|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-15861, DS-15862 | <p>Replaced the <code>ldapsearch</code> and <code>ldapmodify</code> tools with new, backward-compatible versions that offer many new features, including the following examples:</p> <ul style="list-style-type: none"> <li>▪ Improved connection handling</li> <li>▪ Improved output formatting</li> <li>▪ Improved support for bulk operations</li> <li>▪ Support for referrals</li> <li>▪ Support for additional request and response controls</li> <li>▪ Rate limiting</li> </ul> <p>The <code>ldapsearch</code> tool also offers the following abilities:</p> <ul style="list-style-type: none"> <li>▪ Output results in the following formats as an alternative to LDIF: <ul style="list-style-type: none"> <li>▪ JSON</li> <li>▪ CSV</li> <li>▪ Tab-delimited text</li> </ul> </li> <li>▪ Supports multiple data transformations</li> </ul> <p>Additionally, the <code>ldapmodify</code> tool now supports the LDIF control syntax, as well as writing to output and reject files.</p> |
| DS-16405           | <p>The SNMP context name for the server can now be configured by using the new context-name property of the SNMP Subagent plugin. When this property is not set, the server instance name remains the default context name .</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DS-16423           | <p>PingDataSync Server now supports OpenDJ as an external server and as a sync source.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DS-16509           | <p>Updated the access and audit loggers so that, when information is logged about an internal operation that an external client request triggered, the log message includes the connection and operation ID for the request. Also updated the error logger so that, when a message is logged from a thread that is actively processing an operation, the log message includes the connection and operation ID for that operation.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DS-16593           | <p>Fixed an issue in which incorrect names displayed in the usage for the start scripts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DS-16603           | <p>For Active Directory external servers, the bind-dn property can now be a User Principal Name (UPN).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DS-16789           | <p>The script files that stop and start the server have been renamed to <code>stop-server</code> and <code>start-server</code>, respectively. Earlier versions of the scripts are still present.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Ticket ID | Description                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-16858  | The modifierName and modifyTimestamp attributes are now updated when offline configuration changes are made.                                            |
| DS-16906  | Added a disabled-alert-type configuration property to the Alert backend. This property suppresses specific alert types from being added to the backend. |
| DS-17019  | The server now requires Java version 8.                                                                                                                 |
| DS-17078  | Updated some cases in which filtered SCIM searches for groups with missing members were not returned.                                                   |
| DS-17080  | Improved error reporting for the <b>manage-extensions</b> tool.                                                                                         |
| DS-17089  | PingDataSync Server now supports generic LDAP servers as sync destinations.                                                                             |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-17146  | <p>Updated the logic that selects which TLS cipher suites to enable by default, and the logic that prioritizes the cipher suites. Also updated the selection process to use the guidelines that the OWASP "Transport Layer Protection Cheat Sheet" document provides.</p> <p>The following changes are included:</p> <ul style="list-style-type: none"> <li>▪ The server already preferred cipher suites that support forward secrecy over suites that do not. It now prefers DHE over ECDHE, and avoids suites that use non-RSA keys.</li> <li>▪ The server already avoided cipher suites that used known-weak cryptographic weaknesses, including null encryption, the RC4 symmetric cipher, and the MD5 digest algorithm. It now also avoids anonymous encryption, the single-DES symmetric cipher, the IDEA symmetric cipher, and any suite using export-level encryption.</li> <li>▪ The server now prefers cipher suites that use the Galois/Counter Mode (GCM) over the Cipher Block Chaining (CBC) mode.</li> <li>▪ The server now prefers AES-based cipher suites with 256-bit keys over those that use 128-bit keys. For suites with equivalent key sizes, it prefers suites with a stronger message digest algorithm over suites with a weaker digest algorithm (for example, SHA384 over SHA256 over SHA).</li> <li>▪ The server now provides improved support for selecting and prioritizing ciphers when running on the IBM JVM. The IBM JVM uses a different naming convention for its cipher suites than does the Oracle implementation, which previously allowed certain desirable suites to be excluded from the selected set.</li> </ul> |
| DS-17241  | <p>The Administrative Console is no longer compatible with earlier versions of the server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Ticket ID                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-17444                     | <p>Updated the server to reduce the use of the SHA-1 message digest. The server now uses a 256-bit SHA-2 digest instead of a SHA-1 digest in all of the following cases:</p> <ul style="list-style-type: none"> <li>▪ Hashing or signing a backup</li> <li>▪ Signing an LDIF export</li> <li>▪ Signing log data</li> <li>▪ Generating MACs for an encrypted collect-support-data archive</li> <li>▪ Generating unique identifiers for encryption settings definitions</li> <li>▪ Determining whether the configuration changed with the server offline</li> </ul> <p>In all of these cases, the server includes metadata in the output of the cryptographic processing to indicate the digest or MAC algorithm used for that processing, which ensures that the output remains compatible across server versions. For example, an LDIF export that uses a signature generated with the SHA-2 digest can be successfully imported into earlier versions of the server.</p> <p>The fingerprint certificate mapper has also been updated to use the 256-bit SHA-2 digest when mapping a client certificate to the corresponding user entry. The previous MD5 and SHA-1 digests remain supported.</p> <p>Additionally, the example enhanced password-storage scheme that the UnboundID Server SDK provides has been updated to use the 256-bit SHA-2 digest instead of a SHA-1 digest.</p> |
| DS-17531                     | <p>Fixed an issue that could cause a sync pipe to crash due to missing attributes in the changelog.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DS-17544                     | <p>The Administrative Console can be deployed in an external web container, such as Tomcat, using the contents of <code>resource/admin-console.zip</code>, located in the server root.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DS-17545, DS-17546, DS-18008 | <p>Enhanced Attribute Mapping in PingDataSync Server to allow users to filter or exclude values from entries in the Sync Destination.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DS-17576                     | <p>Updated the Server SDK's <code>ServerContext</code> to expose a <code>ValueConstructor</code>, which build String values by using a value-pattern template that references attribute values within an entry. For more information, refer to the Javadoc for the <code>ValueConstructor</code> class that is included with the Server SDK packaging.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-17652  | Fixed an issue in which attribute matching rules were not applied appropriately during synchronization.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DS-17653  | Addressed an issue in which the server would throw a <b>NullPointerException</b> if a <code>com.unboundid.directory.sdk.sync.api.SyncSource</code> implementation did not set a modifier's name in a generated <code>ChangeRecord</code> .                                                                                                                                                                                                                                                                                                     |
| DS-17668  | Sync correlation attributes now support correlating using JSON keys within JSON attribute values. A JSON key can be referenced with syntax <code>&lt;attribute-name&gt;&gt;.&lt;JSON-key&gt;&gt;</code> . If a JSON correlation attribute is used but the JSON key does not exist for the source or destination entry, or if the considered source or destination entry does not possess valid JSON data, the destination entry considered entry is not matched.                                                                               |
| DS-17688  | PingDataSync Server now supports the synchronization of particular fields within JSON attributes. The JSON Attribute configuration object controls the manner in which fields are synchronized, as well as the manner in which source and destination values are correlated.                                                                                                                                                                                                                                                                   |
| DS-17689  | Sync constructed attribute mappings now support extracting JSON fields within JSON attributes by appending <code>.</code> , and then the JSON field, to extract to the attribute name. For example, if the JSON attribute is <code>ubidEmailJSON</code> and the <code>value</code> field is to be extracted, then <code>ubidEmailJSON.value</code> can be specified for the attribute name, resulting in <code>{ubidEmailJSON.value}</code> or, if a regular expression is used, <code>{ubidEmailJSON.value:/regex/replacement/flags}</code> . |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-17693  | <p>Constructed attribute mappings now support modifiers that alter the value of referenced source attributes when added to the end of source attribute references. For example, if the attribute mail is to be included in a constructed JSON value, the modifier jsonEscape can be specified, resulting in <code>{{"userMail":{"mail:jsonEscape"}}</code> or, if a regular expression is used, <code>{{"userMail":{"mail:/regex/replacement/flags:jsonEscape"}}</code>.</p> <div data-bbox="841 520 1463 590" style="border: 1px solid black; padding: 5px;"> <p> <b>Note:</b> <code>{{</code> expands to <code>{</code>, and <code>}}}</code> expands to <code>'</code>.</p> </div> <p>The following modifiers are available:</p> <ul style="list-style-type: none"> <li>▪ jsonEscape — Escapes text for use in a JSON value.</li> <li>▪ ldapFilterEscape — Escapes text for use in an LDAP filter.</li> <li>▪ lowerCase — Converts text to lowercase.</li> <li>▪ trim — Removes leading and trailing whitespace.</li> <li>▪ upperCase — Converts text to uppercase.</li> </ul> |
| DS-17697  | <p>Added additional support to PingDataSync Server for synchronizing Active Directory Groups that contain more than 1,500 members.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DS-17711  | <p>PingDataSync Server now logs an error and continues processing if it encounters a corrupted changelog entry. Previously, the server threw an exception continually and stopped processing subsequent changes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DS-17741  | <p>LDAP referral entries are now synchronized as a raw entry rather than trying to follow the referral.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DS-17742  | <p>LDAP changelog-based Sync Sources, such as the DSEE Sync Source, no longer fetch source entries when none of the Sync Source's configured base-dn values contains the targetDN in the corresponding changelog entry. This change reduces the load that is placed on the source directory servers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DS-17936  | <p>PingDataSync Server now tries to use the source schema, if available, when the destination schema is unavailable.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DS-17968  | <p>Limited the ACI search on the collect support data tool to pull only 100 entries. This change reduces the amount of time the tool requires to run for organizations with a large number of ACIs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DS-17993  | <p>Added additional logging to PingDataSync Server for cases in which attribute mapping fails. The synchronization operation is not halted.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-18003  | Updated the Server SDK so that HTTPServletExtensions can be installed on PingDataSync Server instances.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DS-18026  | Fixed an issue that involved setting the sync connect and response timeouts with incorrect units of time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DS-18100  | A license key is required when setting up a server for the first time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|           | <div style="border: 1px solid black; padding: 5px;"> <p> <b>Important:</b> To request a license, visit the <a href="#">Ping Identity licensing website</a> or contact <a href="mailto:sales@pingidentity.com">sales@pingidentity.com</a>.</p> </div>                                                                                                                                                                                                                                                             |
| DS-18136  | Enhanced the LDAP Sync Destination to allow administrators to configure options for synchronizing user passwords with clear-text, in cases where the LDAP Server does not support pre-encoded password synchronization. Setting <code>password-synchronization-format:clear-text</code> on the LDAP Sync Destination now enables the clear-text synchronization of passwords. By default, passwords are synchronized only in the clear over a secure connection. To override this option, set <code>require-secure-connection-for-clear-text-passwords:false</code> on the LDAP Sync Destination. |
| DS-18169  | Fixed an incompatibility between Java and PKCS12 trust stores and keystores that caused an error during PingDataSync Server installations.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DS-18188  | Removed the ability to create custom HTTP trace loggers by using the Server SDK.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DS-18199  | Updated the default configuration of the File-Based Access Logger (logs/access) so that requests from peer PingDataSync instances are no longer suppressed. This approach simplifies the troubleshooting of connection and health-checking issues between server instances.                                                                                                                                                                                                                                                                                                                       |
| DS-35495  | Updated <code>dsconfig</code> batch mode to operate more efficiently over the WAN by consolidating the number of LDAP searches that are required to retrieve the full configuration when pre-validating configuration changes.                                                                                                                                                                                                                                                                                                                                                                    |

## PingDataSync Server 6.0.0.0 Release Notes

### Upgrade Considerations

Important considerations for upgrading to this version of PingDataSync Server are as follows:

**Note:** Product names have been updated to reflect the UnboundID acquisition by Ping Identity. This change affects naming and branding only. The code base is the same as in prior releases.

- If you are upgrading a server that was running an earlier version of the JDK, run the `dsjavaproperties --initialize` command after the software upgrade to compare the settings of the earlier JDK with the requirements for the new server software. Apply necessary changes to the upgraded server, based on the previous performance settings.
- The 6.0 release makes the following changes to supported platforms:
  - CentOS 7.2 and RedHat 7.2 are now supported operating system versions.
  - SUSE 11 SP4 is now supported, and support for SUSE 11 SP2 has been retired.
  - Linux KVM and VMWare ESXi 6.x have been added as supported virtual machine environments.
  - Deprecation of JDKs 7.x. Customers are strongly advised to use JDK 8 with this release.
  - WildFly 9.x, which is renamed from *JBoss*, is now a supported application server for all web applications, including the Administrative Console and sample applications. Support for JBoss 7.x has been retired. Tomcat support remains unchanged in this release.
  - PBKDF2 is now the default encoding for root passwords. This change affects only new installations.
  - In addition to changing the default password-storage scheme for root users to PBKDF2, the default password-storage scheme for regular users has been changed to salted 256-bit SHA-2.
  - HTTPS defaults to ON, and servers now default to use HTTPS for console and API connections, including the SCIM API. This change might affect automation scripts and development environments in which HTTPS has not previously been in use.
  - Generated user passwords, like those created by the server during a password reset sequence, are now created as passphrases instead of as random character strings. This change makes such passwords easier to type and remember but does not affect upgrades.
  - The `/config` directory file permissions have been changed so that only the server user can access them.
  - Customers who use the optional encryption algorithms that the BouncyCastle library provides are encouraged to upgrade to BouncyCastle 1.54.

## What's New

The following features are new with this release of PingDataSync Server:

- PingDataSync Server now recognizes and handles changes from Active Directory sources, including the non-standard `range=n-m` suffixes for multi-valued attributes.
- Added the ability to apply attribute maps programmatically in Server Extensions so that specific maps can be applied to a cascading set of changes that the extension generates.
- For Java developers whose tools and workflows make use of Maven, the Server SDK `.jar` file has been deployed to Maven Central. To add the Server SDK as a project dependency, developers need only to add a few lines to a project's `pom.xml`. Also, developers can now generate a Server SDK project that Maven-aware IDEs, such as IntelliJ IDEA, can package into an extension bundle that requires no special configuration. This benefit extends to continuous integration systems, such as Jenkins.
- The `dsconfig` tool provides the ability to search for and quickly navigate to configuration objects and properties in which the name, synopsis, or description matches a provided pattern.
- A new `rotate-log` tool and task have been added, which can be used to trigger the rotation of one or more log files.
- The Configuration API is now fully supported for all servers. In this release, the API was changed to match SCIM conventions for attribute naming, resource modeling, and the standard HTTP verbs. The UnboundID SCIM 2 SDK, which is available through GitHub, can now be used with the Configuration API.

- All servers have an updated web Administrative Console, which includes the following changes:
  - New layouts for operational statistics, processing time, queues, monitors, and installed extensions.
  - Alert and alarm displays that summarize the data in `cn=alerts` and `cn=alarms`, based on the configured gauges, as well as filtering and searching for them.
  - A new LDAP Schema Editor for importing schema files, validating, and creating and editing object classes and attribute types. The editor also supports the viewing of the attribute syntaxes, inheritance, and indexes that exist for each attribute, and the dependencies between object classes and attributes.
- The new Administrative Console can be deployed to independent application servers instead of being co-hosted by the servers. This approach simplifies deployment models and increases the separation between the data and application layers.
- To assist with situations in which a large number of changes might decrease the amount of available disk space, or might increase memory usage or the time required to start the server, alerting and gauge features have been added to the Recent Changes Database.
- Servers can now trigger events whenever log files are rotated. This change includes copy on rotate and summarize on rotate listeners, as well as Server SDK support for creating custom log file rotation listeners.
- Root user accounts can now be created, changed, and removed across the topology by using the `dsconfig` tool or the Administrative Console.

#### Known Issues and Workarounds

The following issues are known in the current version of PingDataSync Server:

- When deploying the Administrative Console in Tomcat 8 and accessing the Administrative Console application by using Tomcat's Web Application Manager, some browsers, including Safari and Firefox, generate a path URL that encodes the dash in `ubid-console`. This issue results in a path such as `http://localhost:8888/ubid%2Dconsole/`, which causes session-management errors.

**Workaround:** Copy and paste the generated link into a browser, and replace the encoded dash with a dash (-) character.

- The `PermSize` and `MaxPermSize` JVM properties are no longer supported in JDK 8, and can be ignored.

**Workaround:** To remove these properties, modify the `config/java.properties` file and run `bin/dsjavaproperties` while the server is offline.

- The `dsconfig` tool and the Administrative Console enable the creation and management of new Root DN users in this release. However, the ability to change the password of a currently logged-on administrator is limited.

**Workaround:** To change the administrator's password, use the `ldappasswordmodify` command, and provide the current and new password.

#### Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID | Description                                                                                                             |
|-----------|-------------------------------------------------------------------------------------------------------------------------|
| DS-979    | Added the ability to search for configuration objects and their properties by name with the <code>dsconfig</code> tool. |

| Ticket ID                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-4235                     | <p>Added support for the following log file rotation listeners, which allow for custom processing whenever a log file is rotated out of service so that a server can no longer write to it:</p> <ul style="list-style-type: none"><li>▪ A <i>copy listener</i> copies the rotated log file to an alternate location, optionally compressing it in the process.</li><li>▪ A <i>summarize listener</i> invokes the <b>summarize-access-log</b> tool on the rotated log file.</li></ul> <p>The Server SDK also includes an API for creating custom log file rotation listeners.</p>                                                                                                                                              |
| DS-7505, DS-13571, DS-13860 | <p>Updated the default file permissions for new installations on UNIX-based systems. By default, the files and directories that are included in the <code>.zip</code> file are accessible only to the user who extracted the file's contents. Newly created files and directories are also assigned permissions that can be accessed only by the account that is used to run the server. Existing configuration options for setting file permissions, such as the <code>log-file-permissions</code> and <code>db-directory-permissions</code> properties, continue to behave as before. The new <code>config/server.umask</code> file controls the default permissions for all other newly created files and directories.</p> |

| Ticket ID                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-9407, DS-15183, DS-15220 | <p>Updated the initial server configuration to improve security and usability. These changes apply only to new installations and are not applied when an existing installation is updated. The following changes are included:</p> <ul style="list-style-type: none"> <li>▪ Updated the default password policy to use a default password-storage scheme that uses a salted 256-bit SHA-2 digest rather than a salted SHA-1 digest.</li> <li>▪ Updated the root password policy to use a default password-storage scheme of PBKDF2 rather than salted 512-bit SHA-2.</li> <li>▪ Updated the secure password policy to use a default password-storage scheme of PBKDF2 rather than a CRYPT variant that uses multiple rounds of 256-bit SHA-2.</li> <li>▪ Updated the Password Policy Import plugin so that it attempts to use the default password policy when selecting a password storage schemes to use for entries that do not explicitly specify a password policy. The plugin also falls back to a salted 256-bit SHA-2 scheme instead of a salted SHA-1 scheme.</li> <li>▪ Many of the weaker password-storage schemes have been disabled by default, including the following schemes: <ul style="list-style-type: none"> <li>▪ Base64</li> <li>▪ Clear</li> <li>▪ Unsalted MD5</li> <li>▪ Salted MD5</li> <li>▪ 3DES</li> <li>▪ RC4</li> <li>▪ Unsalted SHA-1</li> </ul> </li> <li>▪ The default password policy has been updated to use a password generator that generates strong yet memorable passphrases rather than shorter and less-memorable strings of randomly selected characters.</li> <li>▪ Many server loggers have been updated to include the following log elements by default: <ul style="list-style-type: none"> <li>▪ Instance name</li> <li>▪ Requester DN</li> <li>▪ Requester IP address</li> <li>▪ Request controls</li> </ul> </li> <li>▪ The exact match identity mapper has been updated to inspect the mail attribute in addition to the uid attribute. When targeting a user with an authentication ID value, as when using SASL authentication or the proxied authorization v2 request control, an email address can now be specified as an alternative to a user ID.</li> <li>▪ The <b>UNBOUNDID-TOTP</b> SASL mechanism handler has been updated to prevent TOTP password reuse by default.</li> <li>▪ Added new request criteria that enable the identification of requests that target the root</li> </ul> |

| Ticket ID                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| DS-10312                                         | Added the server's process ID to the output of the status tool.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DS-10464                                         | Added a new <code>rotate-log</code> tool to request the rotation of one or more log files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| DS-10466, DS-10765, DS-14479, DS-15318, DS-16154 | Addressed issues associated with <code>config-diff</code> . In some situations, for example, <code>config-diff</code> could not generate commands in an order that respected all dependencies. This issue is now fixed. Most expected warnings are excluded by default, but can be included in the output by using the <code>--includeAllWarnings</code> option. Additionally, the <code>--sourceBindPasswordFile</code> and <code>--targetBindPassword</code> options are now applied in conjunction with the <code>--targetConfigGroup</code> and <code>--sourceConfigGroup</code> options.                                                                                                                                                                                 |
| DS-10946                                         | Added a <code>--dry-run</code> option to <code>dsconfig</code> , which can be used in batch mode to validate the configuration changes in a batch file without applying them.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DS-12191                                         | Added support for setting the request header size in the Jetty HTTP configuration server properties.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| DS-13401                                         | Improved the <code>collect-support-data</code> tool to include information that <code>systemd</code> provides on platforms that support it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DS-13700                                         | <p>Updated command-line tools based on the LDAP SDK tool APIs to add the following features:</p> <ul style="list-style-type: none"> <li>▪ Tools can use a properties file to obtain default values for arguments that are not available on the command line. If it exists, the server's <code>config/tools.properties</code> file is used by default. Command-line arguments can be used to specify an alternate properties file or to indicate that no properties file is used.</li> <li>▪ Tools can be launched in an interactive mode, in which the user is prompted for arguments that establish and authenticate a connection, and for any other required arguments. The user can then use an interactive menu to specify values for any remaining arguments.</li> </ul> |
| DS-13823                                         | The <code>collect-support-data</code> tool now captures Kerberos configuration and logging information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| DS-14213                                         | Added the ability to create local constants in LDIF template files by using the new local keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DS-14298                                         | To apply Sync maps programmatically, a new API, <code>applyMaps()</code> , is available for PingDataSync Server plugins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DS-14430                                         | Updated the Apache commons collections library to address the security vulnerability that CVE 2015-4852 describes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                             |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-14548  | Added a monitor entry for each Server SDK extension.                                                                                                                                                                                                                                                                                                                                    |
| DS-14606  | The <b>resync</b> tool now supports sync pipes that use Notification mode.                                                                                                                                                                                                                                                                                                              |
| DS-14694  | Added a <b>--prettyPrint</b> option to the <b>config-diff</b> tool to make the output more human-readable.                                                                                                                                                                                                                                                                              |
| DS-14704  | Updated the <b>restore</b> command so that it can no longer be used to restore a backup of the configuration backend. The command now points the administrator toward safer ways for reverting configuration changes, including using the <b>config-diff</b> command.                                                                                                                   |
| DS-14749  | Updated the server's support for the Twilio Messaging Service so that it uses the newer Messages API, instead of the earlier SMS API, when sending SMS messages. The earlier API has been deprecated, and Twilio now imposes a 120-character limit for messages sent through that API. The Messages API allows the server to take advantage of the full 160 characters per SMS message. |
| DS-14765  | Updated the Active Directory PingDataSync Source so that it correctly handles the range options on attributes that are returned with the DirSync control.                                                                                                                                                                                                                               |
| DS-14807  | Tools that prepare a server for access by another server, such as <b>prepare-external-server</b> , now validate base DN entries before modifications are performed on the prepared server.                                                                                                                                                                                              |
| DS-14857  | Fixed an issue with the <b>dsjavaproperties</b> tool, in which java properties for PermSize and MaxPermSize could be added when using JDK 8, which no longer supports these options.                                                                                                                                                                                                    |
| DS-14878  | To prevent the possible retention of data in memory, memory utilization has been improved when processing entries with large attributes.                                                                                                                                                                                                                                                |
| DS-14923  | Updated the <b>bcrypt</b> , <b>crypt</b> , <b>PBKDF2</b> , and <b>sCrypt</b> password-storage schemes so that they can be used to create new instances.                                                                                                                                                                                                                                 |
| DS-14979  | Fixed a case in which changes to attribute syntax configurations did not apply to undefined attributes, which rely on default attribute types.                                                                                                                                                                                                                                          |
| DS-15015  | Server SDK extensions are now built with a Java source version of 1.7 by default.                                                                                                                                                                                                                                                                                                       |
| DS-15087  | Fixed an issue in which destination attributes with hard-coded values were excluded inappropriately during a resync, when the <b>--excludeSourceAttr</b> option was used.                                                                                                                                                                                                               |

| Ticket ID                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-15088                     | The former suite of Administrative Console applications, each of which was tied to a particular product (for example the <code>dsconsole.war</code> for PingDirectory Server) are no longer available, and have been superseded by a new version of the Administrative Console that can manage any server product. You can choose to access the Administrative Console by hosting it within a server or by deploying it in an external servlet container. For the former option, enable an HTTP Connection Handler and add the Administrative Console Web Application Extension to the handler. For the latter option, download and extract the <code>management-console-[version].zip</code> file, and install the <code>ubid-console.war</code> file according to your container's instructions. |
| DS-15108                     | Replaced the <code>scramble-ldif</code> tool with a more powerful <code>transform-ldif</code> tool with support for several additional transformation types. The new <code>transform-ldif</code> tool is backward-compatible with the former <code>scramble-ldif</code> tool, and the <code>scramble-ldif</code> shell script and batch file are still included with the server to ensure compatibility with scripts that depend on that tool.                                                                                                                                                                                                                                                                                                                                                     |
| DS-15175                     | The Configuration API now returns unquoted, native Javascript values for integer, real number, and Boolean properties. Duration and size property values, such as 1 w or 100 G, continue to be represented as JavaScript string types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| DS-15178                     | Improved the error messages and examples for <code>create-rc-script</code> and <code>create-systemd-script</code> by explicitly suggesting the use of <code>sudo</code> so that the scripts can modify protected files.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| DS-15187                     | Literal curly brackets ( <code>{ }</code> ) can now be included in value patterns and conditional value patterns of constructed attribute mappings by doubling them. Literal <code>{</code> and <code>}</code> are specified by <code>{{{</code> and <code>}}}</code> , respectively.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DS-15221                     | Changed interactive setup default value for HTTPS enablement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| DS-15337                     | Improved the error messages for <code>create-rc-script</code> and <code>create-systemd-script</code> when the directory in which the script will be created does not exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| DS-15361, DS-15363, DS-15434 | Updated interactive setup to display default values. Also improved the overall layout and appearance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DS-15400                     | Addressed an issue in which <code>dsconfig</code> incorrectly permitted the deletion of certain configuration objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-15412  | Improved the error messages that the <b>manage-extensions</b> tool generates when attempting to install invalid extensions.                                                                                                                                                                                                                                   |
| DS-15417  | Updated the global ACIs that ship with the server to use a separate ACI for each control or extended request to allow by default, rather than grouping all desired controls together in one ACI and all desired extended requests together in a second ACI. This change is reflected only in new installations, and not when updating an existing deployment. |
| DS-15422  | Root DN User configuration entries can now be managed fully through the configuration management interfaces, such as <b>dsconfig</b> and the Administrative Console.                                                                                                                                                                                          |
| DS-15437  | Provided a graphical tool, <b>watch-entry</b> , that is intended to demonstrate replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, the background of modified attributes temporarily becomes red. Attributes can also be directly modified.                                                                  |
| DS-15466  | Added logging information when initializing web application and servlet extensions in case an extension causes conflicts or delays.                                                                                                                                                                                                                           |
| DS-15513  | PingDataSync Server now uses the <b>max-connection-age</b> configuration property to limit the age of LDAP connections to external servers.                                                                                                                                                                                                                   |
| DS-15521  | Updated <b>setup</b> to encode the root password with the PBKDF2 password-storage scheme instead of SHA512.                                                                                                                                                                                                                                                   |
| DS-15522  | To prevent Java JVM pauses, the <b>updater</b> tool now increases the <b>PermSize</b> and <b>MaxPermSize</b> parameters to the recommended values.                                                                                                                                                                                                            |
| DS-15571  | To accommodate the Administrative Console, increased the minimum memory requirements for the server process from 256MB to 384MB.                                                                                                                                                                                                                              |
| DS-15592  | Fixed an error that could occur during upgrade when a missing custom schema prevented the configuration from loading.                                                                                                                                                                                                                                         |
| DS-15621  | Updated the Groovy Scripting Language version to 2.4.6.                                                                                                                                                                                                                                                                                                       |
| DS-15622  | Fixed an issue that prevented the deletion of disabled debug loggers.                                                                                                                                                                                                                                                                                         |
| DS-15670  | The <b>prepare-endpoint-server</b> CLI that is included with PingDataSync Server correctly sets permissions when the Synchronization user already exists.                                                                                                                                                                                                     |

| Ticket ID | Description                                                                                                                                                                                                                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-15753  | The Data Services Markup Language (DSML) client and gateway components have been discontinued and are no longer available.                                                                                                                                                                         |
| DS-16224  | Updated the <code>sanitize-log</code> tool to add support for JSON-formatted access and error log files.                                                                                                                                                                                           |
| DS-16728  | Sensitive attribute values can now be redacted in the <code>sync</code> and <code>sync-failed-ops</code> log files. By default, the values of encoded passwords are redacted. The redaction can be configured with the <code>log-redaction-regex</code> property in the global Sync configuration. |

