pair

If a private key and certificate already exist in PEM-encoded format, they can replace both the original private key and the self-signed certificate in `keystore` (instead of replacing the self-signed certificate associated with the original server-generated private key). Use the `manage-certificates` tool that, depending on your operating system, is located in the server's `bin` or `bat` directory.

The following command imports existing certificates into a new keystore file named `keystore.new`:

```
manage-certificates import-certificate \
 --keystore keystore.new \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --private-key-file existing.key \
 --certificate-file existing.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Order the certificates that use the `--certificate-file` option in such a manner that each subsequent certificate functions as the issuer for the previous one. The server certificate is listed first, any intermediate certificates are listed next, and the root CA certificate is listed last. Because some deployments do not feature an intermediate issuer, you might need to import only the server certificate and a single issuer.

Replace the certificate associated with the original key pair

#### About this task

If the certificate that is associated with the original server-generated private key (`server-cert`) has expired or must be replaced with a certificate from a different CA, perform the following steps to replace it:

#### Steps

1. Create a CSR file for the `server-cert`, as follows:

```
manage-certificates generate-certificate-signing-request \
 --keystore keystore \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --use-existing-key-pair \
 --subject-dn "CN=ldap.example.com,O=Example Corporation,C=US" \
 --output-file server-cert.csr
```

2. Submit `server-cert.csr` to a CA for signing.
3. Export the server's private key into `server-cert.key`, as follows:

```
manage-certificates export-private-key \
 --keystore keystore \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --output-file server-cert.key
```

4. Import the certificates obtained from the CA – including the CA-signed server certificate, the root CA certificate, and any intermediate certificates – into `keystore.new`, as follows:

```
manage-certificates import-certificate \
 --keystore keystore.new \
 --keystore-type JKS \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --private-key-file server-cert.key \
 --certificate-file server-cert.crt \
 --certificate-file intermediate.crt \
 --certificate-file root-ca.crt
```

Import earlier trusted certificates into the new keystore

### About this task

The trusted certificates of other servers in the topology must be imported into the new `truststore` file. To export trusted certificates from `truststore` and import them into `truststore.new`, perform the following steps for each trusted certificate:

### Steps

1. Locate the currently trusted certificates, as follows:

```
manage-certificates list-certificates \
 --keystore truststore
```

2. For each alias other than `server-cert`, or whose fingerprint does not match `server-cert`, perform the following steps:

- a. Export the trusted certificate from `truststore`, as follows:

```
manage-certificates export-certificate \
 --keystore truststore \
 --keystore-password-file truststore.pin \
 --alias <trusted-cert-alias> \
 --export-certificate-chain \
 --output-file trusted-cert-alias.crt
```

- b. Import the trusted certificate into `truststore.new`, as follows:

```
manage-certificates import-certificate \
 --keystore truststore.new \
 --keystore-type JKS \
 --keystore-password-file truststore.pin \
 --alias <trusted-cert-alias> \
 --certificate-file trusted-cert-alias.crt
```

### Update the server configuration to use the new certificate

#### About this task

Before updating the server to use the appropriate key pair, update the `listener-certificate` property for the server instance's LDAP listener in the topology registry. To support the transition from an existing certificate to a new one, earlier and newer certificates might appear within their own beginning and ending headers in the `listener-certificate` property.

To update the server configuration to use the new certificate, perform the following steps:

### Steps

1. Export the server's previous `server-cert` into `old-server-cert.crt`, as follows:

```
manage-certificates export-certificate \
 --keystore keystore \
 --keystore-password-file keystore.pin \
 --alias server-cert \
 --output-file old-server-cert.crt
```

2. Concatenate the previous and new certificate into one file.

On Windows, use a text editor like Notepad. On Unix, use the following command:

```
cat old-server-cert.crt new-server-cert.crt > old-new-server-cert.crt
```

3. Use `dsconfig` to update the `listener-certificate` property for the server instance's LDAP listener in the topology registry, as follows:

```
$ bin/dsconfig -n set-server-instance-listener-prop \
 --instance-name <instance-name> \
 --listener-name ldap-listener-mirrored-config \
 --set "listener-certificate<old-new-server-cert.crt"
```

Replace the keystore and truststore files with the new ones

Because the server still uses the previous `server-cert`, you must replace the earlier `keystore` and `truststore` files with the new ones in the server's `config` directory when you want the new `server-cert` to take effect.

```
$ mv keystore.new keystore
 mv truststore.new truststore
```

Retire the previous certificate

Retire the previous certificate by removing it from the topology registry after it expires, as follows:

```
$ dsconfig -n set-server-instance-listener-prop \
 --instance-name <instance-name> \
 --listener-name ldap-listener-mirrored-config \
 --set "listener-certificate<new-server-cert.crt"
```

## Domain Name Service (DNS) caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

### **network-address-cache-ttl**

Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.

### **network-address-outage-cache-enabled**

Caches host name-to-IP address results in the event of a DNS outage. This is set to `true` by default, meaning name resolution results are cached. Unexpected service interruptions may occur during planned or unplanned maintenance, network outages or an infrastructure attack. This cache may allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays due to unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` and/or `options single-request` in `/etc/resolv.conf`.
- If IPv6 requests specifically are causing issues, Add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

## IP address reverse name lookups

Ping Identity servers do not explicitly perform numeric IP address-to-host name lookups. However, address masks configured in Access Control Lists (ACLs), Connection Handlers, Connection Criteria, and Certificate

handshake processing may trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- ACI dns: bind rules under *Managing Access Control* (PingDirectory Server and PingDirectoryProxy Servers)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication* (PingDirectory Server)
- Connection Criteria: *Restricting Server Access Based on Client IP Address* (PingDirectory Server and PingDirectoryProxy Servers)
- Connection Handlers: *Restrict Server Access Using Connection Handlers* (Configuration Reference Guide for all PingData servers)

## Configure the synchronization environment with dsconfig

The `dsconfig` tool can be used to configure any part of PingDataSync Server, but will likely be used for more fine-grained adjustments. If configuring a Sync Pipe for the first time, use the `bin/create-sync-pipe-config` tool to guide through the necessary Sync Pipes creation steps.

### Configure server groups with dsconfig interactive

In a typical deployment, one PingDataSync Server and one or more redundant failover servers are configured. Primary and secondary servers must have the same configuration settings to ensure proper operation. To enable this, assign all servers to a server group using the `dsconfig` tool. Any change to one server will automatically be applied to the other servers in the group.

Run the `dsconfig` command and set the global configuration property for server groups to `all-servers`. On the primary PingDataSync Server, perform the following steps:

```
$ bin/dsconfig set-global-configuration-prop \
 --set configuration-server-group:all-servers
```

Updates to servers in the group are made using the `--applyChangeToServergroup` option of the `dsconfig` command. To apply the change to one server in the group, use the `--applyChangeToSingle-server` option. If additional servers are added to the topology, the `setup` tool will copy the configuration from the primary server to the new server(s).

### Start the Global Sync configuration with dsconfig interactive

About this task

After the Synchronization topology is configured, perform the following steps to start the Global Sync configuration, which will use only those Sync Pipes that have been started:

Steps

1. On the `dsconfig` main menu, type the number corresponding to the Global Sync Configuration.
2. On the Global Sync Configuration menu, type the number corresponding to view and edit the configuration.
3. On the GlobalSync Configuration Properties menu, type the number corresponding to setting the started property, and then follow the prompts to set the value to `TRUE`.
4. On the GlobalSync Configuration Properties menu, type `f` to save and apply the changes.

## Prepare external server communication

About this task

The `prepare-endpoint-server` tool sets up any communication variances that may occur between PingDataSync Server and the external servers. Typically, directory servers can have different security

settings, privileges, and passwords configured on the Sync Source that might reject the import of entries in the Sync Destination.

The `prepare-endpoint-server` tool also creates a Sync User Account and its privileges on all of the external servers (see [Sync user account](#) on page 1331 for more detailed information). The `prepare-endpoint-server` tool verifies that the account has the proper privileges to access the `firstChangeNumber` and `lastChangeNumber` attributes in the root DSE entry so that it can access the latest changes. If the Sync User does not have the proper privileges, PingDataSync Server displays a warning message, which is saved in the `logs/prepare-endpoint-server.log` file.

**Note:**

If the synchronization topology was created using the `create-sync-pipe-config` tool, this command does not need to be run. It is already part of the `create-sync-pipe-config` process.

Perform the following steps to prepare PingDataSync Server for external server communication:

### Steps

1. Use the `prepare-endpoint-server` tool to prepare the directory server instances on the remote host for synchronization as a data source for the subtree, `dc=example,dc=com`. If the user account is not present on the external server, it will be created if a parent entry exists.

```
$ bin/prepare-endpoint-server \
 --hostname sun-ds1.example.com \
 --port 21389 \
 --syncServerBindDN "cn=Sync User,dc=example,dc=com" \
 --syncServerBindPassword secret \
 --baseDN "dc=example,dc=com" \
 --isSource
```

2. When prompted, enter the bind DN and password to create the user account. This step enables the change log database and sets the `changelog-maximum-age` property.
3. Repeat steps 1–2 for any other external source servers.
4. For the destination servers, repeat steps 2–3 and include the `--isDestination` option. If destination servers do not have any entries, a "Denied" message will display when creating the `cn=Sync User` entry.

```
$ bin/prepare-endpoint-server \
 --hostname PingIdentity-ds1.example.com \
 --port 33389 \
 --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
 --syncServerBindPassword sync \
 --baseDN "dc=example,dc=com" \
 --isDestination
```

5. Repeat step 4 for any other destination servers.

## HTTP connection handlers

HTTP Connection Handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire Directory Proxy Server from starting. The server's `start-server` tool will output any errors to the error log. This allows the server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with a HTTP connection handler include:

#### **listen-address**

Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.

#### **listen-port**

Specifies the port on which the connection handler will listen for requests from clients. Required.

#### **use-ssl**

Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.

#### **http-servlet-extension**

Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.

#### **http-operation-log-publisher**

Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.

#### **key-manager-provider**

Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.

#### **trust-manager-provider**

Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.

#### **num-request-handlers**

Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.

#### **web-application-extension**

Specifies the Web applications to be hosted by the server.

### **Configure an HTTP connection handler**

About this task

A HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, a HTTP log publisher. The HTTP servlet extension and log publisher must be configured prior to configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the `ExampleHTTPServletExtension` in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
 --extension-name "Hello World Servlet" \
 --type third-party \
```

```
--set
"extensionclass:com.unboundid.directory.sdk.examples.ExampleHTTPServletEx
tension" \
--set "extension-argument:path=/" \
--set "extension-argument:name=example-servlet"
```

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
--publisher-name "HTTP Common Access Logger" \
--type common-log-file-http-operation \
--set enabled:true \
--set log-file:logs/http-common-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"
```

```
$ bin/dsconfig create-log-publisher \
--publisher-name "HTTP Detailed Access Logger" \
--type detailed-http-operation \
--set enabled:true \
--set log-file:logs/http-detailed-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like listen-port, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
--handler-name "Hello World HTTP Connection Handler" \
--type http \
--set enabled:true \
--set listen-port:8443 \
--set use-ssl:true \
--set "http-servlet-extension>Hello World Servlet" \
--set "http-operation-log-publisher:HTTP Common Access Logger" \
--set "http-operation-log-publisher:HTTP Detailed Access Logger" \
--set "key-manager-provider:JKS" \
--set "trust-manager-provider:JKS"
```

4. By default, the HTTP Connection Handler has an advanced monitor entry property, `keep- stats`, that is set to `TRUE` by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

## HTTP correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which may be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be challenging, as log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When a HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID may also be passed to the LDAP subsystem. For the SCIM 1, Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest`'s `com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

### Configure HTTP Correlation ID Support

Correlation ID support is enabled by default for each HTTP Connection Handler.

- To enable correlation ID support for the HTTPS Connection Handler:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS Connection Handler:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set use-correlation-id-header:false
```

### Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to "X-Request-Id."

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set correlation-id-response-header:X-Request-Id
```

### Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that may be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set correlation-id-request-header:X-Request-Id \
 --set correlation-id-request-header:X-Correlation-Id \
 --set correlation-id-request-header:Correlation-Id \
 --set correlation-id-request-header:X-Amzn-Trace-Id
```

## HTTP Correlation ID Example Use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
 Accept: */*
 Accept-Encoding: gzip, deflate
 Authorization: Bearer ...
 Connection: keep-alive
 Host: localhost:1443
 User-Agent: HTTPie/0.9.9
HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369
{
 "_dn": "uid=user.86,ou=People,dc=example,dc=com",
 "_links": {
 "schemas": [
 {
 "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
 }
],
 "self": {

uid=user.86,ou=People,dc=example,dc=com"
 }
 },
 "mail": [
 "user.86@example.com"
]
}
```

This correlation ID can be used to search the HTTP trace log for matching log records, as follows:

```
$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

## Resync tool

The `resync` tool provides bulk synchronization that can be used to verify the synchronization setup. The tool operates on a single Sync Pipe at a time, retrieves entries from the Sync Source in bulk, and compares the source entries with the corresponding destination entries. If destination entries are missing or attributes are changed, they are updated.

The command provides a `--dry-run` option that can be used to test the matches between the Sync Source and Destination, without committing any changes to the target topology. The `resync` tool also provides options to write debugging output to a log.

### Note:

The `resync` tool should be used for relatively small datasets. For large deployments, export entries from the Sync Source into an LDIF file, run the `bin/translate-ldif` tool to translate and filter the entries into the destination format, and then import the result LDIF file into the Sync Destination.

Use the `resync--help` command for more information and examples. Logging is located in `logs/tools/resync.log` and `logs/tools/resync-errors.log`. If necessary, the logging location can be changed with the `--logFilePath` option.

## Test attribute and DN maps

The `resync` tool can be used to test how attribute maps and DN maps are configured by synchronizing a single entry. If the `--logFilePath` and `--logLevel` options are specified, the `resync` tool generates a log file with details.

Use the `--dry-run` option and specify a single entry, such as `uid=user.0`. Any logging performed during the operation appears in `logs/tools/resync.log`.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
 --sourceSearchFilter "(uid=user.0)" \
 --dry-run \
 --logLevel debug
```

## Verify the synchronization configuration

The most common use for the `resync` tool is to test that the Sync Pipe configuration has been set up correctly. For example, the following procedure assumes that the configuration was set up with the Sync Source topology (two replicated Sun Directory servers) with 2003 entries; the Sync Destination topology (two replicated PingData PingDirectory Server) has only the base entry and the `cn=Sync User` entry. Both source and destination topologies have their LDAP Change Logs enabled. Because both topologies are not actively being updated, the `resync` tool can be run with one pass through the entries.

Use `resync` with the `--dry-run` option to check the synchronization configuration. The output displays a timestamp that can be tracked in the logs.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
 --numPasses 1 \
 --dry-run
Starting Pass 1
Status after completing all passes[20/Mar/2010:10:20:07 -0500]

Source entries retrieved 2003
Entries missing 2002
Entries out-of-sync 1
Duration (seconds) 4
Resync completed in 4 s.
0 entries were in-sync, 0 entries were modified, 0 entries were created,
1 entries are still out-of-sync, 2002 entries are still missing, and
0 entries could not be processed due to an error
```

## Populate an empty sync destination topology

### About this task

The following procedure uses the `resync` tool to populate an empty Sync Destination topology for small datasets. For large deployments, use the `bin/translate-ldif`.

In this example, assume that the Sync Destination topology has only the base entry (`dc=example,dc=com`) and the `cn=Sync User` entry. Perform the following steps to populate an empty Sync Destination:

### Steps

1. Run the `resync` command with the log file path and with the log level `debug`. Logging is located in `logs/tools/resync.log` and `logs/tools/resync-errors.log`.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe \
 --numPasses 1 \
 --logLevel debug
```

2. Open the `logs/resync-failed-DNs.log` file in a text editor to locate the error and fix it. An entry cannot be created because the parent entry does not exist.

```
Entry '(see below)' was dropped because there was a failure at the
resource:
Failed to create entry uid=mlott,ou=People,dc=example,dc=com. Cause:
LDAPException(resultCode=no such object, errorMessage='Entry
uid=user.38,ou=People,dc=example,dc=com cannot be added because its parent
entry ou=People,dc=example,dc=com does not exist in the server',
matchedDN='dc=example,dc=com')
(id=1893859385ResourceOperationFailedException.java:126 Build
revision=4881)
dn: uid=user.38,ou=People,dc=example,dc=com
```

3. Rerun the `resync` command. The command creates the entries in the Sync Destination topology that are present in the Sync Source topology.

```
$ bin/resync --pipe-name sun-to-ds-sync-pipe
```

```
...(output from each pass)...
Status after completing all passes[20/Mar/2016:14:23:33 -0500]

Source entries retrieved 160
Entries in-sync 156
Entries created 4
Duration (seconds) 11

Resync completed in 12 s.

156 entries were in-sync, 0 entries were modified, 4 entries were created,
0 entries are still out-of-sync, 0 entries are still missing, and 0
entries could not be processed due to an error
```

**Note:**

If importing a large amount of data into a PingData PingDirectory Server, run `export-ldif` and `import-ldif` on the newly populated backend for most efficient disk space use. If needed, run `dsreplication initialize` to propagate the efficient layout to additional replicas.

## Set the synchronization rate

### About this task

The `resync` command has a `--ratePerSecondFile` option that enables a specific synchronization rate. The option can be used to adjust the rate during off-peak hours, or adjust the rate based on measured loads for very long operations.

**Note:**

The `resync` command also has a `--ratePerSecond` option. If this option is not provided, the tool operates at the maximum rate.

Run the `resync` tool first at 100 operations per second, measure the impact on the source servers, then adjust as desired. The file must contain a single positive integer number surrounded by white space. If the file is updated with an invalid number, the rate is not updated.

## Steps

1. Create a text file containing the rate. The number must be a positive integer surrounded by white space.

```
$ echo '100 ' >rate.txt
```

2. Run the `resync` command with the `--ratePerSecondFile` option.

```
$ bin/resync --pipe-name "sun-to-ds-sync-pipe" \
 --ratePerSecondPath rate.txt
```

## Synchronize a specific list of DNs

### About this task

The `resync` command enables synchronizing a specific set of DNs that are read from a file using the `--sourceInputFile` option. This option is useful for large datasets that require faster processing by targeting individual base-level searches for each source DN in the file. If any DN fails (parsing, search, or process errors), the command creates an output file of the skipped entries (`resync-failed-DNs.log`), which can be run again.

The file must contain only a list of DNs in LDIF format with `dn:` or `dn: .`. The file can include comment lines. All DNs can be wrapped and are assumed to be wrapped on any lines that begin with a space followed by text. Empty lines are ignored.

Small files can be created manually. For large files, use `ldapsearch` to create an LDIF file, as follows:

### Steps

1. Run an `ldapsearch` command using the special OID "1.1" extension, which only returns the DNs in the DIT. For example, on the Sync Source directory server, run the following command:

```
$ bin/ldapsearch --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --baseDN dc=example,dc=com \
 --searchScope sub "(objectclass=*)" "1.1" > dn.ldif
```

2. Run the `resync` command with the file.

```
$ bin/resync --pipe-name "sun-to-ds-pipe" \
 --sourceInputFile dn.ldif
```

```
Starting pass 1
[20/Mar/2016:10:32:11 -0500]

Resync pass 1
Source entries retrieved 1999
Entries created 981
Current pass, entries processed 981

0 entries could not be processed due to an error
```

3. View the `logs/tools/resync-failed-DNs.log` to determine skipped DNs. Correct the source DNs file, and rerun the `resync` command.

## Realtime-sync tool

The `bin/realtime-sync` tool controls starting and stopping synchronization globally or for individual Sync Pipes. The tool also provides features to set a specific starting point for real-time synchronization.

To see the current status of real-time synchronization, view the monitor properties: `num-sync-ops-in-flight`, `num-ops-in-queue`, and `source-unretrieved-changes`. For example, use `ldapsearch` to view a specific Sync Pipe's monitor information:

```
$ bin/ldapsearch --baseDN cn=monitor \
--searchScope sub "(cn=Sync PipeMonitor: PIPE_NAME)"
```

The Stats Logger can also be used to view status. See the *PingIdentityPingDirectory Server Administration Guide* for details.

### Start real-time synchronization globally

About this task

The `realtime-sync` tool assumes that the synchronization topology is configured correctly.

Perform the following steps to start real time synchronization globally:

#### Steps

1. Run the tool from the `<server-root>/bin` directory. This example assumes that a single Sync Pipe called "dsee-to-ds-sync-pipe" exists.

```
$ bin/realtime-sync start --pipe-name "dsee-to-ds-sync-pipe" \
--port 389 \
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret
```

2. If more than one Sync Pipe is configured, specify each using the `--pipe-name` option. The following example starts synchronization for a bidirectional synchronization topology.

```
$ bin/realtime-sync start --pipe-name "Sun DS to DS" \
--pipe-name "DS to Sun DS" \
--port 389 \
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret
```

### Start or Pause synchronization

Pause or start synchronization by using the `start` and `stop` subcommands. If synchronization is stopped and then restarted, changes made at the Sync Source while synchronization was stopped will still be detected and applied. Synchronization for individual Sync Pipes can be started or stopped using the `--pipe-name` argument. If the `--pipe-name` argument is omitted, then synchronization is started or stopped globally.

The following command stops all Sync Pipes:

```
$ bin/realtime-sync stop --port 389 \
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret \
--no-prompt
```

If a topology has two Sync Pipes, Sync Pipe1 and Sync Pipe2, the following command stops Sync Pipe1.

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
 --port 389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret --no-prompt
```

## Set startpoints

About this task

Startpoints instruct the Sync Pipe to ignore all changes made prior to the current time. Once synchronization is started, only changes made after this command is run will be detected at the Sync Source and applied at the Sync Destination.

The `set-startpoint` subcommand is often run during the initial setup prior to starting real-time synchronization. It should be run prior to initializing the data in the Sync Destination.

The `set-startpoint` subcommand can start synchronization at a specific change log number, or back at a state that occurred at a specific time. For example, synchronization can start 10 minutes prior to the current time.

Perform the following steps to set a synchronization startpoint:

Steps

1. If started, stop the synchronization topology globally with the following command:

```
$ bin/realtime-sync stop --pipe-name "Sync Pipe1" \
 --port 389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret \
 --no-prompt
```

2. Set the startpoint for the synchronization topology. Any changes made before setting this command will be ignored.

```
$ bin/realtime-sync set-startpoint --pipe-name "Sync Pipe1" \
 --port 389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret \
 --no-prompt \
 --beginning-of-changelog
```

```
Set StartPoint task 2011072109564107 scheduled to start immediately
[21/Jul/2016:09:56:41 -0500] severity="INFORMATION" msgCount=0
msgID=1889535170
message="The startpoint has been set for Sync Pipe 'Sync Pipe1'.
Synchronization will resume from the last change number in the Sync
Source"
Set StartPoint task 2011072109564107 has been successfully completed
```

## Restart synchronization at a specific change log event

About this task

Perform the following steps to restart synchronization at a specific event:

## Steps

1. Search for a specific change log event from which to restart the synchronization state. On one of the endpoint servers, run `ldapsearch` to search the change log.

```
$ bin/ldapsearch -p 1389
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret \
--baseDN cn=changelog \
--dontWrap

"(objectclass=*)"
dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog
dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.13,ou=People,dc=example,dc=com
changeType: modify
changes::
cmVwbGFjZTogcm9vbU51bWJlcgpyb29tTnVtYmVyOiAwMTM4Ci0KcmVwbGFjZTogbW9kaW
ZpZXJzTmFtZQptb2RpZml1cnNOYW11OiBjbj1EaXJlY3RvcnkgTWFuYWdlcixjbj1Sb290
IEROcyxjbj1jb25maWcKLQpyZXBsYWNlOiBkcy11cGRhdGUtdGltZQpkcy11cGRhdGUtdG
ltZTo6IEFBQUJKZ25OWlUwPQotCgA=
changenumber: 1
... (more output)
dn: changeNumber=2329,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.49,ou=People,dc=example,dc=com
changeType: modify
changes::
cmVwbGFjZTogcm9vbU51bWJlcgpyb29tTnVtYmVyOiAwNDMzCi0KcmVwbGFjZTogbW9kaW
ZpZXJzTmFtZQptb2RpZml1cnNOYW11OiBjbj1EaXJlY3RvcnkgTWFuYWdlcixjbj1Sb290
IEROcyxjbj1jb25maWcKLQpyZXBsYWNlOiBkcy11cGRhdGUtdGltZQpkcy11cGRhdGUtdG
ltZTo6IEFBQUJKZ25OMC84PQotCgA=
changenumber: 2329
```

2. Restart synchronization from change number 2329 using the `realtime-sync` tool. Any event before this change number will not be synchronized to the target endpoint.

```
$ bin/realtime-sync set-startpoint \
--change-number 2329 \
--pipe-name "Sync Pipe 1" \
--bindPassword secret \
--no-prompt
```

### Change the synchronization state by a specific time duration

The following command will start synchronizing data at the state that occurred 2 hours and 30 minutes prior to the current time on External Server 1 for Sync Pipe 1. Any changes made before this time will not be synchronized. Specify days (d), hours (h), minutes (m), seconds (s), or milliseconds (ms).

Use `realtime-sync` with the `--startpoint-rewind` option to set the synchronization state and begin synchronizing at the specified time.

```
$ bin/realtime-sync set-startpoint \
--startpoint-rewind 2h30m \
--pipe-name "Sync Pipe 1" \
--bindPassword secret \
```

```
--no-prompt
```

## Schedule a real-time sync as a task

### About this task

The `realtime-sync` tool features both an offline mode of operation as well as the ability to schedule an operation to run within PingDataSync Server's process. To schedule an operation, supply LDAP connection options that allow this tool to communicate with the server through its task interface. Tasks can be scheduled to run immediately or at a later time. Once scheduled, tasks can be managed using the `manage-tasks` tool.

Perform the following steps to schedule a synchronization task:

### Steps

1. Use the `--start` option with the `realtime-sync` command to schedule a start for the synchronization topology. The following command will set the start time at July 21, 2016 at 12:01:00 AM. The scheduled task can be stopped with the `--stop` subcommand.

```
$ bin/realtime-sync set-startpoint \
 --pipe-name "sun-to-ds-sync-pipe" \
 --port 389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret \
 --start 20150721000100 \
 --no-prompt
```

```
Set StartPoint task 2009072016103807 scheduled to start Jul 21, 2016
12:01:00 AM CDT
```

2. Run the `manage-tasks` tool to manage or cancel the task.

```
$ bin/manage-tasks --port 7389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret
```

## Configure the PingDirectory Server backend for synchronizing deletes

### About this task

The PingDirectory Server's change log backend's `changelog-deleted-entry-include-attribute` property specifies which attributes should be recorded in the change log entry during a DELETE operation. Normally, PingDataSync Server cannot correlate a deleted entry to the entry on the destination. If a Sync Class is configured with a filter, such as `"include-filter: objectClass=person,"` the `objectClass` attribute must be recorded in the change log entry. Special correlation attributes (other than DN), will also need to be recorded on the change log entry to be properly synchronized at the endpoint server.

On each PingDirectory Server backend, use the `dsconfig` command to set the property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
 --set changelog-deleted-entry-include-attribute:objectClass
```

If the destination endpoint is an Oracle/Sun DSEE (or Sun DS) server, the Sun DSEE server does not store the value of the user deleting the entry, specified in the modifiers name attribute. It only stores the value of the user who last modified the entry while it still existed.

To set up a Sun DSEE destination endpoint to record the user who deleted the entry, use the Ping Identity Server SDK to create a plugin, as follows:

### Steps

1. Update the Sun DSEE schema to include a `deleted-by-syncauxiliary` objectclass. It will only be used as a marker objectclass, and not require or allow additional attributes to be present on an entry.
2. Update the Sun DSEE Retro Change Log plugin to include the `deleted-by-sync` auxiliary objectclass as a value for the `deletedEntryAttrs` attribute.
3. Write an `LDAPSyncDestinationPlugin` script that in the `preDelete()` method modifies the entry that is being deleted to include the `deleted-by-sync` objectclass.
4. Update the Sync Class filter that is excluding changes by the Sync User to also include `(!(objectclass=deleted-by-sync))`.

## Configure DN maps

Similar to attribute maps, DN maps define mappings when destination DNs differ from source DNs. These differences must be resolved using DN maps in order for synchronization to successfully take place. For example, the Sync Source could have a DN in the following format:

```
uid=jdoe,ou=People,dc=example,dc=com
```

While the Sync Destination could have the standard X.500 DN format.

DN mappings allow the use of wild cards for DN transformations. A single wild card (\*) matches a single RDN component and can be used any number of times. The double wild card (\*\*) matches zero or more RDN components and can be used only once.

### Note:

If a literal '\*' is required in a DN then it must be escaped as '\2A'.

The wild card values can be used in the `to-dn-pattern` attribute using `{1}` to replace their original index position in the pattern, or `{attr}` to match an attribute value. For example:

```
*,**,dc=com->{1},ou=012,o=example,c=us
```

For example, using the DN, `uid=johndoe,ou=People,dc=example,dc=com`, and mapping to the target DN, `uid=johndoe,ou=012,o=example,c=us`:

- "\*" matches one RDN component, `uid=johndoe`
- "\*\*" matches zero or more RDN components, `ou=People,dc=example`
- "dc=com" matches `dc=com` in the DN.

The DN is mapped to the `{1},ou=012,o=example,c=us`. "{1}" substitutes the first wildcard element "uid=johndoe", so that the DN is successfully mapped to:

```
uid=johndoe,ou=012,o=example,c=us
```

Regular expressions and attributes from the user entry can also be used in the `to-dn-pattern` attribute. For example, the following expression constructs a value for the `uid` attribute, which is the RDN, out of the initials (first letter of given name and `sn`) and the employee ID (the `eid` attribute) of a user.

```
uid={givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid},{2},o=example
```

### Note:

PingDataSync Server automatically validates any DN mapping prior to applying the configuration.

## Configure a DN map by using dsconfig

### About this task

A DN map can be configured using `dsconfig`, either with the interactive DN Map menu, or from the command line.

Perform the following to configure a DN map:

### Steps

1. Use `dsconfig` to create a DN map for PingDataSync Server.

```
$ bin/dsconfig --no-prompt create-dn-map \
 --map-name nested-to-flattened \
 --set "from-dn-pattern:*,*,dc=example,dc=com" \
 --set "to-dn-pattern:uid={givenname:/^(.) (.*)/\$1/s}{sn:/^(.) (.*)/\$1/s}
(eid},{2},o=example" \
 --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret
```

2. After DN mappings are configured, add the new DN map to a new Sync Class or modify an existing Sync Class.

```
$ bin/dsconfig --no-prompt set-sync-class-prop \
 --pipe-name test-sync-pipe \
 --class-name test-sync-class \
 --set dn-map:test-dn-map \
 --port 389 --bindDN "uid=admin,dc=example,dc=com" \
 --bindPassword secret
```

## Configure synchronization with JSON attribute values

PingDataSync Server supports synchronization of attributes that hold JSON objects. The following scenarios are supported:

- Synchronizing a JSON attribute to another JSON attribute - A subset of fields can be synchronized, optionally retaining fields that appear at the destination but not at the source.
- Synchronizing a JSON attribute to a non-JSON attribute - A single field of the JSON value can be extracted with a constructed attribute mapping.
- **Synchronizing a non-JSON attribute to a JSON attribute** - The source value can be escaped so that it ensures the JSON value is properly formatted.
- **Attribute correlation** - A JSON field can be used when correlating a destination entry with a source entry.

The following examples show configuration scenarios based on the LDAP `ubidEmailJSON` attribute, which has fields of `value`, `type`, `primary`, and `verified`:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home",
 "primary" : true,
 "verified" : true}
```

### Synchronize ubidEmailJSON fully

If a source JSON attribute value should be synchronized fully to a destination JSON attribute value, no special configuration is required.

### Synchronize a subset of fields from the source attribute

For example, the following configuration can be used to synchronize the `value` and `type` fields of `ubidEmailJSON` from the source to a destination. To synchronize this source value:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home",
 "primary" : true}
```

to this value at the destination:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home"}
```

A JSON Attribute configuration object must be created and associated with the Sync Class. This can be done by either explicitly including the fields to synchronize:

```
$ bin/dsconfig create-json-attribute --pipe-name "A to B" \
 --class-name Users \
 --attribute-name ubidEmailJSON \
 --set include-field:type \
 --set include-field:value
```

Or by excluding the fields that should not be synchronized:

```
$ bin/dsconfig create-json-attribute \
 --pipe-name "A to B" \
 --class-name Users \
 --attribute-name ubidEmailJSON \
 --set exclude-field:preferred \
 --set exclude-field:verified
```

If the destination is prepared to only handle a specific subset of fields, then list the fields to include. However, if only a small, known subset of fields from the source should be excluded, then `exclude-field` could be used. In this example, the destination data for the `ubidEmailJSON` attribute will always be a subset of the full data.

#### **Note:**

A Sync Class can be configured to exclude certain attributes from synchronization. Creating a regular attribute mapping will override this setting, and the attribute will be synchronized. Creating a JSON attribute mapping does not override this setting, and the JSON attribute will not be synchronized. A JSON attribute is not a traditional attribute mapping. It only includes information on the destination attribute name. To work around this, the attribute either needs to be mapped from a source attribute, or have its value constructed.

The following scenario illustrates how the destination can include additional fields that are not present at the source.

### Retain destination-only fields

To synchronize changes to the source fields while preserving the value of the `verified` field of the `ubidEmailJSON` attribute at the destination, configure the JSON Attribute as follows:

```
$ bin/dsconfig create-json-attribute \
 --pipe-name "A to B" \
```

```
--class-name Users \
--attribute-name ubidEmailJSON \
--set id-field:value \
--set exclude-field:verified
```

The `verified` field is excluded and `value` is chosen to correlate destination values with source values. For example, given that the source and destination `value` fields match, if the source initially contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home"}
```

and the destination contained:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home",
 "verified" : true},
```

if the source changed to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "other"}
```

then the destination would change to:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "other",
 "verified" : true}
```

However, if the source changed to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
 "type" : "home"}
```

then the destination would be updated to:

```
ubidEmailJSON: {"value" : "john.smith@example.com",
 "type" : "home"}
```

The `verified` field has been dropped because this logically represents a new JSON object rather than an update of an existing one.

### Synchronize a field of a JSON attribute into a non-JSON attribute

If the source stores:

```
ubidEmailJSON: {"value" : "jsmith@example.com",
 "type" : "home"}
```

but the destination stores:

```
mail: jsmith@example.com
```

To synchronize changes between these systems, a constructed attribute mapping must be configured:

```
$ bin/dsconfig create-attribute-mapping \
--map-name "Attribute Map" \
--mapping-name mail \
--type constructed \
--set "value-pattern:{ubidEmailJSON.value}"
```

The `value-pattern` syntax allows attributes to be referenced by placing them in `{}`. JSON fields within the attribute can be referenced by using the syntax `{attribute.field}`. See this property in the Configuration Reference guide, or `dsconfig` tool command help for more information.

After the “Attribute Map” is created, it can be referenced from the Sync Class:

```
$ bin/dsconfig set-sync-class-prop
 --pipe-name "A to B" \
 --class-name Users \
 --set "attribute-map:Attribute Map"
```

**Note:**

While LDAP attribute names are not case sensitive, the JSON field names are. By default, errors related to attribute mapping are not logged. To enable error logging, configure the Debug Logger with the following:

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Debug Logger" \
 --set enabled:true
```

```
$ bin/dsconfig create-debug-target \
 --publisher-name "File-Based Debug Logger" \
 --target-name com.unboundid.directory.sync.mapping \
 --set debug-level:warning
```

### Synchronize a non-JSON attribute into a field of a JSON attribute

This scenario provides a reversal of the previous example. The source stores the following information:

```
mail: jsmith@example.com
```

but the destination stores the following information:

```
ubidEmailJSON: {"value" : "jsmith@example.com"}
```

To construct an attribute value that functions as a JSON object, use *JSON attribute mapping* and *JSON attribute mapping field* configuration objects. The following code provides an example:

```
bin/dsconfig create-attribute-mapping --map-name "Attr Map" \
 --mapping-name ubidEmailJSON \
 --type json

bin/dsconfig create-json-attribute-mapping-field --map-name "Attr Map" \
 --mapping-name ubidEmailJSON \
 --field-name "value" \
 --from-attribute mail
```

For more information about these configuration object types, refer to the configuration reference guide.

You can also use a constructed attribute mapping to construct a JSON attribute value as a raw string, as follows:

```
$ bin/dsconfig create-attribute-mapping \
 --map-name "Attr Map" \
 --mapping-name ubidEmailJSON \
 --type constructed \
 --set 'value-pattern:{"value" : "{mail:jsonEscape}"}'
```

When constructing a value, be aware of the following points:

- Double curly brackets ( {{ }} ) are necessary to represent a single curly bracket ( { } ) in the output. These brackets are typically used to reference attribute values.
- Use the `:jsonEscape` modifier to escape attribute values that appear within a JSON attribute. This step prevents values that include quotes like `'"John Smith" <jsmith@example.com>'` from producing invalid JSON.

In the following example, a JSON Attribute object must be created because the destination value is likely to be augmented with additional information:

```
$ bin/dsconfig create-json-attribute \
 --pipe-name "A to B" \
 --class-name Users \
 --attribute-name ubidEmailJSON \
 --set id-field:value \
 --set include-field:value
```

### Synchronize multiple non-JSON attributes into fields of a JSON attribute

Multiple JSON fields can be defined within a single JSON attribute. For any source attribute that does not exist, the corresponding JSON field is omitted from the JSON attribute. The following code demonstrates the mapping of a standard LDAP schema into the standard PingOne user schema.

```
dsconfig create-attribute-map \
 --map-name PingDirectory_to_PingOne_User_Map
...
dsconfig create-attribute-mapping \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --type json
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name formatted \
 --set from-attribute:cn \
 --json-type string
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name given \
 --set from-attribute:givenName \
 --json-type string
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name family \
 --set from-attribute:sn \
 --json-type string
```

### Correlating attributes based on JSON fields

When the destination of a Sync Pipe is a Ping Directory Server or PingDirectoryProxy Server, source and destination entries can be correlated by referencing a field within a JSON attribute. In the following

example, source entries will be matched with destination entries that have the same `value` field within the `ubidEmailJSON` value.

```
$ bin/dsconfig set-sync-class-prop \
 --pipe-name "A to B" \
 --class-name Users \
 --set destination-correlation-attributes:ubidEmailJSON.value
```

This could also be used with the previous example, which does not store `ubidEmailJSON.value` at the source but maps into it before correlating at the destination.

## Configure fractional replication

### About this task

PingDataSync Server supports fractional replication to any server type. For example, if a replica only performs user authentications, PingDataSync Server can be configured to propagate only the `uid` and `userpassword` password policy attributes, reducing the database size at the replica and the network traffic needed to keep this servers synchronized.

The following example configures a fractional replication, where the `uid` and `userPassword` attributes of all entries in the source topology are synchronized to the destination topology. Because the `uid` and `userPassword` attributes are present, the `objectclass` attribute must also be synchronized. The example assumes that PingDataSync Server and the external servers are configured and a Sync Pipe and Sync Class are defined, but real-time synchronization or bulk resync have not been performed.

Perform the following steps to configure fractional replication from the `dsconfig` interactive menu:

### Steps

1. On the main menu, type the number corresponding to Sync Classes.
2. On the Sync Class menu, type the number corresponding to viewing and editing an existing Sync Class. Assume that only one Sync Class has been defined.
3. Verify that the Sync Pipe and Sync Class exist.
4. On the SyncClass Properties menu, type the number specifying the source LDAP filter (`include-filter` property) that defines which source entries are to be included in the Sync Class.
5. On the Include-Filter Property menu, type the number corresponding to adding a filter value. For this example, type (`objectclass=person`). When prompted, enter another filter. Press Enter to continue. On the menu, enter 1 to use the value when specifying it.
6. On the SyncClass Properties menu, type the number corresponding to the `auto-mapped-source-attribute` property. Change the value from `"-all-"` to a specific attribute, so that only the specified attribute is automatically mapped from the source topology to the destination topology.
7. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to adding the source attributes that will be automatically mapped to the destination attributes of the same name. When prompted, enter each attribute, and then press Enter.

```
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: uid
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: userPassword
Enter another value for the 'auto-mapped-source-attribute' property
[continue]: objectclass
Enter another value for the 'auto-mapped-source-attribute' property
[continue]:
```

8. On the Auto-Mapped-Source-Attribute Property menu, type the number corresponding to removing one or more values. In this example, remove the `"-all-"` value, so that only the `objectclass`, `uid`, and `userPassword` attributes are only synchronized.

9. On the Auto-Mapped-Source-Attribute Property menu, press Enter to accept the values.
10. On the Sync Class Properties menu, type the number corresponding to excluding some attributes from the synchronization process. When using the `objectclass=person` filter, the `cn`, `givenName`, and `sn` attributes must be excluded. Enter the option to add one or more attributes, and then add each attribute to exclude on the `excluded-auto-mapped-source-attributes` Property menu. For this example, exclude the `cn`, and `sn` attributes, which are required attributes of the `Person` objectclass. Also exclude the `givenName` attribute, which is an optional attribute of the `inetOrgPerson` objectclass.

```
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: givenName
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]: sn
Enter another value for the 'excluded-auto-mapped-source-attributes'
property
[continue]:
```

11. On the Excluded-Auto-Mapped-Source-Attributes Property menu, press Enter to accept the changes.

**Note:**

If using `entryUUID` as a correlation attribute, some attribute uniqueness errors may occur while using the `resync` tool. Either set the `excluded-auto-mapped-source-attributes` property value to `entryUUID` on the Sync Class configuration menu, or run `resync` with the `--excludeDestinationAttr entryUUID` argument.

12. On the Sync Class Properties menu, review the configuration and accept the changes.
13. On the server instances in the destination topology, turn off schema checking to avoid a schema error that occurs when the required attributes in the `Person` objectclass are not present. Make sure that the global configuration property for the `server-group` is set to `all-servers`. Use the following command to turn off schema checking on all of the servers in the group.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
--set check-schema:false \
--applyChangeTo server-group \
--port 3389 \
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret
```

14. Run `bin/resync` to load the filtered data from the source endpoint to the target endpoint.

```
$ bin/resync --pipe-name "test-sync-pipe" \
--numPasses 3
```

15. Run `bin/realtime-sync` to start synchronization.

```
$ bin/realtime-sync start --pipe-name "test-sync-pipe" \
--port 7389 \
--bindDN "uid=admin,dc=example,dc=com" \
--bindPassword secret \
--no-prompt
```

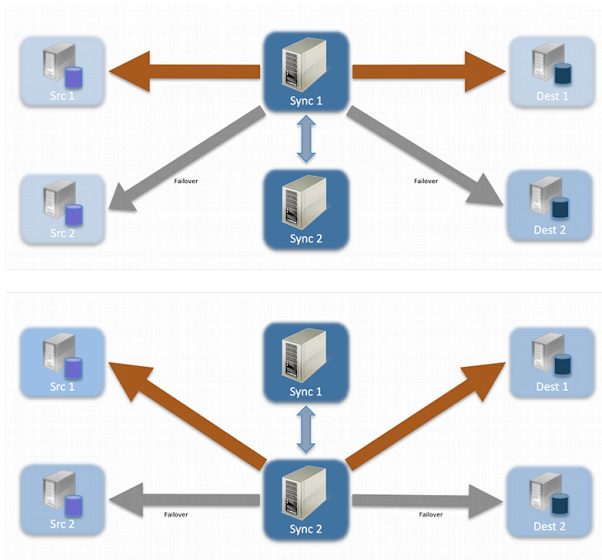

## Configure failover behavior

The following illustrates a simplified synchronization topology with a single failover server on the source, destination, and PingDataSync Server, respectively. The gray lines represent possible failover connections

in the event the server is down. The external servers are prioritized so that src1 has higher priority than src2; dest1 has higher priority than dest2.

The main PingDataSync Server and its redundant failover instance communicate with each other over LDAP and bind using `cn=IntraSync User,cn=Root DNs,cn=config`. The servers run periodic health checks on each other and share information on all changes that have been processed. Whenever the failover server loses connection to the main server, it assumes that the main server is down and begins processing changes from the last known change. Control reverts back to the main server once it is back online.

Unlike the PingDataSync Servers, the external servers and their corresponding failover server(s) do not run periodic health checks. If an external server goes offline, the failover server will receive transactions and remain connected to PingDataSync Server until the Sync Pipe is restarted, regardless of if the main external server comes back online.

### Conditions that trigger immediate failover

Immediate failover occurs when PingDataSync Server receives one of the following error codes from an external server:

- BUSY (51)
- UNAVAILABLE (52)
- SERVER CONNECTION CLOSED (81)
- CONNECT ERROR (91)

If PingDataSync Server attempts a write operation to a target server that returns one of these error codes, PingDataSync Server will automatically fail over to the next highest prioritized server instance in the target topology, issue an alert, and then reissue the retry attempt. If the operation is unsuccessful for any reason, the server logs an error.

### Failover server preference

PingDataSync Server supports endpoint failover, which is configurable using the `location` property on the external servers. By default, PingDataSync Server prefers to connect to and failover to endpoint servers in the same location as itself. If no location settings are configured, PingDataSync Server will iterate through the configured list of external servers on the Sync Source and Sync Destination when failing over.

PingDataSync Server does not perform periodic health checks of external servers, and does not failover automatically to a preferred external server. Due to the cost of sync failover, PingDataSync Server remains connected to a given server until the server stops responding or until the Sync Pipe is restarted. When

a failover occurs, PingDataSync Server returns to the most preferred server, optionally using location settings to identify it, and works its way down the list. The following provides an example configuration of external servers:

```
austin1.server.com:1389
london1.server.com:2389
boston1.server.com:3389
austin2.server.com:4389
boston2.server.com:5389
london2.server.com:6389
```

If the austin1 server were to become unavailable, PingDataSync Server will automatically pick up changes on the next server on the list, london1. If london1 is also down, then the next server, boston1 will be picked up. After PingDataSync Server iterates through the list, it returns to the top of the list. If PingDataSync Server is connected to london2 and it goes down, it will fail over to austin1.

To minimize WAN traffic, configure the `location` property for each external server using the `dsconfig` command on PingDataSync Server. Assume that PingDataSync Server has its own `location` property (set in the Global Configuration) set to "austin."

```
austin1.server.com:1389 location=austin
london1.server.com:2389 location=london
boston1.server.com:3389 location=boston
austin2.server.com:4389 location=austin
boston2.server.com:5389 location=boston
london2.server.com:6389 location=london
```

With the `location` property set for each server, PingDataSync Server gets its changes from server austin1. If austin1 goes down, PingDataSync Server will pick up changes from austin2. If austin2 goes down, the server will iterate through the rest of the list in the order it is configured.

The `location` property has another sub-property, `preferred-failover-location` that specifies a set of alternate locations if no servers in this location are available. If multiple values are provided, servers are tried in the order in which the locations are listed. The `preferred-failover-location` property provides more control over the failover process and allows the failover process to jump to a specified location. Care must be used so that circular failover reference does not take place. Here is an example configuration:

```
austin1.server.com:1389 location=austin preferred-failover-location=boston
london1.server.com:2389 location=london preferred-failover-location=austin
boston1.server.com:3389 location=boston preferred-failover-location=london
austin2.server.com:4389 location=austin preferred-failover-location=boston
boston2.server.com:5389 location=boston preferred-failover-location=austin
london2.server.com:6389 location=london preferred-failover-location=london
```

PingDataSync Server will respect the `preferred-failover-location` if it cannot find any external servers in the same location as itself, it will look for any external servers in its own `preferred-failover-location`. In this example, when austin1 becomes unavailable, it will fail over to austin2 because they are in the same location. If austin2 is unavailable, it will fail over to boston1, which is in the `preferred-failover-location` of PingDataSync Server. If boston1 is unavailable, PingDataSync Server will fail over to boston2, and finally, it will try the london1 and london2 servers.

### Configuration properties that control failover behavior

There are four important advanced properties to fine tune the failover mechanism:

- `max-operation-attempts` (Sync Pipe)
- `response-timeout` (source and destination endpoints)
- `max-failover-error-code-frequency` (source and destination endpoints)
- `max-backtrack-replication-latency` (source endpoints only)

These properties apply to the following LDAP error codes:

### LDAP Error Codes

Error Code	Description
ADMIN_LIMIT_EXCEEDED(11)	Indicates that processing on the requested operation could not continue, because an administrative limit was exceeded.
ALIAS_DEREFERENCING_PROBLEM (36)	Indicates that a problem was encountered while attempting to dereference an alias for a search operation.
CANCELED(118)	Indicates that a cancel request was successful, or that the specified operation was canceled.
CLIENT_SIDE_LOCAL_ERROR(82)	Indicates that a local (client-side) error occurred.
CLIENT_SIDE_ENCODING_ERROR(83)	Indicates that an error occurred while encoding a request.
CLIENT_SIDE_DECODING_ERROR(84)	Indicates that an error occurred while decoding a request.
CLIENT_SIDE_TIMEOUT(85)	Indicates that a client-side timeout occurred.
CLIENT_SIDE_USER_CANCELLED(88)	Indicates that a user canceled a client-side operation.
CLIENT_SIDE_NO_MEMORY(90)	Indicates that the client could not obtain enough memory to perform the requested operation.
CLIENT_SIDE_CLIENT_LOOP(96)	Indicates that a referral loop is detected.
CLIENT_SIDE_REFERRAL_LIMIT_EXCEEDED (97)	Indicates that the referral hop limit was exceeded.
DECODING_ERROR(84)	Indicates that an error occurred while decoding a response.
ENCODING_ERROR(83)	Indicates that an error occurred while encoding a response.
INTERACTIVE_TRANSACTION_ABORTED (30221001)	Indicates that an interactive transaction was aborted.
LOCAL_ERROR(82)	Indicates that a local error occurred.
LOOP_DETECT(54)	Indicates that a referral or chaining loop was detected while processing a request.
NO_MEMORY(90)	Indicates that not enough memory could be obtained to perform the requested operation.
OPERATIONS_ERROR(1)	Indicates that an internal error prevented the operation from being processed properly.
OTHER (80)	Indicates that an error occurred that does not fall into any of the other categories.

Error Code	Description
PROTOCOL_ERROR(2)	Indicates that the client sent a malformed or illegal request to the server.
TIME_LIMIT_EXCEEDED(3)	Indicates that a time limit was exceeded while attempting to process the request.
TIMEOUT(85)	Indicates that a timeout occurred.
UNWILLING_TO_PERFORM(53)	Indicates that the server is unwilling to perform the requested operation.

### The max-operation-attempts property

The `max-operation-attempts` property (part of the Sync Pipe configuration) specifies the maximum number of times to retry a synchronization operation that fails for reasons other than the Sync Destination being busy, unavailable, server connection closed, or connect error.

To change the default number of retries, use `dsconfig` in non-interactive mode to change the `max-operation-attempts` value on the Sync Pipe object. The following command changes the number of maximum attempts from five (default) to four.

```
$ bin/dsconfig set-sync-pipe-prop \
 --pipe-name "Test Sync Pipe" \
 --set max-operation-attempts:4
```

### The response-timeout property

The `response-timeout` property specifies how long PingDataSync Server should wait for a response from a search request to a source server before failing with LDAP result code 85 (client-side timeout). When a client-side timeout occurs, the Sync Source will retry the request according to the `max-failover-error-code-frequency` property before failing over to a different source server and performing the retry. The total number of retries will not exceed the `max-operation-attempts` property defined in the Sync Pipe configuration. A value of zero indicates that there should be no client-side timeout. The default value is one minute.

Assuming a bidirectional topology, the property can be set with `dsconfig` on the Sync Source and Sync Destination, respectively.

```
$ bin/dsconfig set-sync-source-prop \
 --source-name src \
 --set "response-timeout:8 s"
```

```
$ bin/dsconfig set-sync-destination-prop \
 --destination-name U4389 \
 --set "responsetimeout:9 s"
```

### The max-failover-error-code-frequency property

The `max-failover-error-code-frequency` property (part of the Sync Source configuration) specifies the maximum time period that an error code can re-appear until it fails over to another server instance.

This property allows the retry logic to be tuned, so that retries can be performed once on the same server before giving up and trying another server. The value can be set to zero if there is no acceptable error code frequency and failover should happen immediately. It can also be set to a very small value (such as 10 ms) if a high frequency of error codes is tolerable. The default value is three minutes.

To change the `max-failover-error-code-frequency` property, use `dsconfig` in non-interactive mode to change the property on the Sync Source object. The following command changes the frequency from three minutes to two minutes.

```
$ bin/dsconfig set-sync-source-prop \
 --source-name source1 \
 --set "max-failover-error-code-frequency:2 m"
```

### The `max-backtrack-replication-latency` property

The `max-backtrack-replication-latency` property (part of the Sync Source configuration) sets the time period that PingDataSync Server will look for missed changes in the change log due to replication delays. The property should be set to a conservative upper-bound of the maximum replication delay between two servers in the topology. A value of zero implies that there is no limit on the replication latency. The default value is two hours. PingDataSync Server stops looking in the change log once it finds a change that is older than the maximum replication latency than the last change it processed on the failed server.

For example, after failing over to another server, PingDataSync Server must look through the new server's change log to find the equivalent place to begin synchronizing changes.

Normally, PingDataSync Server can successfully backtrack with only a few queries of the directory, but in some situations, it might have to look further back through the change log to make sure that no changes were missed. Because the changes can come from a variety of sources (replication, synchronization, and over LDAP), the replicated changes between directory servers are interleaved in each change log. When PingDataSync Server fails over between servers, it has to backtrack to figure out where synchronization can safely pick up the latest changes.

Backtracking occurs until the following:

- The server determines that there is no previous change log state available for any source servers, so it must start at the beginning of the change log.
- The server finds the last processed replication change sequence number (CSN) from the last time it was connected to that replica, if at all. This process is similar to the `set-startpoint` functionality on the `realtime-sync` tool.
- The server finds the last processed replication CSN from every replica that has produced a change so far, and it determines that each change entry in the next oldest batch of changes has already been processed.
- The server finds a change that is separated by more than a certain duration (specified by the `max-backtrack-replication-latency` property) from the most recently processed change.

The following command changes the maximum backtracking from two hours to three hours.

```
$ bin/dsconfig set-sync-source-prop \
 --source-name source1 \
 --set "max-backtrack-replication-latency:3 h"
```

## Configure traffic through a load balancer

If a PingData server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address should be recorded to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and the PingData server. See the product documentation for the device type. For PingData servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP) and set `use-forwarded-headers` to `true`.
- When `use-forwarded-headers` is set to `true`, the server will use the client IP address and port information in the `X-Forwarded-*` headers instead of the address and port of the entity that's actually

sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

## Configure authentication with a SASL external certificate

### About this task

By default, PingDataSync Server authenticates to the PingDirectory Server using LDAP simple authentication (with a bind DN and a password). However, PingDataSync Server can be configured to use SASL EXTERNAL to authenticate to the PingDirectory Server with a client certificate.

#### **Note:**

This procedure assumes that PingDataSync Server instances are installed and configured to communicate with the backend PingDirectory Server instances using either SSL or StartTLS.

After the servers are configured, perform the following steps to configure SASL EXTERNAL authentication:

### Steps

1. Create a JKS keystore that includes a public and private key pair for a certificate that the PingDataSync Server instance(s) will use to authenticate to the PingDirectory Server instance(s). Run the following command in the instance root of one of the PingDataSync Server instances. When prompted for a keystore password, enter a strong password to protect the certificate. When prompted for the key password, press ENTER to use the keystore password to protect the private key:

```
$ keytool -genkeypair \
 -keystore config/sync-user-keystore \
 -storetype JKS \
 -keyalg RSA \
 -keysize 2048 \
 -alias sync-user-cert \
 -dn "cn=Sync User,cn=Root DNs,cn=config" \
 -validity 7300
```

2. Create a `config/sync-user-keystore.pin` file that contains a single line that is the keystore password provided in the previous step.
3. If there are other PingDataSync Server instances in the topology, copy the `sync-user-keystore` and `sync-user-keystore.pin` files into the `config` directory for all instances.
4. Use the following command to export the public component of the user certificate to a text file:

```
$ keytool -export \
 -keystore config/sync-user-keystore \
 -alias sync-user-cert \
 -file config/sync-user-cert.txt
```

5. Copy the `sync-user-cert.txt` file into the `config` directory of all PingDirectory Server instances. Import that certificate into each server's primary trust store by running the following command from the server root. When prompted for the keystore password, enter the password contained in the `config/truststore.pin` file. When prompted to trust the certificate, enter `yes`.