## PingDataSync Server 5.2.0.0 Release Notes

### Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID                  | Description                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-1261                    | The <code>collect-support-data</code> tool can now use the <code>--timeRange</code> argument to collect logging information within a specified time range.                                                                                                                                                                                                                       |
| DS-1706                    | Updated interactive <code>dsconfig</code> to include an option for toggling between sorting similar properties together and sorting them alphabetically.                                                                                                                                                                                                                         |
| DS-2880                    | When DSEE servers are prepared for synchronization, the <code>nsslapd-changelogmaxentries</code> DSEE configuration property is no longer set to 500,000. The size of DSEE's Retro changelog is now limited entirely by the <code>nsslapd-changelogmaxage</code> configuration property.                                                                                         |
| DS-3095                    | Added a new <code>search-logs</code> tool. Similar to the command-line tool <code>grep</code> , the <code>search-logs</code> tool searches across log files to extract lines that match the provided patterns. The <code>search-logs</code> tool can handle log messages with multiple lines, extract log messages within a specified time range, and include rotated log files. |
| DS-5425                    | Global synchronization no longer needs to be enabled when using the <code>set-startpoint</code> command to set a synchronization start point.                                                                                                                                                                                                                                    |
| DS-8794, DS-9652, DS-12704 | The setup and initial configuration tools now support offline modes that can be used to bootstrap the server configuration while it is not running. The files that these tools generate are saved to the server's resource directory.                                                                                                                                            |
| DS-10010                   | Reduced the memory overhead of debug logging in high-throughput environments by sharing logging buffers across multiple threads.                                                                                                                                                                                                                                                 |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-10447  | Updated the <b>resync</b> command to display additional error messages to the console and a log file. The location of the log file defaults to <code>&lt;server-root&gt;&gt;/logs/tools/resync-errors.log</code> but can be overridden by using the <code>--consoleLogFilePath</code> option.                                                                         |
| DS-10558  | To prevent the circular synchronization of changes, the Sync Source <code>ignore-changes-by-dn</code> configuration parameter now defaults to the default synchronization user, <code>cn=Sync User,cn=Root DNs,cn=config</code> .                                                                                                                                     |
| DS-11067  | Added properties to the task backend for limiting the number of log messages that are retained in task entries, as well as for limiting the size of the in-memory representation of those entries. The server error log still records all log messages that a task generates, even if they are not retained in the corresponding entry in the task backend.           |
| DS-11522  | Updated the server's JVM arguments to always log garbage collection (GC) information to a rotating set of log files stored within <code>logs/jvm/gc.log.N</code> . The file system usage is limited to 300MB. If the server had previously been configured with <b>VERBOSE_GC</b> , then GC logging information is no longer logged to <code>logs/server.out</code> . |
| DS-11936  | Constructed mappings now support mappings that are conditional with the <b>dsconfig</b> parameter <code>conditional-value-pattern</code> . Each parameter consists of an LDAP filter and a pattern, the former of which must be matched for the pattern to be used.                                                                                                   |
| DS-12123  | Updated the Configuration API output to include undefined properties and values.                                                                                                                                                                                                                                                                                      |
| DS-12182  | Updated the <b>setup</b> tool to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup or by using the non-interactive setup.                                                                                                                                                                                                                  |
| DS-12245  | Updated the Configuration API to support filtering, sorting, and paging for object list operations. For more information, refer to <i>PingDataSync Server Administration Guide</i> .                                                                                                                                                                                  |
| DS-12285  | Fixed an issue in which changes to SMTP External Server configurations did not take effect until after a server restart.                                                                                                                                                                                                                                              |
| DS-12287  | Addressed cases in which certain messages might have been suppressed in logs and alerts.                                                                                                                                                                                                                                                                              |
| DS-12483  | Added support for running on Oracle Java 8 and OpenJDK 8 platforms.                                                                                                                                                                                                                                                                                                   |

| Ticket ID          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-12496           | Added logging of all HTTP requests that are disallowed because of CORS. This fix simplifies the process of troubleshooting HTTP 403/Forbidden errors.                                                                                                                                                                                                                                                                                                                         |
| DS-12576           | Updated the Detailed HTTP Operation Log Publisher to log the appropriate return code, 404 NOT FOUND, when defined endpoints do not handle a request.                                                                                                                                                                                                                                                                                                                          |
| DS-12579           | The server can now detect an <code>out of file handles</code> situation on the operating system, and can shut down to prevent running in an unreliable state.                                                                                                                                                                                                                                                                                                                 |
| DS-12616           | Updated the <code>prepare-*</code> tools to avoid unnecessary confirmation for trust of a prepared server's certificate when the <code>--trustStorePath</code> argument specifies a trust store that establishes trust.                                                                                                                                                                                                                                                       |
| DS-12681, DS-13475 | Improved the server's support for selecting TLS cipher suites. When the server is configured to use a specific set of cipher suites, it now validates that the JVM supports all of the configured suites. When the server is not configured to use a specific set of cipher suites, it customizes the set of default suites to prioritize the ones that use strong cryptography, especially suites that offer forward secrecy, and to exclude the ones with known weaknesses. |
| DS-12708           | Fixed an issue in which a JVM bug blocked a Sync Pipe after the following error was reported to the error log: <div data-bbox="850 1234 1468 1318" style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <pre>AckHandler#completed called with a value that's not pending.</pre> </div>                                                                                                                                                                         |
| DS-12727           | Added an Available File Descriptors gauge to monitor the number of available file descriptors. The gauge detects whether a server is running out of file descriptors and can degrade the server appropriately.                                                                                                                                                                                                                                                                |
| DS-12782           | Updated the <code>resync</code> command to include the <code>Recent ops/second</code> statistic, which displays the number of operations per second for the previous ten-second iteration.<br><br>To maintain consistency with other tools, the <code>Average ops/second</code> statistic has been renamed to <code>Overall ops/second</code> .                                                                                                                               |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-12798  | MakeLDIF templates now have the ability to escape special characters like curly braces ({}), angle brackets (<>), and square brackets ([]) by using a backslash (\). For additional examples, refer to <code>config/MakeLDIF/examples-of-all-tags.template</code> .                                                                                                                                                                                               |
| DS-12799  | <p>The following UnboundID product names have changed:</p> <ul style="list-style-type: none"> <li>▪ <i>Identity Data Store</i> has been changed to <i>Data Store</i>.</li> <li>▪ <i>Identity Proxy</i> has been changed to <i>Proxy Server</i>.</li> <li>▪ <i>Identity Data Sync Server</i> has been changed to <i>Data Sync Server</i>.</li> <li>▪ <i>Identity Broker</i> has been changed to <i>Data Broker</i>.</li> </ul>                                     |
| DS-12833  | Updated the alert-handler configuration to indicate whether the alert handler is invoked asynchronously in a background thread or by the thread that generates the alert. For alerts that are generated during the course of processing an operation, invoking potentially time-consuming alert handlers in a background thread can avoid impacting the response time adversely for the operation, while still making administrators aware of the relevant issue. |
| DS-12833  | Updated the server to provide support for SMTP connection pooling. When sending an email message, the server attempts to reuse an existing SMTP connection rather than establish a new connection for each message.                                                                                                                                                                                                                                               |
| DS-12880  | Fixed a rare condition that might have caused the logger rotation and retention thread to exit under heavy file system load or during a network file system outage.                                                                                                                                                                                                                                                                                               |
| DS-12897  | Fixed an issue that changed the <code>dsconfig</code> tool's complexity settings whenever the advanced arguments of some tools were used.                                                                                                                                                                                                                                                                                                                         |
| DS-12969  | Improved the server locking that <code>dsconfig</code> uses in offline batch mode. The server lock is now held for the entire batch duration instead of for each invocation. Also reduced the probability of contention for file locks that server tools use to determine the server status.                                                                                                                                                                      |
| DS-13163  | Addressed an issue in which the data definition language (DDL) log field mappings for the JDBC error log were not previously documented.                                                                                                                                                                                                                                                                                                                          |
| DS-13242  | Updated the <code>prepare-external-server</code> tool to suppress output when run with the <code>--quiet</code> option.                                                                                                                                                                                                                                                                                                                                           |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-13552  | Fixed a log publisher defect that resulted in an unreadable file when compression and signing were enabled simultaneously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DS-13678  | <p>Updated the <code>create-systemd-script</code> tool by adding the following capabilities:</p> <ul style="list-style-type: none"> <li>▪ Resource limits for available open file descriptors (NOFILE)</li> <li>▪ Shared memory reservations (MEMLOCK)</li> </ul> <p>The generated script lists the recommended file descriptors limit and the resource limit setting for enabling large page support. The settings in the <code>create-systemd-script</code> output supersede prior documentation for setting the number of open file descriptors on non-<code>systemd</code> systems.</p> |
| DS-13718  | Fixed an issue in which the <code>resync</code> command incorrectly reported synchronized entries as modified. This issue occurred with Active Directory Sync Destinations.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DS-13769  | Fixed an issue in which the stale state for remote sync pipes could be merged repeatedly with an active PingDataSync Server, either after failover or when starting and stopping the sync pipes. When a sync pipe is deleted, its saved sync pipe state is now removed.                                                                                                                                                                                                                                                                                                                     |
| DS-14061  | Fixed an issue in which a <code>set-startpoint</code> command could fail when synchronizing from an Active Directory LDS source. Additionally, when synchronizing changes to an Active Directory LDS instance, the <code>userAccountControl</code> attribute is no longer included when creating new entries.                                                                                                                                                                                                                                                                               |
| DS-14140  | The <code>ldifsearch</code> command now supports the option <code>---isCompressed</code> for LDIF files that have been compressed with <code>gzip</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| DS-14186  | Fixed an issue in which an active PingDataSync Server could accept a smaller change number when merging the remote state for a changelog Sync Source.                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## PingDataSync Server 5.1.5.2 Release Notes

### Known Issues and Workarounds

When an UnboundID DataSync Server is configured to synchronize only a subset of attributes from an UnboundID datastore or Proxy Server, `delete` operations might not be detected and synchronized.

**Workaround:** To ensure that `delete` operations are detected and synchronized appropriately, add `*` to the `changelog-deleted-entry-include-attribute` configuration property on the changelog backend in the datastore.

## Resolved Issues

The following issue has been resolved with this release of PingDataSync Server:

| Ticket ID | Description                                                                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-14061  | Fixed an issue in which a <code>set-startpoint</code> command could fail when synchronizing from an Active Directory LDS source. Also, when synchronizing changes to an Active Directory LDS instance, the <code>userAccountControl</code> attribute is no longer included when creating new entries. |

**PingDataSync Server 5.1.5.0 Release Notes**

## Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID | Description                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-12727  | Added an Available File Descriptors gauge to monitor the number of available file descriptors. The gauge detects whether a server is running out of file descriptors and can degrade the server appropriately. |
| DS-13718  | Fixed an issue in which the <code>resync</code> command incorrectly reported synchronized entries as modified. This issue occurred with Active Directory Sync Destinations.                                    |

**PingDataSync Server 5.1.0.0 Release Notes**

## Upgrade Considerations

The `summarize-config` tool has been deprecated. To view a summary of changes to the local server configuration, use the `config-diff` tool with the `sourceBaseline` argument.

## What's New

Identity DataSync attribute mappings now support LDAP-filter syntax conditionals, like the `conditional-value-pattern` property. This enhancement increases the flexibility of attribute-to-attribute mapping, based on attribute values that are found in the incoming data.

## Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID | Description                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------------------|
| DS-10010  | Reduced the memory overhead of debug logging in high-throughput environments by sharing logging buffers across multiple threads. |

| Ticket ID | Description                                                                                                                                                                                                                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-10447  | Updated the <code>resync</code> command to display additional error messages to the console and a log file. The location of the log file defaults to <code>&lt;server-root&gt;/logs/tools/resync-errors.log</code> but can be overridden by using the <code>--consoleLogFilePath</code> option. |
| DS-11936  | Constructed mappings now support mappings that are conditional with the <code>dsconfig</code> parameter <code>conditional-value-pattern</code> . Each parameter consists of an LDAP filter and a pattern, the former of which must be matched for the pattern to be used.                       |
| DS-12123  | Updated the Configuration API output to include undefined properties and values.                                                                                                                                                                                                                |
| DS-12182  | Updated the <code>setup</code> tool to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup or by using the non-interactive setup.                                                                                                                                      |
| DS-12245  | Updated the Configuration API to support filtering, sorting, and paging for object list operations. For more information, refer to <i>PingDataSync Server Administration Guide</i> .                                                                                                            |
| DS-12285  | Fixed an issue in which changes to SMTP External Server configurations did not take effect until after a server restart.                                                                                                                                                                        |
| DS-12287  | Addressed cases in which certain messages might have been suppressed in logs and alerts.                                                                                                                                                                                                        |
| DS-12483  | Added support for running on Oracle Java 8 and OpenJDK 8 platforms.                                                                                                                                                                                                                             |
| DS-12496  | Added logging of all HTTP requests that are disallowed because of CORS. This fix simplifies the process of troubleshooting HTTP 403/Forbidden errors.                                                                                                                                           |
| DS-12576  | Updated the Detailed HTTP Operation Log Publisher to log the appropriate return code, <code>404 NOT FOUND</code> , when defined endpoints do not handle a request.                                                                                                                              |
| DS-12579  | The server can now detect an <code>out of file handles</code> situation on the operating system, and can shut down to prevent running in an unreliable state.                                                                                                                                   |
| DS-12708  | Fixed an issue in which a JVM bug blocked a Sync Pipe after the following error was reported to the error log:                                                                                                                                                                                  |
|           | <pre>AckHandler#completed called with a value that's not pending.</pre>                                                                                                                                                                                                                         |

| Ticket ID | Description                                                                                                                                                                                                                                                                                  |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-12798  | MakeLDIF templates now have the ability to escape special characters like curly braces ({}), angle brackets (<>), and square brackets ([]) by using a backslash (\). For additional examples, refer to <code>config/MakeLDIF/examples-of-all-tags.template</code> .                          |
| DS-12880  | Fixed a rare condition that might cause the logger rotation and retention thread to exit under heavy file system load or during a network file system outage.                                                                                                                                |
| DS-12969  | Improved the server locking that <code>dsconfig</code> uses in offline batch mode. The server lock is now held for the entire batch duration instead of for each invocation. Also reduced the probability of contention for file locks that server tools use to determine the server status. |

### PingDataSync Server 5.0.1.0 Release Notes

#### Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID | Description                                                                                                                                                                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-12123  | Updated the Configuration API output to include undefined properties and values.                                                                                                                                                                                            |
| DS-12287  | Addressed cases in which certain messages might be suppressed in logs and alerts.                                                                                                                                                                                           |
| DS-12579  | The server can now detect an <code>out of file handles</code> situation on the operating system, and can shut down to prevent running in an unreliable state.                                                                                                               |
| DS-12708  | Fixed an issue caused by a JVM bug that blocked a Sync Pipe after the following error was reported to the Error log: <div style="background-color: #f0f0f0; padding: 5px; margin-top: 5px;"> <pre>AckHandler#completed called with a value that's not pending.</pre> </div> |

### PingDataSync Server 5.0.0.0 Release Notes

#### What's New

The following features are new with this release of PingDataSync Server:

- Java 7 is now required when setting up a new server or upgrading an existing server.
- Enabled support for the SSLv2Hello TLS protocol by default in JVMs that support it. This feature does not enable support for the insecure SSLv2 protocol, but it can improve compatibility with clients that run earlier versions of Java that might start TLS negotiation with an SSLv2 client hello packet before negotiating to a higher version of the TLS protocol. Support for SSLv2Hello in the initial phase of negotiation does not compromise the strength of the integrity or the confidentiality protection that is ultimately negotiated between the client and the server.

- Added a Monitor History plugin that periodically records `cn=monitor` to timestamped files to aid in isolating intermittent problems. By default, the plugin logs the full `cn=monitor` branch every five minutes to compressed files within `logs/monitor-history/`. Files are deleted automatically, but a sparse set of older files is retained to provide historical perspective on server performance. The `collect-support-data` tool has also been updated to collect some of these files to aid in root-cause analysis.
- Introduced the Configuration HTTP Servlet Extension, which is used for querying and updating the configuration over a REST API. This feature is currently experimental and is subject to change in the future. Your feedback is welcome.

#### Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

| Ticket ID                    | Description                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-8368, DS-12120            | Updated the HTTP Connection Handler to return a <code>404 Not Found</code> response to requests for endpoints that are not handled by a servlet or by web application extensions. Previously, the handler returned a <code>200 OK</code> with no response body.                                 |
| DS-10441                     | Disabled log rotation during startup to prevent potential problems with rotation dependencies on server components that have not yet been initialized.                                                                                                                                          |
| DS-10460                     | Fixed the <code>dsconfig</code> tool to suppress stray output when run in batch mode with the <code>--quiet</code> option.                                                                                                                                                                      |
| DS-11068, DS-11784, DS-11887 | Updated the setup tools to enable the definition of external server instances that are configured to reject unauthenticated requests. Previously, the tools indicated erroneously that such server instances were unavailable.                                                                  |
| DS-11453                     | Reduced the severity of the <code>unrecognized alert type</code> message in the error log from <code>SEVERE_WARNING</code> to <code>NOTICE</code> . The message now states that this event is expected if the server is reverted to a version prior to the implementation of these alert types. |
| DS-11472                     | Fixed the gauge-configuration manager to re-initialize only the gauge that was changed, and not any of the other gauges that did not change.                                                                                                                                                    |
| DS-11487                     | Fixed an issue with the <code>prepare-endpoint-server</code> tool in which the <code>maxChangelogAge</code> argument was not being applied when targeting UnboundID servers.                                                                                                                    |
| DS-11541                     | Fixed the alarm manager to generate alarm-cleared alerts when internal alarms are cleared, and when the alarm manager's <code>generated-alert-types</code> property features the alarm value.                                                                                                   |
| DS-11546                     | Fixed the alarm manager to exclude the details of old, cleared alarms in the <code>alarm-cleared</code> alert message.                                                                                                                                                                          |

| Ticket ID          | Description                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-11624           | Updated the Web Console so that a user's previous session is always invalidated when he or she logs on to the system.                                                                                                                                                                                             |
| DS-11629, DS-11645 | Updated the Web Console to suppress LDAP responses in user messages, such as when the server is unavailable or for authentication failures. Also added a context parameter to exclude stack traces and detailed error messages from appearing in the application's internal error page.                           |
| DS-11637           | Updated the alarm manager to not generate an <code>alarm-normal</code> alert when a gauge's condition abates.                                                                                                                                                                                                     |
| DS-11688           | Fixed an issue in which tools such as <code>dsconfig</code> , <code>status</code> , and <code>dsreplication</code> could not connect to the server over SSL or StartTLS. This issue occurred when a certificate was accepted with the Manually validate option, while using the interactive LDAP connection menu. |
| DS-11719           | Updated the alarm manager to not persist normal alarms.                                                                                                                                                                                                                                                           |
| DS-11719           | Updated the <code>ExampleOverloadHandlerPlugin</code> to monitor the alarm backend for delete actions, so that it can react appropriately to abating gauge conditions.                                                                                                                                            |
| DS-11730           | Removed the <code>alarm-normal</code> alert.                                                                                                                                                                                                                                                                      |
| DS-11751           | Fixed incorrect property references for <code>trustStorePassword</code> and <code>keyStorePasswordFile</code> in <code>tools.properties</code> that corresponded to the wrong argument names.                                                                                                                     |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-11782  | <p data-bbox="849 216 1446 468">Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers and for replication communication. The recently discovered POODLE vulnerability could potentially allow a network attacker to determine the plain text behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.</p> <p data-bbox="849 489 1463 1150">SSLv3 was initially defined in 1996 but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). The newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not adversely affect clients that support the newer TLS protocols. However, if legacy client applications attempt to communicate securely but do not support the newer TLS protocols, update them to support the newer protocols. If known clients do not support a security protocol newer than SSLv3, and if they cannot be updated immediately to support a newer protocol, re-enable SSLv3 support by using the newly introduced <code>allowed-insecure-tls-protocol</code> global configuration property. Because communication using SSLv3 can no longer be considered secure, we recommended that you update all known clients that still use SSLv3.</p> <p data-bbox="849 1171 1463 1764">The server access log can be used to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server generates a <code>SECURITY-NEGOTIATION</code> access log message. The <code>protocol</code> element of a <code>SECURITY-NEGOTIATION</code> access log message specifies the name of the security protocol that has been negotiated between the client and the server, and <code>SECURITY-NEGOTIATION</code> messages with a protocol of <code>SSLv3</code> suggest that the associated client is vulnerable to a POODLE attack. Additionally, if connections are terminated for attempting to use the disallowed SSLv3 protocol, the corresponding access log message for the disconnect must include a message that states the reason for the termination.</p> |

| Ticket ID | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DS-11947  | Increased the possible parallelism within a Sync Pipe by skipping past the operation at the head of the incoming queue, if it cannot be processed, because it depends on an uncompleted active operation. This approach increases the overall throughput of a Sync Pipe when the stream of incoming changes also includes multiple dependent operations that must be processed in order. Examples of dependent operations include changes to the same entry, as well as changes to entries with a parent-child relationship. With these changes, the Sync Server still guarantees that dependent operations are processed in order. |
| DS-11993  | Added a gauge to the server to track JVM memory usage. An alert is generated when the amount of free memory becomes so low that it might impact server performance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| DS-12147  | Updated the server to make it easier to control the order of values in the ssl-protocol and ssl-cipher-suite properties in the LDAP connection handler and crypto manager configuration objects.                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### Overview of the Server

---

The PingDirectory Server is a high performance, extensible directory and PingData Platform, written completely in Java™. The Directory Server centralizes consumer and user identity management

information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment. It provides seamless data management over a distributed system based on a standardized solution that meets the constant performance demands for today's markets. The Directory Server simplifies administration, reduces costs, and secures information in systems that scale for very large numbers of users.

This chapter provides an overview of the Directory Server's features and components.

## Server Features

The PingDirectory Server is a powerful, 100% Java, production-proven PingData Platform solution for mission-critical and large-scale applications. The Directory Server provides an extensive feature-rich set of tools that can meet the production needs of your system.

- **Full LDAP Version 3 Implementation.** The Directory Server fully supports the Lightweight Directory Access Protocol version 3 (LDAP v3), which supports the Request For Comments (RFCs) specified in the protocol. The Directory Server provides a feature-rich solution that supports the core LDAPv3 protocol in addition to server-specific controls and extended operations.
- **High Availability.** The Directory Server supports N-way multi-master replication that eliminates single points of failure and ensures high availability for a networked topology. The Directory Server allows data to be stored across multiple machines and disk partitions for fast replication. The Directory Server also supports replication in entry-balancing proxy server deployments.
- **Administration Tools.** The Directory Server provides a full set of command-line tools, an Administrative Console, and a Java-based setup tool to configure, monitor, and manage any part of the server. The Directory Server has a task-based subsystem that provides automated scheduling of basic functions, such as backups, restores, imports, exports, restarts, and shutdowns. The set of utilities also includes a troubleshooting support tool that aggregates system metrics into a zip file, which administrators can send to your authorized support provider for analysis.
- **Self-Service Account Manager Application.** The Self Service Account Manager project, hosted at <https://github.com/pingidentity/ssam>, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes, and is not a supported application.
- **Delegated Admin Application.** A Javascript-based web application can be installed for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives (CSR) initiating a password reset and unlock; an employee in HR updating an address stored within another employee profile; or an application administrator updating identity attributes or group membership to allow application SSO access.
- **Security Mechanisms.** The Directory Server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry. The Directory Server allows connections over Secure Sockets Layer (SSL) through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include a privilege subsystem for fine-grained granting of rights, a password policy subsystem that allows configurable password validators and storage schemes, and SASL authentication mechanisms to secure data integrity, such as PLAIN, ANONYMOUS, EXTERNAL, CRAM-MD5, Digest-MD5, and GSSAPI. The Directory Server also supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. See the *PingDirectory Server Security Guide* for details.
- **Monitoring and Notifications.** The Directory Server supports monitoring entries using the PingDataMetrics Server, JConsole, Simple Network Management Protocol (SNMP), or using the Administrative Console. Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The Directory Server also supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.

- **Powerful LDAP SDK.** The Directory Server is based on a feature-rich LDAP SDK for Java, designed by Ping Identity. The LDAP SDK is a Java API standard that overcomes the many limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

For more information on the LDAP SDK for Java, to go <http://www.LDAP.com>.

- **SCIM Extension.** The Directory Server provides a System for Cross-domain Identity Management (SCIM) servlet extension to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure and fast manner.
- **Server SDK.** Ping Identity also provides the Server SDK, which is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for the PingDirectory Server, PingDirectoryProxy Server, and Data Sync Server. The servers were designed with a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

## Administration Framework

The Directory Server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances. Administrators can configure changes locally or remotely on a single server or on all servers in a server group. Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the Directory Information Tree (DIT). Administrators can tune the configuration and perform maintenance functions over LDAP using a suite of command-line tools, or an Administrative Console (for configuration and monitoring). The Directory Server also provides plugins to extend the functionality of its components.

## Server Tools Location

Ping Identity distributes the Directory Server, Administrative Console, and LDAP SDK for Java in zip format. After unzipping the file, you can access the `setup` utility in the server root directory, located at `PingDirectory`. The Directory Server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX® or Linux® machines and the `PingDirectory\bat` directory for Microsoft® Windows® machines.

Prior to installing the directory server, read Chapter 2 *Preparing Your Environment*, which presents important information on setting up your machines. Chapter 3 *Installing the Directory Server* presents procedures to install a server instance using the `setup` utility. This utility can be run in one of the two available installation modes: interactive command-line, and non-interactive command-line. Chapter 4 *Configuring the Directory Server* provides procedures to modify the configuration of a server instance or a group of servers using the command-line tools and the Administrative Console.

## Preparing Your Environment

---

The PingDirectory Server offers a highly portable and scalable architecture that runs on multiple platforms and operating systems. The Directory Server is specifically optimized for those operating systems used in environments that process a very large number of entries.

This chapter presents some procedures to set up your server machines for optimal processing efficiency.

## Before You Begin

The Directory Server requires certain software packages for the proper operation of the server. For optimized performance, the PingDirectory Server requires Java for 64-bit architectures. To view the minimum required Java version, access your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

It is also highly recommended that a Network Time Protocol (NTP) system be in place so that multi-server environments are synchronized and timestamps are accurate.

## System requirements

PingDirectory Server has qualified the configurations in this section and has certified that they are compatible with the product. Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software is suspected of causing an issue.

### Platforms

- Windows Server 2019
- Windows Server 2016
- Red Hat Enterprise Linux ES 8
- Red Hat Enterprise Linux ES 7.6
- Red Hat Enterprise Linux ES 7.5
- CentOS 7.6
- CentOS 7.5
- SUSE Linux Enterprise 15
- SUSE Linux Enterprise 12 SP3
- Ubuntu 18.04 LTS
- Ubuntu 16.04 LTS
- Amazon Linux 2
- Amazon Linux

**Note:** This product has been tested with the default configurations of all operating system components. If your organization has customized implementations or has installed third-party plugins, the deployment of this product might be affected.

### Docker

Version: Docker 18.09.0

Host operating system: Ubuntu 18.04 LTS

Kernel: 4.4.0-1052-aws 7.3

**Note:** PingDirectory Server accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

### Java Runtime Environment

- Amazon Corretto 8
- OpenJDK 11
- OpenJDK 8
- Oracle Java SE Development Kit 11 LTS
- Oracle Java SE Development Kit 8

**Note:**

The [Ping Identity Java Support Policy](#) applies to your Java Runtime Environment.

### Browsers

#### Administration Console

- Chrome

- Firefox
- Internet Explorer 11 and later

#### End users

- Chrome
- Edge
- Firefox
- Internet Explorer 11 and later
- Safari

#### Installing Java

For optimized performance, the PingDirectory Server requires Java for 64-bit architectures. You can view the minimum required Java version on your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

Even if your system already has Java installed, you may want to create a separate Java installation for use by the PingDirectory Server to ensure that updates to the system-wide Java installation do not inadvertently impact the Directory Server. This setup requires that the JDK, rather than the JRE, for the 64-bit version, be downloaded.

#### To Install Java (Oracle/Sun)

##### Steps

1. Open a browser and navigate to the Oracle download site.
2. Download the latest version Java JDK. Click the JDK Download button corresponding to the latest Java update.
3. On the Java JDK page, click the Accept Licence Agreement button, then download the version based on your operating system.

## Preparing the Operating System (Linux)

The PingDirectory Server has been extensively tested on multiple operating systems. We have found that several operating system optimizations lead to improved performance. These optimizations include increasing the file descriptor limit on Linux systems, setting file system flushes, editing OS-level environment variables, downloading some useful monitoring tools for Redhat Linux systems, and configuring for Huge Page support.

#### Configuring the File Descriptor Limits

The PingDirectory Server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. If needed, increase the file descriptor limit on the operating system.

If the operating system relies on `systemd`, refer to the Linux operating system documentation for instructions on setting the file descriptor limit.

#### To Set the File Descriptor Limit (Linux)

##### About this task

The Directory Server allows for an unlimited number of connections by default but is restricted by the file descriptor limit on the operating system. Many Linux distributions have a default file descriptor limit of 1024 per process, which may be too low for the server if it needs to handle a large number of concurrent connections.

Once the operating system limit is set, the number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as, `NUM_FILE_DESCRIPTOR=12345`. If these are

not set, the default of 65535 is used. This is strictly optional if wanting to ensure that the server shuts down safely prior to reaching the file descriptor limit.

### Steps

1. Display the current hard limit of your system. The hard limit is the maximum server limit that can be set without tuning the kernel parameters in the `proc` file system.

```
ulimit -aH
```

2. Edit the `/etc/sysctl.conf` file. If there is a line that sets the value of the `fs.file-max` property, make sure its value is set to at least 65535. If there is no line that sets a value for this property, add the following to the end of the file:

```
fs.file-max = 65535
```

3. Edit the `/etc/security/limits.conf` file. If the file has lines that sets the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines to the end of the file (before “#End of file”). Also note that you should insert a tab, rather than spaces, between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

4. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
ulimit -n
```

### Results

**Note:** For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits:

```
/etc/security/limits.d/20-nproc.conf
```

Add or edit the following lines if they do not already exist:

```
* soft nproc 65536
* soft nofile 65536
* hard nproc 65536
* hard nofile 65536
root soft nproc unlimited
```

### File System Tuning

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation. This feature may cause a risk of data loss in cases where a system loses power before all of the data has been written to disk. This may occur if a program is replacing the contents of a file without forcing a write to the disk with `fsync`. Make sure the default `auto_da_alloc` option is enabled on ext4 file systems.

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and noatime to improve server performance. The following changes can be made in the `/etc/fstab` file.

## To Set the File System Flushes

### About this task

With the out-of-the-box settings on Linux systems running the `ext3` file system, the data is only flushed to disk every five seconds. If the Directory Server is running on a Linux system using the `ext3` file system, consider editing the mount options for that file system to include the following:

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

You should also set the flush frequency to the `/etc/fstab` file. Doing the change via the `mount` command alone will not survive across reboots.

## To Set noatime on ext3 and ext4 Systems

### About this task

If you are using an `ext3` or `ext4` file system, set `noatime` to improve performance by turning off any `atime` updates during read accesses. Additionally, set the flush frequency to the `/etc/fstab` file. Performing the change through the `mount` command alone does not survive across reboots.

### Steps

- Run the following command on an `ext3` system.

```
mount -t ext3 -o noatime /dev/fs1
```

- Run the following command on an `ext4` system.

```
mount -t ext4 -o noatime /dev/fs1
```

## Setting the Maximum User Processes

On some Linux distributions (Redhat Enterprise Linux Server/CentOS 6.0 or later), the default maximum number of user processes is set to 1024, which is considerably lower than the same parameter on older distributions (e.g., RHEL/CentOS 5.x). The default value of 1024 leads to some JVM memory errors when running multiple servers on a machine due to each Linux thread being counted as a user process.

At startup, the Directory Server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by `ulimit` is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, an error message will be displayed. It is recommended that the limit be set explicitly in `/etc/security/limit.conf`. For example:

```
* soft nproc 65535
* hard nproc 65535
```

The (\*) can be replaced with the name of the user under which the software will run. These settings can also be manually configured by setting the `NUM_USER_PROCESSES` environment variable to 16383 or by setting the same variable in a file named `config/num-user-processes`.

## About Editing OS-Level Environment Variables

Certain environment variables can impact the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like `PATH`, `LD_LIBRARY_PATH`, and `LD_PRELOAD` to ensure that something set in the environments that are used to start the server does not inadvertently impact its behavior.

If there is a legitimate need to edit any of these environment variables, the values of those variables should be set by manually editing the `set_environment_vars` function of the `lib/_script-util.sh` script. You will need to stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

### Install `sysstat` and `pstack` (Red Hat)

For Red Hat® Linux systems, you should install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting purposes in the event that a problem occurs. The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance statistics, and stack trace information on the server's processes. For Red Hat systems, make sure that these packages are installed, for example:

```
$ sudo yum install sysstat gdb dstat -y
```

### Install `dstat` (SUSE Linux)

The `dstat` utility is used by the `collect-support-data` tool and can be obtained from the OpenSUSE project website. The following example shows how to install the `dstat` utility on SuSE Enterprise Linux 11 SP2:

1. Login as Root.
2. Add the appropriate repository using the `zypper` tool.
3. Install the `dstat` utility.