```
$ keytool -import \
 -keystore config/truststore \
 -alias sync-user-cert \
 -file config/sync-user-cert.txt
```

- Update the configuration for each PingDataSync Server instance to create a new key manager provider that will obtain its certificate from the `config/sync-user-keystore` file. Run the following `dsconfig` command from the server root:

```
$ dsconfig create-key-manager-provider \
 --provider-name "Sync User Certificate" \
 --type file-based \
 --set enabled:true \
 --set key-store-file:config/sync-user-keystore \
 --set key-store-type:JKS \
 --set key-store-pin-file:config/sync-user-keystore.pin
```

- Update the configuration for each LDAP external server in each PingDataSync Server instance to use the newly-created key manager provider, and also to use SASL EXTERNAL authentication instead of LDAP simple authentication. Run the following `dsconfig` command:

```
$ dsconfig set-external-server-prop \
 --server-name dsl.example.com:636 \
 --set authentication-method:external \
 --set "key-manager-provider:Sync User Certificate"
```

#### Next steps

After these changes, PingDataSync Server should re-establish connections to the LDAP external server and authenticate with SASL EXTERNAL. Verify that PingDataSync Server is still able to communicate with all backend servers by running the `bin/status` command. All of the servers listed in the "--- LDAP External Servers ---" section should have a status of `Available`. Review the PingDirectory Server access log can to make sure that the BIND RESULT log messages used to authenticate the connections from PingDataSync Server include `authType="SASL"`, `saslMechanism="EXTERNAL"`, `resultCode=0`, and `authDN="cn=Sync User,cn=RootDNs,cn=config"`.

## Configure an LDAPv3 Sync Source

Synchronization can be performed with an LDAP V3-compliant source, such as IBM SDS (Tivoli Directory Server), Oracle Unified Directory, DSEE, or OpenDJ, by configuring a Generic LDAP Sync Source. PingDataSync Server relies on the source server having a `cn=changelog` implementation. If the server does not have a `cn=changelog` implementation, a Server SDK Change Detector extension can be configured to define the change detection criteria that PingDataSync Server should use.

If multiple Generic LDAP Sync Source instances are defined, the order in which they are added is used as a priority order for failover. If server locations are defined, PingDataSync Server will always fail over to servers that are in the same location. If there are multiple Sync Sources in the same location as PingDataSync Server, then PingDataSync Server will fail over to the first local server in the list and proceed down the list.

During synchronization, when a change is detected by PingDataSync Server, the changed entry is fetched from the source. Initially, the DN of the entry is used to search for the entry. If that search fails then a second search is performed using the `unique-id-attribute` if it is defined. This is typically an operational attribute that is automatically generated by the server, such as `entryUUID`.

## Server SDK extensions

Custom server extensions can be created with the Server SDK. Extension bundles are installed from a .zip archive or a file system directory. Use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

 **Note:**

The `manage-extension` tool must be used with Java extensions packaged using the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation.

The Server SDK enables creating extensions for all PingData servers. Cross-product extensions include:

- Access loggers
- Alert handlers
- Error loggers
- Key Manager providers
- Monitor providers
- Trust Manager providers
- OAuth token handlers
- Manage extension plugins

## Synchronize with PingOne for Customers

---

PingDataSync Server supports PingOne for Customers as a synchronization destination and source for newly created or modified accounts with native password changes between directory servers, relational databases, or other PingOne for Customers systems.

This chapter presents configuration procedures for synchronization between PingDirectory Server, Nokia 8661 Directory Server, or other LDAP source servers or targets with PingOne for Customers.

### Prerequisites

Before attempting to synchronize changes to or from a PingOne for Customers environment, make certain the prerequisites in this section are satisfied.

#### Worker application

A Worker application is an administrator application that can have the same roles as human administrators. You can use Worker applications to create a userless service app that can perform administrator functions. Role assignments determine the functions that the app can perform.

#### Required grant type

By default, Worker applications are configured with the required Client Credentials grant type. They can also be configured to support additional grant/response types, similar to the other app types.

The Worker application can also perform administrator functions with the role of its user. To accomplish this task, give the app one or more additional grant types, which are used instead of the role assignments.

#### Required roles

A role is a collection of permissions that can be assigned to a user. Of the many roles that PingOne for Customers includes by default, only the Identity Data Admin role, which manages identities and identity data, is required for the Worker app that you need to create. Permissions center around managing user identities and include functions like creating users, resetting a user's password, and creating, editing, and deleting populations.

#### Create a Worker application

Before you create a Worker application, make certain you have the following information ready:

- The app name and description
- Redirect URLs for authentication (required for interactive applications only)

Perform the following steps to create a Worker app:

1. At the top of the **Administrator Console**, click **Connections**.
2. Click **Applications**, and then click **+ Application**.
3. From the list of application types, select **Worker**.
4. Click **Configure** to view the **Create App Profile** page.
5. Specify the following information:
  - Application name – Unique identifier for the app.
  - Optional: Description – Brief characterization of the app.
  - Optional: Icon – Pictorial representation of the app. Use a file up to 1MB in JPG, JPEG, GIF, or PNG format.
6. Click **Save and Close**.
 

The app is displayed on the **Applications** page.
7. Make note of the OAuth client ID, which appears directly below the name of the app.
 

This value is required when creating a PingOne for Customers sync destination or source.
8. From the drop-down list to the right of the app, select **Edit** (Pencil).
9. Click **Configuration**.
10. In the **Basic Configuration** section, make a note of the client secret.
 

This value is required when creating a PingOne for Customers sync destination or source.
11. In the **Advanced Configuration** section, make the following selections:
  - For grant type, select **Client Credentials**.
  - For a token endpoint authentication method, select **Client Secret Post**.
12. Click **Save**.
13. In the upper-left corner, click **To Application List**.
14. Enable the app by toggling the corresponding on/off switch.
 

The switch appears green when the app is enabled.
15. At the top of the **Administrator Console**, click **Settings**.
16. In the navigation panel to the left, click **Environment# ># Properties**.
17. Make note of the environment ID.
 

This value is required when creating a PingOne for Customers sync destination or source.

For more information, refer to [PingOne for Customers Administration Guide](#).

### PingOne user resource model

A user resource is a unique identity within PingOne that interacts with the applications and services in the environment to which the user is assigned. Users are associated with an environment and a population, and the service implements directory functions to create, read, update, delete, and search for user resources. For more information, refer to the [Users data model](#) or to the [PingOne for Customers API Guide](#).

The **username** field is required with the PingOne user resource model. This field is a string that specifies the user name, which must be unique within an environment. Limited to 128 characters in length, the **username** must be a well-formed email address or a string of any Unicode letter, mark (like an accent or umlaut), dot, underscore, or hyphen.

## Synchronize changes to a PingOne for Customers environment

This section describes the configuration that is necessary to synchronize changes to a PingOne for Customers environment. To view an example configuration, refer to the file `reference-ping-one-sync-destination-configuration.dsconfig`, which is located in the folder named `resources`.

## Create a PingOne for Customers sync destination

Before you create a PingOne for Customers sync destination, make certain you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

For information about obtaining these values, see "Create a worker application" in [Worker application](#).

The following sample creates a PingOne for Customers sync destination.

```
dsconfig create-sync-destination \
 --destination-name PingOne \
 --type ping-one-customer \
 --set api-url:https://api.pingone.com/v1 \
 --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
 --set environment-id:[PING_ONE_ENV_ID] \
 --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID] \
 --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

## Configure JSON attribute mapping

The JSON Attribute Mapping type has been added, including sub-objects (JSON Attribute Mapping Field) that allow you to map individual fields. If a source attribute does not have a value, the corresponding field is omitted.

**Note:** It is recommended that you use JSON attribute mappings rather than constructed attribute mappings.

The following are examples of using JSON attribute mappings:

```
dsconfig create-attribute-mapping \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --type json
```

```
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name formatted \
 --set from-attribute:cn \
 --json-type string
```

```
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name given \
 --set from-attribute:givenName \
 --json-type string
```

```
dsconfig create-json-attribute-mapping-field \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --field-name family \
```

## Configure constructed attribute mapping

**Note:** It is recommended that you use JSON attribute mappings rather than constructed attribute mappings (see [Configure JSON attribute mapping](#) on page 1394).

The PingOne User model contains simple JSON attributes like `"title": "Director"` as well as complex JSON objects like `{"name": {"given": "Jane", "family": "Doe"}}`. To ensure accurate processing when you construct attribute mappings that interact with complex objects, construct valid JSON strings and use the command `jsonEscape`, as the following example shows.

```
dsconfig create-attribute-mapping \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name name \
 --type constructed \
 --set 'value-pattern:{"given": "{givenname:jsonEscape}", "family": "{sn:jsonEscape}"}'
```

Some attributes in the User resource are operational and cannot be modified by synchronizing data. For more information, refer to the [PingOne for Customers API Guide](#).

### Correlating entries

The PingOne User Resource model provides an attribute named `externalId`. To ensure that users correlate to the appropriate entry in PingDirectory, map `entryUUID` to this value and configure `externalId` as a destination-correlation-attribute on the Sync class.

### Considerations and limitations

This section describes limitations and other constraints to consider when synchronizing changes to a PingOne for Customers environment.

#### Populations

All PingOne user resources must exist within a population. The PingOne Customers synchronization destination provides the following methods for managing a user's population:

- If a single population is in use, set the configuration attribute `default-population-id` on the sync destination.
- If multiple populations are in use, use a constructed attribute mapping.

The following syntax provides an example.

```
dsconfig create-attribute-mapping \
 --map-name PingDirectory_to_PingOne_User_Map \
 --mapping-name population \
 --type constructed \
 --set 'value-pattern:{"id": "[DEFAULT_POPULATION_ID]"}'
```

To set the population properly, make certain to construct a valid JSON object.

## Synchronize changes from a PingOne for Customers environment

This section describes the configuration that is necessary to synchronize changes from a PingOne for Customers environment. To view an example configuration, refer to the file `reference-ping-one-sync-source-configuration.dsconfig`, which is located in the folder named `resources`.

### Create a PingOne for Customers sync source

Before you create a PingOne for Customers sync source, make certain you have the following information ready:

- Environment ID (*environment-id*)
- OAuth client ID (*oauth-client-id*)
- OAuth client secret (*oauth-client-secret*)

For information about obtaining these values, see "Create a worker application" in [Worker application](#).

The following sample creates a PingOne for Customers sync source.

```
dsconfig create-sync-source \
 --source-name PingOne \
 --type ping-one-customer \
 --set api-url:https://api.pingone.com/v1 \
 --set auth-url:https://auth.pingone.com/[PING_ONE_ENV_ID]/as/token \
 --set environment-id:[PING_ONE_ENV_ID] \
 --set oauth-client-id:[PING_ONE_OAUTH_CLIENT_ID] \
 --set oauth-client-secret:[PING_ONE_OAUTH_CLIENT_SECRET]
```

### Configure attribute mapping

The process of synchronizing data utilizes the concepts and structures associated with LDAP entries. Ping Identity recommends that you conceptualize the PingOne User Resource model as an LDAP entry when configuring attribute mappings. Additionally, you might need to use JSON pathing when selecting a value for complex JSON attributes within the user.

```
dsconfig create-attribute-mapping \
 --map-name PingOne_to_PingDirectory_User_Map \
 --mapping-name givenname \
 --type constructed \
 --set "value-pattern:{name.given}"
```

### Correlating entries

To ensure that users correlate to the appropriate entry in PingDirectory, map the `id` attribute from the user resource to `entryUUID` in PingDirectory.

### Considerations and limitations

This section describes limitations and other constraints to consider when synchronizing changes from a PingOne for Customers environment.

#### Bidirectional synchronization

If you plan on configuring bidirectional synchronization between PingOne for Customers and PingDirectory, make certain that you satisfy the following conditions:

- Use separate worker apps for the source and destination.
- To prevent the unnecessary duplication of changes, add the client ID of the destination worker app to the `actor-id-to-ignore` configuration attribute of the source.
- To ensure that no attribute mappings are mismatched, modify the reference `dsconfig` batch files.

#### Password synchronization

PingDataSync Server does not support the synchronizing of passwords from PingOne.

#### Population management

If your PingOne for Customers environment features a large number of populations, or if you want to limit synchronized users to a specific set of populations, provide one or more `population-to-synchronize` configuration attributes to the source. The name or ID of the population can be used.

## Synchronization delay

PingDataSync Server propagates changes throughout PingOne for Customers nearly in real time. However, a delay might occur between the time a change occurs in PingOne and the time it becomes available for PingDataSync Server to synchronize. To help ensure that no changes are missed, a default delay of 5 seconds has been configured within the sync source. For environments of sufficient size or with high rates of change, use the configuration attribute `realtime-sync-polling-offset` on the sync source to increase the delay.

## Synchronize with Active Directory systems

---

PingDataSync Server supports full synchronization for newly created or modified accounts with native password changes between directory server, relational databases, and Microsoft Active Directory systems.

This chapter presents configuration procedures for synchronization between PingDirectory Server, Nokia 8661 Directory Server, or other LDAP source servers or targets with Microsoft Active Directory systems.

### Overview of configuration tasks

To configure synchronization with Active Directory systems, the following tasks are performed:

#### Enable SSL connections

If synchronizing passwords between systems, synchronization with Microsoft Active Directory systems requires that SSL be enabled on the Active Directory domain controller, so that PingDataSync Server can securely propagate the `cn=Sync User` account password and other user passwords to the target.

#### Run the `create-sync-pipe-config` tool

On the Ping Data Sync Server, use the `create-sync-pipe-config` tool to configure the Sync Pipes to communicate with the Active Directory source or target.

#### Configure outbound password synchronization on an PingDirectory Server Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from an PingDirectory Server Sync Source is required. If so, enable the Password Encryption component on all PingDirectory Server sources that receive password modifications. The PingDirectory Server uses the Password Encryption component, analogous to the Password Sync Agent component, to intercept password modifications and add an encrypted attribute, `ds-changelog-encrypted-password`, to the changelog entry. The component enables passwords to be synchronized securely to the Active Directory system, which uses a different password storage scheme. The encrypted attribute appears in the change log and is synchronized to the other servers, but does not appear in the entries.

#### Configure outbound password synchronization on an Active Directory Sync Source

After running the `create-sync-pipe-config` tool, determine if outbound password synchronization from an Active Directory Sync Source is required. If so, install the Password Sync Agent (PSA) after configuring PingDataSync Server.

#### Run the `realtime-sync set-startpoint` tool

The `realtime-sync set-startpoint` command may take several minutes to run, because it must issue repeated searches of the Active Directory domain controller until it has paged through all the changes and receives a cookie that is up-to-date.

## Configuring synchronization with Active Directory

### About this task

The following procedure configures a one-way Sync Pipe with the Active Directory topology as the Sync Source and a PingDirectory Server topology as the Sync Destination.

### Steps

1. From the server-root directory, start PingDataSync Server.

```
$ <server-root>/bin/start-server
```

2. Run the **create-sync-pipe-config** tool to set up the initial synchronization topology.

```
$ bin/create-sync-pipe-config
```

3. On the Initial Synchronization Configuration Tool menu, press Enter to continue the configuration.
4. On the Synchronization Mode menu, press Enter to select Standard mode.
5. On the Synchronization Directory menu, select the option for one-way (1) or bidirectional (2) for the synchronization topology.
6. On the Source Endpoint Type menu, enter the option for Microsoft Active Directory.
7. On the Source Endpoint Name menu, type a name for the source server, or accept the default.
8. On the Server Security menu, select the security connection type for the source server.
9. On the Servers menu, enter the host name and listener port for the Source Server, or press Enter to accept the default (port 636). The server will attempt a connection to the server. After adding the first server, add additional servers for the source endpoints, which will be prioritized below the first server.
10. On the Synchronization User Account DN menu, enter the User Account DN for the source servers. The account will be used exclusively by PingDataSync Server to communicate with the source external servers. Enter a User Account DN and password. The User Account DN password must meet the minimum password requirements for Active Directory domains.
11. Set up the Destination Endpoint servers.

## Active Directory sync user account

The Sync User created for Active Directory is added to the `cn=Administrators` branch and is given most of a root user's permissions. If this account cannot be secured and there is a need to configure the permissions required by the Sync User, the following are required to perform synchronization tasks.

As a Sync Source, these permissions are needed:

- List contents
- Read all properties
- Read permissions

Deleted items are a special case. For the Sync Server to see deleted entries, the user account must have sufficient access to `cn=Deleted Objects,<domain name>`. Giving access to that DN requires using the `dsac1s` tool, such as:

```
Take ownership may be required to make the needed changes.
dsac1s "CN=Deleted Objects,DC=example,DC=com" /takeOwnership
```

```
Give the Sync User generic read permission to the domain.
dsac1s "CN=Deleted Objects,DC=example,DC=com" /G "example\SyncUser":GR
```

```
List the permission for the domain.
```

```
dsacIs "CN=Deleted Objects,DC=example,DC=com"
```

To revoke all permissions from the Sync User, run the following `dsacIs` command:

```
dsacIs "CN=Deleted Objects,DC=example,DC=com" /R "example\SyncUser"
```

If Active Directory is used as a destination for synchronization, the Sync User account should not be changed.

## Prepare external servers

About this task

Perform the following steps to prepare external servers:

Steps

1. After configuring the source and destination endpoints, PingDataSync Server prompts to "prepare" each external server. The process requires trusting the certificate presented to the server, and then testing the connection. If this step is not performed, the process can be completed after configuring the Sync Pipes using the prepare-endpoint-server tool.
2. Configuring this server for synchronization requires manager access. Enter the DN and password of an account capable of managing the external directory server.
3. Enter the maximum age of change log entries. The value is formatted as `[number][time-unit]`, where the time unit format resembles ("8h" for eight hours, "3d" for three days, "1w" for one week). Setting this value caps how long the PingDataSync Server can be offline. A smaller value limits how many changes are stored and is necessary to limit excessive changelog growth in high-modification environments.
4. To prepare another server in the topology, follow the prompts. The previously entered manager credentials can be reused to access additional servers. Repeat the process for each server configured in the system.

## Configure sync pipes and sync classes

About this task

Perform the following steps to configure Sync Pipes and Sync Classes:

Steps

1. On the Sync Pipe Name menu, type a unique name to identify the Sync Pipe, or accept the default.
2. On the Pre-Configured Sync Class Configuration for Active Directory Sync Source menu, enter `yes` to synchronize user CREATE operations, and enter the object class for the user entries at the destination server, or accept the default (user). To synchronize user MODIFY and DELETE operations from Active Directory, enter `yes`.
3. To synchronize passwords from Active Directory, press Enter to accept the default (yes). If synchronizing passwords from Active Directory, install the Ping Identity Password Sync Agent component on each domain controller.
4. To create a DN map for the user entries in the Sync Pipe, enter the base DN for the user entries at the Microsoft Active Directory Sync Source, then enter the base DN for the user entries at the PingDataSync Server Destination.
5. A list of basic attribute mappings from the Microsoft Active Directory Source to the PingDirectory Server destination is displayed. More complex attribute mappings involving constructed or DN attribute mappings must be configured with the `dsconfiG` tool. The following is a sample mapping.

```
Below is a list of the basic mappings that have been set up for user
```

```
entries synchronized from Microsoft Active Directory -> PingDirectory
Server. You can add to or modify this list with any direct attribute
mappings. To set up more complex mappings (such as constructed or DN
attribute mappings), use the 'dsconfig' tool.
```

- 1) cn -> cn
- 2) sn -> sn
- 3) givenName -> givenName
- 4) description -> description
- 5) sAMAccountName -> uid
- 6) unicodePwd -> userPassword

6. Enter the option to add a new attribute mapping. Enter the source attribute, and then enter the destination attribute. The following example maps the `telephoneNumber` attribute (Active Directory) to the `otherTelephone` attribute (PingDirectory Server).

```
Select an attribute mapping to remove, or choose 'n' to add a new one
[Press ENTER to continue]: n
Enter the name of the source attribute: telephoneNumber
Enter the name of the destination attribute: otherTelephone
```

7. If synchronizing group CREATE, MODIFY, and DELETE operations from Active Directory, enter `yes`.
8. Review the basic user group mappings.
9. On the Sync Pipe Sync Class Definitions menu, enter another name for a new Sync Class if required. Repeat steps 2–7 to define this new Sync Class. If no additional Sync Class definitions are required, press Enter to continue.
10. Review the Sync Pipe Configuration Summary, and accept the default ("write configuration"), which records the commands in a batch file (`sync-pipe-cfg.txt`). The batch file can be used to set up other topologies. The following summary shows two Sync Pipes and its associated Sync Classes.

```
>>>> Configuration Summary
 Sync Pipe: AD to PingDirectory Server
 Source: Microsoft Active Directory
 Type: Microsoft Active Directory
 Access Account: cn=Sync
 User, cn=Users, DC=adsync, DC=PingIdentity, DC=com
 Base DN: DC=adsync, DC=PingIdentity, DC=com
 Servers: 10.5.1.149:636
 Destination: PingDirectory Server
 Type: PingDirectory Server
 Access Account: cn=Sync User, cn=Root DNs, cn=config
 Base DN: dc=example, dc=com
 Servers: localhost:389
 Sync Classes:
 Microsoft Active Directory Users Sync Class
 Base DN: DC=adsync, DC=PingIdentity, DC=com
 Filters: (objectClass=user)
 DN Map: **, CN=Users, DC=adsync, DC=PingIdentity, DC=com ->{1}, ou=users,
 dc=example, dc=com
 Synchronized Attributes: Custom set of mappings are defined
 Operations: Creates, Deletes, Modifies
 Sync Pipe: PingDirectory Server to AD
 Source: PingDirectory Server
 Type: PingDirectory Server
 Access Account: cn=Sync User, cn=Root DNs, cn=config
 Base DN: dc=example, dc=com
 Servers: localhost:389
 Destination: Microsoft Active Directory
 Type: Microsoft Active Directory
 Access Account: cn=Sync
 User, cn=Users, DC=adsync, DC=PingIdentity, DC=com
 Base DN: DC=adsync, DC=PingIdentity, DC=com
```

```
Servers: 10.5.1.149:636
Sync Classes:
 PingDirectory Server Users Sync Class
 Base DN: dc=example,dc=com
 Filters: (objectClass=inetOrgPerson)
 DN Map: **,ou=users,dc=example,dc=com ->{1},CN=Users,DC=adsync,
 DC=PingIdentity,DC=com
 Synchronized Attributes: Custom set of mappings are defined
 Operations: Creates,Deletes,Modifies
```

11. To apply the configuration to the local Ping Data Sync Server instance, type `yes`. The configuration is recorded at `<server-root>/logs/tools/createsync-pipe-config.log`.

## Configure password encryption

### About this task

This procedure is required if synchronizing passwords from a PingDirectory Server to Active Directory, or if synchronizing clear text passwords. These steps are not required if synchronizing from Active Directory to a PingData PingDirectory Server, or if not synchronizing passwords.

### Steps

1. On the Ping Directory Server that will receive the password modifications, enable the Change Log Password Encryption component. The component intercepts password modifications, encrypts the password and adds an encrypted attribute, `ds-changelog-encrypted-password`, to the change log entry. The encryption key can be copied from the output if displayed, or accessed from the `<serverroot>/bin/sync-pipe-cfg.txt` file.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Changelog Password
Encryption" \
 --set enabled:true \
 --set changelog-password-encryption-key:<key>
```

2. On PingDataSync Server, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

```
$ bin/dsconfig set-global-sync-configuration-prop \
 --set changelog-password-decryption-key:ej5u9e39pqq68
```

### Next steps

Test the configuration or populate data in the destination servers using bulk resync mode. See Using the resync Tool on the Identity Sync Server. Then, use `realtime-sync` to start synchronizing the data. See Using the realtime-sync Tool for more information. If synchronizing passwords, install the Password Sync Agent (PSA) on all of the domain controllers in the topology.

## Password sync agent

When synchronizing passwords with Active Directory systems, PingDataSync Server requires that the Ping Identity Password Sync Agent (PSA) be installed on all domain controllers in the synchronization topology. This component provides real-time outbound password synchronization from Microsoft Active Directory to any supported Sync Destinations.

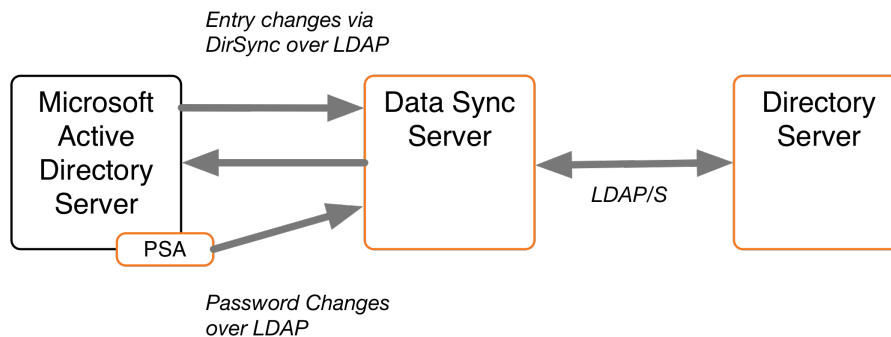

The PSA component provides password synchronization between directories that support differing password storage schemes. The PSA immediately hashes the password with a 160-bit salted secure hash algorithm and erases the memory where the clear-text password was stored. The component only transmits data over a secure (SSL) connection, and follows Microsoft's security guidelines when handling clear-text passwords. The PSA also uses Microsoft Windows password filters, which are part of the local

security authority (LSA) process. The password filters enable implementing password policy validation and change notification mechanisms. For more information, see Microsoft's product documentation.

The default password hashing algorithm is SSHA256. To change the algorithm, create a registry key in the Windows registry under `HKLM\SOFTWARE\UnboundID\PasswordSync` called `PASSWORD_HASHING_ALGORITHM`. The options are SSHA, SSHA1, SSHA256, SSHA384, and SSHA512.

**Note:**

For outbound password synchronization from a PingDirectory Server to Active Directory, enable the Password Encryption component. See [Configure password encryption](#) on page 1401 for more information.

The PSA supports failover between servers. It caches the hashed password changes in a local database until it can be guaranteed that all PingDataSync Servers in the topology have received them. The failover features enable any or all of the PingDataSync Servers to be taken offline without losing any password changes from Active Directory.

The PSA is safe to leave running on a domain controller indefinitely. To stop synchronizing passwords, remove the `userPassword` attribute mapping in PingDataSync Server, or stop the server. The PSA will not allow its local cache of password changes to grow out of control; it automatically cleans out records from its local database as soon as they have been acknowledged. It also purges changes that have been in the database for more than a week.

Before installing the PSA, consider the following:

- Make sure that the Active Directory domain controller has SSL enabled and running.
- Make sure the PingDataSync Servers are configured to accept SSL connections when communicating with the Active Directory host.
- At least one Active Directory Sync Source (ADSyncSource) needs to be configured on PingDataSync Server and should point to the domain controller(s) on which the PSA will reside.
- At the time of installation, all PingDataSync Servers in the sync topology must be online and available.
- The PSA component is for outbound-only password synchronization from the Active Directory Systems. It is not necessary if performing a one-way password synchronization from the PingDirectory Server to the Active Directory server.
- The PSA pre-encodes all passwords with a one-way salted SHA-256 hash before uploading them to PingDataSync. Password changes from Active Directory can only be synchronized to destinations which support setting pre-encoded passwords. Currently, pre-encoded password synchronization is limited to PingDirectory, DSEE, Oracle OUD, and OpenDJ. Active Directory explicitly does not allow for the synchronization of pre-encoded passwords.

## Install the password sync agent

### About this task

The PingDirectory Server distributes the PSA in zip file format with each PingDataSync Server package. The initial installation of the PSA requires a system restart. Perform the following steps to install the PSA:

### Steps

1. On the domain controller, double-click the `setup.exe` file to start the installation.
2. Select a folder for the PSA binaries, local database, and log files.
3. Enter the host names (or IP addresses) and SSL ports of the PingDataSync Servers, such as `sync.host.com:636`. Do not add any prefixes to the host names.
4. Enter the Directory Manager DN and password. This creates an ADSync user on PingDataSync Server.
5. Enter a password (secret key) for the ADSync user that will be used by the PSA when connecting to the PingDataSync Server instances.
6. Click **Next** to begin the installation. All of the specified PingDataSync Servers are contacted, and any failures will roll back the installation. If everything succeeds, a message displays indicating that a restart is required. The PSA will start when the computer restarts, and the LSA process is loaded into memory. The LSA process cannot be restarted at runtime.
7. If synchronizing pre-encoded passwords from Active Directory to a Ping Identity system, allow pre-encoded passwords in the default password policy.

```
$ bin/dsconfig set-password-policy-prop \
--policy-name "Default Password Policy" \
--set allow-pre-encoded-passwords:true
```

## Upgrade or uninstall the password agent

PingDataSync Server provides the `update` tool for upgrades to the server code, including the PSA. The upgrade does not require a restart, because the core password filter is already running under LSA. The upgrade replaces the implementation binaries, which are encapsulated from the password filter DLL.

To uninstall the PSA on the Active Directory system, use **Add/Remove Programs** on the Windows Control Panel. The implementation DLL will be unloaded, and the database and log files are deleted. Only the binaries remain.

The core password filter will still be running under the LSA process. It imposes zero overhead on the domain controller, because the implementation DLL has been unloaded. To remove the password filter itself (located at `C:\WINDOWS\System32\ubidPassFilt.dll`), restart the computer. On restart, the password filter and implementation binaries (in the install folder) can be deleted.

### Note:

The PSA cannot be reinstalled without another reboot.

## Manually configure the password sync agent

Configuration settings for the Password Sync Service are stored in the Windows registry in `HKLM\SOFTWARE\UnboundID>PasswordSync`. Configuration values under this registry key can be modified during runtime. The agent automatically reloads and refreshes its settings from the registry. Verify that the agent is working by checking the current log file, located in `<server-root>\logs\password-sync-current.log`.

## Synchronize with relational databases

PingDataSync Server supports high-scale, highly-available data synchronization between the directory servers and relational database management systems (RDBMS). Any database with a JDBC 3.0 or later driver can be used.

### Use the server SDK

Synchronizing LDAP data to or from a relational database requires creating a JDBC Sync Source or Destination extension to act as an interface between PingDataSync Server and the relational database. The Server SDK provides APIs to develop plugins and third-party extensions to the server using Java or Groovy. The Server SDK's documentation is delivered with the Server SDK build in zip format.

#### **Note:**

Server SDK support is provided with Premium Support for each product. Ping Identity does not provide support for the third party extensions developed using the Server SDK. Contact a Ping Identity support representative for assistance.

Server SDK support is provided with Premium Support for the each product. Ping Identity does not provide support for the third party extensions developed using the Server SDK. Contact a Ping Identity support representative for assistance.

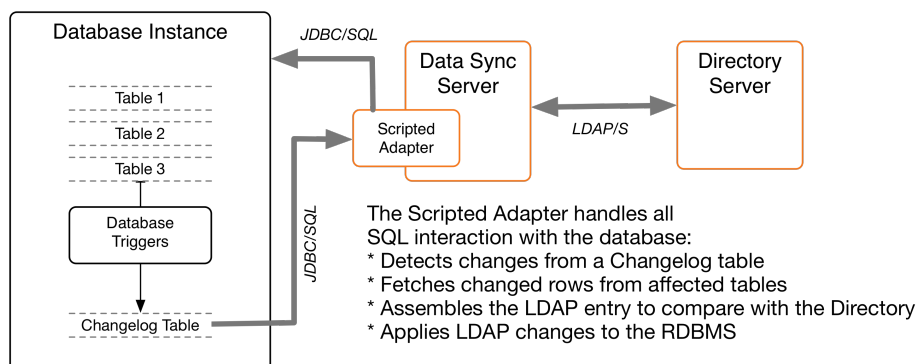

The Server SDK contains two abstract classes that correspond to how the database is used:

```
com.unboundid.directory.sdk.sync.api.JDBCSyncSource
```

```
com.unboundid.directory.sdk.sync.api.JDBCSyncDestination
```

The remainder of the SDK contains helper classes and utility functions to facilitate the script implementation. The SDK can use any change tracking mechanism to detect changes in the database. Examples are provided in the `<server-root>/config/jdbc/samples` directory for Oracle Database and Microsoft SQL Server.

PingDataSync Server uses a scripted adapter layer to convert any database change to an equivalent LDAP entry. The Sync Pipe then processes the data through inclusive (or exclusive) filtering using attribute and DN maps defined in the Sync Classes to update the endpoint servers. For example, a script using Java can be configured by setting the `extension-class` property on a `ThirdPartyJDBCSyncSource` or `ThirdPartyJDBCSyncDestination` configuration object within PingDataSync Server. The following is a sample architecture.

## RDBMS synchronization process

PingDataSync Server synchronizes data between a directory server and an RDBMS system with a Server SDK extension. PingDataSync Server provides multiple configuration options, such as advanced filtering (fractional and subtree), attribute and DN mappings, transformations, correlations, and configurable logging.

To support synchronizing changes, the database must be configured with a change tracking mechanism. An approach involving triggers, (one trigger per table) to record all changes to a change log table, is recommended. The database change log table Ping Identity should record the type of change (INSERT, UPDATE, DELETE), the specific table name, the unique identifier for the changed row, the database entry type, the changed columns (from the source table), the modifier's name, and the changetimestamp.

PingDataSync Server delegates the physical interaction with the database to a user-defined extension, which has full control of the SQL queries. The extension layer provides flexibility in how the mapping semantics between the LDAP environment and the relational database environment are defined. The connection management, pooling, retry logic, and other boilerplate code are handled internally by PingDataSync Server.

The RDBMS Synchronization (DBSync) implementation does not support failover between different physical database servers. Most enterprise databases have a built-in failover layer from which PingDataSync Server can point to a single virtual address and port and still be highly available. A single RDBMS node can scale to multiple directory server endpoints.

## DBSync example

PingDataSync Server provides a DBSync example between two endpoints consisting of a Ping Identity PingDirectory Server source and a RDBMS system, which will be used in this chapter.

The entity-relationship diagram for the normalized database schema is available in `<server-root>/config/jdbc/samples/oracle-db/ComplexSchema.jpg`, and is illustrated here:

Five tables are represented with their primary keys in bold. The entity relations and foreign keys are marked by the relationship lines. The illustration shows mapping to a custom object class on the directory server, while the "groups" table maps to a standard LDAP group entry with `objectclass:groupOfUniqueNames`.

### Example directory server entries

The following example assumes that the directory server's schema is configured to handle the mapped attributes. If configuring a database-to-directory Sync Pipe with a newly installed directory server, make

sure that the schema has the correct `attributeType` and `objectClass` definitions in place. The definitions can be added in a custom `99-user.ldif` file in the `config/schema` folder of the directory server, if necessary.

The following are the LDAP entries that are used in the synchronization example:

```
dn: accountid=0,ou=People,dc=example,dc=com
objectClass: site-user
firstName: John
lastName: Smith
accountID: 1234
email: jsmith@example.com
phone: +1 556 805 4454
address: 17121 Green Street
numLogins: 4
lastLogin: 20070408182813.196Z
enabled: true

dn: cn=Group 1,ou=Groups,dc=example,dc=com
objectClass: groupOfUniqueNames
description: This is Group 1
uniqueMember: accountID=0,ou=People,dc=example,dc=com
uniqueMember: accountID=1,ou=People,dc=example,dc=com
```

## Configure DBSync

### About this task

Configuring a DBSync system includes extra tasks to create the extensions and to configure the database. The overall configuration process is as follows:

### Steps

1. Download the appropriate JDBC driver to PingDataSync Server's `/PingDataSync/lib` directory, and restart the server for the driver to load into the runtime.
2. Open the `java.properties` file with a text editor and add the `jdbc.drivers` argument. Save the file. When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file.
3. Run the `dsjavaproperties` command to apply the change. For example, enter the following for `start-sync-server`:

```
start-sync-server.java-args=-d64 -server -Xmx256m -Xms256m -
XX:+UseConcMarkSweepGC -
Djdbc.drivers=foo.bah.Driver:wombat.sql.Driver:com.example.OurDriver ...
etc.
```

4. Create one or more JDBC extensions based on the Server SDK. If configuring for bidirectional synchronization, two scripts are needed: one for the JDBC Sync Source; the other for the JDBC Sync Destination. Place the compiled extensions in the `/lib/extensions` directory.
5. Configure the database change log table and triggers (presented later). The vendor's native change tracking mechanism can be used, but a change log table should also be configured. Each table requires one database trigger to detect the changes and loads them into the change log table.
6. Configure the Sync Pipes, Sync Classes, external servers, DN and attribute maps for one direction.
7. Run the `resync --dry-run` command to test the configuration settings.
8. Run `realtime-sync set-startpoint` to initialize the starting point for synchronization.
9. Run the `resync` command to populate data on the destination endpoint.
10. Start the Sync Pipes using the `realtime-sync start` command.

11. Monitor PingDataSync Server using the status commands and logs.

12. For bidirectional synchronization, configure another Sync Pipe, and repeat steps 4–8 to test the system.

## Create the JDBC extension

The JDBC extension implementation must be written in Java, or the Groovy scripting language. Consult the Server SDK documentation for details on how to build and deploy extensions. The examples in this guide use Java. Java extensions are more strict and will catch programming errors during compile time rather than at runtime. Groovy is more flexible and can accomplish more with less lines of code.

Groovy scripts must reside in the `/lib/groovy-scripted-extensions` directory (Java implementations reside in `/lib/extensions`), which may also contain other plugins built using the Server SDK. If a script declares a package name, it must live under the corresponding folder hierarchy, just like a Java class. For example, to use a script class called `ComplexJDBCSyncSource` whose package is `com.unboundid.examples.oracle`, place it in `/lib/groovy-scripted-extensions/com/unboundid/examples/oracle` and set the `script-class` property on the Sync Source to `com.unboundid.examples.oracle.ComplexJDBCSyncSource`. There are a few reference implementations provided in the `config/jdbc/samples` directory. Use the `manage-extension` tool in the `bin` directory, or `bat` (Windows) to install or update the extension. See the Server SDK extensions section for more information.

When using custom JDBC endpoints, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -
Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties -i` for the update to the `java.properties` file to take effect.

### Note:

Any changes to an existing script require a manual Sync Pipe restart. Any configuration change automatically restarts the affected Sync Pipe.

The default libraries available on the classpath to the script implementation include:

- Groovy
- LDAP SDK for Java
- JRE

Logging from within a script can be done with the Server SDK's `ServerContext` abstract class. Some of the `ServerContext` methods are not available when the `resync` tool runs, because it runs outside of the PingDataSync Server process. Any logging during a `resync` operation is saved to the `logs/tools/resync.log` file.

## Implement a JDBC sync source

The `JDBCSyncSource` abstract class must be implemented to synchronize data from a relational database. Because PingDataSync Server is LDAP-centric, this class enables database content to be converted into LDAP entries. For more detailed information on the class, see the Server SDK Javadoc.

When using custom JDBC sources, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -
Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties -i` for the update to the `java.properties` file to take effect.

The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK. Depending on the data, implement the following methods:

- `initializeJDBCSyncSource` – Called when a Sync Pipe first starts, or when the **resync** process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncSource` – Called when a Sync Pipe stops, or when the **resync** process stops. Any clean up should be performed here, and all internal resources should be freed.
- `setStartpoint` – Sets the starting point for synchronization by identifying the starting point in the change log. This method should cause all changes previous to the specified start point to be disregarded and only changes after that point to be returned by the `getNextBatchOfChanges` method. There are several different startpoint types (see `SetStartpointOptions` in the Server SDK), and this implementation is not required to support them all. If the specified startpoint type is unsupported, this method throws an exception (`IllegalArgumentException`). This method can be called from two different contexts: when the **realtime-syncset-startpoint** command is used (the Sync Pipe is required to be stopped) or immediately after a connection is established to the source server.

**Note:**

The `RESUME_AT_SERIALIZABLE` startpoint type must be supported. This method is used when a Sync Pipe first starts and loads its state from disk.

- `getStartpoint` – Gets the current value of the startpoint for change detection.
- `fetchEntry` – Returns a full source entry (in LDAP form) from the database, corresponding to the `DatabaseChangeRecord` object that is passed. The **resync** command also uses this class to retrieve entries.
- `acknowledgeCompletedOps` – Provides a means for PingDataSync Server to acknowledge to the database which operations have completed processing.

**Note:**

The internal value for the startpoint should only be updated after a synchronization operation is acknowledged in to this script (through this method). If not, changes could be missed when PingDataSync Server is restarted.

- `getNextBatchOfChanges` – Retrieves the next set of changes for processing. The method also provides a generic means to limit the size of the result set.
- `listAllEntries` – Used by the **resync** command to get a listing of all entries.
- `cleanupChangelog` – In general, we recommend implementing a `cleanupChangelog` method, so that PingDataSync Server can purge old records from the change log table, based on a configurable age.

See the `config/jdbc/samples` directory for example script implementations and the Server SDK Javadoc for more detailed information on each method.

### Implement a JDBC sync destination

The `JDBCSyncDestination` abstract class must be implemented to synchronize data into a relational database. The class enables converting LDAP content to database content. The extension imports classes from the Java API, LDAP SDK for Java API, and the Server SDK, depending on the database configuration.

When using custom JDBC destinations, SQL statements cannot be called unless JDBC drivers are set in the `java.properties` file. For example:

```
start-server.java-args=<...> -
Djdbc.drivers=com.microsoft.sqlserver.jdbc.SQLServerDriver
```

The admin must run `dsjavaproperties -i` for the update to the `java.properties` file to take effect.

Implement the following methods in the script:

- `initializeJDBCSyncDestination` – Called when a Sync Pipe starts, or when the **resync** process starts. Any initialization should be performed here, such as creating internal data structures and setting up variables.
- `finalizeJDBCSyncDestination` – Called when a Sync Pipe stops, or when the **resync** process stops. Any clean up should be performed here, and all internal resources should be freed.
- `createEntry` – Creates a full database entry (or row), corresponding to the LDAP entry that is passed in.
- `modifyEntry` – Modifies a database entry, corresponding to the LDAP entry that is passed in.
- `fetchEntry` – Returns a full destination database entry (in LDAP form), corresponding to the source entry that is passed in.
- `deleteEntry` – Deletes a full entry from the database, corresponding to the LDAP entry that is passed in.

For more detailed information on the abstract class, consult the Server SDK Javadoc.

## Configure the database for synchronization

About this task

Configuring the database for synchronization includes defining:

- A database SyncUser account
- The change tracking mechanism
- The database triggers (one per table) for the application

The following procedure uses the example setup script in `/config/jdbc/samples/oracle-db/OracleSyncSetup.sql`. Items in brackets are user-named labels.

### Note:

Database change tracking necessary if synchronizing FROM the database. If synchronizing TO a database, configure the Sync User account and the correct privileges.

### Steps

1. Create an Oracle login (`SyncUser`) for PingDataSync Server, so that it can access the database server. Grant sufficient privileges to the `SyncUser` for any tables to be synchronized, and change the default password.

```
CREATE USER SyncUser IDENTIFIED BY password
DEFAULT TABLESPACE users TEMPORARY TABLESPACE temp;
GRANT "RESOURCE" TO SyncUser;
GRANT "CONNECT" TO SyncUser;
```

2. Create change log tables on the database as follows:

```
CREATE TABLE ubid_changelog (
 --This is the unique number for the change change_number Number NOT NULL
 PRIMARY KEY,
 --This is the type of change (insert, update, delete). NOTE: This should
 represent
 --the actual type of change that needs to happen on the destination(for
 example a
 --database delete might translate to a LDAPmodify, etc.)
 change_type VARCHAR2(10) NOT NULL,
 --This is the name of the table that was changed table_name VARCHAR(50)
 NOT NULL,
 --This is the unique identifier for the row that was changed. It is up
 to
```

```

--the trigger code to construct this, but it should follow a DN-like
format
--(e.g. accountID={accountID}) where at least the primary key(s) are
--present. If multiple primary keys are required, they should be
delimited
--with a unique string, such as '%%' (e.g. accountID={accountID}%%
--groupID={groupID})
 identifier VARCHAR2(100) NOT NULL,
--This is the database entry type. The allowable values for this must be
--set on the JDBC Sync Source configuration within the Synchronization
--Server.
 entry_type VARCHAR2(50) NOT NULL,
--This is a comma-separated list of columns from the source table that
were updated as part of
--this change.
 changed_columns VARCHAR2(1000) NULL,
--This is the name of the database user who made the change
 modifiers_name VARCHAR2(50) NOT NULL,
--This is the timestamp of the change
 change_time TIMESTAMP(3) NOT NULL, CONSTRAINT chk_change_type
CHECK (change_type IN ('insert','update','delete')) ORGANIZATION
INDEX;

```

3. Create an Oracle function to get the SyncUser name. This is a convenience function for the triggers.

```

CREATE OR REPLACE FUNCTION get_sync_user RETURN VARCHAR2
IS
BEGIN
 RETURN 'SyncUser';
END get_sync_user;

```

4. Create an Oracle sequence object for the change-number column in the change log table.

```

CREATE SEQUENCE ubid_changelog_seq MINVALUE 1 START WITH 1
NOMAXVALUE INCREMENT BY 1 CACHE 100 NOCYCLE;

```

5. Create a database trigger for each table that will participate in synchronization. An example, located in `/config/jdbc/samples/oracle-db/OracleSyncSetup.sql`, shows a trigger for the Accounts table that tracks all changed columns after any INSERT, UPDATE, and DELETE operation. The code generates a list of changed items and then inserts them into the change log table.

## Considerations for synchronizing to database destination

When configuring a directory-to-database Sync Pipe, the following are recommended:

Identify the Object Classes

Create a Sync Class per object class, so that they can easily be distinguished and have different mappings and synchronization rules.

For each Sync Class, set the following items in the configuration menus using the `dsconfig` tool.

### Set the Include-Filter Property

Make sure the `include-filter` property is set on the Sync Class configuration menu to something that will uniquely identify the source entries, such as `objectClass=customer`.

### Create Specific Attribute Mappings

Create an attribute mapping for every LDAP attribute to be synchronized to a database column, add these to a single attribute map, and set it on the Sync Class. With this configured, the script does not need to know about the schema on the directory side. A constructed attribute mapping that maps a literal value to the `objectClass` attribute can be added to the script to determine

the database entry type. For example, "account" -> `objectClass` can be added, which would result in the constructed destination LDAP entry always containing an `objectClass` of "account". If needed, a multi-valued `conditional-value-pattern` property can be used to conditionalize the attribute mapping based on the subtype of the entry or on the value of the attribute. See Conditional Value Mapping for additional information.

### Create Specific DN Maps (optional)

If necessary, create a DN map that recognizes the DN's of the source entries and maps them to a desired destination DN. In most cases, the script will use the attributes rather than the DN to figure out which database entry needs to be changed.

### Set auto-mapped-source-attribute to "-none-"

Remove the default value of "-all-" from the `auto-mapped-source-attribute` on the Sync Class configuration menu, and replace it with "-none-."

### Configure Create-Only Attributes

Any attributes that should be included when created, but never modified (such as `objectclass`) should be specified on the Sync Pipe as a `create-only` attribute. If PingDataSync Server ever computes a difference in that attribute between the source and destination, it will not try to modify it at the destination. To avoid bidirectional loop-back, set the `ignore-changes-by-[user|dn]` property on both Sync Sources when configuring for bidirectional synchronization.

### Synchronizing DELETE Operations

On PingDirectory Server and Nokia 8661 Directory Server systems, configure the `changelog-deleted-entry-include-attribute` property on the changelog backend menu using the `dsconfig` tool. This property allows for the proper synchronization of DELETE operations. For more information, see [Configuring the PingDirectory Server Backend for Synchronizing Deletes](#).

### Attribute-Synchronization-Mode for DBSync

For MODIFY operations, PingDataSync Server detects any change on the source change log, fetches the source entry, applies mappings, computes the equivalent destination entry, fetches the actual destination entry, and then runs a diff between the two entries to determine the minimal set of changes to synchronize. By default, changes on the destination entry are made only for those attributes that were detected in the original change log entry. This is configurable using the `attribute-synchronization-mode` property, which sets the type of diff operation that is performed between the source and destination entries.

If the source endpoint is a database server, set the `attribute-synchronization-mode` property to `all-attributes` on the Sync Class configuration menu. The diff operation will consider all source attributes. Any that have changed will be updated on the destination, even if the change was not originally detected in the change log. This mode is useful when a list of changed columns in the database may not be available. If both endpoints are directory servers, use the default configuration of `modified-attributes-only` to avoid possible replication conflicts.

### Handling MODDN Operations

The concept of renaming an entry (modifyDN) does not have a direct equivalent for relational databases. The `JDBCSyncDestination` API does not handle changes of this type. Instead, the `modifyEntry()` method is called as if it is a normal change. The extension can verify if the entry was renamed by looking at the `SyncOperation` that is passed in (`syncOperation.isModifyDN()`). If true, the `fetchDestEntry` parameter will have the old DN. The new DN can be obtained by calling `syncOperation.getDestinationEntryAfterChange()`.

## Configure a directory-to-database sync pipe

The following configures a one-way Sync Pipe with a PingDirectory Server as the Sync Source and an RDBMS (Oracle) system as the Sync Destination with the `create-sync-pipe-config` tool. Sync Pipes can be configured later using `dsconfig`.

### Create the sync pipe

The following procedures configure the Sync Pipe, external servers, and Sync Classes. The examples are based on the Complex JDBC sample in the `config/jdbc/samples/oracle-db` directory. The `create-sync-pipe-config` tool can be run with the server offline and the configuration can later be imported.

1. Run the `create-sync-pipe-config` tool.

```
$bin/create-sync-pipe-config
```

2. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
3. On the **Synchronization Mode** menu, select **Standard Mode** or **Notification Mode**.
4. On the **Synchronization Directory** menu, choose one-way or bidirectional synchronization.

Configure the sync source

1. On the **Source Endpoint Type** menu, enter the number for the sync source corresponding to the type of source external server.
2. Enter a name for the **Source Endpoint**.
3. Enter the base DN for the directory server, which is used as the base for LDAP searches. For example, enter `dc=example,dc=com`, and then press Enter again to return to the menu. If entering more than one base DN, make sure the DNs do not overlap.
4. On the **Server Security** menu, select the type of communication that PingDataSync Server will use with the endpoint servers.
5. Enter the host and port of the source endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. The server tests that a connection can be established.
6. Enter the DN of the Sync User account and create a password for this account. The Sync User account enables PingDataSync Server to access the source endpoint server. By default, the Sync User account is stored as `cn=SyncUser,cn=RootDNs,cn=config`.

Configure the destination endpoint server

1. On the **Destination Endpoint Type** menu, select the type of datastore on the endpoint server. This example is configuring an Oracle Database.
2. Enter a name for the **Destination Endpoint**.
3. On the **JDBC Endpoint Connection Parameters** menu, enter the fully-qualified host name or IP address for the Oracle database server.
4. Enter the listener port for the database server, or press Enter to accept the default (1521).
5. Enter a database name such as `dbsync-test`.
6. The server attempts to locate the JDBC driver in the `lib` directory. If the file is found, a success message is displayed.

```
Successfully found and loaded JDBC driver for:
jdbc:oracle:thin:@//dbsync-w2k8-vm-2:1521/dbsync-test
```

If the server cannot find the JDBC driver, add it later, or quit the `create-sync-pipe-config` tool and add the file to the `lib` directory.

7. Add any additional JDBC connection properties for the database server, or press Enter to accept the default (no). Consult the JDBC driver's vendor documentation for supported properties.
8. Enter a name for the database user account with which PingDataSync Server will communicate, or press Enter to accept the default (SyncUser). Enter the password for the account.

9. On the Standard Setup menu, enter the number for the language (Java or Groovy) that was used to write the server extension.
10. Enter the fully qualified name of the Server SDK extension class that implements the `JDBCSyncDestination` API.

```
Enter the fully qualified name of the Java class that will implement
com.unboundid.directory.sdk.sync.api.JDBCSyncDestination:
com.unboundid.examples.oracle.ComplexJDBCSyncDestination
```

11. Configure any user-defined arguments needed by the server extension. These are defined in the extension itself and the values are specified in the server configuration. If there are user-defined arguments, enter `yes`.
12. To prepare the Source Endpoint server, which tests the connection to the server with the Sync User account, press **Enter** to accept the default (yes). For the Sync User account, it will return "Denied" as the account has not been written yet to the Directory Server at this time.

```
Testing connection to server1.example.com:1389 Done
Testing 'cn=Sync User,cn=Root DNs,cn=config' access Denied
```

13. To configure the Sync User account on the directory server, press **Enter** to accept the default (yes). Enter the bind DN (`cn=DirectoryManager`) and the bind DN password of the directory server so that you can configure the `cn=Sync User` account. PingDataSync Server creates the Sync User account, tests the base DN, and enables the change log.

```
Created 'cn=Sync User,cn=Root DNs,cn=config'
Verifying base DN 'dc=example,dc=com' Done
Enabling cn=changelog
```

14. Enter the maximum age of the change log entries, or press **Enter** to accept the default.

### Configure the sync pipe and sync classes

The following procedures define a Sync Pipe and two Sync Classes. The first Sync Class is used to match the `accounts` objects. The second Sync Class matches the `group` objects.

1. Continuing from the previous session, enter a name for the Sync Pipe.
2. When prompted to define one or more Sync Classes, enter `yes`.

#### Configure the accounts Sync Class

1. Enter a name for the Sync Class. For example, type `accounts_sync_class`.
2. If restricting entries to specific subtrees, enter one or more base DNs. If not, press **Enter** to accept the default (no).
3. To set an LDAP search filter, type `yes` and enter the filter "`(accountid=*)`". Press **Enter** again to continue. This property sets the LDAP filters and returns all entries that match the search criteria to be included in the Sync Class. In this example, specify that any entry with an `accountID` attribute be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press **Enter** to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press **Enter** to accept the default.

#### Configure the groups Sync Class

For this example, configure another Sync Class to handle the `groups` object class. The procedures are similar to that of the configuration steps for the `accounts_sync_class` Sync Class.

1. On the **Sync Class** menu, enter a name for a new sync class, such as `groups_sync_class`.
2. To restrict entries to specific subtrees, enter one or more base DNs.

3. Set an LDAP search filter. Type `yes` to set up a filter and enter the filter `"(objectClass=groupOfUniqueNames)"`. This property sets the LDAP filters and returns all entries that match the `groupOfUniqueNames` attribute to be included in the Sync Class. If the entry does not contain any of these values, it will not be synchronized to the target server.
4. Choose to synchronize all attributes, specific attributes, or exclude specific attributes from synchronization, or press Enter to accept the default (all).
5. Specify the operations that will be synchronized for the Sync Class, or press Enter to accept the default.
6. At the prompt to enter the name of another Sync Class, press Enter to continue.
7. On the **Default Sync Class Operations** menu, press Enter to accept the default. The Default Sync Class determines how all entries that do not match any other Sync Class are handled.
8. Review the configuration, and press Enter to write the configuration to the server.

Use the `dsconfig` tool to make changes to this configuration. See *Configuring PingDataSync Server* for configuration options and details.

## Considerations for synchronizing from a database source

When synchronizing from a database to a directory or RDBMS server, the following are recommended:

### Identify Database Entry Types

Identify the database entry types that will be synchronized, and:

- Set the `database-entry-type` property on the JDBC Sync Source (this is required), and make sure the entry types are what the triggers are inserting into the change tracking mechanism.
- Create a Sync Class per entry type, and set different mappings and rules for each one.

For each Sync Class, do the following:

- Make sure the `include-filter` property is set to match the entry type.
- Create a specific attribute mapping for every database column to be synchronized to an LDAP attribute and set it on the Sync Class. If this is done, the script will not have to know about the schema on the directory side.
- Create a DN map that recognizes the DNs generated by the script and maps them to the correct location at the destination.
- Remove the default value of `"-all-"` from the `auto-mapped-source-attribute` property on the Sync Class, and replace it with the value `objectClass`. The object class for the fetched source entry is determined by the scripted layer. Values from the database should not be automatically mapped to an attribute with the same name, except the `objectclass` attribute, which should map directly for CREATE operations. If this is not done, an error is generated.
- Change the `destination-correlation-attributes` property to contain the attributes that uniquely represent the database entries on the directory server destination.

### Avoid Bidirectional Loopback

Set the `ignore-changes-by-[user|dn]` property on both Sync Sources when configuring for bidirectional synchronization, to make sure that changes are not looped back by PingDataSync Server.

See *Use the create-sync-pipe tool to configure synchronization* for details about creating the Sync Pipe.

## Synchronize a specific list of database elements

### About this task

The `resync` command enables synchronizing a specific set of database keys that are read from a JDBC Sync Source file using the `--sourceInputFile` option. The contents of the file are passed line-by-line into the `listAllEntries()` method of the `JDBCSyncSource` extension, which is used for the Sync

Pipe. The method processes the input and returns `DatabaseChangeRecord` instances based on the input from the file.

Perform the following steps to synchronize a specific list of database elements using the `resync` tool:

#### Steps

1. Create a file of JDBC Sync Source elements. There is no set format for the file, but it typically contains a list of primary keys or SQL queries. For example, create a file containing a list of primary keys and save it as `sourceSQL.txt`.

```
user.0
user.1
user.2
user.3
```

2. Run the `resync` command with the `--sourceInputFile` option to run on individual primary keys in the file.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--sourceInputFile sourceSQL.txt
```

3. If searching for a specific type of database entry, use the `--entryType` option that matches one of the configured entry types in the `JDBCSyncSource`.

```
$ bin/resync --pipe-name "dbsync-pipe" \
--entryType account \
--sourceInputFile sourceSQL.txt
```

## Synchronize with Apache Kafka

---

Apache Kafka is an open-source streaming platform that communicates state changes in a distributed environment. Changes to a datastore are sent to a *Kafka topic*, which lets customers update other datastores that contain the same information. Although Kafka persists, orders, and transmits changes, it neither detects changes nor applies them to other datastores.

PingDataSync Server supports Kafka as a sync destination with a Ping Identity sync source, such as PingDirectory Server. In this scenario, the Kafka sync destination publishes changes in PingDirectory Server to a Kafka topic, and displays the entry in JSON format both before and after each change. This level of indirection enables other systems and services to react to changes in PingDirectory Server by consuming messages from the topic.

Endpoints that use the Server SDK do not require custom sync destinations.

### Restrictions

The following restrictions affect the manner in which a Kafka sync destination is used:

- The sync source must be a Ping Identity sync source.
- The `changeLog` backend must be enabled on all instances of PingDirectory Server.
- To ensure the availability of an entry's attributes from before and after a change, the configuration property `changelog-include-key-attribute` must include `'*'`.
- The Sync Pipe must be configured in Notification mode (`synchronization-mode:notification`) because a Kafka sync destination cannot retrieve the current version of a destination entry.

### Configure a Kafka sync destination

Use the `dsconfig` command or the Administration Console to synchronize changes to an Apache Kafka environment. You can reuse existing Ping Identity sync sources that were created for other Sync Pipes.

The following objects are required to configure a Kafka sync destination:

- Kafka cluster external server – Defines the procedure for connecting to a Kafka cluster. The Kafka cluster external server can be referenced from multiple Kafka sync destination configuration objects. The only required property is `bootstrap-server`, which identifies some of the Kafka brokers in the environment.

When `use-ssl` is set to `true`, the following configuration changes are made:

- A `trust-manager-provider` is configured to validate the Kafka broker's SSL certificate.
- A `key-manager-provider` is configured to let the Kafka broker authenticate the PingDataSync Kafka producer.
- Kafka sync destination – References the Kafka cluster external server. The Kafka sync destination must specify the name of the topic to use for publishing messages.

To adjust Kafka messages beyond the mapping, attribute filtering, and other configuration changes that PingDataSync Server makes, reference one or more of the `KafkaSyncDestinationPlugin` extension points that are implemented by using the Server SDK.

Run the `prepare-endpoint-server` command for the PingDirectory sync source.

### SSL configuration

The following table identifies the `trust-manager-provider` and `key-manager-provider` properties of the Kafka cluster external server configuration object, as well as the Kafka configuration properties to which they map.

Configuration Object Type	Configuration Property	Kafka Configuration Property
File-based Trust Manager Provider	<code>trust-store-file</code>	<code>ssl.truststore.location</code>
File-based Trust Manager Provider	<code>trust-store-pin</code> , <code>trust-store-pin-property</code> , <code>trust-store-pin-environment-variable</code> , or <code>trust-store-pin-file</code>	<code>ssl.truststore.password</code>
File-based Key Manager Provider	<code>key-store-file</code>	<code>ssl.keystore.location</code>
File-based Key Manager Provider	<code>key-store-pin</code> , <code>key-store-pin-property</code> , <code>key-store-pin-environment-variable</code> , or <code>key-store-pin-file</code>	<code>ssl.keystore.password</code>
File-based Key Manager Provider	<code>private-key-pin</code> , <code>private-key-pin-property</code> , <code>private-key-pin-environment-variable</code> , or <code>private-key-pin-file</code>	<code>ssl.key.password</code>

### Message format

The DN of a changed entry represents the default key for published messages. This value can be overridden in either of the following ways:

- With the `message-key-attribute` property of the Kafka sync destination configuration object
- With a `KafkaSyncDestinationPlugin` extension point

The value of the of the message is a JSON object that includes the following fields:

- `type` – Type of change, such as `ADD`, `MODIFY`, `DELETE`, or `RESYNC`.
- `dn` – DN of the changed entry.

- **changeID** – Unique identifier for the change.
- **modifiedAttributes** – List of modified attributes. This field is available only when the type is **MODIFY**.
- **current** – Entry after the change in JSON format. This field is unavailable when the type is **DELETE**.  
The JSON format of a **current** entry is compatible with the PingDirectory Directory REST API.
- **previous** – Entry before the change in JSON format. This field is unavailable if the type is **RESYNC** or **CREATE**.

The JSON format of a **previous** entry is compatible with the PingDirectory Directory REST API.

### Example ADD

The following code provides an example of an addition:

```
{
 "type": "ADD",
 "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
 "changeID": "changeNumber=1",
 "current": {
 "objectClass": [
 "top",
 "person",
 "organizationalPerson",
 "inetOrgPerson"
],
 "sn": [
 "Smith"
],
 "cn": [
 "John Smith"
],
 "telephoneNumber": [
 "+1 123 123 1234"
],
 "uid": [
 "jsmith"
]
 }
}
```

### Example MODIFY

The following code provides an example of a modification:

```
{
 "type": "MODIFY",
 "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
 "changeID": "changeNumber=2",
 "modifiedAttributes": [
 "telephoneNumber"
],
 "previous": {
 "telephoneNumber": [
 "+1 123 123 1234"
],
 "objectClass": [
 "top",
 "person",
 "organizationalPerson",
 "inetOrgPerson"
],
 "sn": [
```

```

 "Smith"
],
 "cn": [
 "John Smith"
],
 "uid": [
 "jsmith"
]
},
"current": {
 "telephoneNumber": [
 "+1 321 321 3210"
],
 "objectClass": [
 "top",
 "person",
 "organizationalPerson",
 "inetOrgPerson"
],
 "sn": [
 "Smith"
],
 "cn": [
 "John Smith"
],
 "uid": [
 "jsmith"
]
}
}

```

### Example DELETE

The following code provides an example of a deletion:

```

{
 "type": "DELETE",
 "dn" : "uid=jsmith,ou=people,dc=example,dc=com",
 "changeID": "changeNumber=3",
 "previous": {
 "telephoneNumber": [
 "+1 321 321 3210"
],
 "objectClass": [
 "top",
 "person",
 "organizationalPerson",
 "inetOrgPerson"
],
 "sn": [
 "Smith"
],
 "cn": [
 "John Smith"
],
 "uid": [
 "jsmith"
]
 }
}

```

## Message customization

After PingDataSync Server maps the attributes and filters the results, any entries that are changed will utilize the fields of a Kafka message. To restrict the information that is published to a topic, exclude the unwanted attributes from mapping, or include only the attributes that you want to publish.