```
$ zypper install dstat
```

### Disable File System Swapping

About this task

It is recommended that any performance tuning services like `tuned` be disabled. As root, change the current value in the operating system and by adding a line `vm.swappiness = 0` to `/etc/sysctl.conf` to ensure that the correct setting is applied when the system restarts.

If performance tuning is required, `vm.swappiness` can be set by cloning the existing performance profile then adding `vm.swappiness = 0` to the new profile's `tuned.conf` file. This file is located at `/usr/lib/tuned/profile-name/tuned.conf`. The updated profile is then selected by running `tuned-admin profile customized_profile`.

### Omit `vm.overcommit_memory`

Administrators should be aware that an improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file can cause the `setup` or `start-server` tool to fail.

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, it could lead the operating system to grab too much memory, depriving memory for the `setup` or `start-server` tool.

We recommend omitting the property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

### Managing System Entropy

Entropy is used to calculate random data that is used by the system in cryptographic operations. Some environments with low entropy may have intermittent performance issues with SSL-based communication. This is more typical on virtual machines, but can occur in physical instances as well. Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

If necessary, update `$JAVA_HOME/jre/lib/security/java.security` to use `file:/dev/. /urandom` for the `securerandom.source` property.

## Set File System Event Monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates. The Linux system puts a limit on the number of inotify watches a user can receive. To increase the limit, edit `etc/sysctl.conf` to add a line:

```
fs.inotify.max_user_watches = 524288
```

Run the command:

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

## Tune IO Scheduler

Using the correct IO scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load. For file systems running on an SSD, or in a virtualized environment, the `noop` scheduler is recommended. For all other systems, the `deadline` scheduler is recommended. To determine which scheduler is configured on your system, run this command:

```
$ cat /sys/block/<block-device>/queue/scheduler
```

For example:

```
$ cat /sys/block/sda/queue/scheduler
```

Changing the scheduler on a running system can be done with the following command:

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

The change will take effect after the system is restarted. The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

## Running as a Non-Root User (Linux)

To run as a non-root user but still allow connections on a privileged port, two options are available:

- **Use a Load-Balancer or Directory Proxy Server.** In many environments, the server can be run on a non-privileged port but can be hidden by a hardware load-balancer or LDAP Directory Proxy Server.
- **Use `netfilter`.** The `netfilter` mechanism, exposed through the `iptables` command, can be used to automatically redirect any requests from a privileged port to the unprivileged port on which the server is listening.

### Enabling the Server to Listen on Privileged Ports (Linux)

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account. It may be convenient to enable the server to listen on privileged ports while running as a non-root user.

The `setcap` command is used to assign capabilities to an application. The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024). If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), the Java binary can be granted the `cap_net_bind_service` capability with the following command:

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. More strict limitations are imposed on where the operating system will look for shared libraries to load for commands that have capabilities assigned. So it is also necessary to tell the operating system where to look for this library. This can be done by creating the file `/etc/ld.so.conf.d/libjli.conf` with the path to

the directory that contains the `libjli.so` file. For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

Run the following command for the change to take effect:

```
$ sudo ldconfig -v
```

## Installing the Server

After you have prepared your hardware and software system based on the instructions in Chapter 2, you can begin the setup process using of the PingDirectory Server's easy-to-use installation modes.

This chapter presents the various installation options and procedures available to the administrator.

### Getting the Installation Packages

To begin the installation process, obtain the latest ZIP release bundle from Ping Identity and unpack it in a folder of your choice. The release bundle contains the Directory Server code, tools, and package documentation.

#### To Unpack the Build Distribution

Steps

1. Download the latest zip distribution of the Directory Server software.
2. Unzip the compressed zip archive file in a directory of your choice.

```
$ unzip PingDirectory-<version>.zip
```

You can now set up the Directory Server.

### About the Layout of the Directory Server Folders

Once you have unzipped the Directory Server distribution file, you will see the following folders and command-line utilities, shown in the table below.

#### Layout of the Directory Server Folders

| Directories/Files/Tools | Description                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| License.txt             | Licensing agreement for the Directory Server.                                                                                        |
| README                  | README file that describes the steps to set up and start the Directory Server.                                                       |
| bak                     | Stores the physical backup files used with the <code>backup</code> command-line tool.                                                |
| bat                     | Stores Windows-based command-line tools for the Directory Server.                                                                    |
| bin                     | Stores UNIX/Linux-based command-line tools for the Directory Server.                                                                 |
| classes                 | Stores any external classes for server extensions.                                                                                   |
| collector               | Used by the server to make monitored statistics available to the PingDataMetrics Server.                                             |
| config                  | Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates. |
| db                      | Stores the Oracle Berkeley Java Edition database files for the Directory Server.                                                     |

| Directories/Files/Tools | Description                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| docs                    | Provides the product documentation.                                                                                                                                        |
| import-tmp              | Stores temporary imported items.                                                                                                                                           |
| ldif                    | Stores any LDIF files that you may have created or imported.                                                                                                               |
| legal-notice            | Stores any legal notices for dependent software used with the Directory Server.                                                                                            |
| lib                     | Stores any scripts, jar, and library files needed for the server and its extensions.                                                                                       |
| locks                   | Stores any lock files in the backends.                                                                                                                                     |
| logs                    | Stores log files for the Directory Server.                                                                                                                                 |
| metrics                 | Stores the metrics that can be gathered for this server and surfaced in the PingDataMetrics Server.                                                                        |
| resource                | Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server. |
| revert-update           | The <b>revert-update</b> tool for UNIX/Linux systems.                                                                                                                      |
| revert-update.bat       | The <b>revert-update</b> tool for Windows systems.                                                                                                                         |
| setup                   | The <b>setup</b> tool for UNIX/Linux systems.                                                                                                                              |
| setup.bat               | The <b>setup</b> tool for Windows systems.                                                                                                                                 |
| scim-data-tmp           | Used to create temporary files containing SCIM request data.                                                                                                               |
| uninstall               | The <b>uninstall</b> tool for UNIX/Linux systems.                                                                                                                          |
| uninstall.bat           | The <b>uninstall</b> tool for Windows systems.                                                                                                                             |
| update                  | The <b>update</b> tool for UNIX/Linux systems.                                                                                                                             |
| update.bat              | The <b>update</b> tool for Windows systems.                                                                                                                                |
| Velocity                | Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.                                     |

## About the Server Installation Modes

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the **setup** tool. The **setup** tool allows you to quickly install and configure a stand-alone Directory Server instance.

To install a server instance, run the **setup** tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the **setup --cli** command.
- **Non-Interactive Command-Line Mode.** Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, **setup** must be run with the **--no-prompt** option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the Directory Server will run.

## Before You Begin

After you have unzipped the Directory Server ZIP file, you may want to carry out the following functions depending on your deployment requirements:

- **Custom Schema Elements.** If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you may do one of the following:
  - Copy your custom schema file to the `config/schema` directory before running `setup`.
  - Copy your custom schema file to the `config/schema` directory after `setup` and re-start the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
  - Use the **Schema Editor** after `setup`. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.
- **Certificates.** If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory prior to running `setup`. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.
- **Encryption Passphrase.** Encryption for directory data, backups, LDIF exports, and log files can be enabled during `setup` by providing or generating an encryption key with a passphrase.
- **Locations.** Location names are used to define a grouping of PingDirectory Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.
- **Validate ACIs.** Many directory servers allow for less restrictive application of its access control instructions (ACIs), so that they accept invalid ACIs. For example, if a Sun/Oracle server encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server. If you are migrating from a Sun/Oracle deployment to a PingDirectory Server, PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see [Validating ACIs Before Migrating Data](#).

### Important:

**Each Server Deployment Requires an Execution of Setup - Duplicating a Server-root is not Supported.** The installation of the server does not write or require any data outside of the server-root directory. After executing `setup`, copying the server-root to another location or system, in order to *duplicate* the installation, is not a supported method of deployment. The server-root can be moved to another host or disk location if a host or file system change is needed.

## Ping license keys

License keys are required to install all Ping products. To obtain a license key, contact your account representative or [Ping Identity](#).

- A license is always required for setting up a new single server instance and can be used site-wide for all servers in an environment. When cloning a server instance with a valid license, no new license is needed.
- A new license must be obtained when updating a server to a new major version, for example from 6.2 to 7.0. Licenses with no expiration date are valid until the server is upgraded to the next major version. A prompt for a new license is displayed during the update process.

- A license may expire on particular date. If a license does expire, obtain a new license and install it using `dsconfig` or the Administrative Console. The server will provide a notification as the expiration date approaches. License details are available using the server's `status` tool.

When installing the server, specify the license key file in one of the following ways:

- Copy the license key file to the server root directory before running `setup`. The interactive `setup` tool will discover the file and not require input. If the file is not in the server root, the setup tool will prompt for its location.
- If the license key is not in the server root directory, specify the `--licenseKeyFile` option for non-interactive setup, and the path to the file.

## Setting Up the Directory Server in Interactive Mode

The `setup` tool also provides an interactive text-based command-line interface to set up a Directory Server instance.

### To Install the Directory Server in Interactive Mode

#### Steps

1. Unzip the distribution ZIP file, review [Before You Begin](#), and then go to the server root directory. Use the `setup` utility with the `--cli` option to install the server in interactive mode.

```
$./setup
```

If the `JAVA_HOME` environment variable is set to an older version of Java, explicitly specify the path to the Java JDK installation during the setup process. Either set the `JAVA_HOME` environment variable with the Java JDK path or execute the `setup` command in a modified Java environment using the `env` command.

```
$ env JAVA_HOME=/ds/java ./setup
```

2. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
3. Enter the fully qualified host name or IP address of the local host, or press **Enter** to accept the default.
4. Enter the root user DN, or press **Enter** to accept the default (`cn=Directory Manager`).
5. Enter and confirm the root user password.
6. Press **Enter** to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.
7. Enter the port on which the Directory Server will accept connections from HTTPS clients, or press **Enter** to accept the default.
8. Enter the port on which the Directory Server will accept connections from LDAP clients, or press **Enter** to accept the default.
9. The next two options enable using LDAPS or StartTLS. Type `no` to use a standard LDAP connection, or accept the default (`yes`) to enable both. Enabling LDAPS configures the LDAPS Connection Handler to allow SSL over its client connections. Enabling StartTLS configures the LDAP Connection Handler to allow StartTLS.
10. Select the certificate option for this server:
  - Generate a self-signed certificate for testing purposes only.
  - To use an existing certificate using a Java Keystore, enter the keystore path and keystore PIN.
  - To use an existing certificate using use a PKCS#12 keystore, enter the keystore path and the keystore PIN.
  - To use the PKCS#11 token, enter only the keystore PIN.

11. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
  - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
  - Encrypt data with a key generated from a passphrase read from a file.
  - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
  - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
  - Do not encrypt server data.
12. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.
13. Choose an option to generate and import sample data. Type the desired number of entries, or press `Enter` to accept the default number (10000). This option is used for quick evaluation of the Directory Server.
 

See [Initializing Data onto the Server](#) if you want to use other options to initialize the server.
14. Choose the option to tune the amount of memory that will be consumed by the Directory Server and its tools.
15. Press `Enter` to prime or preload the database cache at startup prior to accepting client connections.
 

Priming the cache can increase the startup time for the Directory Server but provides optimum performance once startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this Directory Server instance is starting. Priming the cache also helps determine the recommended JVM option, `CMSInitiatingOccupancyFraction`, when a Java garbage collection pause occurs. See [JVM Garbage Collection Using CMS](#).
16. Enter a location name for this server.
17. Enter a unique instance name for this server. Once set, the name cannot be changed.
18. Press `Enter` to accept the default (yes) to start the Directory Server after the configuration has completed. To configure additional settings or import data, type `no` to keep the server in shutdown mode.
19. Choose an option to continue server set up.
20. On the **Setup Summary** page, confirm the configuration. Press `Enter` to accept the default (set up with the parameters given), enter the option to repeat the installation process, or enter the option to cancel the setup completely.

## Installing the Directory Server in Non-Interactive Mode

You can run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line. Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements.

The non-interactive command-line mode requires that all mandatory options be present for each command call. If there are missing or incorrect arguments, the `setup` tool fails and aborts the process. You must also use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. Additionally, you must also use the `--acceptLicense` option and specify the port using the `--ldapPort` or `--ldapsPort` option. If neither option is specified, an error message is displayed. To view the license, run `bin/review-license` command.

To automatically tune the JVM to use maximum memory, use the `--aggressiveJVMTuning` and `--maxHeapSize {memory}` options. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see [Installing the Directory Server in Non-Interactive Mode with a Truststore](#).

To see a description of the available command-line options for the `setup` tool, use `setup --help`.

## To Install the Directory Server in Non-Interactive Mode

### About this task

The following procedure shows how to install a Directory Server in a production or QA environment with no security enabled.

### Steps

- Unzip the distribution ZIP file, review “Before You Begin”, and then use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode from the `<server-root>` directory. The following command uses the default root user DN (`cn=Directory Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the setup will generate an error message.

```
$./setup --cli --no-prompt --rootUserPassword "password" \
 --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389
```

## To Install the Directory Server in Non-Interactive Mode with a Truststore

### About this task

You can set up the Directory Server using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

### Steps

- Unzip the distribution ZIP file, review [Before You Begin](#), and then, from the server root directory, use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

```
$./setup --cli --no-prompt --rootUserPassword "password" \
 --baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
 --ldapsPort 636 --useJavaKeystore config/keystore.jks \
 --keyStorePasswordFile config/keystore.pin \
 --certNickName server-cert --useJavaTrustStore config/truststore.jks \
 --acceptLicense
```

The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the Administrative Console or the `dsconfig` tool by editing the Trust Manager Provider standard configuration object.

## Installing a Lightweight Server

Users who want to demo or test a lightweight version of the Directory Server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects. All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that will be notified of changes to those objects.

The configuration framework will not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you will first need to remove the reference to it. If you try to remove a configuration object that is referenced, both `dsconfig` and the Administrative Console should prevent you from removing it and will tell you what still references it.

Depending on your test configuration, some example configuration changes that can be made are as follows:

- **Reduce the number of worker threads.** Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
 --set num-worker-threads:8 \
 --set num-administrative-session-worker-threads:4 \
 --set max-work-queue-capacity:100
```

- **Reduce the percentage of JVM memory used for the JE database cache.** When you have a memory-constrained environment, you want to ensure that as much of the memory that is there is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-
percent:5
```

- **Disable the Dictionary Password Validator.** The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it will free up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

- **Remove non-essential schema files.** Although not recommended for production deployments, some candidates that you can remove are the following: 03-rfc2713.ldif, 03-rfc2714.ldif, 03-rfc2739.ldif, 03-rfc2926.ldif, 03-rfc2985.ldif, 03-rfc3712.ldif, 03-uddiv3.ldif.

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

## Running the Status Tool

The Directory Server provides a `status` tool that outputs the current state of the server as well as other information, such as server version, JE Environment statistics, Operation Processing Times, Work Queue, and Administrative Alerts. The `status` tool is located in the `bin` directory (UNIX, Linux) or the `bat` directory (Windows).

### To Run the Status Tool

#### Steps

- Run the `status` command on the command line. The following command displays the current Directory Server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type and current state of the work queue.

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

 --- Server Status ---
Server Run Status: Started 28/Mar/2012:10:47:17.000 -0500
Operational Status: Available
Open Connections: 13
Max Connections: 13
Total Connections: 50

 --- Server Details ---
Host Name: server1.example.com
Administrative Users: cn=Directory Manager

Info : 28/Mar/2012 10:47:17 -0500 : The Directory Server has started
successfully
Info : 28/Mar/2012 10:47:14 -0500 : The Directory Server is starting
Info : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started
successfully
Info : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48 hours
Use the
--maxAlerts and/or --severity options to filter this list

```

**Note:** By default, the `status` command displays the alerts generated in the last 48 hours. You can limit the number of alerts by using the `--maxAlerts` option.

## Where To Go From Here

After you have set up your Directory Server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize your server's throughput.

- **Log into the Administrative Console.** Become familiar with configuration options through the Administrative Console interface. The URL is based on the host name and HTTPS port specified during installation, such as `https://hostname.com:443/console`.
- **Apply Server Configurations.** Apply your server configuration changes individually or using a `dsconfig` batch file. The batch file defines the Directory Server configuration tool, `dsconfig`, commands necessary to configure your server instance. For more information on using batch files, see [Using dsconfig in Batch Mode](#).

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the `bin/migrate-sun-ds-config` command to migrate your configuration settings to this newly installed server instance.

- **Import Data.** Import user data using the `import-ldif` tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

- **Install and Configure the Delegated Admin Application.** A Javascript-based web application can be installed for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives (CSR) initiating a password reset and unlock; an employee in HR updating an address stored within another employee profile; or an application administrator updating identity attributes or group membership to allow application SSO access.
- **Run Performance Tests.** The Directory Server provides two tools for functional performance testing using in-house LDAP clients that accesses the server directly: `searchrate` (tests search performance) and `modrate` (tests modification performance):

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
 --filter "(uid=user.[0-1999])" --attribute givenName --attribute sn \
 --attribute mail --numThreads 10
```

```
$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com" \
 --attribute description --valueLength 12 --numThreads 10
```

## Working with Multiple Backends

You can create multiple local database backends, each containing one or more different base DN's. There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends. The typical entry-balancing configuration involves two local database backends: one backend to serve the global domain data that resides above the entry-balancing point and a backend that is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, the data existing with each backend can be managed independently. In addition, separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends may have the same base DN.
- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DN's on that backend must be subordinate to the base DN of the other backend.
- The total of all `db-cache-percent` values should be no more than 65-70% in most cases and should never be configured to exceed 100%.

## Importing Data

After installation, the database, such as `userRoot`, will need to have data imported. For a server to be added to a replicating set, the database will be imported as part of the `dsreplication initialize` operation, which is performed after `dsreplication enable`. A server that will not be added to a replicating set, or the first server of a future replicating set, should have data imported with the `bin/`

`import-ldif` tool. See Chapter 8, Importing and Exporting Data, for more information about the `bin/import-ldif` tool.

## Generating Sample Data

### About this task

The PingDirectory Server provides LDIF templates that can be used to generate sample entries to initialize your server. You can generate the sample data with the `make-ldif` utility together with template files that come bundled with the ZIP build, or you can use template files that you create yourself. The templates create sequential entries that are convenient for testing the PingDirectory Server with a range of dataset sizes. The Directory Server templates are located in the `config/MakeLDIF`.

To randomize the data, the `make-ldif` command has a `--randomSeed` option that can be used to seed the random number generator. If this option is used with the same seed value, the template will always generate exactly the same LDIF file.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the Admin account full privileges. The templates also include the `uid=admin` and `ou=People` entries necessary for a complete dataset. You can bypass the `make-ldif` command entirely and use the `--templateFile` option with the `import-ldif` tool.

### Steps

- Use the `make-ldif` command to generate sample data. The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \
--ldifFile /path/to/data.ldif --randomSeed 0
```

## To Import Data on the Directory Server Using Offline Import

### Steps

- Create an LDIF file that contains entries, or locate an existing file.

The `import-ldif` tool requires an LDIF file, which conforms to standard LDIF syntax without change records. This means the `changeType` attribute is not allowed in the input LDIF. For information on adding entries to the , see [Managing Entries](#).

- Stop the Directory Server.

- Use the offline `import-ldif` to import data from an LDIF file to the Directory Server. For assistance with the list of options, run `import-ldif --help`.

In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. If any entry is rejected due to a schema violation, then the entry and the reason for the rejection is written to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the DIT or if exclusion filtering is used (`--excludeBranch`, `--excludeAttribute`, or `--excludeFilter`). The `--overwrite` option instructs `import-ldif` to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten. Finally, the `--stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in a LDIF parsing error.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --
rejectFile
rejects.ldif --skipFile skipped.ldif --overwrite --
overwriteExistingEntries --stripTrailingSpaces
```

- Re-start the Directory Server.

## Running the Server

To start the Directory Server, run the `bin/start-server` command on UNIX or Linux systems (an analogous command is in the `bat` folder on Microsoft Windows systems). The `bin/start-server` command starts the Directory Server as a background process when no options are specified. To run the Directory Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

### To Start the Directory Server

#### Steps

Use `bin/start-server` to start the server.

```
$ bin/start-server
```

### To Run the Server as a Foreground Process

#### Steps

1. Enter `bin/start-server` with the `--nodetach` option to launch the Directory Server as a foreground process.

```
$ bin/start-server --nodetach
```

2. You can stop the Directory Server by pressing **CTRL+C** in the terminal window where the server is running or by running the `bin/stop-server` command from another window.

### To Start the Server at Boot Time

By default, the PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command. To configure the Directory Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

#### Steps

1. Create the service unit configuration file in a temporary location where "ds" is the user the PingDirectory will run as.

```
$ bin/create-systemd-script \
 --outputFile /tmp/ping-directory.service \
 --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. Reload `systemd` to read the new configuration file.

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, use the `start` command.

```
$ systemctl start ping-directory.service
```

5. To configure the PingDirectory to start automatically when the system boots, use the `enable` command.

```
$ systemctl enable ping-directory.service
```

6. Log out as root.

If on an RC system, this task is done by creating the startup script with `bin/create-rc-script` and moving it to the `/etc/init.d` directory. Create symlinks to it from the `/etc/rc3.d` directory (staring

with an "S" to ensure that the server is started) and `/etc/rc0.d` directory (starting with a "K" to ensure that the server is stopped).

### Logging into the Administrative Console

After the server is installed, access the Administrative Console, `https://hostname:HTTPport/console/login`, to verify the configuration and manage the server. To log into the Administrative Console, use the initial root user DN specified during setup (by default `cn=Directory Manager`).

The `dsconfig` command or the Administrative Console can be used to create additional root DN users in `cn=Root DNs, cn=config`. These new users require the fully qualified DN as the login name, such as `cn=new-admin, cn=Root DNs, cn=config`. To use a simple user name (with out the `cn=` prefix) for logging into the Administrative Console, the root DN user must have the `alternate-bind-dn` attribute configured with an alternate name, such as "admin."

By default the link to the Administrative Console is `https://hostname:HTTPport/console/login`.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package (`/server-root/resource/admin-console.zip`) can be installed according to that container's documentation.

## Stopping the Directory Server

The Directory Server provides a simple shutdown script, `bin/stop-server`, to stop the server. You can run it manually from the command line or within a script.

If the Directory Server has been configured to use a large amount of memory, then it can take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server can fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process may take.

### To Stop the Server

#### Steps

- Use the `bin/stop-server` tool to shut down the server.

```
$ bin/stop-server
```

### To Schedule a Server Shutdown

#### Steps

- Use the `bin/stop-server` tool with the `--stopTime YYYYMMDDhhmmss` option to schedule a server shutdown.

The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, `20120606134500Z`. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --stopReason "Scheduled offline maintenance"
```

## To Restart the Server

### About this task

Re-start the Directory Server using the `bin/stop-server` command with the `--restart` or `-R` option.

Running the command is equivalent to shutting down the server, exiting the JVM session, and then starting up again.

### Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

```
$ bin/stop-server --restart
```

## Run the Server as a Microsoft Windows Service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables log out of a machine without the server being stopped.

### To Register the Server as a Windows Service

#### About this task

Perform the following steps to register the server as a service:

#### Steps

- Stop the server with `bin/stop-server`. A server cannot be registered while it is running.
- Register the server as a service. From a Windows command prompt, run `bat/register-windows-service.bat`.
- After a server is registered, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

### To Run Multiple Service Instances

#### About this task

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file. To run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

### To Deregister and Uninstall Services

#### About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat/deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

## Log Files for Services

### About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or due to file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

## Uninstalling the Server

The Directory Server provides an `uninstall` command-line utility for quick and easy removal of the code base.

To uninstall a server instance, run the `setup` tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode is a text-based interface that prompts the user for input. You can start the command using the `bin/uninstall` command with the `--cli` option. The utility prompts you for input if more data is required.
- **Non-Interactive Command-Line Mode.** Non-interactive mode suppresses progress information from being written to standard output during processing, except for fatal errors. This mode is convenient for scripting and is invoked using the `bin/uninstall` command with the `--no-prompt` option.

**Note:** For stand-alone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories. For example:

```
$ rm -rf /ds/PingDirectory
```

### To Uninstall the Server in Interactive Mode

#### About this task

Interactive mode uses a text-based, command-line interface to help you remove your instance. If `uninstall` cannot remove all of the Directory Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Server.

#### Steps

1. From the server root directory, run the `uninstall` command.

```
$./uninstall --cli
```

2. Select the components to be removed. If you want to remove all components, press **Enter** to accept the default (remove all). Enter the option to specify the specific components that you want to remove.

```
Do you want to remove all components or select the components to remove?
```

```
1) Remove all components
2) Select the components to be removed
```

```
q) quit
Enter choice [1]:
```

3. For each type of server component, press **Enter** to remove them or type `no` to keep it.

```
Remove Server Libraries and Administrative Tools? (yes / no) [yes]:
```

```
Remove Database Contents? (yes / no) [yes]:
Remove Log Files? (yes / no) [yes]:
Remove Configuration and Schema Files? (yes / no) [yes]:
Remove Backup Files Contained in bak Directory? (yes / no) [yes]:
Remove LDIF Export Files Contained in ldif Directory? (yes / no) [yes]:
```

4. If the Directory Server is part of a replication topology, type `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a stand-alone server, continue to step 7.
5. Type the Global Administrator ID and password to remove the references to this server in other replicated servers. Then, type or verify the host name or IP address for the server that you are uninstalling.
6. Next, select how you want to trust the server certificate if you have set up SSL or StartTLS. For this example, press **Enter** to accept the default.

```
How do you want to trust the server certificate for the Directory Server
on server.example.com:389?
```

```
1) Automatically trust
2) Use a trust store
3) Manually validate
```

```
Enter choice [3]:
```

7. If your Directory Server is running, the server is shutdown before continuing the uninstall process. The uninstall processes the removal requests and completes. View the logs for any remaining files. Manually remove any remaining files or directories, if listed.

### To Uninstall the Server in Non-Interactive Mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option. Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command will fail and abort.

#### Steps

1. From the server root directory, run `uninstall` tool with the `--remove-all` option to remove all of the Directory Server's libraries. The `--quiet` option suppresses output information and is optional. The following command assumes that the Directory Server is stand-alone and not part of a replication topology.

```
$./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

### To Uninstall Selected Components in Non-Interactive Mode

#### Steps

From the server root directory, run `uninstall` with the `--backup-files` option to remove the Directory Server's backup files. Use the `--help` or `-H` option to view the other options available to remove specific components.

```
$./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
```

## Upgrading the Server

---

Ping Identity issues software release builds periodically with new features, enhancements, and fixes for improved server performance. Administrators can use the Directory Server's update utility to upgrade the current server code version.

This chapter presents some update scenarios and their implications that you should consider when upgrading your server code.

### Upgrade Overview and Considerations

The upgrade process involves downloading and unzipping a new version of the Directory Server ZIP file on the server to be updated, and running the `update` utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation to be upgraded.

Consider the following when upgrading replicating servers:

- Upgrade affects only the server being upgraded. The process does not alter the configuration of other servers.
- The `update` tool will verify that the version of Java that is installed meets the new server requirements. To simplify the process, install the version of Java that is supported by the new server before running the tool.
- To be safe, backup the user data (`userRoot`) before an upgrade. Restoring from a backup could be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` utilities will issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This will result in a temporary increase in disk usage for the `replicationChanges` database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology
- Enable new features after all replicating servers are upgraded.

### Update servers in a topology

An update to the current PingDirectory Server release includes significant changes as well as the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts. For the admin backend to be migrated, the `update` tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security option requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to true (such as the `cn=Directory Manager` user) that exists on every server can be used.

After enabling or fixing the configuration of the LDAP connection handler(s) to support the desired connection security mechanism on each server, run the following `dsframework` command on the server being updated so that its admin backend has the most up-to-date information:

```
$ bin/dsframework set-server-properties \
 --serverID serverID \
 --set ldapport:port \
 --set ldapsport:port \
 --set startTLSEnabled:true
```

The **update** tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The **update** tool will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

```
$ bin/dsconfig set-global-configuration-prop \
 --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under **cn=cluster**, **cn=config** (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output. For example:

```
$ bin/config-diff --sourceHost hostName \
 --sourcePort port \
 --sourceBindDN bindDN \
 --sourceBindPassword password \
 --targetHost hostName \
 --targetPort port \
 --targetBindDN bindDN \
 --targetBindPassword password
```

If any of these conditions are not satisfied, the **update** tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

## Restoring a mixed topology to a clean state

### About this task

If you are upgrading a Directory Server version prior to 7.3 to version 7.3 or later and at least one server was previously removed from the topology, you may receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \
 threadID=438 category=REPLICATION severity=NOTICE msgID=118947975
msg="The \
 replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \
 severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997
\
 o=mycompany, the following error happened: (JE 7.5.12) Attempted to
remove \
 non-existent database 997 o=mycompany DatabaseNotFoundException: (JE
7.5.12) \
 Attempted to remove non-existent database 997 o=pingone (DbTree.java:922
\
```

```

DbTree.java:1183 DbTree.java:1235 Environment.java:1001
Environment.java:1221 \
 Environment.java:1204 Environment.java:1009 ReplicationDbEnv.java:1186 \
 DomainDbEnv.java:995 ReplicationDB.java:1002 DbHandler.java:1324
DbHandler.java:1064 \
 DbHandler.java:1042 DbHandler.java:798 DbHandler.java:723
DirectoryThread.java:352 \
(7.3.0.4-20191127203417.000Z-83a75e2a) "

```

Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally:

### Steps

1. Run `bin/export-ldif` on the primary server to export a safe copy of the data.
2. Start the downlevel primary server and stop the upgraded replica server.
3. Run `bin/remove-defunct-server` on the upgraded replica server and do the following at the command prompts:
  - Select the replica server itself.
  - Supply the credentials for the primary server when prompted.
  - Select **[c]** to continue.
  - Enter the path to the local `changeLogDB` when prompted
4. Leave the upgraded replica server stopped and stop the downlevel primary server.
5. Run `bin/dsreplication` on the primary server and do the following:
  - Select **2) Manage the topology (add and remove servers)**.
  - Select **4) Cleanup Server**.
  - Select **[c] to continue**.
  - Enter the path to the local `changeLogDB` when prompted.
6. Start the downlevel primary server and the upgraded replica server.
7. Run `bin/status` on both servers and verify **Replication: disabled** under **Data Sources**.
8. **IMPORTANT:** Upgrade the replica server to version 7.3.0.5 or later (which contains fixes for issues 00668265 and DS-40955).
9. Upgrade the primary server to the same level as the replica server.
10. Re-enable replication between primary and replica server using the `bin/dsreplication` tool.
11. Re-initialize the replica server data from the primary server.
12. Run `bin/status` on both servers to verify that replication is enabled under **Data Sources** and that both servers show the same number of entries.

## To Upgrade the Directory Server

About this task

Perform an upgrade with the following steps.

### Steps

1. Download and unzip the new version of the Directory Server in a location outside the existing server's installation. For these steps, assume the existing server installation is in `/prod/PingDirectory` and the new server version is unzipped into `/home/stage/PingDirectory`.
2. Run the `update` tool provided with the new server package to update the existing Directory Server. The update tool may prompt for confirmation on server configuration changes if it detects customization.

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

## Revert an update

After PingDirectory Server has been updated, you can revert to the last version (one level back) using the `revert-update` tool. The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the PingDirectory Server, you can run the `revert-update` command to revert to its previous state, then run the `revert-update` command again to return to its original state.

Reverting from version 7.x to a version prior to 7.0

Reverting from version 7.0 or later to a pre-7.0 version can be done using the `revert-update` command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 version to 6.2.0.2 or later. These steps are listed when the `update` and `revert-update` tool are run as well. You may need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes may need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the `rebuild-index` tool to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the `logs/config-audit.log` file. If you wish to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following `dsconfig` command:

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
 --bindPassword secret \
 --no-prompt set-global-configuration-prop \
 --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the `admin` backend. As long as new servers are not added to the topology after this update, the `revert-update` command can be used to return to the previous version. However, if new servers are added, then the restored `admin` backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the `admin` backend) will need to know that the reverted server was downgraded to the `admin` backend. This is done by running the following `dsconfig` command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
 --instance-name <Reverted server instance name> \
 --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made master with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
 --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you wish to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the `changeLogDb/` and `db/changeLog/` directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent start ups.

### Revert to the most recent server version

#### Steps

Use `revert-update` in the server root directory to revert back to the most recent version of the server.

```
$ PingDirectory-old/revert-update
```

## Tuning the Server

---

The PingDirectory Server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup. While the majority of the default configuration and JVM settings are suitable for most deployments, it is not uncommon in high performance environments to make slight adjustments to the Directory Server's JVM settings as well as performance and resource-related configuration changes with the `dsconfig` tool.