By using the `KafkaSyncDestinationPlugin` extension point within the Server SDK, you can fully change the message key or value. For more information, including examples, refer to the documentation that is included with the Server SDK packaging.

## Synchronize through PingDirectoryProxy servers

Because most data centers deploy directory servers in a proxied environment, PingDataSync Server can also synchronize data through a proxy server in both load-balanced and entry-balancing deployments. The following proxy endpoints are supported:

- Ping Identity PingDirectoryProxy Servers
- Nokia 8661 Directory Proxy Servers

This chapter details a Sync-through-Proxy deployment and provides background information on how it works. Before setting up PingDataSync Server, review the PingDirectoryProxy Server Administration Guide for information about the PingDirectoryProxy Server.

## Synchronization through a Proxy Server overview

To handle data synchronization through a proxy server, PingData servers have a `cn=changelog` state management system that supports a token-based API.

In a standard, non-proxied configuration, PingDataSync Server polls the source server for changes, determines if a change is necessary, and fetches the full entry from the source. Then, it finds the corresponding entry in the destination endpoint using correlation rules and applies the minimal set of changes. The server fetches and compares the full entries to make sure it does not synchronize any stale data from the change log.

In a proxied environment, PingDataSync Server passes the request through a proxy server to the backend set of directory servers. PingDataSync Server uses the highest priority proxy server designated in its endpoint server configuration and can use others in the event of a failover.

The following figure illustrates a deployment with two endpoints consisting of a proxy server deployment in front of the backend set of directory servers.

## Change log operations

When PingDataSync Server runs a poll for any changes, it sends a get change log batch extended request to the `cn=changelog` backend. The batch request looks for entries in the change log and asks for the server ID, change number, and replica state for each change.

The PingDirectoryProxy Server routes the request to a directory server instance, which then returns a changed entry plus a token identifying the server ID, change number and replica state for each change. The PingDirectoryProxy Server then sends a get change log batch response back to PingDataSync Server with this information. For entry-balancing deployments, the PingDirectoryProxy Server must "re-package" the directory server tokens into its own proxy token to identify the specific data set.

The first time that PingDataSync Server issues the batch request, it also issues a get server ID request to identify the specific server ID that is processing the extended request. The PingDirectoryProxy Server routes the request to the directory server instance, and then returns a server ID in the response. With the next request, PingDataSync Server sends a 'route to server' request that specifies the server instance to access again in this batch session. It also issues a server ID request in the event that the particular server is down. This method avoids round-robin server selection and provides more efficient overall change processing.

## PingDirectory Server and PingDirectoryProxy Server tokens

The PingDirectory Server maintains a change log database index to determine when to resume sending changes (for ADD, MODIFY, or DELETE operations) in its change log. While a simple stand-alone directory server can track its resume point by the last change number sent, replicated servers or servers deployed in entry balancing environments have a different change number ordering in its change log because updates can come from a variety of sources.

The following figure illustrates two change logs in two replicated directory servers, server A and B. "A" represents the replica identifier for a replicated subtree in Server A, and "B" represents the replica identifier for the same replicated subtree in server B. The replica identifiers with a hyphen ("-") mark any local, non-replicated but different changes. While the two replicas record all of the changes, the two change logs have two different change number orderings because updates come in at different times.

Server A			Server B		
ChangeNumber	ReplicaIdentifier	ReplicationCSN	ChangeNumber	ReplicaIdentifier	ReplicationCSN
1001	A <sub>ri</sub>	10	2001	B <sub>ri</sub>	11
1002	-	-	2002	A <sub>ri</sub>	10
1003	A <sub>ri</sub>	15	2003	-	-
1004	B <sub>ri</sub>	11	2004	B <sub>ri</sub>	12
1005	B <sub>ri</sub>	12	2005	A <sub>ri</sub>	15

To track the change log resume position, the PingDirectory Server uses a change log database index to identify the latest change number position corresponding to the highest replication CSN number for a given replica. This information is encapsulated in a directory server token and returned in the get change log batch response to the PingDirectoryProxy Server. The token has the following format:

```
Directory Server Token: server ID, changeNumber, replicaState
```

For example, if the PingDirectoryProxy Server sends a request for any changed entries, and the directory servers return the change number 1003 from server A and change number 2005 from server B, then each directory server token would contain the following information:

```
Directory Server Token A:
serverID A, changeNumber 1003, replicaState {15(A)}
```

```
Directory Server Token B:
 serverID B, changeNumber 2005, replicaState {12(B), 15(A)}
```

### Change log tracking in entry balancing deployments

Change log tracking can become more complex in that a shared area of data can exist above the entry-balancing base DN in addition to each backend set having its own set of changes and tokens.

In the following figure, Server A belongs to an entry-balancing set 1, and server B belonging to an entry-balancing set 2. Shared areas that exist above the entry-balancing base DN are assumed to be replicated to all servers. "SA" represents the replica identifier for that shared area on Server A and "SB" represents the replica identifier for the same area on Server B.

Set 1 - Server A			Set 2 - Server B		
ChangeNumber	ReplicaIdentifier	ReplicationCSN	ChangeNumber	ReplicaIdentifier	ReplicationCSN
1001	SA <sub>ri</sub>	5	2001	SB <sub>ri</sub>	10
1002	A <sub>ri</sub>	10	2002	B <sub>ri</sub>	20
1003	SB <sub>ri</sub>	15	2003	SA <sub>ri</sub>	5

The PingDirectoryProxy Server cannot pass a directory server token from the client to the directory server and back again. In an entry-balancing deployment, the PingDirectoryProxy Server must maintain its own token mechanism that associates a directory server token (changeNumber, replicaIdentifier, replicaState) to a particular backend set.

```
Proxy Token:
backendSetID 1: ds-token 1 (changeNumber, replicaIdentifier, replicaState)
backendSetID 2: ds-token 2 (changeNumber, replicaIdentifier, replicaState)
```

For example, if the PingDirectoryProxy Server returned change 1002 from Server A and change 2002 from Server B, then the Proxy token would contain the following:

```
Proxy Token:
backendSetID 1: ds-token-1 {serverID A, changeNumber 1002, replicaState (5
(SA), 15(A)}
backendSetID 2: ds-token-2 {serverID B, changeNumber 2002, replicaState (10
(SB), 20(B)}
```

For each change entry returned by a backend, the PingDirectoryProxy Server must also decide whether it is a duplicate of a change made to the backend set above the entry-balancing base. If the change is a duplicate, then it is discarded. Otherwise, any new change is returned with a new value of the proxy token.

### Example configuration

This example configures synchronization through a proxy and uses two endpoints consisting of a PingDirectoryProxy Server with a backend set of PingDirectory Servers; both sets are replicated.

The PingDirectoryProxy Server uses an entry-balancing environment for the DN `ou=People,dc=example,dc=com` and provides a subtree view for `dc=example,dc=com` in its client connection policy. For this example, communication is over standard LDAP and failover servers are not installed or designated in PingDataSync Server.

## Configure the source PingDirectory Server

### About this task

The following procedure configures a backend set of directory servers. The procedure is the same for the source servers and the destination servers in a synchronization topology. For directory server installation and configuration details, see the PingDirectory Server Administration Guide.

### Steps

1. On each backend Directory Server that will participate in synchronization, enable the change log database, either from the command line or by using a `dsconfig` batch file.

```
$ dsconfig --no-prompt set-backend-prop \
 --backend-name changelog \
 --set enabled:true
```

2. Stop the server if it is running, and import the dataset for the first backend set into the first server in the backend set prior to the import.

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ../dataset.ldif
$ bin/start-server
```

3. On the first server instance in the first backend set, configure replication between this server and the second server in the same backend set.

```
$ bin/dsreplication enable --host1 ldap-west-01.example.com \
 --port1 389 \
 --bindDN1 "cn=Directory Manager" \
 --bindPassword1 password \
 --replicationPort1 8989 \
 --host2 ldap-west-02.example.com \
 --port2 389 \
 --bindDN2 "cn=Directory Manager" \
 --bindPassword2 password \
 --replicationPort2 9989 \
 --adminUID admin \
 --adminPassword admin \
 --baseDN dc=example,dc=com \
 --no-prompt
```

4. Initialize the second server in the backend set with data from the first server in the backend set. This command can be run from either instance.

```
$ bin/dsreplication initialize \
 --hostSource ldap-west-01.example.com \
 --portSource 389 \
 --hostDestination ldap-west-02.example.com \
 --portDestination 389 \
 --baseDN "dc=example,dc=com" \
 --adminUID admin \
 --adminPassword admin \
 --no-prompt
```

5. Run the following command to check replica status.

```
$ bin/dsreplication status \
 --hostname ldap-west-01.example.com \
 --port 389 \
 --adminPassword admin \
 --no-prompt
```

6. Repeat steps 3 through 6 (import, enable replication, initialize replication, check status) for the second backend set.

## Configure a proxy server

### About this task

The following procedure configures a proxy server, including defining the external servers and configuring the client-connection policy. The procedure is the same for the source servers and the destination servers in a synchronization topology.

For additional changes, use the `dsconfig` tool. For proxy installation and configuration details, see the [PingDirectoryProxy Server Administration Guide](#).

### Steps

1. From the PingDirectoryProxy Server root directory, run the **prepare-external-server** command to set up the `cn=Proxy User` account for access to the backend directory servers. The server tests the connection and creates the `cn=Proxy User` account.

```
$ bin/prepare-external-server --no-prompt \
 --hostname ldap-west-01.example.com \
 --port 389 --bindDN "cn=Directory Manager" \
 --bindPassword password \
 --proxyBindDN "cn=Proxy User,cn=Root DNs,cn=config" \
 --proxyBindPassword pass \
 --baseDN "dc=example,dc=com"
```

2. Repeat step 1 for any other directory server instances.
3. Run the `dsconfig` command to define the external servers and their types. For this example, round-robin load balancing algorithms are defined, which do not require health checks or locations to be specified.

```
$ bin/dsconfig --no-prompt create-external-server \
 --server-name ldap-west-01 \
 --type "ping-identity-ds" \
 --set "server-host-name:ldap-west-01.example.com" \
 --set "server-port:389" \
 --set "bind-dn:cn=Proxy User" \
 --set "password:password" \
```

```
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
--server-name ldap-west-02 \
--type "ping-identity-ds" \
--set "server-host-name:ldap-west-02.example.com" \
--set "server-port:389" \
--set "bind-dn:cn=Proxy User" \
--set "password:password" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
--server-name ldap-west-03 \
--type "ping-identity-ds" \
--set "server-host-name:ldap-west-03.example.com" \
--set "server-port:389" \
--set "bind-dn:cn=Proxy User" \
--set "password:password" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-external-server \
--server-name ldap-west-04 \
--type "ping-identity-ds" \
--set "server-host-name:ldap-west-04.example.com" \
--set "server-port:389" \
--set "bind-dn:cn=Proxy User" \
--set "password:password" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

#### 4. Create a load-balancing algorithm for each backend set.

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
--algorithm-name "test-lba-1" \
--type "round-robin" --set "enabled:true" \
--set "backend-server:ldap-west-01" \
--set "backend-server:ldap-west-02" \
--set "use-location:false" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-load-balancing-algorithm \
--algorithm-name "test-lba-2" \
--type "round-robin" --set "enabled:true" \
--set "backend-server:ldap-west-03" \
--set "backend-server:ldap-west-04" \
--set "use-location:false" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

#### 5. Configure the proxying request processors, one for each load-balanced directory server set. A request processor provides the logic to either process the operation directly, forward the request to another server, or hand off the request to another request processor.

```
$ bin/dsconfig --no-prompt create-request-processor \
--processor-name "proxying-processor-1" --type "proxying" \
--set "load-balancing-algorithm:test-lba-1" \
--set "use-location:false" \
--set "password:password" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

```
$ bin/dsconfig --no-prompt create-request-processor \
--processor-name "proxying-processor-2" --type "proxying" \
--set "load-balancing-algorithm:test-lba-2" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

6. Define an entry-balancing request processor. This request processor is used to distribute entries under a common parent entry among multiple backend sets. A backend set is a collection of replicated directory servers that contain identical portions of the data. Multiple proxying request processors are used to process operations.

Next, define the placement algorithm, which selects the server set to use for new add operations to create new entries. In this example, a round-robin placement algorithm forwards LDAP add requests to backend sets.

```
$ bin/dsconfig --no-prompt create-placement-algorithm \
--processor-name "entry-balancing-processor" \
--algorithm-name "round-robin-placement" \
--set "enabled:true" \
--type "round-robin" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

7. Define the subtree view that specifies the base DN for the entire deployment.

```
$ bin/dsconfig --no-prompt create-subtree-view \
--view-name "test-view" \
--set "base-dn:dc=example,dc=com" \
--set "request-processor: entry-balancing-processor" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

8. Finally, define a client connection policy that specifies how the client connects to the proxy server.

```
$ bin/dsconfig --no-prompt set-client-connection-policy-prop \
--policy-name "default" \
--add "subtree-view:test-view" \
--bindDN "cn=Directory Manager" \
--bindPassword pxy-pwd
```

## Configure PingDataSync Server

About this task

Configure PingDataSync Server after the PingDirectoryProxy Server and its backend set of PingDirectory Server instances are configured and fully functional for each endpoint, which are labeled as `ldap-west` and `ldap-east` in this example.

For information about installing and configuring PingDataSync Server, see [Installing PingDataSync Server](#) on page 1319.

Steps

1. From the PingDataSync Server root directory, run the `create-sync-pipe-config` tool.

```
$ bin/create-sync-pipe-config
```

2. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.

3. On the Synchronization Mode menu, press Enter to select Standard mode.
4. On the Synchronization Directory menu, choose the option for one-way or bidirectional synchronization.
5. On the First Endpoint Type menu, enter the number for the type of backend data store for the first endpoint. In this example, type the number corresponding to the PingDirectoryProxy Server.

```

>>>> First Endpoint Type
Enter the type of datastore for the first endpoint:
1) Ping Identity Directory Server
2) Ping Identity Directory Proxy Server
3) Alcatel-Lucent Directory Server
4) Alcatel-Lucent Proxy Server
5) Sun Directory Server
6) Microsoft Active Directory
7) Microsoft SQL Server
8) Oracle Database
9) Custom JDBC

b) back
q) quit
Enter choice [1]: 2

```

6. Enter a descriptive name for the first endpoint.
7. Enter the base DN where PingDataSync Server can search for the entries on the first endpoint server.
8. Specify the type of security when communicating with the endpoint server.
9. Enter the host name and port of the endpoint server. PingDataSync Server tests the connection. Repeat this step if configuring another server for failover.
10. Enter the Sync User account that will be used to access the endpoint server, or press Enter to accept the default `cn=Sync User,cn=Root DNs,cn=config`. Enter a password for the account.
11. The first endpoint deployment is defined using the PingDirectoryProxy Server (`ldap-west`). Repeat steps 5-10 to define the second proxy deployment (`ldap-east`) on PingDataSync Server.
12. Prepare the endpoint servers in the topology. This step confirms that the Sync User account is present on each server and can communicate between PingDataSync Server and the PingDirectoryProxy Servers. In addition to preparing the PingDirectoryProxy Server, PingDataSync Server prepares the backend set of directory servers as the proxy server passes through the authorization to access these servers.
13. Repeat the previous step to prepare the second endpoint server. If other servers have not been prepared, make sure that they are prior to synchronization.
14. Define the Sync Pipe from proxy 1 to proxy 2. In this example, accept the default "Ping Identity Proxy 1 to Ping Identity Proxy 2."
15. To customize on a per-entry basis how attributes get synchronized, define one or more Sync Classes. Create a Sync Class for the special cases, and use the default Sync Class for all other mappings.
16. For the default Sync Class Operations, specify the operations that will be synchronized.
17. Review the configuration settings, and write the configuration to PingDataSync Server in the `sync-pipe-cfg.txt` file.

## Test the configuration

### About this task

If the `create-sync-pipe-config` tool was not used to create the synchronization configuration, two properties must be verified on each endpoint: `proxy-server` and `use-changelog-batch-request`. The `proxy-server` property should specify the name of the proxy server. The `use-changelog-batch-request` property should be set to `true` on the Sync Source only. The `use-changelog-batch-request` property is not available on the destination endpoint.

The PingDataSync Server connection parameters (hostname, port, bind DN, and bind password) are required.

## Steps

1. The following commands check the properties on a Sync Source.

On the Sync Source:

```
$ bin/dsconfig --no-prompt \
 get-sync-source-prop \
 --source-name "Ping Identity Proxy 1" \
 --property "proxy-server" \
 --property "use-changelog-batch-request"
```

On the Sync Destination:

```
$ bin/dsconfig --no-prompt \
 get-sync-source-prop \
 --source-name "Ping Identity Proxy 2" \
 --property "proxy-server"
```

2. From the server root directory, run the **dsconfig** command to set a flag indicating that the endpoints are PingDirectoryProxy Servers:

```
$ bin/dsconfig --no-prompt \
 set-sync-source-prop \
 --source-name "Ping Identity Proxy 1" \
 --set proxy-server:ldap-west-01 \
 --set use-changelog-batch-request:true
```

```
$ bin/dsconfig --no-prompt \
 set-sync-source-prop \
 --source-name "Ping Identity Proxy 2" \
 --set proxy-server:ldap-east-01
```

3. Run the **resync --dry-run** command to test the configuration settings for each Sync Pipe and debug any issues.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
--dry-run
```

4. Run **realtime-sync set-startpoint** to initialize the starting point for synchronization.

```
$ realtime-sync set-startpoint --end-of-changelog \
 --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2" \
 --port 389 \
 --bindDN "cn=Directory Manager" \
 --bindPassword password
```

### Note:

For synchronization through proxy deployments, the `--change-number` option cannot be used with the **realtime-sync set-startpoint** command, because PingDataSync Server cannot retrieve specific change numbers from the backend directory servers. Use `--change-sequence-number`, `--end-of-changelog`, or other options available for the tool.

5. Run the **resync** command to populate data on the endpoint destination server if necessary.

```
$ bin/resync --pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
```

```
\
--numPasses 3
```

6. Start the Sync Pipe using the `realtime-sync start` command.

```
$ bin/realtime-sync start \
--pipe-name "Ping Identity Proxy 1 to Ping Identity Proxy 2"
```

7. Monitor PingDataSync Server using the status commands and logs.

## Index the LDAP changelog

### About this task

The PingData PingDirectory Server and the Nokia 8661 Directory Server (3.0 or later) both support attribute indexing in the changelog backend to enable get changelog batch requests to filter results that include only changes of specific attributes. For example, in an entry balanced proxy deployment, PingDataSync Server sends a get changelog batch request to the Proxy Server, which will send out individual requests to each backend server.

Each directory server that receives a request must iterate over the whole range of changelog entries, and then match entries based on search criteria for inclusion in the batch. The majority of this processing involves determining whether a changelog entry includes changes to a particular attribute or set of attributes, or not. Changelog indexing can dramatically speed up throughput when targeting specific attributes.

Attribute indexing is configured using the `index-include-attribute` and `index-exclude-attribute` properties on the changelog backend. The properties can accept the specific attribute name or special LDAP values "\*" to specify all user attributes or "+" to specify all operational attributes.

Perform the following steps to configure changelog indexing:

### Steps

1. On all source directory servers, enable changelog indexing for the attributes that will be synchronized. Use the `index-include-attribute` and `index-exclude-attribute` properties. The following example specifies that all user attributes (`index-include-attribute:*`) be indexed in the changelog, except the description and location attributes (`index-exclude-attribute:description` and `index-exclude-attribute:location`).

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
--set "index-include-attribute:*" \
--set "index-exclude-attribute:description \
--set "index-exclude-attribute:location
```

### Note:

There is little performance and disk consumption penalty when using `index-include-attribute:*` with a combination of `index-exclude-attribute` properties, instead of explicitly defining each attribute using `index-include-attribute`. The only cautionary note about using `index-include-attribute:*` is to be careful that unnecessary attributes get indexed.

2. On PingDataSync Server, configure the `auto-map-source-attributes` property to specify the mappings for the attributes that need to be synchronized.

### Results

PingDataSync Server will write a NOTICE message to the error log when the Sync Pipe first starts, indicating whether the server is using changelog indexing or not.

```
[30/Mar/2016:13:21:36.781 -0500] category=SYNC severity=NOTICE
```

```
msgID=1894187256 msg="Sync Pipe 'TestPipe' is not using changelog indexing
on
the source server"
```

## Changelog synchronization considerations

If the Sync Source is configured with `use-changelog-batch-request=true`, PingDataSync Server will use the `get changelog batch request` to retrieve changes from the LDAP changelog. This extended request can contain an optional set of selection criteria, which specifies changelog entries for a specific set of attributes.

PingDataSync Server takes the union of the source attributes from DN mappings, attribute mappings, and the `auto-mapped-source-attributes` property on the Sync Class to create the selection criteria. However, if it encounters the value `"-all-"` in the `auto-mapped-source-attributes` property, it cannot make use of selection criteria because the Sync Pipe is interested in all possible source attributes.

When the PingDirectory Server receives a `get changelog request` that contains selection criteria, it returns changelog entries for one or more of the attributes that meet the criteria.

- For ADD and MODIFY changelog entries, the changes must include at least one attribute from the selection criteria.
- For MODDN changelog entries, one of the RDN attributes must match the selection criteria.
- For DELETE changelog entries, one of the `deletedEntryAttrs` must match the selection criteria.

If `auto-mapped` is not set to `all` source attributes, at least one should be configured to show up in the `deletedEntryAttrs` (with the `changelog-deleted-entry-include-attribute` property on the changelog backend).

Another way to do this is to set `use-reversible-form` to `true` on the changelog backend. This includes all attributes in the `deletedEntryAttrs`.

## Synchronize in Notification Mode

---

PingDataSync Server supports a notification synchronization mode that transmits change notifications on a source endpoint to third-party destination applications.

As with standard mode, notifications can be filtered based on the type of entry that was changed, the specific attributes that were changed, and the type of change (ADD, MODIFY, DELETE). PingDataSync Server can send a notification to arbitrary endpoints by using a custom server extension.

### Notification mode overview

PingDataSync Server supports standard and notification synchronization modes. Notification Mode polls the directory server's LDAP change log for changes on any entry but skips the fetch and compare phases of processing of Standard Mode. Instead, the Sync Destination is notified of the change regardless of the current state of that entry at the source or destination. PingDataSync Server accesses state information on the change log to reconstruct the before-and-after values of any modified attribute (for example, for MODIFY change operation types). It passes in the change information to a custom server extension based on the Server SDK.

Third-party libraries can be employed to customize the notification message to an output format required by the client application or service. For example, the server extension can use a third-party XML parsing library to convert the change notifications to a SOAP XML format.

Notification mode can only be used with an PingDirectory Server, Nokia 8661 Directory Server, PingDirectoryProxy Server, or Nokia 8661 Directory Proxy Server as the source endpoint.

PingDataSync Server can use notification mode with any type of endpoint; therefore, it is not an absolute requirement to have a custom server extension in your system. For example, it is possible to set up a notification Sync Pipe between two LDAP server endpoints.

### Implementation considerations

Before implementing and configuring a Sync Pipe in notification mode, answer the following questions:

- What is the interface to client applications?
- What type of connection logic is required?
- How will the custom server extension handle timeouts and connection failures?
- What are the failover scenarios?
- What data needs to be included in the change log?
- How long do the change log entries need to be available?
- What are the scalability requirements for the system?
- What attributes should be used for correlation?
- What should happen with each type of change?
- What mappings must be implemented?

### Use the server SDK and LDAP SDK

To support notification mode, the Server SDK provides a `SyncDestination` extension to synchronize with any client application. The PingDataSync Server engine processes the notification and makes it available to the extension, which can be written in Java or Groovy. This generic extension type can also be used for standard synchronization mode.

Similar to database synchronization, the custom server extension is stored in the `<server-root>/lib/groovy-scripted-extensions` folder (for Groovy-based extensions) or the jar file in the `<server-root>/lib/extensions` folder (for Java-based extensions) prior to configuring PingDataSync Server for notification mode. Groovy scripts are compiled and loaded at runtime.

The Server SDK's `SyncOperation` interface represents a single synchronized change from the Sync Source to the Sync Destination. The same `SyncOperation` object exists from the time a change is detected, through when the change is applied at the destination.

The LDAP SDK's `UnboundIDChangelogEntry` class (in the `com.unboundid.ldap.sdk.unboundidds` package) has high-level methods to work with the `ds-changelog-before-value`, `ds-changelogafter-values`, and `ds-changelog-entry-key-attr-values` attributes. The class is part of the commercial edition of the LDAP SDK for Java and is

installed automatically with PingDataSync Server. For detailed information and examples, see the LDAP SDK Javadoc.

## Notification mode architecture

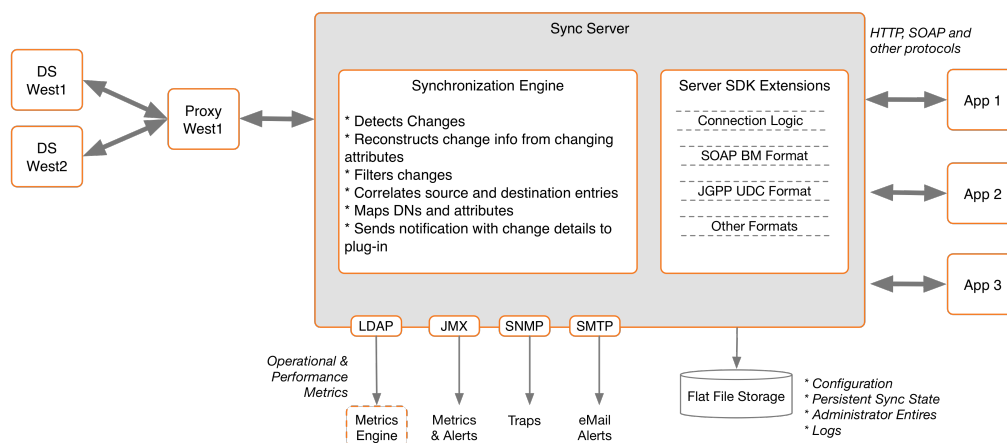

Notification mode, a configuration setting on the Sync Pipe, requires a one-way directional Sync Pipe from a source endpoint topology to a target client application.

PingDataSync Server detects the changes in the PingDirectory Server's LDAP change log, filters the results specified in the Sync Classes, applies any DN and attribute mappings, then reconstructs the change information from the change log attributes. A server extension picks up the notification arguments from the `SyncOperation` interface (part of the Server SDK) and converts the data to the desired output format. The server extension establishes the connections and protocol logic to push the notification information to the client applications or services. All of the operations, administration, and management functions available in standard mode, such as monitoring, (LDAP, JMX, SNMP), alerts (JMX, SNMP, SMTP), and logging features are the same for notification mode.

### **Note:**

The Server SDK includes documentation and examples on how to create a directory server extension to support notification mode.

For a given entry, PingDataSync Server sends notifications in the order that the changes occurred in the change log even if a modified attribute has been overwritten by a later change. For example, if an entry's `telephoneNumber` attribute is changed three times, three notifications will be sent in the order they appeared in the change log.

## Sync source requirements

A separate Sync Pipe is required for each client application that should receive a notification. The Sync sources must consist of one or more instances of the following directory or proxy servers with PingDataSync Server:

- Ping Identity PingDirectory Server and PingDirectoryProxy Server (version 3.0.5 or later)
- Nokia 8661 Directory Server
- The Sync Destination can be of any type

### **Note:**

While the PingDirectoryProxy Server and Nokia 8661 Directory Proxy Server can front other vendor's directory servers, such as Active Directory and Sun DSEE, for processing LDAP operations, PingDataSync

Server cannot synchronize changes from these sources through a proxy server. Synchronizing changes directly from Active Directory and Sun DSEE cannot be done with notification mode.

### Failover capabilities

For sync source failovers, configure replication between the Directory Servers to ensure data consistency between the servers. A PingDirectoryProxy Server can also front the backend PingDirectory Server set to redirect traffic, if connection to the primary server fails. A PingDirectoryProxy Server must be used for synchronizing changes in an entry-balancing environment. Once the primary PingDirectory Server is online, it assumes control with no information loss as its state information is kept across the backend PingDirectory Servers.

For sync destination failovers, connection retry logic must be implemented in the server extension, which will use the Sync Pipe's advanced property settings to retry failed operations. There is a difference between a connection retry and an operation retry. An extension should not retry operations because PingDataSync Server does this automatically. However, the server extension is responsible for re-establishing connections to a destination that has gone down, or failing over to an alternate server. The server extension can also be designed to trigger its own error-handling code during a failed operation.

For PingDataSync Server failovers, the secondary PingDataSync Servers will be at or slightly behind the state where the primary server initiated a failover. Both primary and secondary PingDataSync Servers track the last failed acknowledgement, so once the primary server fails over to a secondary server, the secondary server will not miss a change.

#### Note:

If failover is a concern between PingDataSync Servers, change the `sync-failover-polling-interval` property from 7500 ms to a smaller value. This will result in a quicker failover, but will marginally increase traffic between the two PingDataSync Servers. The `sync-failover-connection-timeout` and `sync-failover-response-timeout` properties may also be updated to use different failover timeout durations. Use `dsconfig` to access the property on the Global Sync Configuration menu.

### Notification sync pipe change flow

Multi-threaded Sync Pipes allow PingDataSync Server to process multiple notifications in parallel in the same manner as synchronizing changes in standard mode, which increases throughput and offsets network latency. A single change-detection thread pulls in batches of change log entries and queues them internally. To guarantee consistency, PingDataSync Server's internal locking mechanisms ensure the following properties:

- Changes to the same entry will be processed in the same order that they appear in the change log.
- Changes to parent entries will be processed before changes to its children.
- Changes to entries with the same RDN value are handled sequentially.

The number of concurrent threads is configurable on the Sync Pipe using the `num-worker-threads` property. In general, single-threading should be avoided.

## Configure notification mode

PingDataSync Server supports notification mode with the following components.

### Use the create-sync-pipe-config tool

The `create-sync-pipe-config` tool supports the configuration of notification mode. Any pre-existing Sync Sources can be read from the local configuration (in the `config.ldif` file).

### No resync command functionality

The `resync` function is disabled on a Sync Pipe in notification mode as its functionality is not supported in this implementation. Notification mode views the directory server's change log as a rolling set of data that pushes out change notifications to its target application.

### LDAP change log features required for notifications

The PingDirectory Server and the Nokia 8661 Directory Server require the following advanced global change log properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

These properties are enabled and configured during the `create-sync-pipe-config` configuration process on PingDataSync Server. The properties can also be enabled on the directory servers by using the `dsconfig` advanced properties setting on the Backend Changelog menu.

#### changelog-include-key-attribute

The `changelog-include-key-attribute` property specifies one or more attributes that should always be included in the change log entry. These are attributes needed to correlate entries between the source and destination, such as `uid`, `employeeNumber`, or `mail`. These properties are also needed for evaluating any filters in the Sync Class. For example, if notifications are only sent for user entries, and the Sync Class included the filter (`objectclass=people`), the `objectclass` attribute must be configured as a `changelog-include-key-attribute` so that the Sync Pipe can evaluate the inclusion criteria when processing the change. In standard mode, values needed in the filter are read from the entry itself after it is fetched instead of from the changelog entry. These attributes are always included in a change log entry, also called a change record, regardless if they have changed or not.

The `changelog-include-key-attribute` property causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the change log entry. This applies for all change types. During a delete operation, the values are from the entry

before it was deleted. The key values are recorded on every change and override any settings configured in the `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute` properties in the directory server changelog (see the Ping Identity PingDirectoryServer Configuration Reference for more information).

Normal LDAP to LDAP synchronization topologies typically use `dn` as a correlation attribute. If `dn` is used as a correlation attribute only, the `changelog-include-key-attribute` property does not need to be set. However, if another attribute is used for correlation, this property must be set during the Sync Pipe configuration.

The LDAP change log attribute, `ds-changelog-entry-key-attr-values`, stores the attribute that is always included in a change log entry on every change for correlation purposes. In addition to regular attributes, virtual and operational attributes can be specified as entry keys.

To view an example, see the Ping Identity PingDirectory Server Administration Guide.

#### `changelog-max-before-after-values`

The `changelog-max-before-after-values` property specifies the maximum number of "before and after" values (default 200) that should be stored for any changed attribute in the change log. Also, when enabled, it will add the `ds-changelog-before-values` and `ds-changelog-after-values` attributes to any change record that contains changes (for Modify and ModifyDN).

The main purpose of the `changelog-max-before-after-values` property is to ensure that an excessively large number of changes is not stored for multi-valued attributes. In most cases, the directory server's schema defines a multi-valued attribute to be unlimited in an entry. For example, if a group entry whose member attribute references 10000 entries, the desire may be to not have all of the attributes if a new member added.

If either the `ds-changelog-before-values` or the `ds-changelog-after-values` attributes exceed the count set in the `changelog-max-before-after-values` property, the attribute values are no longer stored in a change record but its attribute name and number is stored in the `ds-changelog-attr-exceeded-max-values-count` attribute, which appears in the change record.

In addition to this property, set the `use-reversible-form` property to `TRUE`. This guarantees that sufficient information is stored in the change log for all operation types to be able to replay the operations at the destination. The `create-sync-pipe-config` tool configures these properties when it prepares the servers.

The `changelog-max-before-after-values` property configures the following change log attributes:

- `ds-changelog-before-values` – Captures all "before" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).
- `ds-changelog-after-values` – Captures all "after" values of a changed attribute. It will store up to the specified value in the `changelog-max-before-after-values` property (default 200).
- `ds-changelog-attr-exceeded-max-values-count` – Stores the attribute names and number of before and after values on the change log entry after the maximum number of values (set by the `changelog-max-before-after-values` property) has been exceeded. This is a multi-valued attribute with the following format:

```
attr=attributeName,beforeCount=200,afterCount=201
```

where `attributeName` is the name of the attribute and the `beforeCount` and `afterCount` are the total number of values for that attribute before and after the change, respectively. In either case (before or after the change), if the number of values is exceeding the maximum, those values will not be stored.

#### LDAP change log for Notification and Standard Mode

Both Notification and Standard mode Sync Pipes can consume the same LDAP Change Log without affecting the other. Standard mode polls the change record in the change log for any modifications,

fetches the full entries on the source and the destination, and then compares them for the specific changes. Notification mode gets the before and after values of a changed attribute to reconstruct an entry, and bypasses the fetch-and-compare phase. Both can consume the same LDAP Change Log with no performance loss or conflicts.

**Note:**

If the configuration obtains the change log through a PingDirectoryProxy Server, the contents of the change log will not change as it is being read from the change logs on the directory server backend.

## Implementing the server extension

Notification mode relies heavily on the server extension code to process and transmit the change using the required protocol and data formats needed for the client applications.

Create the extension using the Server SDK, which provides the APIs to develop code for any destination endpoint type. The Server SDK's documentation (Javadoc and examples) is delivered with the Server SDK built-in zip format. The SDK provides all of the necessary classes to extend the functionality of PingDataSync Server without code changes to the core product. Once the server extension is in place, use other third-party libraries to transform the notification to any desired output format.

Consider the following when implementing the extension:

### Use the manage-extension tool

Use the manage-extension tool in the `bin` directory or `bat` directory (Windows) to install or update the extension. See [Managing Extensions](#) for more information.

### Review the Server SDK package

Review Server SDK documentation and examples before building and deploy a Java or Groovy extension.

### Connection and protocol logic

The Server SDK extension must manage the notification connection and protocol logic to the client applications.

### Implementing extensions

Test the create methods, the delete methods, and the modify methods for each entry type. Update the configuration as needed. Finally, package the extensions for deployment. Logging levels can be increased to include more details.

### Use the SyncOperation type

The `SyncOperation` class encapsulates everything to do with a given change. Objects of this type are used in all of the synchronization SDK extensions. See the Server SDK Javadoc for the `SyncOperation` class for information on the full set of methods.

### Use the EndpointException type

The Sync Destination type offers an exception type called `EndpointException` to extend a standard Java exception and provide custom exceptions. There is also logic to handle LDAP exceptions, using the LDAP SDK.

### About the PostStep result codes

The `EndpointException` class uses PostStep result codes that are returned in the server extension:

- `retry_operation_limited` – Retry a failed attempt up to the limit set by `max_operation_attempts`.

- `retry_operation_unlimited` – Retry the operation an unlimited number of times until a success, abort, or `retried_operation_limited`. This should only be used when the destination endpoint is unavailable.
- `abort_operation` – Abort the current operation without any additional processing.

### Use the `ServerContext` class for logging

The `ServerContext` class provides several logging methods which can be used to generate log messages and/or alerts from the scripted layer: `logMessage()`, `sendAlert()`, `debugCaught()`, `debugError()`, `debugInfo()`, `debugThrown()`, `debugVerbose()`, and `debugWarning()`. These are described in the Server SDK API Javadocs. Logging related to an individual `SyncOperation` should be done with the `SyncOperation#logInfo` and `SyncOperation#logError` methods.

### Diagnosing script errors

When a Groovy extension does not behave as expected, first look in the error log for stack traces. If `ClassLoader` errors are present, the script could be in the wrong location or may not have the correct package. Groovy checks for errors at runtime. Business logic errors must be systematically found by testing each operation. Make sure logger levels are set high enough to debug.

## Configure the Notification sync pipe

The following procedure configures a one-way Sync Pipe with a PingDirectory Server as the Sync Source and a generic sync destination. The procedure uses the `create-sync-pipe-config` tool in interactive command-line mode and highlights the differences for configuring a Sync Pipe in notification mode.

### Considerations for configuring sync classes

When configuring a Sync Class for a Sync Pipe in notification mode, consider the following:

- Exclude any operational attributes from synchronizing to the destination so that its before and after values are not recorded in the change log. For example, the following attributes can be excluded: `creatorsName`, `createTimeStamp`, `ds-entry-unique-id`, `modifiersName`, and `modifyTimeStamp`. Filter the changes at the change log level instead of making the changes in the Sync Class to avoid extra configuration settings with the following:
  - Use the directory server's `changelog-exclude-attribute` property with (+) to exclude all operational attributes (`change-log-exclude-attribute:+`).
  - Configure a Sync Class that sets the `excluded-auto-mapped-source-attributes` property to each operational attribute to exclude from the synchronization process.
  - Use the directory server's `changelog-exclude-attribute` property to specify each operational attribute to exclude in the synchronization process. Set the configuration using the `dsconfig` tool on the directory server Change Log Backend menu. For example, `setchangelog-exclude-attribute:modifiersName`.
- Use the `destination-create-only-attribute` advanced property on the Sync Class. This property sets the attributes to include on CREATE operations only.
- Use the `replace-all-attr-values` advanced property on the Sync Class. This property specifies whether to use the ADD and DELETE modification types (reversible), or the REPLACE modification type (non-reversible) for modifications to destination entries. If set to `true`, REPLACE is used.
- If targeting specific attributes that require higher performance throughput, consider implementing change log indexing. See [Synchronize through PingDirectoryProxy servers](#) for more information.

### Create the sync pipe

About this task

The initial configuration steps show how to set up a single Sync Pipe from a directory server instance to a generic Sync Destination.

Before starting:

- Place any third-party libraries in the `<server-root>/lib/extensions` folder.
- Implement a server extension for any custom endpoints and place it in the appropriate directory.

Steps

1. If necessary, start PingDataSync Server:

```
$ bin/start-server
```

2. Run the `create-sync-pipe-config` tool.

```
$ bin/create-sync-pipe-config
```

3. At the Initial Synchronization Configuration Tool prompt, press Enter to continue.
4. On the Synchronization Mode menu, select the option for notification mode.
5. On the Synchronization Directory menu, enter the option to create a one-way Sync Pipe in notification mode from directory to a generic client application.

### Configure the sync source

About this task

Steps

1. On the Source Endpoint Type menu, enter the option for the Sync Source type.
2. Choose a pre-existing Sync Source, or create a new sync source.
3. Enter a name for the Source Endpoint and a name for the Sync Source.
4. Enter the base DN for the directory server used for LDAP searches, such as `dc=example,dc=com`, and press Enter to return to the menu. If entering more than one base DN, make sure they do not overlap.
5. On the Server Security menu, select the type of communication that PingDataSync Server will use with endpoint servers.
6. Enter the host and port of the first Source Endpoint server. The Sync Source can specify a single server or multiple servers in a replicated topology. PingDataSync Server contacts this first server if it is available, then contacts the next highest priority server if the first server is unavailable. The server tests the connection.
7. On the Sync User Account menu, enter the DN of the sync user account and password, or press Enter to accept the default, `cn=Sync User,cn=Root DNs,cn=config`. This account allows PingDataSync Server to access the source endpoint server.

### Configure the destination endpoint server

About this task

Steps

1. On the Destination Endpoint Type menu, select the type of datastore on the endpoint server. In this example, select the option for Custom.
2. Enter a name for the Destination Endpoint and a name for the Sync Destination.
3. On the Notifications Setup menu, select the language (Java or Groovy) used to write the server extension.

4. Enter the fully qualified name of the Server SDK extension that implements the abstract class. A Java, extension should reside in the `/lib/extensions` directory. A Groovy script should reside in the `/lib/groovy-scripted-extensions` directory.
5. Configure any user-defined arguments needed by the server extension. Typically, these are connection arguments, which are defined by the extension itself. The values are then entered here and stored in the server configuration.
6. Configure the maximum number of before and after values for all changed attributes. Notification mode requires this. Set the cap to something well above the maximum number of values that any synchronized attribute will have. If this cap is exceeded, PingDataSync Server issues an alert. For this example, we accept the default value of 200.

```
Enter a value for the max changelog before/after values,
or -1 for no limit [200]:
```

7. Configure any key attributes in the change log that must be included in every notification. These attributes can be used to find the destination entry corresponding to the source entry, and are present regardless of whether the attributes changed. Later, any attributes used in a Sync Class include-filter must also be configured as key attributes in the Sync Class.
8. In both standard and notification modes, the Sync Pipe processes the changes concurrently with multiple threads. If changes must be applied strictly in order, the number of Sync Pipe worker threads will be reduced to 1. This will limit the maximum throughput of the Sync Pipe.

#### Next steps

The rest of the configuration steps follow the same process as a standard synchronization mode Sync Pipe. See The Sync User account for more information.

## Access control filtering on the sync pipe

PingDataSync Server provides an advanced Sync Pipe configuration property, `filter-changes-by-user`, which performs access control filtering on a changelog entry for a specific user.

Since the changelog entry contains data from the target entry, the access controls filter out attributes that the user does not have the privileges to see before it is returned. For example, values in the `changes`, `ds-changelog-before-values`, `ds-changelog-after-values`, `ds-changelog-entry-key-attrs-values`, and `deletedEntryAttrs` are filtered out through access control instructions.

#### Note:

This property is only available for notification mode and can be configured using the `create-sync-pipe-config` or the `dsconfig` tool.

The source server must be a PingDirectory Server or Nokia 8661 Directory Server, or a PingDirectoryProxy Server or Nokia 8661 Directory Proxy Server that points to a PingDirectory Server or Nokia 8661 Directory Server.

#### Considerations for access control filtering

- The directory server will not return the changelog entry if the user is not allowed to see the target entry.
- The directory server strips out any attributes that the user is not allowed to see.
- If no changes are left in the entry, no changelog entry will be returned.
- If only some attributes are stripped out, the changelog entry will be returned.
- Access control filtering on a specific attribute value is not supported. Either all attribute values are returned or none.
- If a sensitive attribute policy is used to filter attributes when a client normally accesses the directory server, this policy will not be taken into consideration during notifications since the Sync User is always connecting using the same method. Configure access controls to filter out attributes, not based on

the type of connection made to the server, but based on who is accessing the data. The `filter-changes-by-user` property will be able to evaluate if that person should have access to these attributes.

## Configure the sync pipe to filter changes by access control instructions

About this task

Steps

1. Set the `filter-changes-by-user` property to filter changes based on access controls for a specific user.

```
$ bin/dsconfig set-sync-pipe-prop \
 --pipe-name "Notifications Sync Pipe" \
 --set "filter-changes-by-user:uid=admin,dc=example,dc=com"
```

2. On the source directory server, set the `report-excluded-changelog-attributes` property to include the names of users that have been removed through access control filtering. This will allow PingDataSync Server to warn about attributes that were supposed to be synchronized but were filtered out. This step is recommended but not required.

```
$ bin/dsconfig set-backend-prop \
 --backend-name "changelog" \
 --set "report-excluded-changelog-attributes:attribute-names"
```

### Note:

PingDataSync Server only uses the `attribute-names` setting for the PingDirectory Server's `report-excluded-changelog-attributes` property. It does not use the `attribute-counts` setting for the property.

## Configure synchronization with SCIM

PingDataSync Server provides data synchronization between directory servers or proxy servers and System for Cross-domain Identity Management (SCIM) 1.1 applications over HTTP. Synchronization can be done with custom SCIM applications, or with the PingData PingDirectory Server and PingDirectoryProxy Server configured as SCIM servers using the SCIM extension.

### Synchronize with a SCIM sync destination overview

The SCIM 1.1 protocol is designed to make managing user identity in cloud-based applications and services easier. SCIM enables provisioning identities, groups, and passwords to, from, and between clouds. PingDataSync Server can be configured to synchronize with SCIM service providers.

### Note:

Both the Ping Identity PingDirectory Server and PingDirectoryProxy Server can be configured to be SCIM servers using the SCIM HTTP Servlet Extension.

PingDataSync Server is LDAP-centric and operates on LDAP attributes. The SCIM sync destination server component acts as a translation layer between a SCIM service provider's schema and an LDAP representation of the entries. While PingDataSync Server is LDAP-centric and typically at least one endpoint is an LDAP Directory Server, this is not a strict requirement. For example, a JDBC to SCIM sync pipe can be configured.

PingDataSync Server contains sync classes that define how source and destination entries are correlated. The SCIM sync destination contains its own mapping layer, based on `scimresources.xml` that maps LDAP schema to and from SCIM.

**Note:**

PingDataSync Server can use SCIM only as a sync destination. There is no mechanism in the SCIM protocol for detecting changes, so it cannot be used as a Sync Source.

### SCIM destination configuration objects

The `SCIMSyncDestination` object defines a SCIM 1.1 service provider Sync Pipe destination that is accessible over HTTP through the SCIM protocol. It is configured with the following properties:

- `server` – Specifies the names of the SCIM External Servers that are used as the destination of synchronization.
- `resource-mapping-file` – Specifies the path to the `scim-resources.xml` file, a configuration file that defines the SCIM schema and maps it to the LDAP schema. This file is located in `<server root>/config/scim-resources.xml` by default. This file can be customized to define and expose deployment-specific resources.
- `rename-policy` – Specifies how to handle the rename of a SCIM resource.

The SCIM Sync Destination object is based on the SCIM SDK. Before configuring a SCIM destination, review the following documents on the Simple Cloud web site:

- SCIM Core Schema
- SCIM REST API

### Considerations for synchronizing to a SCIM destination

When configuring an LDAP to SCIM Sync Pipe, consider the following:

#### Use `scim-resources.xml` for attribute and DN mappings

There are two layers of mapping: once at the Sync Class level and again at the SCIM Sync Destination level in the `scim-resources.xml` file. To reduce complexity, do all possible mappings in the `scim-resources.xml` file.

#### Avoid groups unless the SCIM ID is DN based

Group synchronization is supported if the SCIM ID is based on the DN. If the SCIM ID is not the DN itself, it must be one of the components of the RDN, meaning that the DNs of group members must contain the necessary attribute.

#### SCIM modifies entries using PUT

The SCIM Sync Destination modifies entries using the full HTTP PUT method. For every modify, SCIM replaces the entire resource with the updated resource. For information about the implications of this on password updates, see [Password considerations with SCIM](#).

### Rename a SCIM resource

The SCIM 1.1 protocol does not support changes that require the SCIM resource to be renamed, such as a MODDN operation. Instead, when a change is detected to an attribute value that is used as part of the SCIM ID attribute, PingDataSync Server handles it in one of the following ways:

- Deletes the specified SCIM resource and then adds the new resource with the new SCIM ID.
- Adds the new resource with the new SCIM ID and then deletes the old resource.
- Skips the rename portion of the change. If renames are expected on the source endpoint, a careful set of destination-correlation attributes should be chosen so that the destination can still be found after it is renamed on the source.

Configure this by setting the `rename-policy` property of the SCIM sync destination.

### Password considerations with SCIM

Because the SCIM sync destination modifies entries using a full PUT method, special considerations need to be made for password attributes.

A Ping Identity SCIM Server allows password attributes to be omitted from a change when they have not been modified by an operation. This prevents passwords from inadvertently being overwritten during the PUT operation, which does not include the password attribute. Ideally, other SCIM service providers will not wipe a password because a PUT request does not contain it. Check with the SCIM vendor to confirm this behavior before starting a SCIM sync pipe.

## Configure synchronization with SCIM

Configure synchronization with SCIM using the `create-sync-pipe-config` utility and the `dsconfig` command. Configuring synchronization between an LDAP server and a SCIM service provider includes the following:

- Configure one external server for every physical endpoint.
- Configure the Sync Source server and designate the external servers that correspond to the source server.
- Configure the Sync Destination server and designate the external servers that correspond to the SCIM sync destination.
- Configure the LDAP to SCIM Sync Pipe.
- Configure the Sync Classes. Each Sync Class represents a type of entry that needs to be synchronized. When specifying a Sync Class for synchronization with a SCIM service provider, avoid including attribute and DN mappings. Instead use the Sync Class to specify the operations to synchronize and which correlation attributes to use.
- Set the evaluation order for the Sync Classes to define the processing precedence for each class.
- Configure the `scim-resources.xml` file. If possible, change the `<resourceIDMapping>` element(s) to use whatever the SCIM Service Provider uses as the SCIM ID.
- Set Up Communication for each External Server. Run `prepare-endpoint-server` once for every LDAP external server that is part of the Sync Source.
- Use `realtime-sync` to start the Sync Pipe.

### Configure the external servers

About this task

Perform the following to configure an external server for each host in the deployment:

Steps

1. Configure a PingDirectory Server as an external server, which will later be configured as a Sync Source. On PingDataSync Server, run the following `dsconfig` command:

```
$ bin/dsconfig create-external-server \
 --server-name source-ds \
 --type ping-identity-ds \
 --set server-host-name:ds1.example.com \
 --set server-port:636 \
 --set "bind-dn:cn=Directory Manager" \
```

```
--set password:secret \
--set connection-security:ssl \
--set key-manager-provider:Null \
--set trust-manager-provider:JKS
```

2. Configure the SCIM server as an external server, which will later be configured as a Sync Destination. The `scim-service-url` property specifies the complete URL used to access the SCIM service provider. The `user-name` property specifies the account used to connect to the SCIM service provider. By default, the value is `cn=Sync User,cn=Root DNs,cn=config`. Some SCIM service providers may not have the user name in DN format.

```
$ bin/dsconfig create-external-server \
--server-name scim \
--type scim \
--set scim-service-url:https://scim1.example.com:8443 \
--set "user-name:cn=Sync User,cn=Root DNs,cn=config" \
--set password:secret \
--set connection-security:ssl \
--set hostname-verification-method:strict \
--set trust-manager-provider:JKS
```

## Configure the PingDirectory Server sync source

### About this task

Configure the Sync source for the synchronization network. More than one external server can be configured to act as the Sync source for failover purposes. If the source is a PingDirectory Server, also configure the following items:

- Enable the changelog password encryption plugin on any directory server that will receive password modifications. This plugin intercepts password modifications, encrypts the password, and adds an encrypted attribute to the change log entry.
- Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend, so that PingDataSync Server can record which attributes were removed during a DELETE operation.

Perform the following steps to configure the Sync source:

### Steps

1. Run `dsconfig` to configure the external server as the Sync source. Based on the previous example where the PingDirectory Server was configured as `source-ds`, run the following command:

```
$ bin/dsconfig create-sync-source --source-name source \
--type ping-identity \
--set base-dn:dc=example,dc=com \
--set server:source-ds \
--set use-changelog-batch-request:true
```

2. Enable the change log password encryption plugin on any server that receives password modifications. The encryption key can be copied from the output, if displayed, or accessed from the `<server-root>/bin/sync-pipe-cfg.txt` file, if the `create-sync-pipe-config` tool was used to create the sync pipe.

```
$ bin/dsconfig set-plugin-prop \
--plugin-name "Changelog Password Encryption" \
--set enabled:true \
--set changelog-password-encryption-key:<key>
```

3. On PingDataSync Server, set the decryption key used to decrypt the user password value in the change log entries. The key allows the user password to be synchronized to other servers that do not use the same password storage scheme.

```
$ bin/dsconfig set-global-sync-configuration-prop \
 --set changelog-password-decryption-key:ej5u9e39pq-68
```

4. Configure the `changelog-deleted-entry-include-attribute` property on the changelog backend.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
 --set changelog-deleted-entry-include-attribute:objectClass
```

### Configure the SCIM sync destination

Configure the SCIM sync destination to synchronize data with a SCIM service provider. Run the `dsconfig` command:

```
$ bin/dsconfig create-sync-destination \
 --destination-name scim \
 --type scim \
 --set server:scim
```

### Configure the sync pipe, sync classes, and evaluation order

About this task

Configure a Sync Pipe for LDAP to SCIM synchronization, create Sync classes for the Sync Pipe, and set the evaluation order index for the Sync classes.

#### Note:

The Synchronization mode must be set to Standard. Notification Mode cannot be used with SCIM.

#### Steps

1. Once the source and destination endpoints are configured, configure the Sync Pipe for LDAP to SCIM synchronization. Run the `dsconfig` command to configure an LDAP-to-SCIM Sync Pipe:

```
$ bin/dsconfig create-sync-pipe \
 --pipe-name ldap-to-scim \
 --set sync-source:source \
 --set sync-destination:scim
```

2. The next set of steps define three Sync Classes. The first Sync Class is used to match user entries in the Sync Source. The second class is used to match group entries. The third class is a DEFAULT class that is used to match all other entries.

Run the `dsconfig` command to create the first Sync Class and set the Sync Pipe Name and Sync Class name:

```
$ bin/dsconfig create-sync-class \
 --pipe-name ldap-to-scim \
 --class-name user
```

3. Use `dsconfig` to set the base DN and filter for this Sync class. The `include-base-dn` property specifies the base DN in the source, which is `ou=people,dc=example,dc=com` by default. This Sync Class is invoked only for changes at the `ou=people` level. The `include-filter` property specifies an LDAP filter that tells PingDataSync Server to include `inetOrgPerson` entries as user entries.

The `destination-correlation-attributes` specifies LDAP attributes that allow PingDataSync Server to find the destination resource on the SCIM server. The value of this property will vary. See [Identify a SCIM resource at the destination](#) for details.

```
$ bin/dsconfig set-sync-class-prop \
 --pipe-name ldap-to-scim \
 --class-name user \
 --add include-base-dn:ou=people,dc=example,dc=com \
 --add "include-filter:(objectClass=inetOrgPerson)" \
 --set destination-correlation-attributes:externalId
```

4. Create a second Sync class, which is used to match group entries:

```
$ bin/dsconfig create-sync-class \
 --pipe-name ldap-to-scim \
 --class-name group
```

5. For the second Sync class, set the base DN and the filters to match the group entries.

```
$ bin/dsconfig set-sync-class-prop \
 --pipe-name ldap-to-scim \
 --class-name group \
 --add include-base-dn:ou=groups,dc=example,dc=com \
 --add "include-filter:(|(objectClass=groupOfEntries)\
 (objectClass=groupOfNames)(objectClass=groupOfUniqueNames)\
 (objectClass=groupOfURLs))"
```

6. For the third Sync class, create a DEFAULT Sync class that is used to match all other entries. To synchronize changes from only user and group entries, set `synchronize-creates`, `synchronize-modifies`, and `synchronize-delete` to false.

```
$ bin/dsconfig create-sync-class \
 --pipe-name ldap-to-scim \
 --class-name DEFAULT \
 --set evaluation-order-index:99999 \
 --set synchronize-creates:false \
 --set synchronize-modifies:false \
 --set synchronize-deletes:false
```

7. After all of the Sync classes needed by the Sync Pipe are configured, set the evaluation order index for each Sync class. Classes with a lower number are evaluated first. Run `dsconfig` to set the evaluation order index for the Sync class. The actual number depends on the deployment.

```
$ bin/dsconfig set-sync-class-prop \
 --pipe-name ldap-to-scim \
 --class-name user \
 --set evaluation-order-index:100
```

### Configure communication with the source server

Configure communication between PingDataSync Server and the LDAP source servers with the `prepare-endpoint-server` tool. If user accounts do not exist, this tool creates the appropriate user account and its privileges. Also, because the source is an PingDirectory Server, this tool enables the changelog.

#### Note:

The `prepare-endpoint-server` tool can only be used on LDAP directory servers. For the SCIM Server, manually create a sync user entry.

Run the **prepare-endpoint-server** command to setup communication between PingDataSync Server and the source server(s). The tool will prompt for the bind DN and password to create the user account and enable the change log.

```
$ bin/prepare-endpoint-server \
 --hostname dsl.example.com \
 --port 636 \
 --useSSL \
 --trustAll \
 --syncServerBindDN "cn=Sync User,cn=Root DNs,cn=config" \
 --syncServerBindPassword "password" \
 --baseDN "dc=example,dc=com" \
 --isSource
```

## Start the sync pipe

About this task

The **realtime-sync** tool sets a specific starting point for real-time synchronization, so that changes made before the current time are ignored.

Steps

1. Run the **realtime-sync** tool to set the startpoint for the Sync source.