This chapter provides guidance for tuning the Directory Server and its tools for both optimum performance with regard to throughput and disk space usage. This chapter presents the following topics:

### About Minimizing Disk Access

Most critical to directory server performance is minimizing disk access. Defining a JVM heap size that can contain the entire contents of the database cache in memory is essential to minimizing read operations from disk and achieving optimal performance. It is also important to understand that the database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate within the transaction logs. Therefore, during normal operation, the on-disk size of the database transaction logs do not represent the memory needed to cache the database.

Another consideration is to minimize the size of the database based on the known characteristics of your data. Minimizing the size of the database not only reduces hard disk requirements but also reduces the memory requirements for the database cache. The Directory Server has the capability to automatically compact common parent DNs, which is an example of optimizing the database size based on known characteristics of the data.

Another consideration is to consider the write load on your server and its affect on the database. While write operations will always require an associated write to disk, an environment that sustains a high load of write operations may consider tuning the background database cleaner to minimize the size of the database on disk.

### Memory Allocation and Database Cache

The Directory Server's optimal performance is dependent on the proper allocation of memory to the JVM heap, the number of processor cores in the system, and the correct combination of JVM options for optimized garbage collection. The `setup` tool for the Directory Server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system. However, in most production deployments, additional tuning may be required to meet the performance objectives for your system.

Most often, directory server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure as well as the expected database usage. This section describes the basic components of the Directory Server footprint and logic behind the automated tuning of the `setup` tool.

### Directory Server Process Memory

The Directory Server is comprised mostly of a JVM heap and a marginal amount of memory allocated by the JVM's execution of native code. While we frequently refer to the JVM Heap as the maximum memory consumed by the Directory Server, the actual process size will be slightly larger than the `Xmx` value due to accumulation of small chunks of native code that Java requires for things, such as SSL sockets.

### MY TITLE JDK Heap Structure

Within the JVM Heap, the principal memory components are the New and Old Generations. The New Generation is a smaller area of memory where all data is initially allocated and is cleaned of garbage often. Any data that stays "alive" long enough will be promoted to the Old Generation for the longer term. The Old Generation is where the database cache will eventually reside. The Old Generation size is computed from the leftover heap after defining the `MaxHeapSize` and New Generation sizes; therefore, it is not explicitly stated in the JVM options. A typical set of Generation definitions for the JVM is as follows, where `mx` and `ms` values represent the heap size:

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX:NewSize=2g
```

**Note:** The `mx` and `ms` values should always be the same, and the `MaxNewSize/NewSize` values should be the same. This will help avoid negative changes in performance.

The `MaxNewSize/NewSize` values should never need to exceed 2g. The `setup` and `dsjavaproperties` tools set `MaxNewSize/NewSize` values based on the results of extensive performance testing, and should not need to be changed.

### A Method for Determining Heap and Database Cache Size

The most straightforward approach to defining the proper memory allocation of the directory server components is to use the Directory Server `setup` command on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the `setup` tool will allow. After running `setup`, any schema and production database settings should be defined in preparation for the database import using the `import-ldif` tool.

**Note:** At the moment after an `import-ldif`, the database is at its most optimized state on disk with no inactive records. Over time, the on-disk representation of the database will grow as much as 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

After the database is imported, the server should be started and a configuration change made to the backend. In this scenario, set the `prime-method` to "preload" on the userRoot backend configuration. Once the change is made, re-start the Directory Server and watch for a successful preload message at the end of startup. If preloading did not complete, the server should be stopped. The `start-server.java-args` entry in the `config/java.properties` file should be edited to use larger values for `-Xmx` and `-Xms` arguments. Then run the `bin/dsjavaproperties` command and restart the server. If preloading

completed successfully, the database cache utilization percentage will be of interest. The `status` command will display something like the following:

```

--- JE Environment ---
ID : Cache Full : Cache : On-Disk : Alert
-----:-----:-----:-----:-----
userRoot : 30% : 1.1 gb : 868.6mb : None

```

Looking at the above output and knowing that the database is fully loaded into cache, the 30% utilization is comfortable cushion for future database growth. In general, it is best to leave at least 10-20% cache headroom available.

During this scenario, it was clear from the `start-server` output that the database primed completely and our interpretation of the `status` output was sound. To see the state of the database cache with more detail, perform an `ldapsearch` on the backend monitor.

In addition to the user configured backends, there may be backends for replication and changelog. The heap is shared among all backends. The amount allocated to each backed is calculated according to the procedure in the next section.

### Automatic DB Cache Percentages

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured JVM heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. The allocation can be changed if needed. When setting up the server, perform the following steps:

- Install the server with necessary memory. The server will autotune the size of the cache.
- Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
- Divide the server cache based on the expected size of the data in each backend.

### Automatic Memory Allocation

If the Memory Tuning feature is enabled during setup, the `setup` algorithm determines the maximum JVM heap size based on the total amount of available system memory. If Memory Tuning is not selected, the server allocates a maximum JVM heap of 384 MB. The Directory Server also allows you to specify the maximum heap size during the setup process. You can enable Memory Tuning during the setup process by selecting the feature during the interactive command-line mode, adding the `--jvmTuningParameter` option using the `setup` tool in non-interactive command-line mode, or regenerating the java properties file with `bin/dsjavaproperties` and the `--jvmTuningParameter` options (seen in [JVM Properties for Server and Command-Line Tools](#) page 75).

If Memory Tuning is selected, the server can allocate the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

### Allocated Max JVM Memory if Tuning is Enabled

| Available Memory                 | Allocated JVM Memory                                                                                                                                                                                                                                                                  |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16 GB or more using a 64-bit JVM | The maximum JVM heap size will be set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory (which should be the case for systems with up to 160 GB of memory), then the initial heap size will be set to equal the maximum heap size. |
| 6 GB#16 GB using a 64-bit JVM    | total system memory - 4 GB                                                                                                                                                                                                                                                            |
| 4 GB–6 GB using a 64-bit JVM     | 2 GB                                                                                                                                                                                                                                                                                  |
| 2 GB–4 GB                        | 512 MB                                                                                                                                                                                                                                                                                |

| Available Memory | Allocated JVM Memory |
|------------------|----------------------|
| 1 GB–2 GB        | 384 MB               |

### Automatic Memory Allocation for the Command-Line Tools

At setup, the Directory Server automatically allocates memory to each command-line utility based upon the maximum JVM heap size. The server sets each command-line utility in the `config/java.properties` with `-Xmx/Xms` values depending on the expected memory needs of the tools. Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file: one with `.online` and one with `.offline` added to the name. The online invocations of the tools typically require minimal memory as the task is performed within the Directory Server's JVM. The offline invocations of the tools, for example, `import-ldif.offline` and `rebuild-index.offline`, can require the same amount of memory that is needed by the Directory Server.

Beyond the offline tool invocations, some tools, such as `ldap-diff` and `verify-index`, may need more than the minimal memory if large databases are involved. The table below lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

### Default Memory Allocation to the Command-Line Tools

| Command-Line Tools                                                                                                              | Allocated JVM Memory                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Database Preloading

Key to Directory Server performance is the ability to maintain the database contents in the database cache within the JVM memory. With a properly sized database cache, a priming method of "preload" directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, the server can be started with the `start-server --skipPrime` command. If the priming method is `none` or the `--skipPrime` option is specified at startup, the database cache will slowly build as entries are accessed. This could take several days to reach optimal performance.

The "preload" priming method is suitable for nearly all Directory Server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The Directory Server database `prime-method` property configures how the caches get primed, what gets primed (data, internal nodes, system indexes) and where it gets primed (database cache, file system cache, or both). The `prime-method` property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts, and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

- **Preload All Data.** Prime the contents of the backend into the database cache.
- **Preload Internal Nodes Only.** Prime only internal database structure information into the database cache, but do not prime any actual data. (This corresponds to the cache-keys-only cache-mode.)

- **Cursor Across Indexes.** Use the `cursor-across-indexes` property to iterate through backend contents. This is similar to (and may be slower than) using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

### Configuring Database Preloading

Use the `dsconfig` tool to set the database priming method. If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they will be performed. Changing the preloading option requires re-starting the Directory Server. The following procedure shows how to configure database preloading.

#### To Configure Database Preloading

##### Steps

1. Set the prime method to "preload" to load the database contents from disk into memory when the server starts up. This eliminates the need for the server to gradually prime the database cache using client traffic, and ensures that the server has optimal performance when it starts to receive client connections.

```
$ bin/dsconfig set-backend-prop \
 --backend-name userRoot \
 --set prime-method:preload
```

2. Re-start the Directory Server to apply the changes using `bin/stop-server` and then, `bin/start-server`.

#### To Configure Multiple Preloading Methods

##### Steps

1. To achieve the benefits of preloading without delaying server startup, `prime-method` can be set to `preload-internal-nodes-only`, which caches all of the keys within the database but not the values. The database values themselves can be cached in the background once the server has been started with the `cursor-across-indexes` option.

```
$ bin/dsconfig set-backend-prop \
 --backend-name userRoot \
 --add prime-method:preload-internal-nodes-only \
 --add prime-method:cursor-across-indexes \
 --set background-prime:true
```

2. Re-start the Directory Server to apply the changes using `bin/stop-server` and then, `bin/start-server`.

#### To Configure System Index Preloading

##### Steps

1. Some environments have many indexes configured, though only a few are used for performance-sensitive traffic. In this case, server start up time can be reduced by only preloading the necessary indexes into the database at startup.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
 --set prime-method:preload \
 --set prime-all-indexes:false \
 --set system-index-to-prime:dn2id \
 --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
```

```

--index-name mail \
--set prime-index:true

$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
--index-name uid \
--set prime-index:true

$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
--index-name entryUUID \
--set prime-index:true

```

- Restart the Directory Server to apply the changes using `bin/stop-server` and then, `bin/start-server`.

## Databases on Storage Area Networks, Network-Attached Storage, or running in Virtualized Environments

There are several considerations when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks. A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property `database-on-virtualized-or-network-storage` can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property, and in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events may outweigh the penalty. The exact overhead of enabling `database-on-virtualized-or-network-storage` depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. Incremental and full backup strategies should be used instead if performance is unacceptable.

To enable `database-on-virtualized-or-network-storage` for each applicable backend, use the following command as an example, which references the configuration for the `userRoot` backend:

```

$ bin/dsconfig set-global-configuration-prop \
--set database-on-virtualized-or-network-storage:true

```

This should be set to `false` if the database is on a local disk.

## Database Cleaner

Production environments that have a high volume of write operations may require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted. The Directory Server stores its Oracle® Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labelled `nnnnnnnn.jdb`, where `nnnnnnnn` is an 8-digit hexadecimal number that starts at `00000000` and is increased by 1 for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (`db`) files.

The cleaner threads begin by scanning the records in each `db` file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active due to modifications or deletions, the cleaner threads leave it untouched. After the `db` file no longer has active records, the cleaner threads can either delete the file or rename the discarded file. Note that because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The Local DB Backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-`

`utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to 75, which indicates that database cleaning ensures that at least 75% of the total log file space is devoted to live data. Note that this property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for db cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic may need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the Directory Server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the `dsconfig` tool (select **Backend# select advanced properties# db-num-cleaner-threads**).

## Compacting Common Parent DNs

The PingDirectory Server compacts entry DNs by tokenizing common parent DNs. Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage. The Directory Server automatically defines tokens for base DNs for the backend (for example, `dc=example,dc=com`). You can also define additional common base DNs that you want to tokenize. For example, use the following configuration to tokenize two branches, `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
 --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
 --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
```

## Import Thread Count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count may lead to improved import performance, while selecting a value that is too large can actually cause import performance to degrade. If minimizing LDIF import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the dataset being imported.

You can use the `dsconfig` command to set the number of import threads as follows:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set import-thread:24
```

## JVM Properties for Server and Command-Line Tools

The Directory Server and tools refer to the `config/java.properties` file for JVM options that include important memory settings. The `java.properties` file sets the default Java arguments for the Directory Server and each command-line utility including the default `JAVA_HOME` path.

The `java.properties` is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if aggressive memory tuning option was selected at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See the section on [Memory Allocation and Database Cache](#) for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (`start-server`) or command-line tools, the most common change required to `java.properties` is when it is desired to update the JVM version. A single edit will apply the new JVM to all server and tool use.

### Applying Changes Using `dsjavaproperties`

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the `bin/dsjavaproperties` utility. The `dsjavaproperties` tool uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script (or `lib\set-java-home.bat` on Microsoft Windows systems), which is used by the Directory Server and all of its supporting

tools to identify the Java environment and its JVM settings. During the process, **dsjavaproperties** calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated `set-java-home` script.

The **dsjavaproperties** utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the Directory Server compares the MD5 digest with the version stored in `set-java-home` and sends a message to standard error if the digests differ:

```
WARNING -- File /ds/PingDirectory
 /config/java.properties has been edited without
running dsjavaproperties to apply the changes
```

### To Update the Java Version in the Properties File

About this task

To change the version of java that is used by the server and tools, it is necessary to edit the `config/java.properties` file and apply the change by invoking `bin/dsjavaproperties` with no command line options. Also, the server must be restarted for the change to take affect.

Inside `config/java.properties`, alter the value of `default.java-home` to point to the java correct JRE. Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration.

```
$ bin/dsjavaproperties
```

### To Regenerate the Java Properties File

About this task

The **dsjavaproperties** command provides a `--initialize` option that allows you to regenerate the Java Properties file specifically if you set up the Directory Server using standard memory usage but opt for aggressive memory tuning after setup. Rather than reconfigure the Java Properties file by re-running `setup` or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file will be renamed with a ".old" suffix.

Steps

- Run the **dsjavaproperties** command to regenerate the java properties file for aggressive memory tuning:

```
$ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
```

## JVM Garbage Collection Using CMS

To ensure reliable server performance with Java, the Directory Server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection. There are several garbage collection options, with CMS being the ideal choice for consistent system availability. The CMS collector runs as one or more background threads, for the most part, within the JVM, freeing up space in JVM Heap from an area called the Old Generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called `CMSInitiatingOccupancyFraction`. This percentage value, which applies to the Old Generation, is a recommendation for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

To understand this CMS property, it is important to know how large the Old Generation is and how much data in the Old Generation is expected to be occupied by the database cache. Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the

`CMSInitiatingOccupancyFraction` value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation due to an inability for CMS to keep up. Because CMS takes processing resources away from the Directory Server, it is not recommended to set the `CMSInitiatingOccupancyFraction` at or below the expected database cache size, which would result in the constant running of CMS in the background. See the section on Memory Footprint and Database Cache for a description of determining Old Generation size.

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM will resort to pausing all application processing to allow a full garbage collection. This event, referred to as a *stop-the-world* pause, does not break existing TCP connections or alter the execution of the Directory Server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the Directory Server will generate an alert, after the pause, and record the pause time in the error log.

Because determining an ideal `CMSInitiatingOccupancyFraction` can be difficult, the approach we have taken is to warn if the Directory Server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, it is not possible for an administrator to determine the ideal occupancy threshold value in advance. Therefore, to warn of any impending garbage collection pauses, the Directory Server calculates a recommended value for the `CMSInitiatingOccupancyFraction` property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, you will see an administrative alert indicating the current state of the `CMSInitiatingOccupancyFraction` and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE
severity=NOTICE msgID=458886
msg="PingDirectory Server

msg="The Directory Server has started successfully"
```

The Directory Server only makes a recommendation if all of the backends are preloaded and the `CMSInitiatingOccupancyFraction` JVM property is explicitly set, which is done automatically. For example, if you installed the Directory Server and specified that the database be preloaded (or

"primed") at startup, then the Directory Server can make a good recommendation for the Directory Server when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value may be an inaccurately low value.

**Note:** The generated value for the Directory Server property could change over time with each Directory Server build, Java release, or changes in data set. If the current value is fairly close to the recommended value, then there is no need to change the property unless the server experiences a JVM pause.

If the Directory Server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the Directory Server property, run `dsjavaproperties`, and restart the server.

## To Determine the CMSInitiatingOccupancyFraction

### Steps

1. If you set the `Preload Database at startup` option during the installation, then skip to step 3. If you are not sure, retrieve the `prime-method` property for the backend as follows:

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
 --property prime-method
```

2. If the `prime-method` property was not configured, use `bin/dsconfig` to set the property to `PRELOAD`, and then, restart the Directory Server to preload the database cache.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
 --set prime-method:preload
```

```
$ bin/stop-server
$ bin/start-server
```

3. At startup, you will see an administrative message if the current `CMSInitiatingOccupancyFraction` property is below the recommended value. You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.
4. If you were unable to see the recommended `CMSInitiatingOccupancyFraction` property at startup presented in the previous step, first you must pre-tune the value of the `CMSInitiatingOccupancyFraction` property to ensure that all of the data is imported into the server and preloading is enabled in the backend. Next, retrieve the recommended `CMSInitiatingOccupancyFraction` value by issuing the following search. If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backend(s).

```
$ bin/ldapsearch --baseDN "cn=monitor" \
 "(objectclass=ds-memory-usage-monitor-entry)" \
 cms-initiating-occupancy-fraction \
 recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

```
dn: cn=JVM Memory Usage,cn=monitor
cms-initiating-occupancy-fraction:80
recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
```

5. Open the `config/java.properties` file using a text editor, manually edit the `CMSInitiatingOccupancyFraction` or any other property to its recommended value in the `start-server.java-args` property, and then, save the file when finished. (The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.):

```
start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
-XX:NewSize=1g -XXParallelGCThreads=16 -XX:+UseConcMarkSweepGC
-XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
```

```
-XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
-XX:CMSMaxAbortablePrecleanTime=3600000
-XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
-XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
-XX:+UseBiasedLocking -XX:+UseLargePages
-XX:+HeapDumpOnOutOfMemoryError
```

The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. Also, the `-XX:ParallelCMSThreads` should be limited to 8.

6. Run the `bin/dsjavaproperties` command to apply the changes.

```
$ bin/dsjavaproperties
```

7. Restart the Directory Server.

## Tuning For Disk-Bound Deployments

For best performance, configure the Directory Server to fully cache the DIT in the backend database cache. Directory Server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set (when the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario).
- Use uncached attributes and/or entries as described in the following section.
- Use a Directory Proxy Server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

### To Tune for Disk-Bound Deployments

About this task

To configure the server for a disk-bound configuration, follow these steps:

Steps

1. When installing the server, choose the "aggressive" option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.
3. Set operating system `vm.swappiness` to 0 to protect the Directory Server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

## Uncached Attributes and Entries

Although achieving optimal Directory Server performance requires that the entire data set be fully cached, there may be deployments in which fully caching the data set is not possible due to hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data. The Directory Server already provides support for controlling caching on a per-database basis (e.g., to cache only certain indexes and/or system databases), but these features may not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the Directory Server provides two new options: the ability to exclude certain *entries* from the cache, and the ability to exclude certain *attributes* from the cache. The Directory Server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete and/or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a particularly large attribute

and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it will only include internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database will be included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of "uncached-id2entry".

**Backup/Restore.** There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup will successfully save your database contents including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration will be properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

**Replication.** Replication does not propagate information about which portions of entries may have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

**LDIF Import/Export.** When LDIF content is imported into the server, the uncached attribute and uncached entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that may have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters, or to include or exclude specific attributes.

**Server Access Log.** Server access log messages may include `uncachedDataAccessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAccessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database, or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data, and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

**Uncached Entry/Attribute Properties.** The Directory Server provides three new advanced properties on the Local DB Backend to control the caching mode for the `uncached-id2entry` database:

- **uncached-id2entry-cache-mode.** Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended, otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the *PingDirectory Server Configuration Reference*.
- **uncached-attribute-criteria.** Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.
- **uncached-entry-criteria.** Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry

writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

## To Configure Uncached Attributes and Entries

### About this task

The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the *PingDirectory Server Configuration Reference*.

### Steps

1. Run `dsconfig` to uncache entries that match the criteria. Here, the filter will uncache all entries that have its location set to "austin" (i.e., `l=austin`).

```
$ bin/dsconfig create-uncached-entry-criteria \
 --criteria-name "Fully Uncached l=austin" --type filter-based \
 --set enabled:true --set "filter:(l=austin)"
```

2. Run `dsconfig` to uncache attributes that match the criteria (`attribute-type: jpegPhoto`). The `--type simple` option indicates that the simple uncache attribute criteria be used to specify the `attribute-type` that should be uncache, which in this example is `jpegPhoto`. For those entries that are fully stored in the `uncached-id2entry` database container, the uncache attribute will be ignored.

```
$ bin/dsconfig create-uncached-attribute-criteria \
 --criteria-name "Uncached jpegPhoto" --type simple \
 --set enabled:true --set attribute-type:jpegPhoto
```

3. Set the uncache properties for the `userRoot` backend.

```
$ bin/dsconfig set-backend-prop \
 --backend-name userRoot \
 --set "uncached-entry-criteria:Fully Uncached l=austin" \
 --set "uncached-attribute-criteria:Uncached jpegPhoto"
```

4. Run the `re-encode-entries` tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains. The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend. The following command initiates a task that re-encodes all fully-encode entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

```
$ bin/re-encode-entries --hostname directory.example.com --port 389 \
 --bindDN uid=admin,dc=example,dc=com --bindPassword password \
 --backendID userRoot --skipFullyUncachedEntries \
 --skipPartiallyUncachedEntries --ratePerSecond 100
```

## Configuring the Server

---

The out-of-the-box, initial configuration settings for the PingDirectory Server provide an excellent starting point for most general-purpose Directory Server applications. However, additional tuning might be necessary to meet the performance, hardware, operating system, and memory requirements for your production environment.

The Directory Server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the Directory Server provides command-line and an Administrative Console to configure the server. The Directory Server also includes tools to create server groups, so that configuration changes can be applied to multiple servers at one time.

This chapter presents the following topics:

## About the Configuration Tools

The PingDirectory Server configuration can be accessed and modified in the following ways:

- **Using the Administrative Console** . The PingDirectory Server provides an Administrative Console for graphical server management and monitoring. The console provides equivalent functionality as the `dsconfig` command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands should you need to back out of a configuration.
- **Using the dsconfig Command-Line Tool**. The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes: interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

## About dsconfig Configuration Tool

The `dsconfig` tool is the text-based management tool used to configure the underlying Directory Server configuration. The tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The `dsconfig` tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

## Using dsconfig in Interactive Command-Line Mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements. The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` script without any arguments. You will be prompted for connection and authentication information to the Directory Server, and then a menu will be displayed of the available operation types.

In some cases, a default value will be provided in square brackets. For example, `[389]` indicates that the default value for that field is port 389. You can press **Enter** to accept the default. To skip the connection and authentication prompts, provide this information using the command-line options of `dsconfig`.

### To Configure the Server Using dsconfig Interactive Mode

Steps

1. Launch the `dsconfig` tool in interactive command-line mode.

```
$ bin/dsconfig
```

2. Next, enter the LDAP connection parameters. Enter the Directory Server host name or IP address, or press **Enter** to accept the default.
3. Enter the number corresponding to the type of LDAP connection (1 for LDAP, 2 for SSL, 3 for StartTLS) that you are using on the Directory Server, or press **Enter** to accept the default (1).
4. Next, type the LDAP listener port number, or accept the default port. The default port is the port number of the server local to the tool.
5. Enter the user bind DN (default, `cn=Directory Manager`) and the bind DN password.
6. On the **Directory Server Configuration Console** main menu, type a number corresponding to the configuration that you want to change. Note that the number can change between releases or within

the same release, depending on the options selected (for example, in cases where more expert level objects and and properties are displayed).

In this example, select the number for Backend. Then, set the `db-cache-percent` to 40%. The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the `setup` utility is sufficient.

7. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.
8. Select the backend to work with. In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`. Press **Enter** to accept the default.
9. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
10. Enter the option to change the value, and then type the value for the `db-cache-percent` property. In this example, type `40` for "40 %".
11. Review the changes, and then type `f` to apply them.

Before you apply the change, the `dsconfig` interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building `dsconfig` script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent `dsconfig` non-interactive command, type `d`. For more information, see [Getting the Equivalent dsconfig Non-Interactive Mode Command](#).

12. In the **Backend management** menu, type `q` to quit the `dsconfig` tool.

## To View dsconfig Advanced Properties

About this task

For most configuration settings, some properties are more likely to be modified than others. The `dsconfig` interactive mode provides an option that hides or shows additional advanced properties that administrators might want to configure.

Steps

1. Repeat steps 1–9 in the previous section using `dsconfig` in Interactive Command-Line Mode.
2. From the **Local DB Backend properties** menu, type `a` to display the advanced properties, which toggles any hidden properties.

## Using dsconfig Interactive Mode: Viewing Object Menus

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The purpose of object levels is to simply present only those properties that an administrator will likely use. The Object type is a convenience feature designed to unclutter menu readability.

The following object menus are available:

- **Basic.** Only includes the components that are expected to be configured most frequently.
- **Standard.** Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.
- **Advanced.** Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be potentially harmful if configured incorrectly.
- **Expert.** Includes all components in the Basic, Standard, and Advanced menus plus other components that should almost never require configuration or that could seriously impact the functionality of the server if not properly configured.

## To Change the dsconfig Object Menu

### Steps

1. Repeat steps 1–6 in the section using `dsconfig` in To Install the Directory Server in Interactive Mode.
2. On the **PingDirectory Server configuration** main menu, type `o` (letter “o”) to change the object level. By default, Basic objects are displayed.
3. Enter a number corresponding to a object level of your choice: 1 for Basic, 2 for Standard, 3 for Advanced, 4 for Expert.
4. View the menu at the new object level. Additional configuration options for the Directory Server components are displayed.

### Using dsconfig Interactive: Viewing Administrative Alerts

The `dsconfig` tool and the Administrative Console provide a useful feature that displays notifications for certain operations that require further administrator action to complete the process. If you change a certain backend configuration property, the admin action will appear in two places during a `dsconfig` interactive session: when configuring the property and before you apply the change. For example, if you change the `db-directory` property on the `userRoot` backend (that is, specify the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files), you will see an admin action reminder during one of the steps (shown below).

The admin action alert will also appear as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type “f” to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: f
One or more configuration property changes require administrative action or
confirmation/notification.

Those properties include:

* db-directory: Modification requires that the Directory Server be stopped,
the database directory manually relocated, and then the Directory Server
restarted. While the Directory Server is stopped, the directory and files
pertaining to this backend in the old database directory must be manually
moved or copied to the new location.

Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

Currently, only a small set of properties display an admin action alert appear in `dsconfig` interactive mode and the Administrative Console. For more information on the properties, see the *PingDirectory Server Configuration Reference*.

## Using dsconfig in Non-Interactive Mode

The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line. To use administrative scripts to automate configuration changes, run the `dsconfig` command in non-interactive mode, which is convenient scripting applications. Note, however, that if you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

You can use the `dsconfig` tool to update a single configuration object using command-line arguments to provide all of the necessary information. The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of

arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the `dsconfig` tool as follows:

```
$ bin/dsconfig --no-prompt list-backends \
 --hostname server.example.com \
 --port 389 \
 --bindDN uid=admin,dc=example,dc=com \
 --bindPassword password
```

If your system uses SASL GSSAPI (Kerberos), you can invoke `dsconfig` as follows:

```
$ bin/dsconfig --no-prompt list-backends \
 --saslOption mech=GSSAPI \
 --saslOption authid=admin@example.com \
 --saslOption ticketcache=/tmp/krb5cc_1313 \
 --saslOption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you wish to invoke. To always display the advanced properties, use the `--advanced` command-line option.

**Note:** Global arguments can appear anywhere on the command line (including before the subcommand, and after or intermingled with subcommand-specific arguments). The subcommand-specific arguments can appear anywhere after the subcommand.

## To Configure the Server Using `dsconfig` Non-Interactive Mode

### Steps

- Use the `dsconfig` command in non-interactive mode to change the amount of memory used for caching database contents and to specify common parent DNs that should be compacted in the underlying database.

```
$ bin/dsconfig set-backend-prop \
 --backend-name userRoot \
 --set db-cache-percent:40 \
 --add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \
 --add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

## To View a List of `dsconfig` Properties

### Steps

- Use the `dsconfig` command with the `list-properties` option to view the list of all `dsconfig` properties. Remember to add the LDAP connection parameters.

```
$ bin/dsconfig list-properties
```

- Use the `dsconfig` command with the `list-properties` option and the `--complexity <menu level>` to view objects at and below the menu object level. You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

3. If the server is offline, you can run the command with the `--offline` option. You do not need to enter the LDAP connection parameters.

```
$ bin/dsconfig list-properties --offline --complexity advanced --includeDescription
```

You can also view the `<server-root>/docs/config-properties.txt` that contains the property information provided with the server.

## Getting the Equivalent dsconfig Non-Interactive Mode Command

While the `dsconfig` non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be quite time consuming.

To facilitate easy and quick configuration, you can use an option to display the equivalent non-interactive command using `dsconfig` interactive mode. The command displays the equivalent `dsconfig` command to recreate the configuration in a scripted configuration or to more quickly enter any pending changes on the command line for another server instance.

**Note:** There are two other ways to get the equivalent `dsconfig` command. One way is by looking at the `logs/config-audit.log`. It might be more convenient to set the Directory Server up the way you want and then get the `dsconfig` arguments from the log. Another way is by configuring an option using the Administrative Console. The console shows the equivalent `dsconfig` command prior to applying the change.

### To Get the Equivalent dsconfig Non-Interactive Mode Command

#### Steps

1. Using `dsconfig` in interactive mode, make changes to a configuration but do not apply the changes (that is, do not enter "f").
2. Enter `d` to view the equivalent non-interactive command.
3. View the equivalent command (seen below), and then press **Enter** to continue. For example, based on an example in the previous section, changes made to the `db-cache-percent` returns the following:

```
Command line to apply pending changes to this Local DB Backend:
dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host since it is presumed that the command would be used to connect to a different remote host.

## Using dsconfig Batch Mode

The PingDirectory Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command will fail and abort the batch process without applying any changes to the Directory Server. The `dsconfig` command supports a `--batch-continue-on-error` option which instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Server and use them in the batch file. The batch file can have blank lines for spacing and lines

starting with a pound sign (#) for comments. The batch file also supports a "\n" line continuation character for long commands that require multiple lines.

The Directory Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to PingDirectory Server machines.

## To Configure the Directory Server in dsconfig Batch Mode

### Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Server. The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with a pound sign (#) for comments. The batch file also supports a "\n" line continuation character for long commands that require multiple lines.

```
This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

Here we create the entry-count placement algorithm with the
default behavior of adding entries to the smallest backend
dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

Note that once the entry-count placement algorithm is created
and enabled, we can delete the round-robin algorithm.
Since an entry-balancing proxy must always have a placement
algorithm, we add a second algorithm and then delete the
original round-robin algorithm created during the setup
procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. Use `dsconfig` with the `--batch-file` option to read and execute the commands.

## About Recurring Tasks and Task Chains

For regular maintenance items that need to be done on the PingDirectory Server, you can create recurring tasks and task chains with the `dsconfig create-recurring-task` command. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations. Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

You create tasks and then add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry.
- The task-specific attributes to include in the task entry, if any.
- Whether to alert on task start, success, and/or failure.

- Any addresses to email on task start, success, and/or failure.
- Whether to cancel an instance of the task if it is dependent upon another task, and that task does not complete successfully.

After you create a task, add one or more tasks to and schedule them with a task chain using the `dsconfig create-recurring-task-chain` command.

A recurring task chain includes:

- An ordered list of the tasks to invoke.
- The months, days, times, and time zones in which each task can be scheduled to start.
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown.
- The behavior to exhibit if the server is offline when the start time occurs.

**Note:**

Changing the schedule for an existing recurring task chain only takes effect the next time that an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. That existing instance still runs at the originally scheduled time; when that run is complete, the server schedules the next iteration according to the then-current schedule logic.

Also, you cannot simply cancel the existing instance to get the next instance to run ten minutes earlier. When you cancel an iteration of a recurring task chain, the server automatically schedules the next instance for the earliest time that matches the scheduling criteria that is later than the one that was just canceled. It will never schedule a new instance for earlier than or the same time as one that you manually canceled.