```
$ bin/realtime-sync set-startpoint \
 --end-of-changelog \
 --pipe-name ldap-to-scim
```

2. When ready to start synchronization, run the following command:

```
$ bin/realtime-sync start \
 --pipe-name ldap-to-scim \
 --no-prompt
```

## Map LDAP schema to SCIM resource schema

The resources configuration file is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for standard SCIM Users and Groups resources, and mappings to standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes. It is installed with the PingDirectory Server. This file can be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

The default configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. In all cases, this must be changed to match the attribute that the destination SCIM service provider is using for its SCIM resource ID. For example, if the destination uses the value of the `uid` attribute, modify the `scim-resources.xml` file to change the `resourceIDMapping` as follows:

```
<resourceIDMapping ldapAttribute="uid"/>
```

Ideally, this would be an attribute that exists on the source LDAP entry. If not, PingDataSync Server can construct it using a Constructed Attribute Mapping. For example, the SCIM service provider used the first and last initials of the user, concatenated with the employee ID (given by the `eid` attribute) as the SCIM resource ID. In this case, an attribute mapping would be constructed as follows:

```
$ dsconfig create-attribute-mapping \
```

```
--map-name MyAttrMap \
--mapping-name scimID \
--type constructed \
--set 'value-pattern:{givenname:/^(.)(.*)/$1/s}{sn:/^(.)(.*)/$1/s}{eid}'
```

This creates an attribute called `scimID` on the mapped entry when processed by the Sync engine. For example, if the user's name was John Smith, with employee ID 12345, then the `scimID` would be `js12345`. Once this is done, configure the `scim-resources.xml` file as follows:

```
<resourceIDMapping ldapAttribute="scimID" />
```

This will cause it to pull out the constructed `scimID` value from the entry and use that at the SCIM resource ID when making requests to the service provider.

**Note:**

Constructed attribute mappings support multivalued source attributes for conditional (using the `conditional-value-pattern` property) and non-conditional (using the `value-pattern` property) value patterns. Only one of the source attributes that contribute to a given value pattern can be multivalued.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the PingDirectory Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. If using the SCIM HTTP Servlet Extension for the PingDirectory Server, this can be implemented in many ways, such as:

- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). Make sure that any attributes that contain binary data are declared using `dataType=binary` in the `scim-resources.xml` file. When using the Identity Access API, make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes that contain binary data. This instructs the server to base64-encode the data before returning it to clients.

If attributes that are not declared as binary in the schema and contain binary data (or just data that is invalid in XML), the server will check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values that include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scimresources.xml` file.

### **<resource> element**

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A `resource` element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

#### **<attribute> element**

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An `attribute` element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
- `simple`: specifies a simple, singular SCIM attribute.
- `complex`: specifies a complex, singular SCIM attribute.
- `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
- `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

#### **<simple> element**

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false`.

A `simple` element contains the following XML element in sequence:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

#### **<complex> element**

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard type, primary, and display sub-attributes do not need to be specified.

**<simpleMultiValued> element**

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

**<complexMultiValued> element**

A `complexMultiValued` element has the following XML attributes:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard `addresses` SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

`canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

**<subAttribute> element**

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is `false`.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, and `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case- ignore match. The default value is `false`.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

**<canonicalValue> element**

A `canonicalValue` element has the following XML attributes:

- **name:** specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element in sequence:

- **subMapping:** an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

### <mapping> element

A `mapping` element has the following XML attributes:

- **ldapAttribute:** a required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- **transform:** an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP, and LDAP to SCIM. The available transformations are described in [Map LDAP schema to SCIM resource schema](#).

### <subMapping> element

A `subMapping` element has the following XML attributes:

- **name:** a required element specifying the name of the sub-attribute that is mapped.
- **ldapAttribute:** a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- **transform:** an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. Available transformations are described in [Map LDAP schema to SCIM resource schema](#).

### <LDAPSearch> element

A `LDAPSearch` element has the following XML attributes:

- **baseDN:** a required element specifying the LDAP search base DN to be used when querying for the SCIM resource.
- **filter:** a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- **resourceIDMapping:** an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN.

#### Note:

The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them with an `ID` attribute.

### <resourceIDMapping> element

A `resourceIDMapping` element has the following XML attributes:

- **ldapAttribute:** a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- **createdBy:** a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `<scim-consumer>`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or `directory`, (as would be the case if the mapped LDAP attribute is `entryUUID`).

If the LDAP attribute value is not listed as destination correlation attribute, this setting is not used by PingDataSync Server.

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
 <baseDN>ou=people,dc=example,dc=com</baseDN>
 <filter>(objectClass=inetOrgPerson)</filter>
 <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

### <LDAPAdd> element

A `LDAPAdd` element has the following XML attributes:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

### <fixedAttribute> element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The default value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made.

A `fixedAttribute` element contains the following XML element:

- `fixedValue`: one or more elements specifying the fixed LDAP values.

## Identify a SCIM resource at the destination

When a SCIM Sync Destination needs to synchronize a change to a SCIM resource on the destination SCIM server, it must first fetch the destination resource. If the destination resource ID is known, the resource will be retrieved by its ID. If not, a search is performed using the mapped destination correlation attributes. Configuring this requires coordination between the Sync Class and the `scim-resources.xml` mapping file.

The `scim-resources.xml` mapping file treats the value of the `<resourceIDMapping>` element's `ldapAttribute` attribute as the SCIM ID of the source entry. If this value is also listed as a value of the Sync Class's `destination-correlation-attributes` property, then the value of this LDAP attribute is used as the SCIM ID of the destination resource.

If no value of `destination-correlation-attributes` matches the `<resourceIDMapping>` element's `ldapAttribute` attribute, the SCIM ID of the destination resource is considered unknown. In this case, the SCIM Sync Destination treats the values of `destination-correlation-attributes` as search terms, using them to construct a filter for finding the destination resource. Each value of `destination-correlation-attributes` will be mapped to a corresponding SCIM attribute name, and equality matches will be used in the resulting filter.

If the `ldapAttribute` value is not listed as a destination correlation attribute, this setting is not used by PingDataSync Server.

The following table illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

## Identifying a SCIM resource

Method for retrieving SCIM resource	Condition	Example condition	Example request
Retrieve resource directly	Used if a destination-correlation-attribute value matches the <resourceIDMapping>ldapAttribute value.	destination-correlation-attribute=mail,uid;<resourceIDMapping>ldapAttribute="mail" createdBy="directory"/>	GET scim/Users/person@example.com
Retrieve resource using search	Used if no destination-correlation-attribute value matches the <resourceIDMapping>ldapAttribute value.	destination-correlation-attribute=mail,uid;<resourceIDMapping>ldapAttribute="entryUUID" createdBy = "directory"/>	GET /scim/Users?filter=emails+eq"person@example.com" and userName+eq"person"

The unique ID of a destination SCIM resource will most likely be unknown, and the search method will need to be used. However, not all SCIM service providers support the use of filters. Therefore, not all SCIM service providers may be usable as SCIM Sync Destinations.

## Manage logging, alerts, and alarms

Each PingData server supports extensive logging features to track all aspects of the PingData topology.

### Logs and log publishers

PingData servers support different types of log publishers that can be used to provide the monitoring information for operations, access, debug, and error messages that occur during normal server processing. The server provides a standard set of default log files as well as mechanisms to configure custom log publishers with their own log rotation and retention policies.

#### Types of log publishers

Several types of log publishers can be used to log processing information about the server, including:

##### Audit loggers

Provide information about actions that occur within the server. Specifically, this type of log records all changes applied, detected or failed; dropped operations that were not completed; changes dropped due to being out of scope, or no changes needed for an operation. The log also shows the entries that were involved in a process.

##### Error loggers

Provide information about warnings, errors, or significant events that occur within the server.

##### Debug loggers

Provide detailed information about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.

### Access loggers

Provide information about LDAP operations processed within the server. This log only applies to operations performed in the server. This includes configuration changes, searches of monitor data, and bind operations for authenticating administrators using the command-line tools and the Administrative Console.

### View the list of log publishers

View the list of log publishers on each server using the `dsconfig` tool:

```
$ bin/dsconfig list-log-publishers
Log Publisher : Type : enabled
-----:-----:-----
Debug ACI Logger : debug-access : false
Expensive Operations Access : file-based-access : false
Logger
Failed Operations Access Logger
File-Based Access Logger
File-Based Audit Logger
: file-based-access : true
: file-based-access : true
: file-based-audit : false
File-Based Debug Logger
File-Based Error Logger
Replication Repair Logger
: file-based-debug : false
: file-based-error : true
: file-based-error : true
```

### Log compression

PingData servers support the ability to compress log files as they are written. Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled when the logger is created. Compression cannot be turned on or off once the logger is configured. If the server encounters an existing log file at startup, it will rotate that file and begin a new one rather than attempting to append it to the previous file.

Compression is performed using the standard `gzip` algorithm. Because it can be useful to have an amount of uncompressed log data for troubleshooting, having a second logger defined that does not use compression may be desired.

Configure compression by setting the `compression-mechanism` property to have the value of `gzip` when creating a new logger. See [Create a new log publisher](#) on page 1455 for details.

### Configure log file encryption

#### About this task

The server supports the ability to encrypt log files as they are written. The `encrypt-log` configuration property controls whether encryption will be enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension (and if both encryption and compression are enabled, the extension will be `.gz.encrypted`). Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off once the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This will also reduce

the overall size of the log file. The **encrypt-file** tool (or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`) is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the **encryption-settings create** command. By default, the encryption will be performed with the server's preferred encryption settings definition. To explicitly specify which definition should be used for the encryption, the `encryption-settings-definition-id` property can be set with the ID of that definition. It is recommended that the encryption settings definition is created from a passphrase so that the file can be decrypted by providing that passphrase, even if the original encryption settings definition is no longer available. A randomly generated encryption settings definition can also be created, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data may remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written. To examine the contents of a log file that is being actively written, use the **rotate-log** tool to force the file to be rotated before attempting to examine it.

The following commands can be used to set log file encryption:

### Steps

1. Use **dsconfig** to enable encryption for a Log Publisher. In this example, the File-basedAccess Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted
Access" \
 --type file-based-access \
 --set enabled:true \
 --set compression-mechanism:gzip \
 --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
 --set encrypt-log:true \
 --set log-file:logs/encrypted-access \
 --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --set "rotation-policy:Size Limit Rotation Policy" \
 --set "retention-policy:File Count Retention Policy" \
 --set "retention-policy:Free Disk Space Retention Policy" \
 --set "retention-policy:Size Limit Retention Policy"
```

2. To decrypt and decompress the file:

```
$ bin/encrypt-file --decrypt \
 --decompress-input \
 --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
 --output-file decrypted-access
Initializing the server's encryption framework...DoneWriting decrypted
data to file '/ds/PingDirectory/decrypted-access' using a key generated
from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'Success
fully wrote 123,456,789 bytes of decrypted data
```

## Synchronization logs and messages

TPingDataSync Server provides a standard set of default log files to monitor the server activity. View this set of logs in the `<server-root>/logs` directory. The following default log files are available.

## PingDataSync Server logs

Log file	Description
access	File-based Access Log that records LDAP operations processed by PingDataSync Server. Access log records can be used to provide information about problems during operation processing and provide information about the time required to process each operation.
config-audit.log	Records information about changes made to the server configuration in a format that can be replayed using the <code>dsconfig</code> tool.
errors	File-based Error Log that provides information about warnings, errors, and significant events that are not errors but occur during server processing.
server.out	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information will be written to <code>server.out</code> .
server.pid	Stores the server's processID.
server.status	Stores the timestamp, a status code, and an optional message that provides additional information about the server status.
setup.log	Records messages that occur during the initial server configuration with the <code>setup</code> command.
sync	File-based Sync Log that records synchronization operations processed by the server. Specifically, the log records all changes applied, detected or failed; dropped operations that were not synchronized; changes dropped due to being out of scope, or no changes needed for synchronization.
sync-pipe-cfg.txt	Records the configuration changes used with the <code>bin/create-sync-pipe-config</code> tool. The file is placed wherever the tool is run. Typically, this is in <code>&lt;server-root&gt;</code> or in the <code>bin</code> directory.
tools	Holds logs for long running utilities. Current and previous copies of the log are present in the directory.
update.log	Records messages that occur during a server upgrade.

## Sync log message types

PingDataSync Server logs certain types of log messages with the sync log. Message types can be included or excluded from the logger, or added to a custom log publisher.

### Sync log message types

Message type	Description
change-applied	Default summary message. Logged each time a change is applied successfully.
change-detected	Default summary message. Logged each time a change is detected.
change-failed-detailed	Default detail message. Logged when a change cannot be applied. It includes the reason for the failure and details about the change that can be used to manually repair the failure.

Message type	Description
dropped-op-type-not-synchronized	Default summary message. Logged when a change is dropped because the operation type (for example, ADD) is not synchronized for the matching Sync Class.
dropped-out-of-scope	Default summary message. Logged when a change is dropped because it does not match any Sync Class.
no-change-needed	Default summary message. Logged each time a change is dropped because the modified source entry is already synchronized with the destination entry.
change-detected-detailed	Optional detail message. Logged each time a change is detected. It includes attribute values for added and modified entries. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
entry-mapping-details	Optional detail message. Logged each time a source entry (attributes and DN) are mapped to a destination entry. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
change-applied-detailed	Optional detail message. Logged each time a change is applied. It includes attribute values for added and modified entries. This information is useful for diagnosing problems, but it causes log files to grow faster, which impacts performance.
change-failed	Optional summary message. Logged when a change cannot be applied. It includes the reason for the failure but not enough information to manually repair the failure.
intermediate-failure	Optional summary message. Logged each time an attempt to apply a change fails. Note that a subsequent retry of applying the change might succeed.

## Create a new log publisher

### About this task

PingData servers provide customization options to create log publishers with the `dsconfig` command. After creating a new log publisher, configure the log retention and rotation policies. For more information, see [Configure log retention and log rotation policies](#).

### Steps

1. Use the `dsconfig` command to create and configure the new log publisher. (If using `dsconfig` in interactive mode, log publishers are created and managed under the Log Publisher menu.) The following example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
 --type file-based-access --publisher-name "Disconnect Logger" \
 --set enabled:true \
 --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --set "rotation-policy:Size Limit Rotation Policy" \
 --set "retention-policy:File Count Retention Policy" \
 --set log-connects:false \
 --set log-requests:false --set log-results:false \
```

```
--set log-file:logs/disconnect.log
```

To configure compression on the logger, add the following option to the previous command:

```
--set compression-mechanism: gzip
```

Compression cannot be disabled or turned off once configured for the logger. Determine logging requirements before configuring this option.

2. View log publishers with the following command:

```
$ bin/dsconfig list-log-publishers
```

## Configure log signing

### About this task

PingData servers support the ability to cryptographically sign a log to ensure that it has not been modified. For example, financial institutions require tamper-proof audit logs files to ensure that transactions can be properly validated and ensure that they have not been modified by a third-party entity or internally by an unauthorized person.

When enabling signing for a logger that already exists, the first log file will not be completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled will be considered completely valid. For the same reason, if a log file is still open for writing, then signature validation will not indicate that the log is completely valid because the log will not include the necessary "end signed content" indicator at the end of the file.

To validate log file signatures, use the **validate-file-signature** tool provided in the `bin` directory of the server (or the `bat` directory on Windows systems). Once this property is enabled, disable and then re-enable the log publisher for the changes to take effect.

Perform the following steps to configure log signing:

### Steps

1. Use **dsconfig** to enable log signing for a Log Publisher. In this example, set the `sign-log` property on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set sign-log:true
```

2. Disable and then re-enable the Log Publisher for the changes to take effect.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set enabled:false
```

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set enabled:true
```

3. To validate a signed file, use the **validate-file-signature** tool to check if a signed file has been altered.

```
$ bin/validate-file-signature --file logs/audit
```

```
All signature information in file 'logs/audit' is valid
```

If any validation errors occur, a message displays that is similar to this:

```
One or more signature validation errors were encountered while validating
the contents of file 'logs/audit':
* The end of the input stream was encountered without encountering the end
of an active signature block. The contents of this signed block cannot be
trusted because the signature cannot be verified
```

## Configure log retention and log rotation policies

PingData servers enable configuring log rotation and log retention policies.

### Log retention

When any retention limit is reached, the server removes the oldest archived log prior to creating a new log. Log retention is only effective if a log rotation policy is in place.

A new log publisher must have at least one log retention policy configured. The following policies are available:

#### File Count Retention policy

Sets the number of log files for the server to retain. The default file count is 10 logs. If the file count is set to 1, the log will continue to grow indefinitely without being rotated.

#### Free Disk Space Retention policy

Sets the minimum amount of free disk space. The default free disk space is 500 MB.

#### Size Limit Retention policy

Sets the maximum size of the combined archived logs. The default size limit is 500 MB.

#### Custom Retention policy

Create a new retention policy that meets the server's requirements. This will require developing custom code to implement the desired log retention policy.

#### Never Delete Retention policy

Used in a rare event that does not require log deletion.

### Log rotation

When a rotation limit is reached, the server rotates the current log and starts a new log. A new log publisher must have at least one log rotation policy configured. The following policies are available:

#### Time Limit Rotation policy

Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every seven days.

#### Fixed Time Rotation policy

Rotates the logs every day at a specified time (based on 24-hour). The default time is 2359.

#### Size Limit Rotation policy

Rotates the logs when the file reaches the maximum size. The default size limit is 100 MB.

### Never Rotate policy

Used in a rare event that does not require log rotation.

### Configure the log rotation policy

Use `dsconfig` to modify the log rotation policy for the access logger:

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Access Logger" \
 --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

### Configure the log retention policy

Use `dsconfig` to modify the log retention policy for the access logger:

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Access Logger" \
 --set "retention-policy:Free Disk Space Retention Policy"
```

## Configure log listeners

The server provides two log file rotation listeners: the copy log file rotation listener and the summarize log file rotation listener, which can be enabled with a log publisher. Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file will be subject to deletion by a log file retention policy, but the copy will not be automatically removed.

Use the following command to create a new copy log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
 --listener-name "Copy on Rotate" \
 --type copy \
 --set enabled:true \
 --set copy-to-directory:/path/to/archive/directory \
 --set compress-on-copy:true</screen>
```

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that will be written there. The server will automatically monitor free disk space on the target file system and will generate administrative alerts if the amount of free space gets too low.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently rotated log file and writes its output to a file in a specified location.

This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-log` tool, including the `file-based-access` and `operation-timing-access` logger types. Use the following command to create a new summarize log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
 --listener-name "Summarize on Rotate" \
 --type summarize \
 --set enabled:true \
```

```
--set output-directory:/path/to/summary/directory
```

The summary output files have the same name as the rotated log file, with an extension of `.summary`. If the `output-directory` property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically be deleted. Though files are generally small in comparison to the log files themselves, make sure that there is enough space available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

## System alarms, alerts, and gauges

An alarm represents a stateful condition of the server or a resource that may indicate a problem, such as low disk space or external server unavailability. A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state. Gauges are used for monitoring continuous values like CPU load or free disk space (Numeric Gauge), or an enumerated set of values such as 'server available' or 'server unavailable' (Indicator Gauge). Gauges generate alarms, when the gauge's severity changes due to changes in the monitored value. Like alerts, alarms have severity (NORMAL, WARNING, MINOR, MAJOR, CRITICAL), name, and message. Alarms will always have a `Condition` property, and may have a `Specific Problem` or `Resource` property. If surfaced through SNMP, a `ProbableCause` property and `AlarmType` property are also listed. Alarms can be configured to generate alerts when the alarm's severity changes.

There are two alert types supported by the server - standard and alarm-specific. The server constantly monitors for conditions that may need attention by administrators, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`. The server can be configured to generate alarm-specific alerts instead of, or in addition to, standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

The server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. Existing gauges can be tailored to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered. The Stats Logger can be used to view historical information about the value and severity of all system gauges.

PingData servers are compliant with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state can result in one or more alerts. An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when `Condition` and `Resource` property are the same. The Alarm Manager, which governs the actions performed when an alarm state is entered, is configurable through the `dsconfig` tool and Administrative Console.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. Alarms can be viewed with the `status` tool. As with other alert types, alert handlers can be configured to manage the alerts generated by alarms. A complete listing of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

### Alert handlers

Alert notifications can be sent to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The server provides a number of alert handler implementations configured with the `confined` tool, including:

#### Error Log Alert Handler

Sends administrative alerts to the configured server error logger(s).

### JMX Alert Handler

Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. The server uses JMX for monitoring entries and requires that the JMX connection handler be enabled.

### SNMP Alert Handler

Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.

If needed, the Server SDK can be used to implement additional, third-party alert handlers.

### Configure alert handlers

Alert handlers can be configured with the `dsconfig` tool. PingData servers support JMX, SMTP, and SNMP. Use the `--help` option for a list of configuration options. The following is a sample command to create and enable an SMTP Alert handler from the command line:

```
$ bin/dsconfig create-alert-handler \
 --handler-name "SMTP Alert Handler" \
 --type smtp \
 --set enabled:true \
 --set "sender-address:alerts@example.com" \
 --set "recipient-address:administrators@example.com" \
 --set "message-subject:Directory Admin Alert \%%alert-type\%%" \
 --set "message-body:Administrative alert:\n\%%alert-message\%%"
```

## Test alerts and alarms

### About this task

After alarms and alert handlers are configured, verify that the server takes the appropriate action when an alarm state changes by manually increasing the severity of a gauge. Alarms and alerts can be verified with the `status` tool.

### Steps

1. Configure a gauge with `dsconfig` and set the `override-severity` property to `critical`. The following example uses the CPU Usage (Percent) gauge.

```
$ dsconfig set-gauge-prop \
 --gauge-name "CPU Usage (Percent)" \
 --set override-severity:critical
```

2. Run the `status` tool to verify that an alarm was generated with corresponding alerts. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms. The sample output has been shortened to show just the alarms and alerts information.

```
$ bin/status
```

```

## Use the status tool

PingData servers provides the **status** tool, which outputs the health of the server. The **status** tool polls the current health of the server and displays summary information about the number of operations processed in the network. The tool provides the following information:

### Status tool sections

Status section	Description
Server Status	Displays the server start time, operation status, number of connections (open, max, and total).
Server Details	Displays the server details including host name, administrative users, install path, server version, and Java version.

Status section	Description
Connection Handlers	Displays the state of the connection handlers including address, port, protocol and current state.
Admin Alerts	Displays the 15 administrative alerts that were generated over the last 48-hour period. Limit the number of displayed alerts using the <code>--maxAlerts</code> option. For example, <code>status --maxAlerts 0</code> suppresses all alerts.

## Synchronization-specific status

The `status` tool displays the following information for PingDataSync Server.

### PingDataSync Server status information

Status section	Description
Sync Topology	Displays information about the connected Sync topology and any standby PingDataSync Server instances.
Summary for Sync Pipe	<p>Displays the health status for each Sync Pipe configured on the topology. Status for each Sync Pipe includes the following:</p> <ul style="list-style-type: none"> <li>▪ Started – Indicates whether the Sync Pipe has started.</li> <li>▪ Current Ops Per Second – Lists the current throughput rate in operations per second.</li> <li>▪ Percent Busy – Lists the number of current operations currently divided by the number of worker threads.</li> <li>▪ Changes Detected – Lists the total number of changes detected.</li> <li>▪ Ops Completed Total – Lists the total number of changes detected and completed.</li> <li>▪ Num Ops In Flight – Lists the number of operations that are in flight.</li> <li>▪ Num Ops In Queue – Lists the number of operations that are on the input queue waiting to be synchronized.</li> <li>▪ Source Unretrieved Changes – Lists how many outstanding changes are still in the source change log that have not yet been retrieved by PingDataSync Server. If this is greater than zero, it indicates a backlog, because the internal queue is too full to include these changes.</li> <li>▪ Failed Op Attempts – Lists the number of failed operation attempts.</li> <li>▪ Poll For Source Changes Count – Lists the number of times that the source has been polled for changes.</li> </ul>

Status section	Description
Operations completed for the Sync Pipe	<p data-bbox="500 212 1369 268">Displays the completed operation statistics for the sync pipe, including the following:</p> <ul data-bbox="500 289 1466 1024" style="list-style-type: none"> <li>▪ Success – Lists the number of changes that completed successfully.</li> <li>▪ Out Of Scope – Lists the number of changes that were included in the Sync Pipe, but were dropped because they did not match criteria in a Sync Class.</li> <li>▪ Op Type Not Synced – Lists the number of changes that completed because the operation type is not synchronized.</li> <li>▪ No Change Needed – Lists the number of changes that completed because no change was needed.</li> <li>▪ Entry Already Exists – Lists the number of changes that completed unsuccessfully because the entry already existed for a Create operation.</li> <li>▪ No Match Found – Lists the number of changes that completed unsuccessfully because no match for an operation (such as Modify) was found.</li> <li>▪ Multiple Matches Found – Lists the number of changes that completed unsuccessfully because multiple matches for a source entry were found at the destination.</li> <li>▪ Failed During Mapping – Lists the number of changes that completed unsuccessfully because there was a failure during attribute or DN mapping.</li> <li>▪ Failed At Resource – Lists the number of changes that completed unsuccessfully because they failed at the source.</li> <li>▪ Unexpected Exception – Lists the number of changes that completed unsuccessfully because there was an unexpected exception during processing.</li> <li>▪ Total – Lists the number of operations completed.</li> </ul>
Sync Pipe source stats	<p data-bbox="500 1060 1390 1087">Displays the source statistics for the external server, including the following:</p> <ul data-bbox="500 1108 1466 1654" style="list-style-type: none"> <li>▪ Is Connected – Indicates whether the Sync Source is connected or not.</li> <li>▪ Connected Server – Indicates the host name and port number of the connected server.</li> <li>▪ Successful Connect Attempts – Indicates the number of successful connection attempts.</li> <li>▪ Failed Connect Attempts – Indicates the number of failed connection attempts.</li> <li>▪ Forced Disconnects – Indicates the number of forced disconnects.</li> <li>▪ Root DSE Polls – Indicates the number of polling attempts of the root DSE.</li> <li>▪ Unretrieved Changes – Indicates the number of unretrieved changes.</li> <li>▪ Entries Fetched – Indicates the number of entries fetched from the source.</li> <li>▪ Failed To Decode Changelog Entry – Indicates the operations that failed to decode changelog entries.</li> <li>▪ Ops Excluded By Modifiers Name – Indicates the number of operations excluded by modifier's name.</li> <li>▪ Num Backtrack Batches Retrieved – Indicates the number of backtrack batches retrieved.</li> </ul>

Status section	Description
Sync Pipe destination stats	<p>Displays the destination statistics for the external server, including the following:</p> <ul style="list-style-type: none"> <li>▪ Is Connected – Indicates whether the Sync Source is connected or not.</li> <li>▪ Connected Server – Indicates the connection URL of the connected server.</li> <li>▪ Successful Connect Attempts – Indicates the number of successful connection attempts.</li> <li>▪ Failed Connect Attempts – Indicates the number of failed connection attempts.</li> <li>▪ Forced Disconnects – Indicates the number of forced disconnects.</li> <li>▪ Entries Fetched – Indicates the number of entries fetched.</li> <li>▪ Entries Created – Indicates the number of entries created.</li> <li>▪ Entries Modified – Indicates the number of entries modified.</li> <li>▪ Entries Deleted – Indicates the number of entries deleted.</li> </ul>

## StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD Endpoint type that you can use to transfer metrics data in the StatsD format.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

For a list of available metrics, use the interactive **dsconfig** menu for the Stats Collector Plugin or in the Administrative Console, edit the **Stats Collector** plugin as explained in the second example.

You configure the Monitoring Endpoint using the **dsconfig** command. When you configure Monitoring Endpoint, you include:

- The endpoint's hostname
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

For example, to configure a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using **dsconfig**:

```
dsconfig create-monitoring-endpoint \
 --type statsd \
 --endpoint-name StatsDEndpoint \
 --set enabled:true \
 --set hostname:localhost \
 --set server-port:8125 \
 --set connection-type:unencrypted-udp
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
3. Click **New Monitoring Endpoint**.

You can send data to any number of monitoring endpoints.

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint. To send metrics with the StatsD monitoring endpoint, you must enable the Stats Collector Plugin. Also, you must configure the Stats Collector Plugin to indicate the metrics to send.

To enable the Stats Collector Plugin or to configure the type of data sent, use the `dsconfig` command or the Administrative Console. For example, to enable the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using `dsconfig`:

```
dsconfig set-plugin-prop \
 --plugin-name "Stats Collector" \
 --set enabled:true \
 --set host-info:cpu \
 --set host-info:disk \
 --set status-summary-info:basic
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**
3. Edit the **Stats Collector** plugin.

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk as explained in [Sending Metrics to Splunk with StatsD](#) on page 883.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation. Configure the StatsD monitoring endpoint to use the correct host and port. The `dsconfig create-monitoring-endpoint` example above uses a host of localhost and a port of 8125. You can also set these values in the Administrative Console.

## Sending Metrics to Splunk with StatsD

About this task

With the StatsD Endpoint type, you can send metric data to a Splunk installation.

In Splunk, you can use SSL to secure ports that are open for StatsD.

### Note:

StatsD metrics are typically sent over UDP. By using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

You can configure open UDP (or TCP) ports in Splunk to accept only connections from a certain hostname or IP address.

To securely send UDP (or TCP) data to Splunk, you can:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Have the forwarder communicate with the Splunk Indexer over SSL.

## Monitor PingDataSync Server

PingDataSync Server exposes its monitoring information under the `cn=monitor` entry. Various tools can be used to surface the server's information including the PingDataMetrics Server, the Administrative Console, JConsole, LDAP command-line tools, or SNMP. The following information is collected for PingDataSync Server. To configure the PingData PingDataMetrics Server to display PingDataSync Server data, see the Ping Identity PingDataMetrics Server Administration Guide.

**PingDataSync Server monitoring component**

Component	Description
Active Operations	Provides information about the operations currently being processed by the server including the number of operations, information about the operation, and the number of active persistent searches.
Backend	Provides general information about the state of the server backend, including the backend ID, base DN(s), entry counts, entry count for the <code>cn=admin</code> data, writability mode, and whether it is a private backend. The following backend monitors are provided: <ul style="list-style-type: none"> <li>▪ adminRoot</li> <li>▪ ads-truststore</li> <li>▪ alerts</li> <li>▪ backup</li> <li>▪ config</li> <li>▪ monitor</li> <li>▪ schema</li> <li>▪ tasks</li> <li>▪ userRoot</li> </ul>
Berkeley DB JE Environment	Provides information about the state of the Oracle Berkeley DB Java Edition database used by the PingDataSync Server backend.
Client Connections	Provides information about all client connections to the server.
Disk Space Usage	Provides information about the disk space available to various components of the server. The disk space usage monitor evaluates the free space at locations registered through the <code>DiskSpaceConsumer</code> interface. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations may still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the <code>config</code> directory, the location of every log file, all JE backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the <code>DiskSpaceConsumer</code> interface.
Connection Handler	Provides information about the available connection handlers on the server, which include the LDAP and LDIF connection handlers. These handlers are used to accept client connections.
General	Provides general information about the server, including product name and server version.
JVM Stack Trace	Provides a stack trace of all threads processing within the JVM.
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages, and operations handled.
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time, and number of processing times between <code>0ms</code> and <code>1ms</code> .