### LDIF Export as a Recurring Task

For new installations, LDIF exports occur by default every day at 1:05 a.m. (in the JVM's default time zone, which is generally the time zone configured for the underlying system). At this time, the server will export the contents of each non-administrative backend to a file in the server root "ldif" directory. The LDIF exports are compressed and encrypted, if the global configuration is set to encrypt LDIF exports by default (which is enabled if encryption is configured during setup). The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release, but is not enabled by default. LDIF export can export multiple backends in the same recurring task. The `backend-id` property can include multiple backends, or an `exclude-backend-id` property can exclude one or more backends. These optional properties are mutually exclusive, so only one can be provided.

- If the `backend-id` property has one or more values, only the backends with those IDs will be exported.
- If the `exclude-backend-id` property has one or more values, all public backends (all backends containing user-supplied data) except those listed will be exported.
- If neither the `backend-id` property nor the `exclude-backend-id` property supply values, all public backends will be exported.

### Lockdown Mode as a Recurring Task

Recurring tasks can be created to place the server in lockdown mode and take the server out of lockdown mode. These tasks are useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server will report itself as unavailable, and will also reject requests from any user that doesn't have the `lockdown-mode` privilege. The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.

3. Desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter and leave lockdown mode tasks each have one optional property that can be used to supply a description for why that the server is being placed in this mode.

### File Retention Recurring Task

A recurring task can be configured to remove files in a specified directory that match a given pattern, excluding files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files will be removed before the most recent file.

If the file name pattern includes a "`{timestamp}`" element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the file's creation time if that is available, or the last modified time if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, lexicographic ordering is used to differentiate between them. Lexicographic ordering is applicable only for files with no `retain-file-age` property configured, or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the `retain-file-age` value, then those files are retained.

At least one of the `retain-file-count`, `retain-file-age`, or `retain-aggregate-file-size` properties must be specified.

### To Create a Recurring Task and Task Chain

About this task

Use `dsconfig` to create one or more tasks and then add them to a task chain for scheduling.

Steps

1. Create a task. The following creates a backup task.

```
$ bin/dsconfig create-recurring-task \
 --task-name backup-1 \
 --type backup \
 --set 'email-on-failure:admin2@company.com' \
 --set 'email-on-failure:admin@company.com' \
 --set compress:true \
 --set encrypt:true \
 --set "retain-previous-full-backup-age:4 w" \
 --set retain-previous-full-backup-count:10
```

2. Create a task chain to schedule and run recurring tasks.

```
$ bin/dsconfig create-recurring-task-chain \
 --chain-name "backup chain" \
 --set recurring-task:backup-1 \
 --set scheduled-date-selection-type:selected-days-of-the-month \
 --set scheduled-day-of-the-month:last-day-of-the-month \
 --set scheduled-time-of-day:02:00
```

## Exec Tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks. The server has a number of restrictions to safeguard the use of these commands and ensure that they cannot be used by unauthorized individuals. The set of commands that can be executed is also limited. One of these restrictions is that the absolute path to the command to execute must be listed in the `<server-root>/config/exec-command-whitelist.txt` file. Other safeguards and requirements include:

- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following configuration change enables this:

```
$ bin/dsconfig set-global-configuration-prop \
 --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the **exec-task** privilege. The server does not grant permission to run this task to any user by default, not even root users. The following configuration changes grant the **exec-task** privilege to a single root user, all root users, or a single non-root user:

```
$ bin/dsconfig set-root-dn-user-prop --user-name "{username}" \
 --add privilege:exec-task
```

```
$ bin/dsconfig set-root-dn-prop \
 --add default-root-privilege-name:exec-task
```

```
dn: {userdn}
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

The **schedule-exec-task** tool can be used to create an exec task from the command line. For example, the following command can be used to schedule an exec task to run the **verify-index** tool to check the integrity of the **cn** index in the backend that hosts "**dc=example,dc=com**", assuming that the server is installed in **/ds**:

```
$ bin/schedule-exec-task --hostname directory.example.com \
 --port 389 \
 --bindDN uid=admin,dc=example,dc=com \
 --promptForBindPassword \
 --waitForCompletion \
 --logCommandOutput \
 /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

## Topology Configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a master/slave architecture for mirroring shared data across the topology. All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group. Servers can be added to an existing topology at installation.

**Note:** To remove a server from the topology, it must be uninstalled with the **uninstall** tool.

### Topology Master Requirements and Selection

A topology master server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers. The master always sends a digest of its subtree contents on each update. If the node has a different digest than the master, it knows it's not synchronized. The servers will pull the entire subtree from the master if they detect that they are not synchronized. A server may detect it is not synchronized with the master under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its master, then it knows it's not synchronized.
- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The master of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a master, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the master. If a new server can be the master, it will communicate that to the other servers, if no other server has advertised that it should be the master. This ensures that all servers accept the same master at approximately the same time (within a few milliseconds of each other). If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master. (The master server itself is considered while determining this majority.)
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `mirrored-subtree-manager-forced-as-master-error` critical alarm will be raised.

### Topology Components

When a server is installed, it can be added to an existing topology, which will clone the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

#### Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, `force-as-master-formirrored-data`. This should be set to true on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a master because a majority of servers is not available. A server with this setting enabled will be assigned the role of master, if no suitable master can be determined.

The Config File Handler Backend defines three topology (`mirrored-subtree`) settings:

- `mirrored-subtree-peer-polling-interval` – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that may warrant a new master selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable master is found, the polling frequency is adjusted to 100 milliseconds until a new master is selected.
- `mirrored-subtree-entry-update-timeout` – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the master on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if master selection is in progress at the time the update operation was received.
- `mirrored-subtree-search-timeout` – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

### Topology settings

Topology meta-data is stored under the `cn=topology, cn=config` subtree and cluster data is stored under the `cn=cluster, cn=config` subtree. The only setting that can be changed is the cluster name.

### Monitor Data for the Topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology. Topology data includes the following:

- The server ID of the current master, if the master is not known.
- The instance name of the current master, or if a master is not set, a description stating why a master is not set.
- A flag indicating if this server thinks that it should be the master.
- A flag indicating if this server is the current master.
- A flag indicating if this server was forced as master.
- The total number of configured peers in the topology group.
- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its master, or another node in the topology if the master is unknown.
- The amount of time in milliseconds where multiple masters were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as master.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master.
- The number of operations processed by this server as master that were successful.
- The number of operations processed by this server as master that failed to validate.
- The number of operations processed by this server as master that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the master.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the master.

## Servers and Certificates

PingDirectory Server uses the following main types of certificates:

- *Listener certificates* are used to secure communication by way of TLS.
- *Inter-server certificates* are used to authenticate between server instances in a topology.

The following sections describe these certificate types in more detail.

### Listener Certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client, and the certificate at the head of the chain functions as a listener certificate. Because the client decides whether to trust the certificate chain, we recommend that the chain be signed by an issuer whom the client is likely to trust, or that the client can be easily configured to trust.

Although you can create self-signed certificates with long lifespans, a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, and some authorities use considerably shorter validity windows. For example, the nonprofit Let's Encrypt service, which obtains trusted certificates free of charge as long as you can prove that you control the relevant domains, issues certificates that are valid for up to three months only.

Short certificate lifespans might prove inconvenient for administrators who need to replace them, but they offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a relatively short validity window minimizes the timeframe during which a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, the inconvenience can be kept to a minimum.

Listener certificates are stored in keystores that are referenced by key manager providers, which in turn provide the logic and configuration needed to access the key stores. If a server component like a connection handler requires access to a certificate that it presents to a peer during the TLS-negotiation process, that component must reference the key manager provider that points to the keystore containing

the appropriate certificate. If the keystore contains multiple certificates, and if the component that references the keystore includes a property that specifies the certificate's nickname, the certificate with the alias is selected. Otherwise, the server lets the JVM select a certificate, and the one that it chooses might not be well-defined.

The server also provides *trust manager providers*, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified truststore file, but other options include the JVM-default truststore, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

**Note:** Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

## Replacing Listener Certificates

About this task

Certification authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you probably need to replace the certificates on a regular basis. This task includes the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

Although you can replace certificates manually, the `replace-certificate` tool helps to automate the process. The `replace-certificate` tool is particularly useful because it provides information about multiple listener certificates, at least during the transitional phase that occurs when you install them.

The `replace-certificate` tool offers the following modes of operation:

- Interactive mode – Walks you through the process of obtaining a new certificate and installing it in the server. In addition to the convenience this offers, interactive mode also displays the non-interactive commands that are required to achieve the same result.
- Non-interactive mode – Useful when scripting the process of replacing a certificate.

The `replace-listener-certificate` subcommand handles all of the work that is involved in replacing a listener certificate. Besides the arguments that are required to authenticate to PingDirectory Server, such as `--bindDN` and `--bindPasswordFile`, the `replace-listener-certificate` subcommand also takes arguments that provide the following information:

- Details about the keystore that contains the new certificate.
- Updates that must be made to the key and trust manager providers.
- Whether to signal the HTTP connection handler to reload its certificates after the update is complete.

The following arguments are available:

- `--source-key-store-file {path}` – Path to the JKS or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
- `--source-key-store-password {password}` – Cleartext password that is needed to access the contents of the source keystore.
- `--source-key-store-password-file {path}` – Path to the file that contains the password necessary to access the contents of the source keystore. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.
- `--source-certificate-alias {alias}` – Password that is required to access the appropriate private key in the source keystore. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the keystore password is used as the private key password.

- `--source-private-key-password-file {path}` – Path to the file that contains the password needed to access the appropriate private key in the source keystore. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the keystore password is used as the private key password.
- `--key-manager-provider {name}` – Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and it must be enabled. Defaults to JKS if a value is not specified.
- `--trust-manager-provider {name}` – Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and it must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.
- `--use-jvm-default-trust-manager-provider` – Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the `cacerts` truststore provided with the JVM, rather than updating an existing trust manager provider.
- `--target-certificate-alias {alias}` – Alias to use for the new certificate in the key manager provider's keystore, as well as for appropriate updates in the trust manager provider's truststore. Defaults to an alias of `server-cert` if a value is not specified.

**Note:** If the key manager provider's keystore, or the trust manager provider's truststore, already contains an entry with the given alias, the existing entry is renamed.

- `--reload-http-connection-handler-certificates` – Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.

LDAP connection handlers react to the change immediately, and start presenting the new certificate chain during subsequent TLS negotiations. However, HTTPS connection handlers continue using the former certificate until the connection handler is restarted, or until the connection handler is asked specifically to reload its certificates.

**Note:** This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

The following example uses Interactive mode to replace the listener certificate chain. The output includes the non-interactive commands that are needed to perform the corresponding operations:

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses forTLS
 communication
2 - Replace the inter-server certificate that the server uses to
 authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
 topology registry
4 - Purge any retired inter-server certificates for this server from the
 topology registry
q - Quit without doing anything

Enter your choice: 1
```

```
Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}
```

NOTE: 'JKS' is the only key manager provider that is suitable to be updated with a new listener certificate. Automatically selecting that provider

Which trust manager provider do you wish to update with information needed to trust the new listener certificate?

- 1 - JKS
- d - Use the JVM-default trust manager provider to trust any certificate signed by an authority in the JVM's default set of trusted issuers

Enter your choice [1]: **1**

How would you like to obtain the new listener certificate?

- 1 - Generate a new self-signed certificate
- 2 - Generate a request for a certificate to be signed by a certification authority
- 3 - Use a certificate in an existing key store
- q - Quit without doing anything

Enter your choice: **2**

Enter the subject DN that you would like to use for the new certificate. The subject DN typically includes some or all of the following components:

- \* CN -- The common name for the certificate. This is typically the fully-qualified name (not an IP address) that most clients will use to connect to the server (alternate names and IP addresses may be provided later). We strongly recommend including a CN attribute in the certificate subject
- \* OU -- Typically the name of the department or organizational unit that manages the server
- \* O -- Typically the name of the company or organization that manages the server
- \* L -- Typically the name of the city or locality in which the server is located
- \* ST -- Typically the full name (NOT an abbreviation) of the state or province in which the server is located
- \* ST -- Typically the two-character ISO 3166 country code for the country in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: **CN=ds1.example.com,O=Example Corp,C=US**

Enter the complete set of resolvable names (not IP addresses) that clients are expected to use to access the server. These names will be included in the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk as a wildcard in the leftmost component that will match any host name in that component. For example, '\*.example.com' indicates that the certificate may be used in any server whose fully-qualified name consists of exactly three components, and in which the last two components are

```
'example.com'
```

```
The current set of DNS names to include in the set of subject alternative names is:
```

```
* ds1.example.com
* ip6-localhost
* localhost
```

```
What would you like to do?
```

```
1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate
```

```
Enter your choice [1]: 2
```

```
Enter the new DNS name to include: ds.example.com
```

```
The current set of DNS names to include in the set of subject alternative names is:
```

```
* ds.example.com
* ds1.example.com
* ip6-localhost
* localhost
```

```
What would you like to do?
```

```
1 - Use the current set of DNS names
2 - Add another DNS name
3 - Remove a specific DNS name
4 - Clear the current set of DNS names
5 - Do not include any subject alternative DNS names in the certificate
```

```
Enter your choice [1]: 1
```

```
Enter the complete set of IPv4 and IPv6 addresses that clients are expected to use to access the server. These addresses will be included in the certificate's subject alternative name extension. Wildcards are not allowed
```

```
The current set of IP addresses to include in the set of subject alternative names is:
```

```
* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:feld:811d
```

```
What would you like to do?
```

```
1 - Use the current set of IP addresses
2 - Add another IP address
```

- 3 - Remove a specific IP address
- 4 - Clear the current set of IP addresses
- 5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: **1**

Generating a certificate signing request with the following command:

```
manage-certificates \
 generate-certificate-signing-request \
 --output-file /ds/tmp/replace-certificate-certificate-signing-request-6730986100632343057.pem \
 --output-format PEM \

How would you like to import the signed certificate into the key store?

- 1 - I expect to get the signed certificate back right away. Walk me through the process of importing it into the key store
- 2 - I will manually import the signed certificate

Enter your choice [1]: **1**

Enter the path to the file containing the signed certificate (and optionally any necessary issuer certificates): /ca/server-cert.pem

NOTICE: Certificate file '/ca/server-cert.pem' ends with certificate 'CN=dsl.example.com,O=Example Corp,C=US' that was signed by issuer 'CN=Example Intermediate CA,O=Example Corp,C=US', but that issuer certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Intermediate CA,O=Example Corp,C=US' certificate (and optionally its issuer chain): /ca/intermediate-ca-cert.pem

NOTICE: Certificate file '/ca/intermediate-ca-cert.pem' ends with certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' that was signed by issuer 'CN=Example Root CA,O=Example Corp,C=US', but that issuer certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Root CA,O=Example Corp,C=US' certificate (and optionally its issuer chain): /ca/root-ca-cert.pem

Would you like to request that the server reload any certificates associated with HTTP connection handlers configured with support for HTTPS so that they will start using the new certificate right away? Note that this may prevent clients from resuming TLS sessions created before the reload

- 1 - Yes. Reload the certificates associated with any HTTPS-enabled HTTP connection handlers
- 2 - No. Do not reload the certificates. HTTPS connection handlers will continue to use their current certificates until the server (or at least the connection handler) is restarted, or until the reload-http-connection-handler-certificates tool is run
- q - Quit without doing anything else

Enter your choice [1]: **1**

About to invoke the following command:

```

replace-certificate \
 replace-listener-certificate \
 --bindDN "cn=Directory Manager" \
 --bindPassword '*****REDACTED*****' \
 --key-manager-provider JKS \
 --trust-manager-provider JKS \

```

```

--source-key-store-file /ds/tmp/replace-certificate-temporary-key-
\
store-281484917294163222.jks \
--source-key-store-password-file /ds/config/ads-truststore.pin \
--source-certificate-alias generated-certificate \
--reload-http-connection-handler-certificates

```

Do you want to invoke this command?

- 1 - Yes, run this replace-certificate command
- 2 - No. Quit without doing anything else

Enter your choice [1]: **1**

Successfully replaced the listener certificate

As part of its processing steps, the **replace-certificate** tool updates the server instance listener configuration object to include the new listener certificate. Instead of replacing any certificates that may already reside within the configuration object, the **replace-certificate** tool merges them with the new certificate. To remove earlier certificates from the server instance listener configuration, use the **purge-retired-listener-certificates** subcommand, which does not take arguments other than the ones that are required to authenticate to the server.

The following code provides an example:

```

$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses for TLS
communication
2 - Replace the inter-server certificate that the server uses to
authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
topology registry
4 - Purge any retired inter-server certificates for this server from the
topology registry
q - Quit without doing anything

Enter your choice: 3

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

About to invoke the following command:

replace-certificate \
 purge-retired-listener-certificates \
 --bindDN "cn=Directory Manager" \
 --bindPassword '*****REDACTED*****'

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No. Quit without doing anything else

Enter your choice [1]: 1

```

```
NOTE: Purging one non-active listener certificate from entry
'cn=ldap-listener-mirrored-config,cn=Server Instance
Listeners,cn=dsl,cn=Server
Instances,cn=Topology,cn=config'
Successfully updated entry 'cn=ldap-listener-mirrored-config,cn=Server
Instance
Listeners,cn=dsl,cn=Server Instances,cn=Topology,cn=config'

Successfully purged one retired listener certificate
```

## Inter-Server Certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process. Because this certificate is not exposed to clients, a trusted issuer does not need to sign it. Instead, the topology registry, which represents a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can also be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates also include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

### Replacing the Inter-Server Certificate

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

During the installation process, the inter-server certificate is generated with a long lifespan, and therefore does not require replacement under normal circumstances. We discourage replacing the inter-server certificate unless you suspect that its private key is compromised.

To replace the inter-server certificate, use the **replace-certificate replace-inter-server-certificate** command, which performs the following steps:

As when replacing a listener certificate

- Acquires the new inter-server certificate from a provided JKS or PKCS #12 keystore.
- Makes the necessary updates to the appropriate server keystore. In the case of the inter-server certificate, the relevant keystore resides in the `config/ads-truststore` file.
- Updates the server instance configuration object to include the new inter-server certificate.

To avoid the need to replace the inter-server certificate on a regular basis, we recommend that you use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair
- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

The **replace-inter-server-certificate** subcommand takes a subset of the arguments that are used with the **replace-listener-certificate** subcommand, including the following arguments:

- `--source-key-store-file {path}--source-key-store-password {password}`
- `--source-key-store-password-file {path}`

- `--source-certificate-alias {alias}`
- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`

The following example replaces the inter-server certificate in interactive mode, and includes the non-interactive command that achieves the same result:

**\$ bin/replace-certificate**

This tool can be used to replace the listener certificate or the inter-server certificate for this Directory Server server instance

Which action would you like to perform?

- 1 - Replace a listener certificate that the server uses for TLS communication
- 2 - Replace the inter-server certificate that the server uses to authenticate to other instances in the topology
- 3 - Purge any retired listener certificates for this server from the topology registry
- 4 - Purge any retired inter-server certificates for this server from the topology registry
- q - Quit without doing anything

Enter your choice: **2**

**WARNING:** The inter-server certificate is used only for the purpose of authenticating this server instance to other servers in the topology, and to encrypt some legacy secrets. It is NOT used to encrypt communication (listener certificates are used for that purpose), and the trust mechanism that we use for authenticating inter-server certificates is stronger when using self-signed certificates than when using certificates signed by a publicly trusted authority

We strongly discourage replacing the inter-server certificate unless you believe that the key has been compromised. Any errors in the process of replacing the certificate could render the server unable to authenticate to other instances in the topology, and may interfere with replication or other forms of inter-server communication, and also the server's ability to perform certain types of encryption and digital signing

Are you sure you want to replace the inter-server certificate?

- 1 - No. Do not replace the inter-server certificate
- 2 - Yes. Proceed with replacing the inter-server certificate

Enter your choice [1]: **2**

Enter the DN of the account to use to authenticate to the server

[cn=Directory Manager]: cn=Directory Manager

Enter the password for that user: **{password}**

How would you like to obtain the new inter-server certificate?

- 1 - Generate a new self-signed certificate
- 2 - Generate a request for a certificate to be signed by a certification

- authority
- 3 - Use a certificate in an existing key store. Note that each server instance must have a unique inter-server certificate, and we do not recommend using the same certificate as both a listener certificate and an inter-server certificate
- q - Quit without doing anything

Enter your choice: **1**

Enter the subject DN that you would like to use for the new certificate. The subject DN typically includes some or all of the following components:

- \* CN -- The common name for the certificate. This is typically the fully-qualified name (not an IP address) that most clients will use to connect to the server (alternate names and IP addresses may be provided later). We strongly recommend including a CN attribute in the certificate subject
- \* OU -- Typically the name of the department or organizational unit that manages the server
- \* O -- Typically the name of the company or organization that manages the server
- \* L -- Typically the name of the city or locality in which the server is located
- \* ST -- Typically the full name (NOT an abbreviation) of the state or province in which the server is located
- \* ST -- Typically the two-character ISO 3166 country code for the country in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: **CN=ds1,O=Example Corp,C=US**

Enter the complete set of resolvable names (not IP addresses) that clients are expected to use to access the server. These names will be included in the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk as a wildcard in the leftmost component that will match any host name in that component. For example, '\*.example.com' indicates that the certificate may be used in any server whose fully-qualified name consists of exactly three components, and in which the last two components are 'example.com'

The current set of DNS names to include in the set of subject alternative names is:

- \* ds1.example.com
- \* ip6-localhost
- \* localhost

What would you like to do?

- 1 - Use the current set of DNS names
- 2 - Add another DNS name
- 3 - Remove a specific DNS name
- 4 - Clear the current set of DNS names
- 5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: **1**

Enter the complete set of IPv4 and IPv6 addresses that clients are expected to use to access the server. These addresses will be included in the certificate's subject alternative name extension. Wildcards are not allowed

The current set of IP addresses to include in the set of subject alternative names is:

```
* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:feld:811d
```

What would you like to do?

- 1 - Use the current set of IP addresses
- 2 - Add another IP address
- 3 - Remove a specific IP address
- 4 - Clear the current set of IP addresses
- 5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: **1**

Generating a self-signed certificate with the following command:

```
manage-certificates \
generate-self-signed-certificate \
--keystore /ds/tmp/replace-certificate-temporary-key-store- \
12068302381295037387.jks \
--keystore-password-file '*****REDACTED*****' \
--keystore-type JKS \
--alias generated-certificate \
--subject-dn "CN=ds1,O=Example Corp,C=US" \
--validity-start-time 20191111120632 \
--days-valid 7300 \
--key-algorithm RSA \
--key-size-bits 2048 \
--signature-algorithm SHA256withRSA \
--key-usage digitalSignature \
--key-usage keyEncipherment \
--extended-key-usage server-auth \
--extended-key-usage client-auth \
--subject-alternative-name-dns ds1.example.com \
--subject-alternative-name-dns ip6-localhost \
--subject-alternative-name-dns localhost \
--subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
--subject-alternative-name-ip-address 10.5.1.133 \
--subject-alternative-name-ip-address 10.5.3.99 \
--subject-alternative-name-ip-address 127.0.0.1 \
--subject-alternative-name-ip-address 127.0.1.1 \
--subject-alternative-name-ip-address 172.30.12.185 \
--subject-alternative-name-ip-address fe80:0:0:0:3957:af69:bd92:6c73 \
--subject-alternative-name-ip-address fe80:0:0:0:ace8:231f:e348:db8d \
```

```
--subject-alternative-name-ip-address fe80:0:0:0:fc94:6eff:fe1d:811d
```

Successfully generated the self-signed certificate

About to invoke the following command:

```
replace-certificate \
 replace-inter-server-certificate \
 --bindDN "cn=Directory Manager" \
 --bindPassword '*****REDACTED*****' \
 --source-key-store-file /ds/tmp/replace-certificate-temporary-key-
\
 store-12068302381295037387.jks \
 --source-key-store-password-file /ds/config/ads-truststore.pin \
 --source-certificate-alias generated-certificate
```

Do you want to invoke this command?

- 1 - Yes, run this replace-certificate command
- 2 - No. Quit without doing anything else

Enter your choice [1]: **1**

Successfully replaced the inter-server certificate

The new inter-server certificate is merged with the existing values in the server instance configuration entry. To delete earlier values that are no longer needed, use the **purge-retired-inter-server-certificates** subcommand. The following code provides an example:

```
$ bin/replace-certificate
```

This tool can be used to replace the listener certificate or the inter-server certificate for this Directory Server server instance

Which action would you like to perform?

- 1 - Replace a listener certificate that the server uses for TLS communication
- 2 - Replace the inter-server certificate that the server uses to authenticate to other instances in the topology
- 3 - Purge any retired listener certificates for this server from the topology registry
- 4 - Purge any retired inter-server certificates for this server from the topology registry
- q - Quit without doing anything

Enter your choice: **4**

Enter the DN of the account to use to authenticate to the server

[cn=Directory Manager]: cn=Directory Manager

Enter the password for that user: **{password}**

About to invoke the following command:

```
replace-certificate \
 purge-retired-inter-server-certificates \
 --bindDN "cn=Directory Manager" \
 --bindPassword '*****REDACTED*****'
```

```

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No. Quit without doing anything else

Enter your choice [1]: 1

Initializing the server's encryption framework...
Successfully purged one retired inter-server certificate from the topology
registry

```

## X.509 Certificates

PingDirectory Server supports X.509 certificates, the type that you are most likely to encounter. [RFC 5280](#) describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

- X.509 encoding version – Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or future version of the specification.
- Serial number of the certificate – Integer value that uniquely identifies a certificate as issued by a certification authority. Although serial numbers were frequently generated in sequential order in the past, they are now required to be unpredictable with at least 20 bits of entropy.
- Subject DN – Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see XREF to Certificate subject DNs.
- Issuer DN – Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.
- Validity window – Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:
  - `notBefore` – Specifies the earliest time at which the certificate is considered valid.
  - `notAfter` – Specifies the latest time at which the certificate is considered valid.
- Public key – Public portion of a pair of cryptographically linked keys. For more information, see XREF to Certificate key pairs.
- Signature – Type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. As its name implies, a *self-signed certificate* is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

- Subject unique ID – Uniquely identifies the certificate. Because this component has been deprecated in favor of the subject key identifier extension, it is generally omitted from X.509v3 certificates.
- Issuer unique ID – Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.
- Set of extensions – Provides additional context for the certificate and the manner in which it is used. For more information, see XREF to Certificate extensions.

## Certificate Subject DNs

A certificate's subject distinguished name (DN) provides information about the manner in which the certificate is to be used. Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. Unlike an LDAP DN, however, the attribute names in a certificate subject DN are typically written all in uppercase characters. (Attribute names in an LDAP DN are typically written in lowercase or CamelCase characters.)

A certificate's subject DN is also referred to as its *subject*. The following attributes commonly appear in a certificate subject:

- **CN** – Common name. For a listener certificate, the **CN** attribute typically identifies the host name that clients use to access the certificate, although the subject alternative name extension provides a more highly recommended mechanism for accomplishing the same task. Most certificate subject DN's include at least the **CN** attribute.
- **E** – Email address.
- **OU** – Name of the organizational unit, such as the relevant department.
- **O** – Name of the organization or company.
- **L** – Name of the locality, such as the appropriate city.
- **ST** – Full name of the state or province.
- **C** – ISO 3166 country code.

A certificate subject includes at least one attribute-value pair, and the **CN** attribute is typically present. Other attributes can be omitted, although the **O** and **C** attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

### Certificate Key Pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key. Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult. (In cryptographic terms, the process is computationally infeasible).

When generating a key pair, one key is designated as the *public key*, and the other key is designated the *private key*. The public key can be made widely available, but the private key must be kept secret and not shared with anyone. As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- **Encryption** – If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Because you alone possess the private key, only you can decrypt the message.

Encryption is also referred to as *confidentiality*.

- **Digital signatures** – If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

#### **Note:**

When generating a digital signature, the entire message is generally not encrypted. Instead, only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.

This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that, not only did the message come from you, but it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- **RSA** – Based on the multiplication of large prime numbers.
- **EC** – Based on computations that involve special types of elliptical curves.

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, we recommend that you use an RSA certificate and choose a key size of at least 2,048 bits.

If all your clients support EC certificates, we recommend that you use an EC certificate with a key size of at least 256 bits.

## Certificate Extensions

Extensions provide additional context for a certificate. The following examples represent some of the more common extension types:

- Subject key identifier – Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.
- Authority key identifier – Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.
- Subject alternative name – Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

 **Note:** Clients must take this information into account when deciding whether to trust a server's certificate.

The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

- Key usage – Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:
  - `digitalSignature` – Indicates that the certificate can be used for digitally signing data, excluding certificates and CRLs.
  - `nonRepudiation` – Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.
  - `keyEncipherment` – Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.
  - `dataEncipherment` – Indicates that the certificate can be used for encrypting data directly.
  - `keyAgreement` – Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.
  - `keyCertSign` – Indicates that the certificate can act as a certification authority and be used for signing other certificates.
  - `cRLSign` – Indicates that the certificate can be used to sign certificate revocation lists (CRLs).
  - `encipherOnly` – When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.
  - `decipherOnly` – When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.
- Extended key usage – Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:
  - `serverAuth` – Indicates that the server can present the certificate to the client during TLS negotiation.
  - `clientAuth` – Indicates that the client can present the certificate to the server during TLS negotiation.
  - `codeSigning` – Indicates that the certificate can be used to sign source and compiled code.
  - `emailProtection` – Indicates that the certificate can be used to sign or encrypt email messages.
  - `timeStamping` – Indicates that the certificate can be used to assert the time that an event occurred.
  - `ocspSigning` – Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.
- Basic constraints – Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can appear beneath it in a certificate chain.

## Certificate Chains

A *certificate chain* is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate. During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certification authority certificate, such as a root CA, the chain contains two certificates: the server certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and finally the root CA.

Intermediate certification authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

**Note:** If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising even one of the certificates. A compromised certificate must be revoked, along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

**Note:** The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not necessarily need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates, and can leave it off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. Upon receiving such an incomplete chain, the client looks in its default trust store to determine whether it contains the issuer certificate, which it can identify by using properties like the issuer DN or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the *end-entity certificate*. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is also referred to as the *server certificate*. If the certificate appears at the head of a chain that a client presents, it is also referred to as a *client certificate*. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

## Representing Certificates, Private Keys, and Certificate Signing Requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called *PEM* can be used. PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in [RFC 5958](#) describes the encoding for private keys. This approach also uses a DER encoding with a PEM variant that uses `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----` rather than `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----`. RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in [RFC 2986](#) describes the certificate signing request (CSR) format. This format also uses a DER encoding with a PEM variant that uses a header of -----BEGIN CERTIFICATE REQUEST----- and a footer of -----END CERTIFICATE REQUEST-----.

**Note:** Some implementations use the alternate, nonstandard forms -----BEGIN NEW CERTIFICATE REQUEST----- and -----END NEW CERTIFICATE REQUEST-----.

## Certificate Trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain, and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that, in reality, it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the trickery, and the malicious application might be capable of stealing data or altering the communication. Consequently, we recommend that you avoid "trust all" or "blind trust" options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps:

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

This step is generally performed by ensuring that the root CA certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

The chain is not trusted under the following conditions:

- When the `notBefore` value of any certificate in the chain is later than the current time.
- When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate (at the head of the chain) is suitable for the server with which the client thinks it is communicating.

The client must verify that the address used to connect to the server matches one of the following values:

- The CN attribute of the certificate's subject.
- One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

## Keystores and Truststores

A *keystore* is a type of database that holds certificates. The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format.
- File that uses the standard PKCS #12 format.
- Collection of files that holds certificates and private keys, typically in PEM or DER format.
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11.

PingDirectory Server supports file-based keystores by using the JKS and PKCS #12 formats, and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

- *Private key entries* contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.
- *Trusted certificate entries* contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.
- *Secret key entries* contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, which is sometimes called a *PIN*, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

**Note:** A *truststore* is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore (such as a private corporate certification authority), a separate truststore is required.

## Transport Layer Security

The phrase *transport layer security* (TLS) describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other. TLS is the successor to *secure sockets layer* (SSL), and the two terms are often used interchangeably, even though such usage might not technically be correct.

**i Note:** *SSL* remains the more widely recognized term. The abbreviation *TLS* occasionally generates confusion with the StartTLS extended operation, particularly in LDAP. For more information, see XREF to StartTLS.

TLS provides security in the form of the following main components:

- *Certificate trust* is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see XREF to earlier section about Certificate Trust.
- *Cipher selection* involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:
  - Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
  - Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called *asymmetric encryption* because different keys are used to encrypt and decrypt data.
  - If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than rely solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key that they will use after completing the negotiation process.

### TLS Handshakes

The process of negotiating the TLS is referred to as the *handshake*. Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLSv1.2 handshake:

1. The client sends a `hello` message that provides the server with the following information:
  - Highest supported version of the TLS protocol.
  - The cipher suites that the client uses.
  - Set of extensions with additional information, like the address that the client uses to communicate with the server, the signature algorithms and elliptic curves that the client supports, and whether the client supports secure renegotiation.
2. The server returns a `server hello` message that provides the client with the following information:
  - TLS protocol version that the server uses.
  - The cipher suite that the server selects.

The server can also provide its own extensions to the client.
3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.

7. The client can optionally send a `certificate` message to the server with its own certificate chain.

**Note:**

The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain.

The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server.

The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.

9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS version 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. (TLS version 1.2 requires two round-trips.) To accomplish this task, TLS version 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. As a result, the server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

### Key Agreement

*Key agreement* processing provides a critical component of TLS negotiation. It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

- RSA key exchange – The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.
- Diffie-Hellman (DH) key exchange – The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, we recommend that you use ECHDE over DHE, and either of those options over RSA. The Diffie-Hellman algorithms provide a substantial benefit over RSA in the form of forward secrecy.

Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. However, the use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

### Key Agreement

*Key agreement* processing provides a critical component of TLS negotiation. It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

- RSA key exchange – The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.
- Diffie-Hellman (DH) key exchange – The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, we recommend that you use ECHDE over DHE, and either of those options over RSA. The Diffie-Hellman algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. However, the use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

### LDAP StartTLS Extended Operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS). The client then begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, however, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the **StartTLS** extended operation.

The **StartTLS** extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use *opportunistic encryption*, in which the client performs the following steps:
  - Queries the root DSE to determine whether the server supports StartTLS.
  - Secures the connection, if possible.

Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To make certain that a communication is always secure, we recommend using LDAPS instead of establishing an insecure connection that you secure later with the **StartTLS** extended operation. If you enable support for unencrypted LDAP communication, as **StartTLS** requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

**Note:** Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, PingDirectory Server does not support this strategy.

### About the `manage-certificates` Tool

PingDirectory Server offers a `manage-certificates` tool that enables interaction with JKS and PKCS #12 key stores. Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

### Available Subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

- `list-certificates` – Lists the certificates in a keystore.
- `import-certificate` – Imports a certificate into a trusted certificate entry, or imports a certificate chain and private key into a private key entry.
- `export-certificate` – Exports a certificate from a keystore.
- `export-private-key` – Exports a private key from a keystore.
- `generate-self-signed-certificate` – Generates a self-signed certificate.
- `generate-certificate-signing-request` – Generates a certificate-signing request that can be provided to a certification authority.
- `sign-certificate-signing-request` – Signs a certificate-signing request with a specified issuer certificate.
- `check-certificate-usability` – Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
- `trust-server-certificate` – Initiates the TLS-negotiation process with a specified server to obtain its certificate chain, so that a truststore can be updated with the necessary information to trust the chain.
- `display-certificate-file` – Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
- `display-certificate-signing-request-file` – Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
- `change-certificate-alias` – Changes the alias for an entry in a keystore.
- `change-keystore-password` – Changes the password for a keystore.
- `change-private-key-password` – Changes the password that protects the private key for a specified entry in a keystore.

### Common Arguments

Most of the `manage-certificates` subcommands require access to a JKS or PKCS #12 keystore. In such instances, use the `--keystore` argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the `--keystore-type` argument, followed by a value of JKS or PKCS12. If you do not specify the keystore type, a default value of JKS is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- `--keystore-password`, followed by the clear-text password for the keystore.

- `--keystore-password-file`, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- `--prompt-for-keystore-password`. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- `--private-key-password`, followed by the plaintext password.
- `--private-key-password-file`, followed by the path to a file that contains the clear-text or encrypted password.
- `--prompt-for-private-key-password`, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the `--alias` argument, followed by the name of the alias for that entry.

### Listing the Certificates in a Keystore

About this task

To list the certificates in a keystore, use the `list-certificates` subcommand. This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

- `--alias {alias}` – Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
- `--display-pem-certificate` – Includes a PEM-encoded representation of each certificate as part of the output.
- `--verbose` – Includes details about each certificate.

The following command demonstrates the basic listing of a keystore that contains a single certificate chain:

```
$ bin/manage-certificates list-certificates \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin

Alias: server-cert (Certificate 1 of 2 in a chain)
Subject DN: CN=ds1.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:09 AM CST
 (8 minutes, 15 seconds ago)
Validity End Time: Sunday, November 8, 2020 at 11:26:09 AM CST
 (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint: 42:f8:85:97:bf:88:bc:74:4b:5b:ce:0c:54:43:9b:44:6b:
 81:23:a3

## Generating Self-Signed Certificates

### About this task

Because a *self-signed certificate* claims itself as its own issuer, the process of creating one is straightforward. Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, we do not recommend using them as listener certificates in production environments.

The `manage-certificates` tool offers a `generate-self-signed-certificate` subcommand that can be used to create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available:

- `--subject-dn {subject}` – Subject DN for the certificate to create. This value is required.
- `--days-valid {number}` – Number of days that the certificate remains valid. Defaults to 365 if no value is specified.
- `--validity-start-time {timestamp}` – Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form `YYYYMMDDhhmmss`, where a value of `20190102030405` indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
- `--key-algorithm {name}` – Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically RSA or EC. Defaults to RSA if no value is specified.

**Note:** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.

- `--key-size-bits {number}` – Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified.

Typical key sizes are as follows:

- RSA key – 2048 or 4096 bits. If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used.
- Elliptic curve key – 256 or 384 bits.
- `--signature-algorithm {name}` – Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than RSA, then `--signature-algorithm {name}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified.

Typical signature algorithms include `SHA256withRSA` for certificates with RSA keys, and `SHA256withECDSA` for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of `SHA256withRSA` is used.

- `--replace-existing-certificate` – Uses the new certificate to replace an existing certificate in the keystore (within the same alias), and reuses the key for that certificate.
- `--inherit-extensions` – Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
- `--subject-alternative-name-dns {name}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (\*) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.
- `--subject-alternative-name-ip-address {address}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject

alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.

- `--subject-alternative-name-email-address {address}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
- `--subject-alternative-name-uri {uri}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
- `--subject-alternative-name-oid {oid}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.
- `--basic-constraints-is-ca {value}` – Indicates that the certificate is expected to have a basic constraints extension, with a specified value of true or false, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates.
  - For root and intermediate CA certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of true.
  - For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of false.
  - For a self-signed certificate, we recommend specifying the `--basic-constraints-is-ca {value}` argument with a value of false to indicate that the certificate is not considered a CA certificate.
- `--basic-constraints-maximum-path-length {number}` – Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of true.

A path length constraint value of 0 indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of 1 indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than 1 indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.

- `--key-usage {value}` – Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed:
  - digital-signature
  - non-repudiation
  - key-encipherment
  - data-encipherment
  - key-agreement
  - key-cert-sign
  - crl-sign
  - encipher-only
  - decipher-only

To include multiple key usages, specify the `--key-usage {value}` argument multiple times.

- `--extended-key-usage {value}`
  - `server-auth`
  - `client-auth`
  - `code-signing`
  - `email-protection`
  - `time-stamping`
  - `ocsp-signing`

To include multiple extended key usages, specify the `--extended-key-usage {value}` argument multiple times.

For example, the following command can be used to generate a self-signed server certificate:

```
bin/manage-certificates generate-self-signed-certificate \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin \
 --keystore-type JKS \
 --alias server-cert \
 --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
 --key-algorithm EC \
 --key-length-bits 256 \
 --signature-algorithm SHA256withECDSA \
 --subject-alternative-name-dns ds.example.com \
 --subject-alternative-name-dns ds1.example.com \
 --subject-alternative-name-dns localhost \
 --subject-alternative-name-ip-address 1.2.3.4 \
 --subject-alternative-name-ip-address 127.0.0.1 \
 --subject-alternative-name-ip-address 0:0:0:0:0:0:1 \
 --key-usage digital-signature \
 --key-usage key-encipherment \
 --key-usage key-agreement \
 --extended-key-usage server-auth \
 --extended-key-usage client-auth
```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=ds.example.com,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST
 (0 seconds ago)
Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST
 (364 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)

```

## Generating Certificate Signing Requests

About this task

A *certificate signing request* (CSR) contains all of the information that a certification authority requires to issue a certificate. [RFC 2986](#) defines the request format, which is also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject DN for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a keystore with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. However, the following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

- `--output-file {path}` – Path to a file to which the certificate signing request is written. If this value is not provided, the request written only to the terminal in PEM form.
- `--output-format {value}` – Format to use when writing the certificate signing request. This value can be PEM or DER, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to PEM if the `--output-format {value}` argument is not provided.
- `--use-existing-key-pair` – Indicates that the certificate signing request uses a key pair that already exists in the keystore with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the keystore.

The following example command creates a certificate signing request:

```
bin/manage-certificates generate-certificate-signing-request \
 --output-file ds1-cert.csr \
 --output-format PEM \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin \
 --keystore-type JKS \
 --alias server-cert \
 --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
 --key-algorithm EC \
 --key-length-bits 256 \
 --signature-algorithm SHA256withECDSA \
 --subject-alternative-name-dns ds.example.com \
 --subject-alternative-name-dns ds1.example.com \
 --subject-alternative-name-dns localhost \
 --subject-alternative-name-ip-address 1.2.3.4 \
```

```

--subject-alternative-name-ip-address 127.0.0.1 \
--subject-alternative-name-ip-address 0:0:0:0:0:0:1 \
--key-usage digital-signature \
--key-usage key-encipherment \
--key-usage key-agreement \
--extended-key-usage server-auth \
--extended-key-usage client-auth

```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file '/ds/build/package/PingDirectory/ds1-cert.csr'.

If the contents of the resulting certificate signing request file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the keystore. For more information, see XREF.

To print the contents of a certificate signing request file, use the **display-certificate-signing-request-file** subcommand, which supports the following arguments:

- **--certificate-signing-request-file {path}** – Path to the file that contains the certificate signing request to display.
- **--verbose** – Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command:

```

$ bin/manage-certificates display-certificate-signing-request-file \
 --certificate-signing-request-file ds1-cert.csr

PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)

```

The following example demonstrates the verbose output:

```

$ bin/manage-certificates display-certificate-signing-request-file \
 --certificate-signing-request-file ds1-cert.csr \
 --verbose

## Importing Signed and Trusted Certificates

About this task

To import certificates into a keystore, use the **manage-certificates import-certificate** command, which is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry, and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a truststore. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the keystore and the alias into which the certificate or certificate chain is imported, the **manage-certificates import-certificate** command accepts the following arguments:

- **--certificate-file {path}** – Path to the file that contains the certificate to import. The certificate can be in PEM or DER format, and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the **--certificate-file {path}** argument multiple times when you import a certificate chain.
- **--private-key-file {path}** – Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.
- **--no-prompt** – Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the keystore that generates the certificate signing request:

```

$ bin/manage-certificates import-certificate \
 --keystore config/keystore \

```

```
--keystore-password-file config/keystore.pin \
--alias server-cert \
--certificate-file ds1-cert.pem \
--certificate-file ca-cert.pem
```

The following certificate chain will be imported into the keystore into alias 'server-cert', preserving the existing private key associated with that alias:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
 (4 minutes, 16 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
 (364 days, 23 hours, 55 minutes, 43 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb

```

```
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
 (13 minutes, 32 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
 (7299 days, 23 hours, 46 minutes, 27 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP384r1)
SHA-1 Fingerprint:
 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
 77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:
 12:7b:10:1f:26:05:b7:b9:0d:02:e0:38:3e
```

Do you want to import this certificate chain into the keystore? **yes**

Successfully imported the certificate chain.

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

- `--certificate-file {path}` – Path to the file that contains the certificate to view.
- `--verbose` – Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

## Exporting Certificates

About this task

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a keystore to a file in PEM or DER format. The `export-certificate` subcommand supports the normal arguments about the keystore and certificate alias, in addition to the following arguments:

- `--output-file {path}` – Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.
- `--output-format {format}` – Format in which exported certificates are written. The value can be PEM or DER, but the DER format can be used only if the output is written to a file. Defaults to PEM if no value is specified.
- `--export-certificate-chain` – Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported .
- `--separate-file-per-certificate` – Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain:

```
$ bin/manage-certificates export-certificate \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin \
 --alias server-cert \
 --output-file server-cert.pem \
 --output-format PEM \
 --export-certificate-chain \
 --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST
 (3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
 (364 days, 20 hours, 33 minutes, 36 seconds from
now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
SHA-1 Fingerprint:
 02:51:25:43:3e:68:f5:71:36:e3:5d:df:74:de:f6:a1:5a:db:0f:eb
SHA-256 Fingerprint:
 1d:b5:eb:3c:f5:ff:bf:79:a2:a5:86:b8:e4:33:76:4d:d7:50:dc:a4:34:95:37:be:89:45:
 86:1f:5d:79:c3:93

Successfully exported the following certificate to '/ds/server-cert.pem.2':
Subject DN: CN=Example Root CA,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:00:07 PM CST
 (3 hours, 35 minutes, 39 seconds ago)
Validity End Time: Saturday, November 5, 2039 at 10:00:07 PM CDT
 (7299 days, 20 hours, 24 minutes, 20 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP384r1)
SHA-1 Fingerprint:
 0e:5c:21:c9:a5:36:0a:24:eb:aa:55:b6:a5:94:0e:e0:56:03:22:e6
SHA-256 Fingerprint:
 77:cf:66:d7:3c:8a:fd:67:2d:b7:36:fd:60:1d:ca:eb:1b:03:b1:12:7b:10:1f:26:
 05:b7:b9:0d:02:e0:38:3e
```

The `export-certificate` subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the `export-private-key` subcommand, which supports the following arguments, in addition to the usual keystore and alias arguments:

- `--output-file {path}` – Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.
- `--output-format {format}` – Format in which the exported private key is written. The value can be PEM or DER, but the DER format is used only if the output is written to a file. Defaults to PEM if no value is specified.

The following code provides an example:

```
$ bin/manage-certificates export-private-key \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin \
 --alias server-cert \
 --output-file server-cert-key.pem \
 --output-format PEM
```

```
Successfully exported the private key.
```

## Using manage-certificates as a Simple Certification Authority

### About this task

If your PingDirectory Server instances need to support an arbitrary or unknown set of clients, we recommend that you configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service. If you control every client that will access the servers, however, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can also use the `manage-certificates` tool to create a CA certificate that you can use to sign certificate-signing requests.

### Steps

#### 1. Create a certification authority certificate.

A *certification authority certificate* is a self-signed certificate that possesses the following extensions:

- A *key usage extension* that includes at least the `keyCertSign` usage.
- A *basic constraints extension* that identifies the certificate as a CA certificate.

If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

The following example creates a new root CA certificate:

```
$ bin/manage-certificates generate-self-signed-certificate \
 --keystore /ca/root-ca-keystore \
 --keystore-password-file /ca/root-ca-keystore.pin \
 --keystore-type JKS \
 --alias root-ca-cert \
 --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
 --days-valid 7300 \
 --key-algorithm RSA \
 --key-size-bits 4096 \
 --signature-algorithm SHA256withRSA \
 --basic-constraints-is-ca true \
 --basic-constraints-maximum-path-length 1 \
 --key-usage key-cert-sign \
```

**--key-usage crl-sign**

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

Subject DN: CN=Example Root CA,O=Example Corp,C=US

Issuer DN: CN=Example Root CA,O=Example Corp,C=US

Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0 seconds ago)

Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST

(7299 days, 23 hours, 59 minutes, 59 seconds from now)

Validity State: The certificate is currently within the validity window.

Signature Algorithm: SHA-256 with RSA

Public Key Algorithm: RSA (4096-bit)

SHA-1 Fingerprint:

bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64

SHA-256 Fingerprint:

d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:  
61:e2:aa:40:08:3a:ff

## 2. Export the public portion of the root CA certificate for future reference.

When you import a signed certificates, you can import the public portion of the root CA certificate as a standalone certificate into truststores, as well as into part of a certificate chain.

## 3. To create an intermediate CA certificate, create a new certificate signing request for it.

The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, however, its basic constraints extension must have a path length constraint of 0, rather than 11, to indicate that it is used only to sign end-entity certificates, and that it cannot create subordinate CA certificates by itself.

The following example command creates a certificate signing request:

```
$ bin/manage-certificates generate-certificate-signing-request \
 --keystore /ca/intermediate-ca-keystore \
 --keystore-password-file /ca/intermediate-ca-keystore.pin \
 --keystore-type JKS \
 --alias intermediate-ca-cert \
 --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
 --key-algorithm RSA \
 --key-size-bits 4096 \
 --signature-algorithm SHA256withRSA \
 --basic-constraints-is-ca true \
 --basic-constraints-maximum-path-length 0 \
 --key-usage key-cert-sign \
 --key-usage crl-sign \
 --output-file /ca/intermediate-ca-cert.csr \
 --output-format PEM
```

Successfully created a new JKS keystore.

Successfully generated the key pair to use for the certificate signing request.

Successfully wrote the certificate signing request to file  
'/ca/intermediate-ca-cert.csr'.

#### 4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate.

To perform this step, use the `sign-certificate-signing-request` subcommand, which takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

- The keystore that contains the certificate uses the provided keystore arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
- To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
- To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
- To specify the format, PEM or DER, in which the certificate is written to the output file, provide an `--output-format` argument.
- To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
- To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

**Note:** Because the requester generated the key, you cannot specify the key algorithm or the key length.

- To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

The following example command signs the certificate signing request for an intermediate CA certificate:

```
$ bin/manage-certificates sign-certificate-signing-request \
 --keystore /ca/root-ca-keystore \
 --keystore-password-file /ca/root-ca-keystore.pin \
 --signing-certificate-alias root-ca-cert \
 --days-valid 7300 \
 --include-requested-extensions \
 --request-input-file /ca/intermediate-ca-cert.csr \
 --certificate-output-file /ca/intermediate-ca-cert.pem \
 --output-format PEM
```

Read the following certificate signing request:

```
PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
```

Do you really want to sign this request? yes

Successfully wrote the signed certificate to file  
'/ca/intermediate-ca-cert.pem'.

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

**Note:** Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

## Enabling TLS Support During Setup

### About this task

To enable TLS support in the server, we recommend that you complete one of the following tasks during the setup procedure:

- Provide a keystore that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When you use the **setup** tool in Interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example:

```
Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS? After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

Do you want to enable StartTLS? (yes / no) [yes]: yes

Certificate server options:

 1) Generate self-signed certificate (recommended for testing purposes
 only)
 2) Use an existing certificate located on a Java Keystore (JKS)
 3) Use an existing certificate located on a PKCS12 keystore
 4) Use an existing certificate on a PKCS11 token

Enter option [1]: 2

Java Keystore (JKS) path: /ca/ds1-keystore
Keystore PIN: {password}

Truststore options:

 1) Generate a default JKS truststore
 2) Use an existing JKS truststore
 3) Use an existing PKCS12 truststore

Enter option [1]: 2

JKS truststore path: /ca/truststore
Truststore password (can be blank): {password}
```

When using **setup** in non-interactive mode, use the following arguments to configure TLS support:

- **--ldapsPort {port}** – Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
- **--httpsPort {port}** – Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.

- `--enableStartTLS` – LDAP connection handler enables support for the StartTLS extended operation.
- `--generateSelfSignedCertificate` – `setup` generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- `--useJavaKeyStore {path}` – Server uses the specified JKS keystore to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- `--usePKCS12KeyStore {path}` – Server uses the specified PKCS #12 keystore to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- `--usePKCS11KeyStore` – Server uses a PKCS #11 keystore, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The JVM must already be configured to access the appropriate keystore through PKCS #11.
- `--keyStorePassword {password}` – Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 keystore. The `setup` tool assumes that the private key password matches the keystore password.
- `--keyStorePasswordFile {path}` – Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 keystore.
- `--certNickname {alias}` – Alias of the private key entry in the specified keystore that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the keystore contains multiple certificates.
- `--useJavaTrustStore {path}` – Server uses the specified JKS truststore to determine whether to trust certificate chains that are presented to it during TLS negotiation.
- `--usePKCS12TrustStore {path}` – Server uses the specified PKCS #12 truststore to determine whether to trust certificate chains that are presented to it during TLS negotiation.
- `--trustStorePassword {password}` – Password that is needed to interact with the specified JKS or PKCS #11 truststore.
- `--trustStorePasswordFile {path}` – Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 truststore.

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate:

```
$./setup \
 --no-prompt \
 --acceptLicense \
 --ldapPort 389 \
 --ldapsPort 636 \
 --httpsPort 443 \
 --enableStartTLS \
 --useJavaKeyStore config/keystore \
 --keyStorePasswordFile config/keystore.pin \
 --certNickname server-cert \
 --useJavaTrustStore config/truststore \
 --trustStorePasswordFile config/truststore.pin \
 --baseDN dc=example,dc=com \
 --rootUserDN "cn=Directory Manager" \
 --rootUserPasswordFile root-pw.txt \
 --maxHeapSize 10g \
 --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
 --instanceName ds1 \
 --location Austin \
 --noPropertiesFile
```

```
Ping Identity Directory Server 8.0.0.0
```

```
Initializing Done
```

```
Configuring Directory Server Done
```

```
Configuring Certificates Done
Starting Directory Server Done

Access product documentation from docs/index.html
```

## Enabling TLS Support after Setup

About this task

If the server has been set up without support for TLS, you can enable TLS support later by completing the following tasks:

1. Obtain a certificate chain.

For more information about obtaining a certificate chain, see [Certificate Chains](#) on page 496. To prepare a JKS or PKCS #12 keystore with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a truststore that the server can use.

2. Configure the key and trust manager providers. For more information, see [Configuring Key and Trust Manager Providers](#) on page 519.
3. Configure connection handlers. For more information, see [Configuring Connection Handlers](#) on page 520.

### Configuring Key and Trust Manager Providers

About this task

After you have a keystore, configure a key manager provider to access it. The server is preconfigured with key manager providers, named `JKS` and `PKCS12`, that can be used with JKS or PKCS #12 keystores, respectively. As the following example shows, you can update the appropriate key manager provider in most cases to reference the keystore that you plan to use:

```
dsconfig set-key-manager-provider-prop \
 --provider-name JKS \
 --set enabled:true \
 --set key-store-file:config/keystore \
 --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate truststore, as the following example shows:

```
dsconfig set-trust-manager-provider-prop \
 --provider-name JKS \
 --set enabled:true \
 --set include-jvm-default-issuers:true \
 --set trust-store-file:config/truststore \
 --set trust-store-pin-file:config/truststore.pin
```

**Note:** If all clients and servers are expected to use certificates that are signed by issuers and are included in the JVM's default truststore, you can use the `JVM-Default` trust manager provider to accomplish this task.

## Configuring Connection Handlers

About this task

After you configure the key and trust manager providers, update the connection handlers to use these. For the LDAP connection handler, which accepts non-secure connections by default, the following command enables StartTLS with a configuration change:

```
dsconfig set-connection-handler-prop \
--handler-name "LDAP Connection Handler" \
--set allow-start-tls:true \
--set key-manager-provider:JKS \
--set trust-manager-provider:JKS \
--set ssl-cert-nickname:server-cert \
--set ssl-client-auth-policy:optional
```

If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. For example, `allow-start-tls` must be set to `false`, and `use-ssl` must be set to `true` as shown below:

```
dsconfig set-connection-handler-prop \
--handler-name "LDAPS Connection Handler" \
--set enabled:true \
--set key-manager-provider:JKS \
--set trust-manager-provider:JKS \
--set ssl-cert-nickname:server-cert \
--set ssl-client-auth-policy:optional
```

The following example uses a similar configuration change to enable the HTTPS connection handler:

```
dsconfig set-connection-handler-prop \
--handler-name "HTTPS Connection Handler" \
--set enabled:true \
--set listen-port:443 \
--set key-manager-provider:JKS \
--set trust-manager-provider:JKS \
--set ssl-cert-nickname:server-cert
```

## Updating the Topology Registry

About this task

After the server connection handlers are updated to enable TLS, update the *topology registry* to provide information about the new configuration. The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following types of entries require updating:

- Server instance listener configuration – Provides information that is needed to trust the TLS certificates that instances in the topology present.
- Server instance configuration – Provides information about options for communicating with those instances.

The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use `dsconfig` to import the certificate from a file, as the following example shows:

```
bin/dsconfig set-server-instance-listener-prop \
--instance-name ds1 \
--listener-name ldap-listener-mirrored-config \
--set server-ldap-port:636 \
--set connection-security:ssl \
--set 'listener-certificate>/ca/ds1-cert.pem'
```

The less-than operator (`>`) in the final line indicates that the value is read from a file rather than provided directly. In addition, you may not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance. The following code sets the LDAPS and HTTPS ports, indicate that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance:

```
dsconfig set-server-instance-prop \
--instance-name ds1 \
--set ldaps-port:636 \
--set https-port:443 \
--set preferred-security:ssl \
--set start-tls-enabled:true
```

## Troubleshooting TLS-Related Issues

This section describes strategies for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

### Log Messages

About this task

If you need to troubleshoot TLS-related issues, we recommend that you start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit could be a network problem, a firewall that is blocking attempts to communicate, or something as simple as the client trying to use an incorrect address or port.

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages:

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are attempting to use LDAPS, one of the following log messages typically appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process, and that the issue likely occurred after the TLS session was established. This

message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.

- **DISCONNECT** message – Suggests that the issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends at least in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

**Note:** The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

### **manage-certificates check-certificate-usability**

The `manage-certificates` tool offers a `check-certificate-usability` subcommand that can be used to examine a specified entry in a keystore, and to identify potential issues that might interfere with secure communication. The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the keystore includes a private key and a complete certificate chain.
- Checks whether the certificate at the root of the chain is found in the JVM's default set of trusted certificates.
- Ensures that the current time lies is within the validity window for all certificates in the chain.
- Validates the signatures for all certificates in the chain.
- Warns if the end-entity certificate is self-signed.
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage.
- Warns if an the issuer certificates does not have a key usage extension with the `keyCertSign` usage.
- Warns if an issuer certificates does not have a basic constraints extension indicating that it can operate as a certification authority. If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256. The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.
- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits.

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified:

```
$ bin/manage-certificates check-certificate-usability \
 --keystore config/keystore \
 --keystore-password-file config/keystore.pin \
 --alias server-cert
```

```
Successfully retrieved the certificate chain for alias 'server-cert':
```

```
Subject DN: CN=ds1.example.com,O=Example Corp,C=US

OK: The certificate chain is complete. Each subsequent certificate is
the issuer for the previous certificate in the chain, and the chain ends
with a self-signed certificate.

OK: Certificate 'CN=ds1.example.com,O=Example Corp,C=US' has a valid
signature.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
valid signature.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a valid
signature.

OK: Certificate 'CN=ds1.example.com,O=Example Corp,C=US' will expire at
Wednesday, November 11, 2020 at 03:52:44 PM CST (364 days, 23 hours, 54
minutes, 14 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US'
will expire at Monday, November 7, 2039 at 03:52:42 PM CST (7299 days, 23
hours, 54 minutes, 12 seconds from now), which is not in the near future.

```

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23 hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' at the head of the chain includes an extended key usage extension, and that extension includes the serverAuth usage.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a 2048-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit RSA public key, which is considered strong.

No usability errors or warnings were identified while validating the certificate chain.

If any usability issues are identified, they might be responsible for communication problems.

## ldapsearch

The **ldapsearch** command-line utility is a simple but powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following arguments for TLS-related communication are the most useful:

- **--hostname {address}** – Address of the server to which the connection is established.
- **--port {port}** – TCP port of the server to which the connection is established. The standard port for non-secure LDAP (or LDAP to be secured with StartTLS) is 389, and the standard port for secure LDAPS is 636. However, many deployments use alternate ports, especially non-privileged ports above 1024.
- **--useSSL** – Indicates that the tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
- **--trustStorePath {path}** – Path to the truststore that is used during the course of determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument

nor the `--trustAll` argument is provided, the tool prompts you interactively about whether to trust server certificated that are not signed by an issuer in the JVM's default truststore.

- `--trustStoreFormat {format}` – Format for the truststore, which is typically JKS or PKCS12.
- `--trustStorePassword {password}` – Password that is needed to access the contents of the truststore.
- `--trustStorePasswordFile {path}` – Path to the file that contains the password that is needed to access the contents of the truststore.
- `--trustAll` – Indicates that the tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, we do not recommended it for general use.
- `--keyStorePath {path}` – Path to the keystore to use if a client certificate chain is presented to the server. Use this argument only when one of the following conditions is satisfied:
  - The server is configured to require clients to present a certificate.
  - You intend to use the certificate to authenticate through SASL EXTERNAL.
- `--keyStoreFormat {format}` – Format for the keystore, which is typically JKS or PKCS12.
- `--keyStorePassword {password}` – Password that is needed to access the keystore.
- `--keyStorePasswordFile {path}` – Path to the file that contains the password necessary to access the keystore.
- `--certNickname {alias}` – Alias of the private key entry in the keystore to use when obtaining the certificate chain to present to the server.
- `--useSASLExternal` – Indicates that the client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.
- `--enableSSLDebugging` – Indicates that the tool is expected to enable the low-level TLS-debugging feature that the JVM provides.

The following command represents the simplest method for testing TLS communication with PingDirectory Server:

```
$ bin/ldapsearch \
 --hostname ds1.example.com \
 --port 636 \
 --useSSL \
 --baseDN "" \
 --scope base \
 "(objectClass=*)"
```

The server presented the following certificate chain:

```
Subject: CN=ds1.example.com,O=Example Corp,C=US
Valid From: Tuesday, November 12, 2019 at 08:28:08 PM CST
Valid Until: Wednesday, November 11, 2020 at 08:28:08 PM CST
SHA-1 Fingerprint:

```

If no trust-related arguments are provided, the tool uses the JVM's default truststore to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default truststore, `ldapsearch` prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a truststore instead of being prompted interactively, use the `--trustStorePath` argument that points to the appropriate truststore. If you are using a JKS truststore, you probably do not need to provide the truststore password. If you are using a PKCS #12 truststore, though, you most likely need to provide the truststore password, as the following example shows:

```

$ bin/ldapsearch \
 --hostname ds1.example.com \
 --port 636 \
 --useSSL \
 --trustStorePath config/truststore.p12 \
 --trustStorePasswordFile config/truststore.pin \
 --trustStoreFormat PKCS12 \
 --baseDN "" \
 --scope base \
 "(objectClass=*)"
dn:

Result Code: 0 (success)
Number of Entries Returned: 1

```

To present a client certificate chain to the server – for example, because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required`, or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism – provide at least the keystore and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client keystore contains multiple certificates.

The following code provides an example:

```

$ bin/ldapsearch \
 --hostname ds1.example.com \

```

```

--port 636 \
--useSSL \
--trustStorePath config/truststore.p12 \
--trustStorePasswordFile config/truststore.pin \
--trustStoreFormat PKCS12 \
--keyStorePath client-keystore \
--keyStorePasswordFile client-keystore.pin \
--certNickname client-cert \
--useSASLExternal \
--baseDN "" \
--scope base \
"(objectClass=*)"
dn:

Number of Entries Returned: 1

```

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see [Low-Level TLS Debugging](#) on page 527.

### Low-Level TLS Debugging

If you must resort to low-level debugging options, we recommend that you enable the JVM's support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process. For other tools, perform the following steps:

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool:

```
-Djavax.net.debug=all
```

2. To make the change take effect, run the `bin/dsjavaproperties` command.

The next time the tool is run, it generates voluminous output detailing the TLS-related processing that the JVM is performing. Potential clues in the output might allow you or the team to identify the issue.

To enable low-level debugging within the server, perform the following steps:

1. In the `config/java.properties` file, add the following line to the `start-server.java-args` property:

```
-Djavax.net.debug=all
```

2. Run `bin/dsjavaproperties`.
3. Restart the server.

Because this approach requires multiple server restarts, it is not highly attractive. However, you might be able to obtain more information without a restart by using the debugging support that is built into the server. To enable this level of support, make the following configuration changes:

```

dsconfig create-debug-target \
--publisher-name "File-Based Debug Logger" \
--target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
--set debug-level:verbose

dsconfig set-log-publisher-prop \

```

```
--publisher-name "File-Based Debug Logger" \
--set enabled:true
```

After you make these changes, the `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. Although this file does not provide as much detail as the JVM's built-in debugging information, it might help to pinpoint the cause of the problem, and to identify potential solutions. When you no longer require this level of debugging, disable the debug log publisher and remove the debug target, as follows:

```
dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Debug Logger" \
 --set enabled:false

dsconfig delete-debug-target \
 --publisher-name "File-Based Debug Logger" \
 --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
```

To troubleshoot TLS communication with a non-Java client that does not offer its own TLS debugging mechanism, and if the server-side debugging support is insufficient, use a network protocol analyzer to capture the communication between the client and the server, and to examine its content. The free open-source [Wireshark utility](#) is an excellent graphical tool that runs on a variety of platforms and provides excellent support for understanding TLS communication. Even if you cannot decipher the encrypted content, you can view at least some of the handshake messages. Unfortunately, more of the handshake is encrypted in TLS version 1.3 than in earlier versions of the protocol. Although this change improves security and privacy, it may interfere with troubleshooting attempts.

## Using the Configuration API

PingDirectory Server provides a Configuration API, which may be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's `host:port` in the `/config` context. Due to the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used for hosting the Configuration extension.

### Authentication and Authorization with the Configuration API

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
 --extension-name Configuration \
 --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

### Relationship Between the Configuration API and the `dsconfig` Tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes may be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes may be excluded from responses by specifying the `excludedAttributes` parameter.

Operations supported by the API are those typically found in REST APIs:

| HTTP Method | Description                                                                                                                                                                                                                                                                                                                                                                                 | Related <code>dsconfig</code> Example                                                                   |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| GET         | Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> . Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .                                                                                           | <code>get-backend-prop</code> , <code>list-backends</code> , <code>get-global-configuration-prop</code> |
| POST        | Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .                                                                                                                                                                                                                                                                          | <code>create-backend</code>                                                                             |
| PUT         | Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> . | <code>set-backend-prop</code> , <code>set-global-configuration-prop</code>                              |
| PATCH       | Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                 | <code>set-backend-prop</code> , <code>set-global-configuration-prop</code>                              |
| DELETE      | Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .                                                                                                                                                                                                                                                                   | <code>delete-backend</code>                                                                             |

The `OPTIONS` method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. The URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

### GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot",
 "meta": {
 "resourceType": "Local DB Backend",

### GET List Example

The following is a sample GET request for all local backends:

```

GET /config/backends/
Host: example.com:5033
Accept: application/scim+json

```

The response (which has been shortened):

```

{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],
 "totalResults": 24,
 "Resources": [
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:ldif"
],
 "id": "adminRoot",
 "meta": {
 "resourceType": "LDIF Backend",
 "location": "http://localhost:5033/config/backends/adminRoot"
 },
 "backendID": "adminRoot",

```

```

 "backupFilePermissions": "700",
 "baseDN": [
 "cn=topology,cn=config"
],
 "enabled": "true",
 "isPrivateBackend": "true",
 "javaClass":
"com.unboundid.directory.server.backends.LDIFBackend",
 "ldifFile": "config/admin-backend.ldif",
 "returnUnavailableWhenDisabled": "true",
 "setDegradedAlertWhenDisabled": "false",
 "writabilityMode": "enabled"
 },
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:trust-store"
],
 "id": "ads-truststore",
 "meta": {
 "resourceType": "Trust Store Backend",
 "location": "http://localhost:5033/config/backends/ads-
truststore"
 },
 "backendID": "ads-truststore",
 "backupFilePermissions": "700",
 "baseDN": [
 "cn=ads-truststore"
],
 "enabled": "true",
 "javaClass":
"com.unboundid.directory.server.backends.TrustStoreBackend",
 "returnUnavailableWhenDisabled": "true",
 "setDegradedAlertWhenDisabled": "true",
 "trustStoreFile": "config/server.keystore",
 "trustStorePin": "*****",
 "trustStoreType": "JKS",

 },
 {
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:alarm"
],
 "id": "alarms",
 "meta": {
 "resourceType": "Alarm Backend",
 "location": "http://localhost:5033/config/backends/alarms"
 },
 ...
 }
}

```

### PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API, supports a subset of possible values for the path attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

```

{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
}

```

```
}

```

is analogous to:

```
$ dsconfig set-backend-prop
 --backend-name userRoot \
 --set "description:A new backend"

```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

```
{
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --add je-property:je.env.backgroundReadLimit=0

```

- An operation to remove a value from a multi-valued property. In this case, `path` specifies a SCIM filter identifying the value to remove:

```
{
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.cleaner.adjustUtilization=false

```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is value:

```
{
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --remove je-property:je.nodeMaxEntries=32

```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
 --reset id2childrenIndexEntryLimit

```

The following is the full example request. The API responds with the entire modified configuration object, which may include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

```
PATCH /config/backends/userRoot
```

```
Host: example.com:5033
Accept: application/scim+json
```

```
{
 "schemas" : ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
 "Operations" : [{
 "op" : "replace",
 "path" : "description",
 "value" : "A new backend."
 }, {
 "op" : "add",
 "path" : "jeProperty",
 "value" : "je.env.backgroundReadLimit=0"
 }, {
 "op" : "remove",
 "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
 }, {
 "op" : "remove",
 "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
 }, {
 "op" : "remove",
 "path" : "id2childrenIndexEntryLimit"
 }]
}
```

#### Example response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot2",

```

## Configuration API Paths

The Configuration API is available under the `/config` path. A full listing of supported sub-paths is available by accessing the base `/config/ResourceTypes` endpoint:

```
GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json
```

Sample response (abbreviated):

```
{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:ListResponse"
],
 "totalResults": 520,
 "Resources": [
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "dsee-compat-access-control-handler",
 "name": "DSEE Compat Access Control Handler",
 "description": "The DSEE Compat Access Control
 Handler provides an implementation that uses syntax
 compatible with the Sun Java System Directory Server
 Enterprise Edition access control handler.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-
access-control-handler"
 }
 },
 {
 "schemas": [
 "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
],
 "id": "access-control-handler",
 "name": "Access Control Handler",
 "description": "Access Control Handlers manage the
 application-wide access control. The server's access
 control handler is defined through an extensible
 interface, so that alternate implementations can be created.
 Only one access control handler may be active in the server
 at any given time.",
 "endpoint": "/access-control-handler",
 "meta": {
 "resourceType": "ResourceType",
 "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
 }
 },
 {
 ...
 }
]
}
```

The response's `endpoint` elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name such as `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

### Sorting and Filtering Objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both get and list operations.

| GET Parameter | Description                                                                                                                                                                               |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| filter        | Values can be simple SCIM filters such as <code>id eq "userRoot"</code> or compound filters like <code>meta.resourceType eq "Local DB Backend" and baseDn co "dc=example,dc=com"</code> . |
| sortBy        | Specifies a property value by which to sort.                                                                                                                                              |
| sortOrder     | Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.                                                                                                    |
| startIndex    | 1-based index of the first result to return.                                                                                                                                              |
| count         | Indicates the number of results per page.                                                                                                                                                 |

### Updating Properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
 "description" : "A new description."
}
```

Response:

```
{
 "schemas": [
 "urn:unboundid:schemas:configuration:2.0:backend:local-db"
],
 "id": "userRoot",
 "meta": {
 "resourceType": "Local DB Backend",
 "location": "http://example.com:5033/config/backends/userRoot"
 },
 "backendID": "userRoot",
 "backgroundPrime": "false",

"writabilityMode": "enabled"
}

```

## Administrative Actions

Updating a property may require an administrative action before the change can take effect. If so, the server will return 200 Success, and any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```
"urn:unboundid:schemas:configuration:messages:2.0": {
 "required-actions": [
 {
 "property": "baseContextPath",
 "type": "'componentRestart",
 "synopsis": "In order for this modification to take effect, the
component
 must be restarted, either by disabling and re-enabling it,
or
 by restarting the server"
 },
 {
 "property": {
 "type": "other",
 "synopsis": "If this limit is increased, then the
 contents of the backend must be exported to LDIF
 and re-imported to allow the new limit to be used
 for any id2children keys that had already hit the
 previous limit."
 }
 }
]
}
```

## Updating Servers and Server Groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified. For example:

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

## Configuration API Responses

Clients of the API should examine the HTTP response code in order to determine the success or failure of a request. The following are response codes and their meanings:

| Response Code  | Description                                                                                                                                                                                                                                            | Response Body                                                  |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| 200 Success    | The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object. | List of objects, or object properties, administrative actions. |
| 204 No Content | The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.                                                                                                                             | None.                                                          |

| Response Code              | Description                                                                                                                                                                                                                                               | Response Body                       |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| 400 Bad Request            | The request contents are incorrectly formatted or a request is made for an invalid API version.                                                                                                                                                           | Error summary and optional message. |
| 401 Unauthorized           | User authentication is required. Some user agents such as browsers may respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.                                                       | None.                               |
| 403 Forbidden              | The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint such as an object is edit-only and cannot be deleted.                                                                           | None.                               |
| 404 Not Found              | The requested path does not refer to an existing object or object relation.                                                                                                                                                                               | Error summary and optional message. |
| 409 Conflict               | The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referred to by another object. | Error summary and optional message. |
| 415 Unsupported Media Type | The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.                                                                                                                                            | None.                               |
| 500 Server Error           | The server encountered an unexpected error. Please report server errors to customer support.                                                                                                                                                              | Error summary and optional message. |

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages may change, and their presence may depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
 "schemas": [
 "urn:ietf:params:scim:api:messages:2.0:Error"
],
 "status": 404,
 "scimType": null,
 "detail": "The Local DB Index does not exist."
}
```

## Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory Server. The Directory REST API gives developers, who are more comfortable with REST than LDAP, access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and SCIM provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access

to identity data. But because it is a less common standard for identity stores, it may not offer as much functionality or be as easy to use as the Directory REST API.

Rather than trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

The Directory REST API can be used for the following operations:

| HTTP operation | Resource endpoint                                         | Description                                           | Allowed query parameters                                                                                                                                                       |
|----------------|-----------------------------------------------------------|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DELETE         | <code>/directory/v1/{dn}</code>                           | Delete an entry.                                      |                                                                                                                                                                                |
| GET            | <code>/directory/v1</code>                                | Get metadata about the API and server.                |                                                                                                                                                                                |
| GET            | <code>/directory/v1/{dn}</code>                           | Retrieve a single entry.                              | <ul style="list-style-type: none"> <li>▪ expand</li> <li>▪ includeAttributes</li> <li>▪ excludeAttributes</li> </ul>                                                           |
| GET            | <code>/directory/v1/{dn}/subtree</code>                   | Search an entry's descendants.                        | <ul style="list-style-type: none"> <li>▪ filter</li> <li>▪ searchScope</li> <li>▪ cursor</li> <li>▪ limit</li> <li>▪ includeAttributes</li> <li>▪ excludeAttributes</li> </ul> |
| GET            | <code>/directory/v1/schemas</code>                        | Retrieve the schemas of all available object classes. |                                                                                                                                                                                |
| GET            | <code>/directory/v1/schemas/{objectclass}</code>          | Retrieve schema for object class.                     |                                                                                                                                                                                |
| GET            | <code>/directory/v1/schemas/_operationalAttributes</code> | Retrieve schema for operational attributes.           |                                                                                                                                                                                |
| GET            | <code>/directory/v1/me</code>                             | Alias for retrieving the current user.                |                                                                                                                                                                                |
| PATCH          | <code>/directory/v1/{dn}</code>                           | Modify an entry (add or delete values).               | expand                                                                                                                                                                         |
| POST           | <code>/directory/v1</code>                                | Create a new entry.                                   | expand                                                                                                                                                                         |
| PUT            | <code>/directory/v1/{dn}</code>                           | Modify or rename an entry.                            | expand                                                                                                                                                                         |

The Directory REST API has the following properties, and can be configured with `dsconfig`:

- **basic-auth-enabled**: Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users will need a Bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic auth is enabled by default.
- **identity-mapper**: If HTTP Basic authentication is enabled, the identity mapper referenced by this DN must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.

- **access-token-validator**: Specifies the subset of this server's Access Token Validators (by DN), which may be used to validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server may be used. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.
- **access-token-scope**: The scope which must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication can be used. By default, no value is provided. Changes to this value take effect immediately.
- **audience**: A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
- **max-page-size**: The maximum number of entries to be returned in one page from the search endpoint (actual results returned may be lower due to the limit query parameter on the request and the actual number of available results). The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.
- **schemas-endpoint-objectclass**: The list of object classes that will be returned by the `/schemas/` endpoint in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

The following example uses `dsconfig` to configure an `objectClass` entity:

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST
API" \
 --add schemas-endpoint-objectclass:ubidPerson
```

## Configure the Server Using the Administrative Console

The PingDirectory Server provides a Administrative Console for server configuration and monitoring that has the same functionality as that of the `dsconfig` command. When logging on to the Administrative Console, the console does not persistently store any credentials for authenticating to the Directory Server but uses the credentials provided by the user when logging in. When managing multiple directory server instances, the provided credentials must be valid for each instance.

### To Log on to the Administrative Console

About this task

To log on to the console, enter a fully qualified DN (for example, `cn=admin2,cn=Topology Admin Users,cn=Topology,cn=config`). See [Configuring a Global Administrator](#) for instructions.

Steps

1. Start the Directory Server.

```
$ bin/start-server
```

2. Open a browser to `http://server-name:389/console/login`.

3. Enter the root user DN and password, then click **Login**.

The console does not persistently store any credentials for accessing the Directory Server. Instead, it uses the credentials provided by the user when logging into the console. When managing multiple directory server instances, the provided credentials must be valid at each instance.

## To Configure the Server Using the Console

### Steps

1. Log into the Administrative Console. Click **Configuration** to open the **Configuration** menu, and then click **Backends**.

- At the top of the Administrative Console page, click **Show Advanced Properties**. Click **Backends**. For this example, click **userRoot**.

The screenshot shows the 'Edit Local DB Backend' configuration page in the PingIdentity PingData Administrative Console. The page title is 'Edit Local DB Backend' and it includes a sub-header: 'The Local DB Backend uses the Berkeley DB Java Edition to store user-provided data in a local repository.' The configuration is organized into a 'General Configuration' section with the following fields:

- Backend ID**: userRoot
- Description**: (empty text box)
- Enabled**:  Enabled
- Base DN**: A list containing 'dc=example,dc=com' with a '+', '-', and 'x' button.
- Writability Mode**: enabled
- Set Degraded Alert When Disabled**:  Enabled
- Return Unavailable When Disabled**:  Enabled
- Notification Manager**: (empty dropdown menu)
- Is Private Backend**:  Enabled

- Change or enter values in the `userRoot` configuration. For this example, change the `DB Cache Percent` value to 40, and then click **Save**.

## Generating a Summary of Configuration Components

The Directory Server provides a `config-diff` tool that generates a summary of the configuration in a local or remote directory server instance. The tool is useful when comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers to your network. The tool can interact with the local configuration regardless of whether the server is running or not.

Run the `config-diff --help` option to view other available tool options.

### To Generate a Summary of Configuration Components

#### Steps

- Run the `config-diff` tool to generate a summary of the configuration components on the directory server instance. The following command runs a summary on a local online server.

```
$ bin/config-diff
```

- The following example compares the current configuration of the local server to the baseline, pre-installation configuration, ignoring any changes that could be made by the installer, and writes the output to the `configuration-steps.dsconfig` file. This provides a script that can be used to configure a newly installed server identically to the local server:

```
$ bin/config-diff --sourceLocal \
 --sourceBaseline \
 --targetLocal \
 --exclude differs-after-install \
```

```
--outputFile configuration-steps.dsconfig
```

## About Root User, Administrator, and Global Administrators

The Directory Server provides three different classes of administrator accounts: root user, administrator, and global administrator. The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set (see [Default Root Privileges](#)). The root user "account" is an entry that is stored in the server's configuration under the `cn=Root DNs,cn=config` and bypasses access control evaluation, and can be created manually, or with the `dsconfig` tool. This account has full access to the entire set of data in the Directory Information Tree (DIT) as well as full access to the server configuration and its operations. One important difference between other vendors' servers and the Directory Server's implementation is that the root user's rights are granted through a set of privileges. This allows the Directory Server to have multiple root users on its system if desired; however, the normal practice is to set up administrator user entries. Also, by default, the Root User has no resource limits.

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators entries typically have limited access to the entire set of data in the directory information tree (DIT), which is controlled by access control instructions. These entries reside in the backend configuration (for example, `uid=admin,dc=example,dc=com`) and are replicated between servers in a replication topology. In some cases, administrator user accounts may be unavailable when the server enters lockdown mode unless the administrator is given the lock-down mode privilege.

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology, where configuration changes to one server can be applied to all of the servers at one time. Global Administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend are always mirrored across servers in a replication topology. These users can be assigned privileges like other admin users but are typically used to manage the data under `cn=Topology,cn=config`.

## Managing Root Users Accounts

The PingDirectory Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file (for example, under `cn=Root DNs,cn=config`). The root user is the LDAP-equivalent of a UNIX super-user account and inherits its read-write privileges from the default root privilege set. Root users can be created and updated with the `dsconfig` tool. Root user entries are stored in the server's configuration. The following is a sample command to create a new root user:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
 --set last-name:Smith \
 --set first-name:Joanne \
 --set user-id:jsmith \
 --set 'email-address:jsmith@example.com' \
 --set mobile-telephone-number:8889997777 \
 --set home-telephone-number:5556667777 \
 --set work-telephone-number:4445556666
```

To limit full access to all of the Directory Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change. Having separate user accounts for each administrator also makes it possible to enable password policy functionality (such as password expiration, password history, and requiring secure authentication) for each administrator.

## Default Root Privileges

The PingDirectory Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

**Note:** Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

### Default Root Privileges

| Privilege                               | Description                                                                                                                                                               |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| audit-data-security                     | Allows the associated user to execute data security auditing tasks.                                                                                                       |
| backend-backup                          | Allows the user to perform backend backup operations.                                                                                                                     |
| backend-restore                         | Allows the user to perform backend restore operations.                                                                                                                    |
| bypass-acl                              | Allows the user to bypass access control evaluation.                                                                                                                      |
| config-read                             | Allows the user to read the server configuration.                                                                                                                         |
| config-write                            | Allows the user to update the server configuration.                                                                                                                       |
| disconnect-client                       | Allows the user to terminate arbitrary client connections.                                                                                                                |
| ldif-export                             | Allows the user to perform LDIF export operations.                                                                                                                        |
| ldif-import                             | Allows the user to perform LDIF import operations.                                                                                                                        |
| lockdown-mode                           | Allows the user to request a server lockdown.                                                                                                                             |
| manage-topology                         | Allows the user to modify topology setting.                                                                                                                               |
| metrics-read                            | Allows the user to read server metrics.                                                                                                                                   |
| modify-acl                              | Allows the user to modify access control rules.                                                                                                                           |
| password-reset                          | Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.   |
| permit-get-password-policy-state-issues | Allows the user to access password policy state issues.                                                                                                                   |
| privilege-change                        | Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.                            |
| server-restart                          | Allows the user to request a server restart.                                                                                                                              |
| server-shutdown                         | Allows the user to request a server shutdown.                                                                                                                             |
| soft-delete-read                        | Allows the user access to soft-deleted entries.                                                                                                                           |
| stream-values                           | Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT. |
| third-party-task                        | Allows the associated user to invoke tasks created by third-party developers.                                                                                             |
| unindexed-search                        | Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.                                                                            |
| update-schema                           | Allows the user to update the server schema.                                                                                                                              |

| Privilege         | Description                                                                                                                                   |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| use-admin-session | Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads. |

The Directory Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

### Other Available Privileges

| Privilege                                  | Description                                                                                                                                                                                                 |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bypass-pw-policy                           | Allows the associated user bypass password policy rules and restrictions.                                                                                                                                   |
| bypass-read-aci                            | Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations. |
| jmx-notify                                 | Allows the associated user to subscribe to receive JMX notifications.                                                                                                                                       |
| jmx-read                                   | Allows the associated user to perform JMX read operations.                                                                                                                                                  |
| jmx-write                                  | Allows the associated user to perform JMX write operations.                                                                                                                                                 |
| permit-externally-processed-authentication | Allows the associated user accept externally processed authentication.                                                                                                                                      |
| permit-proxied-mschapv2-details            | Allows the associated user to permit MS-CHAP V2 handshake protocol.                                                                                                                                         |
| proxied-auth                               | Allows the associated user to accept proxied authorization.                                                                                                                                                 |

## Configuring Administrator Accounts

An administrator account is any account in the user backend that is assigned one or more privileges, or given access to read and write operations beyond that of a normal user entry. The privilege mechanism is the same as that used for Root DN accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the Directory Information Tree (DIT). Fine-grained read and write access can be granted using the access control definitions available via the `aci` attribute. Administrator entries reside in the backend configuration (for example, `uid=admin,dc=example,dc=com`) and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts. The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges. Note that if you generated sample data at install, you can view an example `uid=admin` entry using `ldapsearch`. The second example shows a more realistic example, where the user is part of the Administrators group. Note that both examples are based on a simple DIT. Actual deployment cases depends on your schema.

### To Set Up a Single Administrator Account

#### Steps

1. Create an LDIF file with an example Administrator entry.

```
dn: uid=admin,dc=example,dc=com
objectClass: person
```

```
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
givenName: Admin
uid: admin
cn: Admin User
sn: User
userPassword: password
```

2. Then add the entry using the `ldapmodify` tool.

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. Create another LDIF file to add the access control instruction (ACI) to the root suffix, or base DN to give full access to the new administrator. The ACI grants full access to all user attributes, but not to operational attributes. If you want to grant access to operational attributes as well as user attributes, use `(targetattr = "*|+)"` in the access control instruction.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr = "*")
 (version 3.0; acl "Grant full access for the admin user";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

4. Then add the entry using the `ldapmodify` tool.

```
$ bin/ldapmodify --filename admin.ldif
```

5. Verify the additions using `ldapsearch`. The first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including access control instructions, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base
 "(objectclass=*)" "+"
```

6. Add specific privileges to the Admin account. In this example, add the `password-reset` privilege to the admin account from the command line. After typing the privileges, press **CTRL-D** to process the modify operation.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

```
Processing MODIFY request for uid=admin,dc=example,dc=com
MODIFY operation successful for DN uid=admin,dc=example,dc=com
```

7. Assign a password policy for the Admin account. For example, create an "Admin Password Policy", then add the password policy to the account.

```
$ bin/dsconfig create-password-policy \
 --policy-name "Admin Password Policy" \
 --set "description:Password policy for administrators" \
 --set password-attribute:userpassword \
 --set "default-password-storage-scheme:Salted SHA-256" \
 --set password-change-requires-current-password:true \
 --set force-change-on-reset:true \
 --set "max-password-age:25w 5d" \
 --set grace-login-count:3 \
 --no-prompt
```

- Apply the password policy to the account. In this example, the password policy is being added from the command line. The following `ldapmodify` command should be executed with a bind DN that has sufficient rights, such as a Root DN.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config
```

## To Change the Administrator Password

### About this task

Root users are governed by the Root Password Policy and by default, their passwords never expire. However, if a root user password must be changed, use the `ldappasswordmodify` tool.

### Steps

- Open a text editor and create a text file containing the new password. In this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

- Use `ldappasswordmodify` to change the root user's password.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager"\
--bindPassword secret --newPasswordFile rootuser.txt
```

- Remove the text file.

```
$ rm rootuser.txt
```

## To Set Up an Administrator Group

### About this task

The following example shows how to set up a group of administrators that have access rights to the whole Directory Server. The example uses a static group using the `GroupOfUniqueNames` object class.

### Steps

- Create an LDIF file with an example Administrator group, and save it as `admin-group.ldif`.

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
objectClass: groupofuniquenames
objectClass: top
uniqueMember: uid=user.0, ou=People, dc=example,dc=com
uniqueMember: uid=user.1, ou=People, dc=example,dc=com
cn: Dir Admins
ou: Groups
```

- Then, add the entries using the `ldapmodify` tool.

```
$ bin/ldapmodify --defaultAdd --filename admin-group.ldif
```

3. Create another LDIF file to add the access control instruction (ACI) to the root suffix, or base DN to provide full access to the Directory Server to the new administrator. Save the file as `admin-aci.ldif`.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (target="ldap:///dc=example,dc=com")
 (targetattr != "aci")
 (version 3.0; acl "allow all Admin group";
 allow(all) groupdn = "ldap:///cn=Dir
Admins,ou=Groups,dc=example,dc=com";)
```

4. Then, add the ACI using the `ldapmodify` tool:

```
$ bin/ldapmodify --filename admin-aci.ldif
```

5. Verify the additions using `ldapsearch`. The first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including access control instructions, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
 "(objectclass=*)" "+"
```

6. Add specific privileges to each Admin account using an LDIF file, saved as `admin-priv.ldif`. In this example, add the `password-reset` privilege to the `user.0` admin account from the command line. Add the privilege using the `ldapmodify` tool. Repeat the process for the other administrators configured in the Admin group.

```
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset

$ bin/ldapmodify --filename admin-priv.ldif
```

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

7. Assign a password policy for the Admin account using an LDIF file, saved as `admin-pwd-policy.ldif`. For example, create an "Admin Password Policy", then add the password policy to the account. Apply the password policy to the account using the `ldapmodify` tool.

```
dn: uid=user.0,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config

$ bin/ldapmodify --filename admin-pwd-policy.ldif
```

## Configuring a Global Administrator

A global administrator is created when replication is enabled, and is responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology, where configuration changes to one server can be applied to all of the servers at a time.

Global Administrator(s) are stored in the topology registry. These entries are always mirrored between servers in a topology. Global Administrators can be assigned privileges like other admin users but are

typically used to manage the data under `cn=topology,cn=config` and `cn=config`. You can create new global administrators and remove existing global administrators using the **dsconfig** tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

### To Create a Global Administrator

#### Steps

1. Use **dsconfig** to create a new global administrator.

```
$ bin/dsconfig create-topology-admin-user \
 --user-name admin2 \
 --set alternate-bind-dn:cn=admin2 \
 --set password:rootPassword
```

2. To verify the creation of the new administrator, use the **list-topology-admin-users** subcommand with **dsconfig**.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin : generic
admin2 : generic
```

### To Remove a Global Administrator

#### Steps

1. Use **dsconfig** to delete an existing global administrator.

```
$ bin/dsconfig delete-topology-admin-user --user-name admin2
```

2. To verify the deletion of the global administrator, use the **list-topology-admin-users** option with **dsconfig**.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin : generic
```

## Configuring Server Groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group. After you have set up a server group, you can make an update on one server using **dsconfig**, then you can apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **dsconfig** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **dsconfig** in interactive command-line mode, you will be asked if you want to apply the change to a single server or to all servers in the server group.

### About the Server Group Example

You can create an administrative server group using the **dsconfig** tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group as outlined in Replication Configuration.

The following example procedure adds three Directory Server instances into the server group labelled "group-one".

## To Create a Server Group

### Steps

1. Create a group called "group-one" using **dsconfig**.

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group. If you have set up replication between a set of servers, these server entries will have already been created by the **dsreplication enable** command.

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server1
```

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server2
```

```
$ bin/dsconfig set-server-group-prop \
 --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

```
$ bin/dsconfig set-global-configuration-prop \
 --set configuration-server-group:group-one
```

4. Test the server group. In this example, enable the log publisher for each directory server in the group, **server-group**, by using the **--applyChangeTo server-group** option.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set enabled:true \
 --applyChangeTo server-group
```

5. View the property on the first directory server instance.

```
$ bin/dsconfig get-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

6. Repeat step 5 on the second and third directory server instance.
7. Test the server group by disabling the log publisher on the first directory server instance by using the **--applyChangeTo single-server**.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --set enabled:disabled \
 --applyChangeTo single-server
```

8. View the property on the first directory server instance. The first directory server instance should be disabled.

```
$ bin/dsconfig get-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --property enabled
```

```
Property : Value(s)
-----:-----
enabled : false
```

- View the property on the second directory server instance. Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

```
$ bin/dsconfig get-log-publisher-prop \
 --publisher-name "File-Based Audit Logger" \
 --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

## Configuring Client Connection Policies

Client connection policies help distinguish what portions of the DIT the client can access. They also enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use will be reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

Once a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are also associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

### Understanding the Client Connection Policy

Client connection policies are based on two things:

- **Connection criteria.** The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.
- **Evaluation order index.** If multiple client connection policies are defined in the server, then each of them must have a unique value for the **evaluation-order-index** property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

### When a Client Connection Policy is Assigned

A client connection policy can be associated with a client connection at the following times:

- When the connection is initially established. This association occurs exactly once for each client connection.

- After completing processing for a StartTLS operation. This association occurs at most once for a client connection, because StartTLS cannot be used more than once on a particular connection. You also may not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection, because the bind request can be processed many times on a given connection.

StartTLS and bind requests will be subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. Once they have completed, then subsequent operations will be subject to the constraints of the new client connection policy assigned to that client connection. This policy may or may not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and will be applicable when the client reconnects.

All other types of operations will be subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. So, the server will not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy will never be re-evaluated for a search operation.

### Restricting the Type of Search Filter Used by Clients

You can restrict the types of search filters that a given client may be allowed to use to prevent the use of potentially expensive filters, like range or substring searches. You can use the `allowed-filter-type` property to provide a list of filter types that may be included in the search requests from clients associated with the client connection policy. This setting will only be used if search is included in the set of allowed operation types. This restriction will only be applied to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

The `minimum-substring-length` property can be used to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes will be rejected. For example, the server can be configured to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting will only be used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing very short substrings can require the server to perform more expensive processing. The search requires a lot more server effort to assemble a candidate entry list for short substrings because the server has to examine a lot more index keys.
- Allowing very short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server (a process known as "trawling"). If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

### Setting Resource Limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources. You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy may only be used to enforce additional restrictions on a client connection. You can never use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties will only impact client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made will continue to be subject to the configuration that was in place at the time it was associated with that policy.