Component	Description
System Information	Provides general information about the system and the JVM on which the server is running, including host name, operating system, JVM architecture, Java home, and Java version.
Version	Provides information about the product version, including build ID and revision number.
Work Queue	<p>Provides information about the state of the PingDataSync Server work queue, which holds requests until they can be processed by a worker thread. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations be processed using the administrative thread pool, the requester must have the <code>use-admin-session</code> privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p>

## DevOps and infrastructure as code

Derived from the words *development* and *operations*, the term *DevOps* refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- **Pets** — With the *pets service model*, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.
- **Cattle** — With the *cattle service model*, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-master datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDataSync Server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Prior to server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from

the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see [Server profiles](#) on page 933.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDataSync Servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

## Server profiles

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- **dsconfig**
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDataSync Server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks — like Docker, Kubernetes, and Ansible — is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 934.
- Facilitates deployment automation by representing configuration as code.

- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the **manage-profile replace-profile** subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, **manage-profile setup** can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the **manage-profile** tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the **manage-profile** tool, see [About the manage-profile tool](#) on page 936.

### Variable substitution

The **manage-profile** tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example profile variables file.

```
MY_VARIABLE=value
MY_OTHER_VARIABLE=anothervalue
```

In this example, the tool provides the `PING_SERVER_ROOT` and `PING_PROFILE_ROOT` variables. The following table describes the built-in variables.

Built-in variable	Description
<code>PING_SERVER_ROOT</code>	Evaluates to the absolute path of the server's root directory.
<code>PING_PROFILE_ROOT</code>	Evaluates to the individual profile's root directory.

For more information about the tool's usage, run the command `bin/manage-profile --help`.

### Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the **manage-profile generate-profile** subcommand. The **manage-profile** tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
 |-- dsconfig/
 |-- misc-files/
 |-- server-root/
 | |-- post-setup/
 | |-- pre-setup/
 |-- server-sdk-extensions/
 |-- setup-arguments.txt
```

### setup-arguments.txt

When creating a profile, the first step is to add arguments to the file `setup-arguments.txt`. When **manage-profile** setup is run, these arguments are passed to the server's setup tool. To view the arguments that are available in this file, run the server's **setup --help** command.

To provide the equivalent, non-interactive CLI arguments after any prompts have been completed, run **setup** interactively. The `setup-arguments.txt` file in the profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

### dsconfig/

**dsconfig** batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain **dsconfig** commands to apply to server.

Because the **dsconfig** batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

### server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

### server-sdk-extensions/

Add server SDK extension ZIP files to the `server-sdk-extensions` directory. Use the **manage-extension** tool to install them, and include any configuration that is necessary for the extensions in the profile's **dsconfig** batch files.

### variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the **manage-profile** tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

### server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

### misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the **manage-profile** tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

### About the manage-profile tool

The **manage-profile** tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the **manage-profile** tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

#### manage-profile generate-profile

To create a server profile from a configured server, use the **generate-profile** subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by **generate-profile**, and must be provided values when other **manage-profile** subcommands use the generated profile.

#### manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the **setup** subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the server root files
- Runs the setup tool
- Runs the `dsconfig` batch files
- Installs the server SDK extensions

- Sets the server's cluster name to a unique value

**Note:** Cluster-wide configuration is automatically mirrored across all servers in the topology with the same cluster name. In a DevOps deployment with immutable servers, configuration mirroring introduces risk. Therefore, in most cases, cluster names should be unique for each server to avoid configuration mirroring.

While `manage-profile setup` is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

### **manage-profile replace-profile**

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

**Note:** The `manage-profile replace-profile` tool can update the server version when needed.

**Note:** The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

### **Server profiles in a Pets service model**

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server. Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new pet server has been set up with a server profile, `manage-profile` `replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 936.

## Troubleshooting

---

There are several ways to troubleshoot issues with PingDataSync Server.

### Synchronization troubleshooting

The majority of synchronization problems involve the connection state of the external servers and the synchronization of the data between the two endpoints. Make sure PingDataSync Server can properly fail over to another endpoint or server instance if the connection fails on the highest priority external server.

Another factor in troubleshooting synchronization is determining if the DN and attribute mappings were properly configured and if the information is properly being synchronized across the network. Typical scenarios include checking for any entry failures and mapping issues.

#### Note:

Use the `resync` tool to validate Sync Classes and data mappings from one endpoint to another. The tool provides a `dry-run` option that verifies data operations without actually affecting the data.

The following log files are specific to PingDataSync Server, and contain details about the synchronization processes:

#### Sync Log

Provides information about the synchronization operations that occur within the server. Specifically, the Sync Log records all changes applied, detected or failed; dropped operations that were not synchronized; changes dropped due to being out of scope, or no changes needed for synchronization. The log also shows the entries that were involved in the synchronization process.

#### Sync Failed Operations Log

Provides a list of synchronization operations that have failed.

#### Resync Log

Provides summaries or details of synchronized entries and any missing entries in the Sync Destination.

#### Resync Error Log

Provides error information for `resync` operations.

### Management tools

Each PingData server provides command-line tools to manage, monitor, and diagnose server operations. Each tool provides a description of the subcommands, arguments, and usage examples needed to run the tool.

#### Note:

For detailed information and examples of the command-line tools, see the Configuration Reference Guide in the `<server-root>/docs` directory, or linked from the Administrative Console.

To view detailed argument options and examples, use `--help` with the each tool:

```
$ bin/dsconfig --help
```

For those utilities that support additional subcommands (such as `dsconfig`), list the subcommands with the following:

```
$ bin/dsconfig --help-subcommands
```

View more detailed subcommand information by using `--help` with the specific subcommand:

```
$ bin/dsconfig list-log-publishers --help
```

## Troubleshooting tools

PingData provides utilities to troubleshoot the state of each server and to determine the cause of any issues. The following tools are available for diagnosing any problems and are located in the `<server-root>/bin` directory, or the `<server-root>/bat` directory on Windows systems:

### Troubleshooting tools

Tool	Description
status	Provides a high-level view of the current operational state of the server and displays any recent alerts that have occurred in past 24 hours.
ldap-diff	Used to compare one or more entries across two server endpoints to determine data issues.
ldapsearch	Retrieves the full entries from two different servers to determine the exact content of an entry from each server.
logs	<p>The logs directory provides important logs that should be used to troubleshoot or monitor any issue with the server. Logs include server-specific operations and the following general logs:</p> <ul style="list-style-type: none"> <li>▪ Error Log – Provides information about warnings, errors, or significant events that occur within the server.</li> <li>▪ Debug Log – Provides detailed information, if enabled, about processing performed by the server, including any exceptions caught during processing, detailed information about data read from or written to clients, and accesses to the underlying database.</li> <li>▪ Access loggers – Provide information about LDAP operations processed within the server. This log only applies to operations performed in the server. This includes configuration changes, searches of monitor data, and bind operations for authenticating administrators using the command-line tools and the Administrative Console.</li> </ul>
collect-support-data	Used to aggregate the results of various support tools data for the Ping Identity Support team to diagnose. For more information, see <a href="#">Use the collect-support-data tool</a> .
config-diff	Generate a summary of the configuration changes in a local or remote server instance. The tool can be used to compare configuration settings when troubleshooting issues, or when verifying configuration settings on new servers.

## Use the status tool

PingData servers provides the **status** tool, which outputs the health of the server. The **status** tool polls the current health of the server and displays summary information about the number of operations processed in the network. The tool provides the following information:

### Status tool sections

Status section	Description
Server Status	Displays the server start time, operation status, number of connections (open, max, and total).
Server Details	Displays the server details including host name, administrative users, install path, server version, and Java version.
Connection Handlers	Displays the state of the connection handlers including address, port, protocol and current state.
Admin Alerts	Displays the 15 administrative alerts that were generated over the last 48-hour period. Limit the number of displayed alerts using the <code>--maxAlerts</code> option. For example, <code>status -- maxAlerts 0</code> suppresses all alerts.

## Use the collect-support-data tool

### About this task

PingData servers provide information about their current state and any problems encountered. If a problem occurs, run the **collect-support-data** tool in the `/bin` directory. The tool aggregates all relevant support files into a zip file that can be sent to a support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools for the operating system.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the **collect-support-data** tool may vary between systems. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

### Steps

1. Navigate to the server root directory.
2. Run the **collect-support-data** tool. Include the host, port number, bind DN, and bind password.

```
$ bin/collect-support-data \
--hostname 100.0.0.1 --port 389 \
--bindDN "cn=Directory Manager"
--bindPassword secret \
--serverRoot /opt/PingData<server> \
--pid 1234
```

3. Email the zip file to a support provider.

## Use the Sync log

The Sync log, located in the `logs` directory (`<server-root>/logs/sync`), provides useful troubleshooting information on the type of operation that was processed or completed. Most log entries provide the following common elements in their messages:

## Sync log elements

Sync log element	Description
category	Indicates the type of operation, which will always be SYNC.
severity	Indicates the severity type of the message: INFORMATION, MILD_WARNING, SEVERE_WARNING, MILD_ERROR, SEVERE_ERROR, FATAL_ERROR, DEBUG, or NOTICE.
msgID	Specifies the unique ID number assigned to the message.
op	Specifies the operation number specific to PingDataSync Server.
changeNumber	Specifies the change number from the source server assigned to the modification.
replicationCSN	Specifies the replication change sequence number from the source server.
replicaID	Specifies the replica ID from the source server if there are multiple backend databases.
pipe	Specifies the Sync Pipe that was used for this operation.
msg	Displays the result of this operation.

### Sync log example 1

The following example displays an informational message that a modification to an entry was detected on the source server.

```
$ tail -f logs/sync
[17/May/2015:15:46:19 -0500] category=SYNC severity=INFORMATION
msgID=1893728293
op=14 changeNumber=15 replicationCSN=00000128A7E3C7D31E960000000F
replicaID=7830
pipe="DS1 to DS2" msg="Detected MODIFY of uid=user.993,ou=People,dc=example,
dc=com at ldap://server1.example.com:1389"
```

### Sync log example 2

The next example shows a successful synchronization operation that resulted from a MODIFY operation on the source server and synchronized to the destination server.

```
[18/May/2015:13:54:04 -0500] category=SYNC severity=INFORMATION
msgID=1893728306 op=701
changeNumber=514663 replicationCSN=00000128ACC249A31E960007DA67
replicaID=7830
pipe="DS1 to DS2" class="DEFAULT" msg="Synchronized MODIFY of
uid=user.698,ou=People,
dc=example,dc=com at ldap://server1.example.com:1389 by modifying entry
uid=user.698,
ou=People,dc=example,dc=com at ldap://server3.example.com:3389"
```

### Sync log example 3

The next example shows a failed synchronization operation on a MODIFY operation from the source server that could not be synchronized on the destination server. The log displays the LDIF-formatted modification that failed, which came from a schema violation that resulted from an incorrect attribute mapping (telephoneNumber -> telephone) from the source to destination server.

```
[18/May/2015:11:29:49 -0500] category=SYNC severity=SEVERE_WARNING
msgID=1893859389
op=71831 changeNumber=485590 replicationCSN=00000128AC3DE8D51E96000768D6
```

```

replicaID=7830 pipe="DS1 to DS2" class="DEFAULT" msg="Detected MODIFY of
uid=user.941,ou=People,dc=example,dc=com at ldap://server1.example.com:1389,
but
failed to apply this change because: Failed to modify entry uid=user.941,
ou=People,dc=example,dc=com on destination 'server3.example.com:3389'.
Cause: LDAPException(resultCode=65(object class violation), errorMessage='
Entry uid=user.941,ou=People,dc=example,dc=com cannot be modified because
the
resulting entry would have violated the server schema: Entry
uid=user.941,ou=People,
dc=example,dc=com violates the Directory Server schema configuration because
it
includes attribute telephone which is not allowed by any of theobjectclasses
defined in that entry') (id=1893859386
ResourceOperationFailedException.java:125
Build revision=6226). Details: Source change detail:
dn: uid=user.941,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: 027167170433915
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
Equivalent destination changes:
dn: uid=user.941,ou=People,dc=example,dc=com
changetype: modify
replace: telephone
telephone: 818002279103216
Full source entry:
dn: uid=user.941,ou=People,dc=example,dc=com
objectClass: person
... (more output)
Mapped destination entry:
dn: uid=user.941,ou=People,dc=example,dc=com
telephone: 818002279103216
objectClass: person
objectClass: inetOrgPerson
... (more output) ...

```

## Troubleshoot synchronization failures

While many PingDataSync Server issues are deployment-related and are directly affected by the hardware, software, and network structure used in the synchronization topology, most failures usually fall into one of the following categories:

### Entry Already Exists

When an add operation was attempted on the destination server, an entry with the same DN already exists.

### No Match Found

A match was not found at the destination based on the current Sync Classes and correlation rules (DN and attribute mapping). When this value has a high count, correlation rule problems are likely.

### Failure at Resource

Indicates that some other error happened during the synchronization process that does not fall into the first two categories. Typically, these errors are communication problems with a source or destination server.

Statistics for these and other types of errors are kept in the `cn=monitor` branch and can be viewed directly using the `status` command.

## Troubleshoot "Entry Already Exists" failures

### About this task

If there is a count for the `EntryAlready Exists` statistic using the `status` tool, verify the problem in the sync log. For example, the `status` tool displays the following information:

```

--- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result : Count
-----:-----
Success : 0
Out Of Scope : 0
Op Type Not Synced : 0
No Change Needed : 0
Entry Already Exists : 1
No Match Found : 1
Multiple Matches Found : 0
Failed During Mapping : 0
Failed At Resource : 0
Unexpected Exception : 0
Total : 2

```

Verify the change by viewing the `<server-root>/logs/sync` file to see the specific operation, which could be due to someone manually adding the entry on the target server:

```

op=2 changeNumber=529277 replicationCSN=00000128AD0D9BA01E960008137D
replicaID=7830
pipe="DS1 to DS2" class="DEFAULT" msg="Detected ADD of
uid=user.1001,ou=People,
dc=example,dc=com at ldap://server1.example.com:1389, but cannot create this
entry at the destination because an equivalent entry already exists at
ldap://server3.
example.com:3389. Details: Search using [search-criteria dn:
uid=user.1001,ou=People,
dc=example,dc=com attrsToGet: [*, dn]] returned results;
[uid=user.1001,ou=People,
dc=example,dc=com]. "

```

Perform the following steps to troubleshoot this type of problem:

### Steps

1. Assuming that a possible DN mapping is ill-formed, first run the `ldap-diff` utility to compare the entries on the source and destination servers. Then look at the `ldap-diff` results with the mapping rules to determine why the original search did not find a match.

```

$ bin/ldap-diff \
 --outputLDIF config-difference.ldif \
 --baseDN "dc=example,dc=com" \
 --sourceHost server1.example.com \
 --targetHost server2.example.com \
 --sourcePort 1389 \
 --targetPort 3389 \
 --sourceBindDN "cn=Directory Manager" \
 --sourceBindPassword password \
 --searchFilter "(uid=1234)"

```

2. Review the destination server access logs to verify the search and filters used to find the entry. Typically, the key correlation attributes are not synchronized.
3. If the mapping rule attributes are not synchronized, review the Sync Classes and mapping rules, and use the information from the `ldap-diff` results to determine why a specific attribute may not be getting updated. Some questions to answer are as follows:
  - Is there more than one Sync Class that the operation could match?
  - If using an `include-base-dn` or `include-filter` in the mapping rules, does this exclude this operation by mistake?
  - If using an attribute map, are the mappings correct? Usually, the cause of this error is in the destination mapping attribute settings. For example, if a set of correlation attributes is defined as: `dn, mobile, accountNumber`, and the `accountNumber` changes for some reason, future operations on this entry will fail. To resolve this, either remove `accountNumber` from the rule, or add a second rule as: `dn, mobile`. The second rule is used only if the search using the first set of attributes fails. In this case, the entry is found and the `accountNumber` information is updated.
4. If deletes are being synchronized, check to see if there was a previous delete of this entry that was not synchronized properly. In some cases, simpler logic should be used for deletes due to the available attributes in the change logs. This scenario could cause an entry to not be deleted for some reason, which would cause an issue when a new entry with the same DN is added later. Use this information for mapping rules to see why the original search did not find a match.
5. Look at the destination directory server access logs to verify the search and filters it used to find the entry. Typically, the key attribute mappings are not synchronized.

### Troubleshoot "No Match Found" failures

#### About this task

If there is a count for the No Match Found statistic using the `status` tool, verify the problem in the sync log. For example, if the `status` tool displays the following:

```

--- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result : Count
-----:-----
Success : 0
Out Of Scope : 0
Op Type Not Synced : 0
No Change Needed : 0
Entry Already Exists : 1
No Match Found : 1
Multiple Matches Found : 0
Failed During Mapping : 0
Failed At Resource : 0
Unexpected Exception : 0
Total : 2

```

Verify the change in the `<server-root>/logs/sync` file to see the specific operation:

```

[12/May/2016:10:30:45 -0500] category=SYNC severity=MILD_WARNING
msgID=1893793952
op=4159648 changeNumber=6648922 replicationCSN=4beadaf4002f21150000
replicaID=8469-
ou=test,dc=example,dc=com pipe="DS1 to DS2" class="Others" msg="Detected
DELETE of
'uid=1234,ou=test,dc=example,dc=com' at ldap://server1.example.com:389, but
cannot
DELETE this entry at the destination because no matching entries were found
at
ldap://
server2.example.com:389. Details: Search using [search-criteria dn:

```

```
uid=1234,ou=test,dc=alu,dc=com filter:
(nsUniqueId=3a324c60-5ddb11df-80ffe681-
717b93af) attrsToGet: [*, accountNumber, dn, entryuuid, mobile, nsUniqueId,
object-
Class]] returned no results."
```

Perform the following steps to fix the issue:

### Steps

1. Test the search using the filter in the error message, if displayed. For example, if the sync log specifies filter: (nsUniqueId=3a324c60-5ddb11df-80ffe681-717b93af), use the **ldapsearch** tool to test the filter. If it is successful, is there anything in the attribute mappings that would exclude this from working properly?
2. Test the search using the full DN as the base. For example, use **ldapsearch** with the full DN (uid=1234,ou=People,dc=example,dc=com). If it is successful, does the entry contain the attribute used in the mapping rule? If the attribute is not in the entry, determine if there is a reason why this value was not synchronized. Look at the attribute mappings and the filters used in the Sync Classes.

### Troubleshoot "Failed at Resource" failures

#### About this task

If there is a count for the "Failed at Resource" statistic using the **status** tool, verify the problem in the sync log. For example, if the **status** tool displays the following information:

```
--- Ops Completed for 'DS1 to DS2' Sync Pipe ---
Op Result : Count
-----:-----
Success : 0
Out Of Scope : 0
Op Type Not Synced : 0
No Change Needed : 0
Entry Already Exists : 0
No Match Found : 0
Multiple Matches Found : 0
Failed During Mapping : 0
Failed At Resource : 1
Unexpected Exception : 0
Total :1
```

This will register after a change is detected at the source in any of the following cases:

- If the fetch of the full source entry fails. The entry exists but there is a connection failure, server down, timeout, or something similar.
- If the fetch of the destination entry fails or if the modification to the destination fails for an exceptional reason (but not for "Entry Already Exists," "Multiple Matches Found," or "No Match Found" issues).

Verify the change by viewing the `<server-root>/logs/sync` file to see the specific operation. If any of the following result codes are listed, the server is experiencing timeout errors:

- resultCode=timeout: errorMessage=A client-side timeout was encountered while waiting 60000ms for a search response from server server1.example.com:1389
- resultCode=timeout: errorMessage=An I/O error occurred while trying to read the response from the server
- resultCode=server down: errorMessage=An I/O error occurred while trying to read the response from the server

- resultCode=server down: errorMessage=The connection to server server1.example.com:1389 was closed while waiting for a response to search request SearchRequest
- resultCode=object class violation: errorMessage='Entry device=1234,dc=example,dc=com violates the Directory Server schema configuration because it contains undefined object class

With these "Failure at Destination" timeout errors, look at the following settings in the PingDirectory Server to determine if adjustments are needed:

### Steps

1. For External Server Properties, check the connect-timeout property. This property specifies the maximum length of time to wait for a connection to be established before giving up and considering the server unavailable.
2. For the Sync Destination/Sync Source Properties, check the response-timeout property. This property specifies the maximum length of time that an operation should be allowed to be blocked while waiting for a response from the server. A value of zero indicates that there should be no client-side timeout. In this case, the server's default will be used.

```
$ bin/dsconfig --no-prompt --port 389 \
 --bindDN "cn=Directory Manager" \
 --bindPassword password list-external-servers \
 --property connect-timeout
```

External Server	Type	connect-timeout	response-timeout
server1.example.com:389	sundsee-ds	10 s	-
server2.example.com:389	sundsee-ds	10 s	-
server3.example.com:389	ping-identity-ds	10 s	-
server4.example.com:389	ping-identity-ds	10 s	-

3. For Sync Pipe Properties, check the max-operation-attempts, retry-backoff-initialwait, retry-backoff-max-wait, retry-backoff-increase-by, retry-backoff-percentage-increase. These Sync Pipe properties provide tuning parameters that are used in conjunction with the timeout settings. When a Sync Pipe experiences an error, it will use these settings to determine how often and quickly it will retry the operation.

```
$ bin/dsconfig --no-prompt list-sync-pipes \
 --property max-operation-attempts --property retry-backoff-initial-wait \
 --property retry-backoff-max-wait --property retry-backoff-increase-by \
 --property retry-backoff-percentage-increase \
 --port 389 --bindDN "cn=Directory Manager" \
 --bindPassword password
```

## Installation and maintenance issues

The following are common installation and maintenance issues and possible solutions.

### The setup program will not run

If the `setup` tool does not run properly, some of the most common reasons include the following:

A Java environment is not available

The server requires that Java be installed on the system prior to running the `setup` tool.

If there are multiple instances of Java on the server, run the `setup` tool with an explicitly defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation. For example:

```
$ env JAVA_HOME=/ds/java ./setup
```

Another issue may be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, use the following command to override any other environment variables:

```
$ env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

#### Unexpected arguments provided to the JVM

If the `setup` tool attempts to launch the `java` command with an invalid set of arguments, it may prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, run the following command:

```
$ unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

#### The server has already been configured or started

The `setup` tool is only intended to provide the initial configuration for the server. It will not run if it detects that it has already been run.

A previous installation should be removed before installing a new one. However, if there is nothing of value in the existing installation, the following steps can be used to run the `setup` program:

- Remove the `config/config.ldiff` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories in the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.
- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

#### The server will not start

If the server does not start, then there are a number of potential causes.

#### The server or other administrative tool is already running

Only a single instance of the server can run at any time from the same installation root. Other administrative operations can prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The <server> could not acquire an exclusive lock on file
/ds/PingData<server>/locks/server.lock:
The exclusive lock requested for file
/ds/PingData<server>/locks/ server.lock
was not granted, which indicates that another
process already holds a shared or exclusive lock on
that file. This generally means that another instance
of this server is already running.
```

If the server is not running (and is not in the process of starting up or shutting down), and there are no other tools running that could prevent the server from being started, it is possible that a previously held lock

was not properly released. Try removing all of the files in the locks directory before attempting to start the server.

#### There is not enough memory available

When the server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, the server generates an error message indicating that it could not be started.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed, the server might need to be re-configured to use a smaller amount of memory.
- Another process on the system is consuming memory and there is not enough memory to start the server. Either terminate the other process, or reconfigure the server to use a smaller amount of memory.
- The server just shut down and an attempt was made to immediately restart it. If the server is configured to use a significant amount of memory, it can take a few seconds for all of the memory to be released back to the operating system. Run the `vmstat` Installation and maintenance issues command and wait until the amount of free memory stops growing before restarting the server.
- If the system is configured with one or more memory-backed file systems (such as `/tmp`), determine if any large files are consuming a significant amount of memory. If so, remove them or relocate them to a disk-based file system.

#### An invalid Java environment or JVM option was used

If an attempt to start the server fails with 'no valid Java environment could be found,' or 'the Java environment could not be started,' and memory is not the cause, other causes may include the following:

- The Java installation that was previously used to run the server no longer exists. Update the `config/java.properties` file to reference the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation has been updated, and one or more of the options that had worked with the previous Java version no longer work. Re-configure the server to use the previous Java version, and investigate which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, its value may override the path to the Java installation used to run the server (defined in the `config/java.properties` file). Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before starting the server.

Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, such as:

```
$ env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

#### An invalid command-line option was used

There are a small number of arguments that can be provided when running the `bin/start-server` command. If arguments were provided and are not valid, the server displays an error message. Correct or remove the invalid argument and try to start the server again.

### The server has an invalid configuration

If a change is made to the server configuration using `dsconfig` or the Administrative Console, the server will validate the change before applying it. However, it is possible that a configuration change can appear to be valid, but does not work as expected when the server is restarted.

In most cases, the server displays (and writes to the error log) a message that explains the problem. If the message does not provide enough information to identify the problem, the `logs/config-audit.logfile` provides recent configuration changes, or the `config/archived-configs` directory contains configuration changes not made through a supported configuration interface. The server can be started with the last valid configuration using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

To determine the set of configuration changes made to the server since the installation, use the `config-difftool` with the arguments `--sourceLocal --targetLocal --sourceBaseline`. The `dsconfig --offline` command can be used to make configuration changes.

### Proper permissions are missing

The server should only be started by the user or role used to initially install the server. However, if the server was initially installed as a non-root user and then started by the root account, the server can no longer be started as a non-root user. Any new files that are created are owned by root.

If the user account used to run the server needs to change, change ownership of all files in the installation to that new user. For example, if the server should be run as the "ds" user in the "other" group, run the following command as root:

```
$ chown -R ds:other /ds/PingData<server>
```

### The server has shutdown

Check the current server state by using the `bin/server-state` command. If the server was previously running but is no longer active, potential reasons may include:

- Shut down by an administrator – Unless the server was forcefully terminated, then messages are written to the error and server logs stating the reason.
- Shut down when the underlying system crashed or was rebooted – Run the `uptime` command on the underlying system to determine what was recently started or stopped.
- Process terminated by the underlying operating system – If this happens, a message is written to the system error log.
- Shut down in response to a serious problem – This can occur if the server has detected that the amount of usable disk space is critically low, or if errors have been encountered during processing that left the server without worker threads. Messages are written to the error and server logs (if disk space is available).
- JVM has crashed – If this happens, then the JVM should provide a fatal error log (a `hs_err_pid<processID>.log` file), and potentially a core file.

### The server will not accept client connections

Check the current server state by using the `bin/server-state` command. If the server does not appear to be accepting connections from clients, reasons can include the following:

- The server is not running.
- The underlying system on which the server is installed is not running.
- The server is running, but is not reachable as a result of a network or firewall configuration problem. If that is the case, connection attempts should time out rather than be rejected.

- If the server is configured to allow secure communication through SSL or StartTLS, a problem with the key manager or trust manager configuration can cause connection rejections. Messages are written to the server access log for each failed connection attempt.
- The server may have reached its maximum number of allowed connections. Messages should be written to the server access log for each rejected connection attempt.
- If the server is configured to restrict access based on the address of the client, messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, it can stop listening for new requests. A message should be written to the server error log with information about the problem. Restarting the server can also solve the issue. Another option is to create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

### The server is unresponsive

Check the current server state by using the `bin/server-state` command. If the server process is running and appears to be accepting connections but does not respond to requests received on those connections, potential reasons for this include:

- If all worker threads are busy processing other client requests, new requests are forced to wait until a worker thread becomes available. A stack trace can be obtained using the `jstack` command to show the state of the worker threads and the waiting requests.  
If all worker threads are processing the same requests for a long time, the server sends an alert that it might be deadlocked. All threads might be tied up processing unindexed searches.
- If a request handler is busy with a client connection, other requests sent through that request handler are forced to wait until it is able to read data. If there is only one request handler, all connections are impacted. Stack traces obtained using the `jstack` command will show that a request handler thread is continuously blocked.
- If the JVM in which the server is running is not properly configured, it can spend too much time performing garbage collection. The effect on the server is similar to that of a network or firewall configuration problem. A stack trace obtained with the `pstack` utility will show that most threads are idle except the one performing garbage collection. It is also likely that a small number of CPUs is 100% busy while all other CPUs are idle. The server will also issue an alert after detecting a long JVM pause that will include details.
- If the JVM in which the server is running has hung, the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If there is a network or firewall configuration problem, communication attempts with the server will fail. A network sniffer will show that packets sent to the system are not receiving TCP acknowledgment.
- If the host system is hung or lost power with a graceful shutdown, the server will be unresponsive.

### Problems with the Administrative Console

If a problem occurs when trying to use the Administrative Console, reasons may include one of the following:

- The web application container that hosts the console is not running. If an error occurs while trying to start it, consult the logs for the web application container.
- If a problem occurs while trying to authenticate, make sure that the target server is online. If it is, the access log may provide information about the authentication failure.
- If a problem occurs while interacting with the server instance using the Administrative Console, the access and error logs for that instance may provide additional information.

## Problems with SSL communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
 --publisher-name "File-Based Debug Logger" \
 --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
 --set debug-level:verbose \
 --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Debug Logger" \
 --set enabled:true \
 --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-ds` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

## Conditions for automatic server shutdown

All PingData servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The PingDirectory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
 --set unrecoverable-database-error-mode:initiate-server-shutdown
```

## Insufficient memory errors

If the server shuts down due to insufficient memory errors, it is possible that the allocated heap size is not enough for the amount of data being returned. Consider increasing the heap size, or reducing the number of request handler threads using the following `dsconfig` command:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTP Connection Handler" \
 --set num-request-handlers:<num-of-threads>
```

## Enable JVM debugging

About this task

Enable the JVM debugging options to track garbage collection data for the system. These options can impact JVM performance, but provide valuable data to tune the server. While the `jstat` utility with the `-gc` option can be used to obtain some information about garbage collection activity, there are additional arguments that can be added to provide additional detail, such as:

```
-XX:+PrintGCDetails
-XX:+PrintTenuringDistribution
-XX:+PrintGCApplicationConcurrentTime
-XX:+PrintGCApplicationStoppedTime
-XX:+PrintGCDateStamps
```

Steps

1. On the server, navigate to the `config/java.properties` file.

2. Edit the `config/java.properties` file. Add any additional arguments to the end of the line that begins with `start-<server>.java-args`.
3. Save the file.
4. Run the following command for the new arguments to take effect the next time the server is started:

```
$ bin/dsjavaproperties
```