## Resource Limiting Properties

| Property                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maximum-concurrent-connections         | <p>Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit will be enforced.</p> <p>If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy (e.g., newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation) will cause that connection to be terminated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| terminate-connection                   | <p>Specifies that any client connection for which the client connection policy is selected (whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation) will be immediately terminated.</p> <p>This property can be used to define criteria for connections that you do not want to be allowed to communicate with the Directory Server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| maximum-connection-duration            | <p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the Directory Server, regardless of the amount of activity on that connection.</p> <p>A value of "0 seconds" (default) indicates that no limit will be enforced. If a connection associated with the client connection policy has been established for longer than this time, then it will be terminated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| maximum-idle-connection-duration       | <p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the Directory Server without any requests in progress.</p> <p>A value of "0 seconds" (default) indicates that no additional limit will be enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection will be the smaller of the <code>maximum-idle-connection-duration</code> from the client connection policy and the idle time limit that would otherwise be in effect for that client.</p> <p>This property can be used to apply a further restriction on top of any value that may be enforced by the <code>idle-time-limit</code> global configuration property (which defines a default idle time limit for client connections) or the <code>ds-rlim-idle-time-limit</code> operational attribute (which may be included in a user entry to override the default idle time limit for that user).</p> |
| maximum-operation-count-per-connection | <p>Specifies the maximum number of operations that a client associated with the client connection policy will be allowed to request. A value of zero (default) indicates that no limit will be enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Property                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maximum-concurrent-operations-per-connection            | <p>Specifies the maximum number of operations that may be active at any time from the same client. This limit is only applicable to clients that use asynchronous operations with multiple outstanding requests at any given time.</p> <p>A value of zero (default) indicates that no limit will be enforced.</p> <p>If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request will be delayed and/or rejected based on the value of the <code>maximum-concurrent-operation-wait-time-before-rejecting</code> property.</p>                                                                                              |
| maximum-concurrent-operation-wait-time-before-rejecting | <p>Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection.</p> <p>A value of "0 seconds" (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection will be immediately rejected.</p> <p>If an outstanding operation completes before this time expires, then the server may be allowed to process that operation. If the time expires, the new request will be rejected.</p>                     |
| maximum-ldap-join-size-limit                            | <p>Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the <code>ds-rlim-ldap-join-size-limit</code> operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control will have a "size limit exceeded" (integer value 4) result code.</p>                                                                                                                            |
| allowed-request-control                                 | <p>Specifies the OIDs of the request controls that clients associated with the client connection policy will be allowed to use.</p> <p>If any <code>allowed-request-control</code> OIDs are specified, then any request which includes a control not in that set will be rejected. If no <code>allowed-request-control</code> values are specified (default), then any control whose OID is not included in the set of <code>denied-request-control</code> values will be allowed.</p>                                                                                                                                                                                                    |
| denied-request-control                                  | <p>Specifies the OIDs of the request controls that clients associated with the client connection policy will not be allowed to use. If there are any <code>denied-request-control</code> values, then any request containing a control whose OID is included in that set will be rejected.</p> <p>If there are no <code>denied-request-control</code> values (default), then any request control will be allowed if the <code>allowed-request-control</code> property is also empty, or only those controls whose OIDs are included in the set of <code>allowed-request-control</code> values will be allowed if at least one <code>allowed-request-control</code> value is provided.</p> |

| Property                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allowed-filter-type      | <p>Specifies the types of components which may be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set will be rejected. The set of possible filter types include:</p> <ul style="list-style-type: none"> <li>▪ and</li> <li>▪ or</li> <li>▪ not</li> <li>▪ equality</li> <li>▪ sub-initial</li> <li>▪ sub-any</li> <li>▪ sub-final</li> <li>▪ greater-or-equal</li> <li>▪ less-or-equal</li> <li>▪ approximate-match</li> <li>▪ extensible-match</li> </ul> <p>By default, all filter types will be allowed. Also note that no restriction will be placed on the types of filters which may be used in searches with a base scope.</p>     |
| allow-unindexed-searches | <p>Specifies whether clients associated with the client connection policy will be allowed to request searches which cannot be efficiently processed using the configured set of indexes. Note that clients will still be required to have the <code>unindexed-search</code> privilege, so this option will not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it may be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so.</p> <p>By default, this has a value of "true", indicating that any client associated with the client connection policy that has the <code>unindexed-search</code> privilege will be allowed to request unindexed searches.</p> |
| minimum-substring-length | <p>Specifies the minimum number of bytes, which may be present in any sub-Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit will be enforced. This property may be used to prevent clients from issuing overly-vague substring searches that may require the Installing the Directory Server to examine too many entries over the course of processing the request.</p>                                                                                                                                                                                                                                                                                                                             |

| Property                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maximum-search-size-limit | <p>Specifies the maximum number of entries that may be returned from any single search operation requested by a client associated with this client connection policy. Note that this property only specifies a maximum limit and will never increase any limit that may already be in effect for the client via the <code>size-limit</code> global configuration property or the <code>ds-rlim-size-limit</code> operational attribute.</p> <p>A value of zero (default) indicates that no additional limit will be enforced on top of whatever size limit might already be in effect for an associated connection.</p> <p>If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client will be the smaller of the size limit from that search request, the <code>maximum-search-size-limit</code> from the client connection policy, and the size limit that would otherwise be in effect for that client.</p> |

### Defining the Operation Rate

You can configure the maximum operation rate for individual client connections as well as collectively for all connections associated with a client connection policy. If the operation rate limit is exceeded, the Directory Server may either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of less than twelve operations per second, but with bursts of up to one thousand operations per second.

Rate limit strings should be specified as a maximum count followed by a slash and a duration. The count portion must contain an integer, and may be followed by a multiplier of k (to indicate that the integer should be interpreted as thousands), m (to indicate that the integer should be interpreted as millions), or g (to indicate that the integer should be interpreted as billions). The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), and may be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

### Client Connection Policy Deployment Example

In this example scenario, we assume the following:

- Two external LDAP clients are allowed to bind to the Directory Server.
- Client 1 should be allowed to open only 1 connection to the server.
- Client 2 should be allowed to open up to 5 connections to the server.

### Defining the Connection Policies

We need to set a per-client connection policy limit on the number of connections that may be associated with a particular client connection policy. We have to define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, we must create a third client connection policy that applies to unauthenticated clients, because client connections are always unauthenticated as soon as they are

established and before they have sent a bind request. Plus, clients are not required to send a bind request as their first operation.

Therefore, we define the following three client connection policies:

- **Client 1 Connection Policy**, which only allows client 1, with an evaluation order index of 1.
- **Client 2 Connection Policy**, which only allows client 2, with an evaluation order index of 2.
- **Unauthenticated Connection Policy**, which allows unauthenticated clients, with an evaluation order index of 3.

We define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none, so that it will only apply to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This DN may be full DN for the target user, or it may be the base DN for a branch that contains a number of users that you want treated in the same way.

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

### How the Policy is Evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy. The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value will be examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection will be associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection will be terminated.

So, in our example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy, because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies will be re-evaluated. If client 2 performs the bind, then the Client 1 Connection Policy will not match but the Client 2 Connection Policy will, so the connection will be re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server will check to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection will be terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy, because it is the client connection policy already assigned to the client connection. Once the bind has completed, then the server will reevaluate the client connection policy against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. Once the

bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria do not match, so the client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy, because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed, because this is the client connection policy assigned to the client connection for client 1. The connection is not reevaluated, before or after processing the search operation.

### To Configure a Client Connection Policy Using the Console

#### Steps

1. Open the Administrative Console. Provide a user name and password, and then click **Login**.
2. In the **Core Server** section, click **Client Connection Policies**. If you do not see **Client Connection Policies** on the menu, change the Object Types filter to **Standard**.
3. Click **Add New** to add a new policy.
4. Enter a Policy ID. If you want to base your new client connection policy on an existing policy, select it from the **Template** menu.
5. Configure the properties of the client connection policy. To enable the policy, select **Enabled**.
6. Enter the order in which you want the new policy to be evaluated in the **Evaluation Order Index** box, and then click **Continue**. A policy with a lower index is evaluated before a policy with a higher index. The Directory Server uses the first evaluated policy that applies to a client connection.
7. Select the connection criteria that match the client connection for this policy. Click **View and edit** to change the criteria. Click **Select New** to add new criteria. Select the operations allowed for clients that are members of this connection group. Use the **Add and Remove** buttons to make operations available to clients. Specify the extended operations that clients are allowed and denied to use.
8. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
9. Check the **Include Backend Subtree Views** check box if you want to automatically include the subtree views of backends configured in the Directory Server. You can also choose to include and exclude specific base DN's using the appropriate fields.
10. Once you have finished configuring the properties of your client connection policy, click **Confirm then Save** to review the `dsconfig` command equivalent and save your changes. Click **Save Now** to save your changes without first reviewing the `dsconfig` output.

### To Configure a Client Connection Policy Using dsconfig

#### About this task

You can configure a client connection policy using the `dsconfig` tool in interactive mode from the command line. You can access the **Client Connection Policy** menu on the **Standard objects** menu.

#### Steps

1. Use the `dsconfig` tool to create and configure a client connection policy. Specify the host name, connection method, port number, and bind DN as described in previous procedures.
2. On the Directory Server main menu, change to the **Standard objects** menu by entering `o` and then entering the number for the Standard menu.
3. On the Directory Server main menu, enter the number associated with **Client Connection Policy**.
4. On the **Client Connection Policy management** menu, type the number corresponding to **Create a new connection policy**.
5. Enter `n` to create a new client connection policy from scratch.
6. Next, enter a name for the new client connection policy.

7. On the **Enabled Property** menu, select true to enable the connection policy.
8. On the **Evaluation-Order Property** menu, type a value between 0 and 2147483647 to set the evaluation order for the policy. A client connection policy with a lower evaluation-order will be evaluated before one with a higher number. For this example, type 9999.
9. On the **Client Connection Policy** menu, review the configuration. If you want to make any further modifications, enter the number corresponding to the property. Enter **⏎** to finish the creation of the client connection policy.

Any changes that you make to the client connection policy do not apply to existing connections. They will only apply to new connections.

### Restricting Server Access Based on Client IP Address

Another common use case is to limit client access to the Directory Server. Two methods are available:

- **Connection Handlers.** You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.
- **Client Connection Policies.** You can take a more fine-grained approach by restricting access by configuring a new Client Connection Policy, then create a new connection criteria and associate it with the connection policy. Connection criteria define sets of criteria for grouping and describing client connections based on a number of properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy may be associated with zero or more Connection Criteria, and server components may use Connection Criteria to indicate which connections should be processed and what kind of processing should be performed (e.g., to select connections and/or operations for filtered logging, or to classify connections for network groups).

#### *To Restrict Server Access Using the Connection Handlers*

##### Steps

- Use `dsconfig` to set the `allowed-client` property for the LDAP connection handler. You should specify the address mask for the range of allowable IP addresses that can establish connections to the Directory Server. You should also specify the loopback address, 127.0.0.1, so that you will still be able to configure the server using the `dsconfig` tool on the local host.

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "LDAP Connection Handler" \
 --set "allowed-client:10.6.1.*" \
 --set allowed-client:127.0.0.1
```

#### *To Restrict Server Access Using Client Connection Policies*

##### Steps

1. Create a simple connection criteria. The following example uses the `dsconfig` tool in non-interactive mode. It allows only the Directory Server's IP address and loopback to have access.

```
$ bin/dsconfig set-connection-criteria-prop \
 --criteria-name allowed-ip-addr \
 --add included-client-address:10.6.1.80 \
 --add included-client-address:127.0.0.1
```

2. Assign the criteria to the client connection policy. After you have run the following command, access is denied to remote IP addresses. The Directory Server does not require a restart.

```
$ bin/dsconfig set-client-connection-policy-prop \
 --policy-name new-policy \
 --set connection-criteria:allowed-ip-addr
```

3. Add a remote IP range to the criteria. For this example, add 10.6.1.\*. Access from any remote servers is allowed. The Directory Server does not require a restart.

```
$ bin/dsconfig set-connection-criteria-prop \
 --criteria-name allowed-ip-addr \
 --add "included-client-address:10.6.1.*"
```

4. To restore default behavior, you can remove the criteria from the connection policy. The Directory Server does not require a restart. Remember to include the LDAP or LDAPS connection parameters (for example, host name, port, bindDN, bindPassword) with the `dsconfig` command.

```
$ bin/dsconfig set-client-connection-policy-prop \
 --policy-name new-policy --remove connection-criteria:allowed-ip-addr
```

#### *To Automatically Authenticate Clients that Have a Secure Communication Channel*

##### About this task

The Directory Server provides an option to automatically authenticate clients that have a secure communication channel (either SSL or StartTLS) and presented their own certificate. This option is disabled by default, but when enabled, the net effect will be as if the client issued a SASL EXTERNAL bind request on that connection.

This option will be ignored if the client connection is already authenticated (e.g., because it is using StartTLS but the client had already performed a bind before the StartTLS request). If the bind attempt fails, then the connection will remain unauthenticated but usable. If the client subsequently sends a bind request on the connection, then it will be processed as normal and any automatic authentication will be destroyed.

##### Steps

- Run the following `dsconfig` command.

```
$ bin/dsconfig set-connection-handler-prop \
 --handler-name "LDAPS Connection Handler" \
 --set "auto-authenticate-using-client-certificate:true"
```

## Securing the Server with Lockdown Mode

The Directory Server provides tools to enter and leave lockdown mode if the server requires a security lockdown. In lockdown mode, only users with the `lockdown-mode` privilege can perform operations, while those without the privilege are rejected. Root users have this privilege by default; other administrators can be given this privilege. Lockdown mode can also be configured as a recurring task.

The Directory Server can be manually placed into lockdown mode to perform some administrative operation while ensuring that other client requests are not allowed to access any data in the server. In addition, some configuration problems (particularly problems that could lead to inadvertent exposure of sensitive information, like an access control rule that cannot be properly parsed) cause the server to place itself in lockdown mode, so that an administrator can manually correct the problem. Lockdown mode does not persist across restarts. The directory server can be taken out of lockdown mode by using either the `leave-lockdown-mode` tool or by restarting the server. If administrators want to start a server in lockdown mode, they can use the `start-server --lockdownMode` option.

Any client request to the Directory Server in lockdown mode receives an "Unavailable" response.

### To Manually Enter Lockdown Mode

##### Steps

- Use `enter-lockdown-mode` to begin a lockdown mode.

```
$ bin/enter-lockdown-mode
```

## To Leave Lockdown Mode

### Steps

- Use `leave-lockdown-mode` to end lockdown mode.

```
$ bin/leave-lockdown-mode
```

## To Start a Server in Lockdown Mode

### Steps

- Use the `--lockdownMode` option with the `start-server` tool to start a server in lockdown mode.

```
$ bin/start-server --lockdownMode
```

## Configuring Maximum Shutdown Time

During shutdown, some database checkpointing and cleaning threads may remain active even after the default time period on systems with very large or very busy database backends. If checkpointing or cleaning is aborted prematurely, it could possibly lead to significantly longer startup times for the Directory Server. The Directory Server provides an option for administrators to set the maximum time a shutdown process should take. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

Administrators can use the `dsconfig` tool to increase the maximum shutdown time to allow database operations to complete.

### To Configure the Maximum Shutdown Time

#### Steps

- Use the `dsconfig` tool to increase the maximum shutdown time for your system. The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).

```
$ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-time:6m"
```

Remember to include the LDAP or LDAPS connection parameters (e.g., host name, port, bindDN and bindDN password) with the `dsconfig` command.

The `maximum-shutdown-time` property can also be changed using the `dsconfig` tool in interactive mode. From the main menu, select **Global Configuration**, and then select the option to display advanced properties.

## Working with Referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the Directory Server but can be accessed on another server. Referrals can be used when entries are located on another server. The Directory Server implements two types of referrals depending on the requirement.

- Referral on Update plugin.** The Directory Server provides a Referral on Update plugin to create any referrals for update requests (add, delete, modify, or modDN operations) on read-only servers. For example, given two replicated directory servers where one server is a master (read-write) and the other, a read-only server, you can configure a referral for any client update requests on the second directory server to point to the master server. If a client application sends an add request, for example, on the second directory server, the directory server responds with a referral that indicates any updates should be made on the master server. All read requests on the read-only server will be processed as normal.

- **Smart Referrals.** The Directory Server supports smart referrals that map an entry or a specific branch of a DIT to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT will send a referral to the server designated in the LDAP URL.

### Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server. LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax:

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

where

- *ldap[s]* indicates the type of LDAP connection to the Directory Server. If the Directory Server connects over a standard, non-encrypted connection, then *ldap* is used; if it connects over SSL, then *ldaps* is used. Note that any search request initiated by means of an LDAP URL is anonymous by default, unless an LDAP client provides authentication.
- *hostname* specifies the host name or IP address of the Directory Server.
- *port* specifies the port number of the Directory Server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.
- *base-dn* specifies the distinguished name (DN) of an entry in the DIT. The Directory Server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.
- *attributes* specifies those attributes for which the Directory Server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.
- *scope* specifies the scope of the search, which could be one of the following: *base* (only search the specified base DN entry), *one* (only search one level below the specified base DN), *sub* (search the base entry and all entries below the specified base DN). If no scope is provided, the server performs a base search.
- *filter* specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses +.

### Creating Referrals

You can create a smart referral by adding an entry with the `referral` and `extensibleObject` object classes or adding the object classes to a specific entry. The referral object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a DIT is located on another server.

#### To Create a Referral

##### Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the `ldapmodify` command.

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

### 3. Verify the addition by searching for a user.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4) "
```

```
SearchReference (referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

#### To Modify a Referral

##### Steps

- Use `ldapmodify` with the `manageDSAIT` control to modify the `ref` attribute on the referral entry.

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

#### To Delete a Referral

##### Steps

- Use `ldapdelete` with the `manageDSAIT` control to delete the referral entry.

```
$ bin/ldapdelete \
--control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

## Configuring a Read-Only Server

The PingDirectory Server provides a means to configure a hub-like, read-only directory server for legacy systems that require it. The read-only directory server participates in replication but cannot respond to any update requests from an external client. You can configure the Directory Server by setting the writability mode to `internal-only`, which makes the server operate in read-only mode. Read-only mode directory servers can process update operations from internal operations but reject any write requests from external clients. Because the Directory Server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a master server. The client must perform the operation again on the server named in the referral.

**Note: For Implementers of Third Party Extensions.** Many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any Directory Server using that extension will effectively respond to external update requests, even though the Directory Server is configured to operate in read-only mode, as described above. One possible workaround is to split the extension into two extensions, one for reads and one for writes, then disabling (or not deploying) the write-only extension when configuring a Directory Server in read-only mode.

#### To Configure a Read-Only Server

##### Steps

1. Install two replicating directory servers. See [Enabling Replication](#) for various ways to set up your servers.
2. On the second server, use the `dsconfig` command to set the writability mode of the server to `internal-only`.

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set writability-mode:internal-only
```

3. On the second server, use the `dsconfig` tool to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to `server1.example.com:1389`. The referral itself is defined as a plugin of type `Referral on Update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
 --type referral-on-update \
 --set enabled:true \
 --set referral-base-url:ldap://server1.example.com:1389/ \
 --set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10. The resulting message is available in the server's access log.

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

## Configuring HTTP Access for the Directory Server

Although most clients communicate with the PingDirectory Server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP. Ping Identity offers an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

### Configuring HTTP Servlet Extensions

To use the HTTP connection handler, you must first configure one or more servlet extensions. Servlet extensions are responsible for obtaining Java servlets (using the Java Servlet 3.0 specification as described in JSR 315) and registering them to be invoked using one or more context paths. If you plan to deploy the SCIM extension, then you should follow the instructions in Chapter 24, "*Managing the SCIM Servlet Extension*." For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

### Web Application Servlet Extensions

A Web application may be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

When deploying a Web application from a directory, you may specify the location of the `web.xml` deployment descriptor if it is not in the standard location. You may also specify the directory used by the server for temporary files. At runtime the web application has access to the server classes.

### Java-based Servlet Extensions

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation. Then, install it using the `manage-extension` tool as follows:

```
$ bin/manage-extension --install/path/to/extension.zip
```

The Java-based extension may then be configured for use in the server using `dsconfig` or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

**Note:** Web Application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts may arise from use of different versions of commonly used jars or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources which may require a dedicated Java Virtual Machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log may also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

### Groovy-Scripted Extensions

For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory (based on the package for those scripts) below the `lib/groovy-scripted-extensions` directory. Then, create a new Groovy Scripted HTTP Servlet Extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

### Configuring HTTP Operation Loggers

Servlet extensions may write error log messages in the same way as any other kind of server component, but interaction with HTTP clients will not be recorded in the server access log. However, if a servlet extension performs internal operations to interact with data held in the directory server, then those operations may be captured in the access log. To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in a format like the following:

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600] "GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request.
- The RFC 1413 (ident) identity of the client. Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity will always be represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication, or a dash to indicate that the request was not authenticated.
- The time that the request was received.
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used.
- The integer representation of the HTTP status code for the response to the client.
- The number of bytes included in the body of the response to the client.

To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object, specifying the path and name for the active log file to be written and the rotation and retention policies that should be used to manage the log files. In general, properties for Common Log File HTTP Operation Log Publisher objects have the same meaning and use as they do for other kinds of loggers.

You can use the Server SDK to create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types.

## Example HTTP Log Publishers

When troubleshooting HTTP Connection Handler issues, administrators should first look at the logs to determine any potential problems. The following section shows some `dsconfig` commands and their corresponding log files.

**Default Configuration Example.** You can configure a default detailed HTTP Log Publisher with default log rotation and retention policies as follows:

```
$ bin/dsconfig create-log-publisher \
 --publisher-name "HTTP Detailed Access Logger" \
 --type detailed-http-operation \
 --set enabled:true \
 --set log-file:logs/http-detailed-access \
 --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --set "rotation-policy:Size Limit Rotation Policy" \
 --set "retention-policy:File Count Retention Policy" \
 --set "retention-policy:Free Disk Space Retention Policy" \
 --set "retention-policy:Size Limit Retention Policy"
```

The corresponding log file provides access information below. The log message contains the following elements:

- The time that the request was received.
- The request ID issued by the client, including the IP address, port, HTTP method, and URL.
- The authorization type, request content type, and status code.
- The response content length.
- The redirect URI.
- The response content type.

The HTTP log file is shown as follows:

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604 from="10.5.1.10:53269"
method="GET" url="https://10.5.1.129:443/Gimel/Users/

**Configuration with Request/Response Header Names and Values.** The following example adds request/response header names and values, including the "Content-Type" request header, which is normally suppressed by default.

```
$ bin/dsconfig set-log-publisher-prop \
 --publisher-name "HTTP Detailed Access Logger" \
 --set log-request-headers:header-names-and-values \
 --remove suppressed-request-header-name:Content-Type \
 --set log-response-headers:header-names-and-values
```

The following is a log example of a query request by a SCIM Server using the property, `scim-query-rate`. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, http method, content type, connection, user agent.
- The response header for the access-control credentials.

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307 from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?attributes=username,title,

```

## Configuring HTTP Connection Handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire Directory Server from starting. The Directory Server's **start-server** tool will output any errors to the error log. This allows the Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include:

- **listen-address.** Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.

- **listen-port.** Specifies the port on which the connection handler will listen for requests from clients. Required.
- **use-ssl.** Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.
- **http-servlet-extension.** Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.
- **http-operation-log-publisher.** Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.
- **key-manager-provider.** Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.
- **trust-manager-provider.** Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.
- **num-request-handlers.** Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.
- **web-application-extension.** Specifies the Web applications to be hosted by the server.

## To Configure an HTTP Connection Handler

### About this task

An HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, an HTTP log publisher. The HTTP servlet extension and log publisher must be configured prior to configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

### Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the `ExampleHTTPServletExtension` in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
 --extension-name "Hello World Servlet" \
 --type third-party \
 --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
 --set "extension-argument:path=/" \
 --set "extension-argument:name=example-servlet"
```

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
 --publisher-name "HTTP Common Access Logger" \
 --type common-log-file-http-operation \
 --set enabled:true \
 --set log-file:logs/http-common-access \
 --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
 --set "rotation-policy:Size Limit Rotation Policy" \
 --set "retention-policy:File Count Retention Policy" \
 --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
 --publisher-name "HTTP Detailed Access Logger" \
```

```
--type detailed-http-operation \
--set enabled:true \
--set log-file:logs/http-detailed-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like `listen-port`, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
--handler-name "Hello World HTTP Connection Handler" \
--type http \
--set enabled:true \
--set listen-port:8443 \
--set use-ssl:true \
--set "http-servlet-extension:Hello World Servlet" \
--set "http-operation-log-publisher:HTTP Common Access Logger" \
--set "http-operation-log-publisher:HTTP Detailed Access Logger" \
--set "key-manager-provider:JKS" \
--set "trust-manager-provider:JKS"
```

4. By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to TRUE by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

## To Configure an HTTP Connection Handler for Web Applications

About this task

Steps

1. Create the Web application servlet extension.

```
$ bin/dsconfig create-web-application-extension \
--extension-name "Hello Web Application" \
--set "base-context-path:/hello-app" \
--set "document-root-directory:/opt/hello-web-app"
```

2. By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to TRUE by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

## HTTP Correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which may be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be challenging, as log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID may also be passed to the LDAP subsystem. For the SCIM 1,

Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest`'s `com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

### Configure HTTP Correlation ID Support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

#### Steps

- To enable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set use-correlation-id-header:false
```

#### Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to "X-Request-Id."

```
$ dsconfig set-connection-handler-prop \
 --handler-name "HTTPS Connection Handler" \
 --set correlation-id-response-header:X-Request-Id
```

#### Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that may be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
 --set correlation-id-request-header:X-Request-Id \
 --set correlation-id-request-header:X-Correlation-Id \
 --set correlation-id-request-header:Correlation-Id \
 --set correlation-id-request-header:X-Amzn-Trace-Id
```

#### HTTP Correlation ID Example Use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
```

```

Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

{
 "_dn": "uid=user.86,ou=People,dc=example,dc=com",
 "_links": {

## Domain Name Service (DNS) Caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

- **network-address-cache-ttl** – Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
- **network-address-outage-cache-enabled** – Caches host name-to-IP address results in the event of a DNS outage. This is set to true by default, meaning name resolution results are cached. Unexpected service interruptions may occur during planned or unplanned maintenance, network outages or an

infrastructure attack. This cache may allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays due to unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` and/or `options single-request` in `/etc/resolv.conf`.
- If IPv6 requests specifically are causing issues, Add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

## IP Address Reverse Name Lookups

PingDirectory Server does not explicitly perform numeric IP address-to-host name lookups. However, address masks configured in Access Control Lists (ACLs), Connection Handlers, Connection Criteria, and Certificate handshake processing may trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- `ACL dns`: bind rules under *Managing Access Control* (Directory Server and Directory Proxy Server)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication* (Directory Server)
- `Connection Criteria`: *Restricting Server Access Based on Client IP Address* (Directory Server and Directory Proxy Server)
- `Connection Handlers`: restrict server access using Connection Handlers (Configuration Reference Guide for all servers)

## Configuring Traffic Through a Load Balancer

If a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, then it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address must be recorded to the trace log, enable `X-Forwarded-*` handling in both the intermediate HTTP server and PingDirectory Server. For PingDirectory Servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP), and set `use-forwarded-headers` to `true`.
- When `use-forwarded-headers` is set to `true`, the server will use the client IP address and port information in the `X-Forwarded-*` headers instead of the address and port of the entity that's actually sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

On the load balancer, configure settings to provide the `X-Forwarded-*` information, such as `X-Forwarded-Host`:. See the product documentation for the device type.

## Working with the Referential Integrity plugin

Referential integrity is a plugin mechanism that maintains the DN references between an entry and a group member attribute. For example, if you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the Directory Server.

The Referential Integrity plugin is disabled by default. When enabled, the plugin performs integrity updates on the specified attributes (for example, `member` or `uniquemember`) after a delete, modify DN, or a rename (i.e., subordinate modifyDN) operation is logged to the `logs/referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Three important points about the Referential Integrity plugin:

- All specified attributes that are configured for Referential Integrity must be indexed.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas; therefore, you must manually enable the plugin on each replica.
- The plugin settings must also be identical on all machines.
- Subtree delete operations are not allowed if the referential integrity plugin is enabled and configured to operate in synchronous mode. It must be configured to operate in asynchronous mode (by specifying a nonzero update interval) if subtree delete operations will be performed.

## To Enable the Referential Integrity plugin

### Steps

1. Determine the attributes needed for your system. By default, the `member` and the `uniquemember` attributes are set for the plugin.
2. Run the `dsconfig` tool to enable the Referential Integrity plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
--set enabled:true
```

## Working with the Unique Attribute plugin

The Unique Attribute plugin is used to enforce uniqueness constraints on the values of one or more attributes across a portion of the Directory Server. The plugin checks for uniqueness prior to an add, modify, or modify DN request and will instruct the server to reject the request if a constraint violation is found.

The plugin is disabled by default as it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, but only on new ADD, MODIFY, or MODDN operations. However, administrators can use the `identify-unique-attribute-conflicts` tool to ensure that no such conflicts exist in the data.

**i Important:** All attributes for which uniqueness should be enforced should be indexed for equality in all backends. The LDAP SDK uniqueness request control can be used for enforcing uniqueness on a per-request basis. See the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control. See the ASN.1 specification to implement support for it in other APIs.

Attribute uniqueness can be enforced in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a Directory Proxy Server. In such environments, all servers should have identical uniqueness configurations. Note that it is not possible to *completely* prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts will be detected after the changes have been replicated and will trigger administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers (e.g., environments that use entry balancing or that store different portions of the DIT on different servers), you can implement the Global Uniqueness Attribute plugin on the Directory Proxy Server, instead of enabling the attribute uniqueness plugin on the Directory Server. For more information, see the *PingDirectoryProxy Server Administration Guide*.

## To Enable the Unique Attribute plugin

### Steps

1. Determine which attributes must be unique in your data.
2. Run the `dsconfig` tool to enable the plugin. By default, the plugin type property is set to `postsynchronizationadd, postsynchronizationmodify, postsynchronizationmodifydn,`

`preoperationadd`, `preoperationmodify`, and `preoperationmodifydn`. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option. For example, use `--set plugin-type:preoperationadd` with the following command if you only want to check for attribute uniqueness prior to ADD operation.

```
$ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
 --set enabled:true
```

## Working with the Purge Expired Data plugin

The Purge Expired Data plugin is used to delete expired entries or attribute values, and cleanup expired PingFederate Persistent Access Grants. When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. It is recommended that the Purge Expired Data plugin be enabled on multiple servers in a topology. One server can be configured to delete data, while others can be searching for expired data.

The Purge Expired Data plugin is created and configured with the `dsconfig` tool. Configuration options include the base DN and filter, the items to be purged, how to identify expired data, and the frequency for polling and purging. The search for expired data must be indexed. An alarm is raised if the server purging data falls behind the configured `max-updates-per-second`. Monitoring information is available in the Admin Console, or `cn=monitor`.

### To Configure the Purge Expired Data plugin for Expired Entries

About this task

This example deletes all unverified account entries that have not been accessed in the past eight weeks. They could be accounts that potential customers started to create through an application's registration process, but then did not complete. The phone number or email address that was provided during registration was not verified, and should be allowed to be used by another account. The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

Steps

1. If necessary, enable the Last Access Time plugin:

```
$ bin/dsconfig set-plugin-prop \
 --plugin-name "Last Access Time" \
 --set enabled:true
```

2. The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering. An index on that attribute must be created:

```
$ bin/dsconfig create-local-db-index \
 --backend-name userRoot \
 --index-name ds-last-access-time \
 --set index-type:ordering
```

3. If there is data present in the directory, rebuild the index:

```
$ bin/rebuild-index \
 --baseDN dc=example,dc=com \
 --index ds-last-access-time
```

4. Create the plugin that purges account entries `objectclass=account` that are not verified `verified=false` after eight weeks of inactivity:

```
$ bin/dsconfig create-plugin \
 --plugin-name "Purge Old Unvalidated Accounts" \
 --type purge-expired-data \
 --set enabled:true \
```

```
--set datetime-attribute:ds-last-access-time \
--set "expiration-offset:8 w" \
--set "filter:(&(objectClass=account)(verified=false))"
```

## To Configure the Purge Expired Data plugin for Expired Attribute Values

### About this task

The Purge Expired Data plugin can also be used to delete values of an attribute that have expired. For example, an application may track information about an employee's session, but the session should expire after 24 hours. There may be multiple active sessions tracked across different devices, with session information that looks like this:

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
"ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2
like Mac OS X; en-us)
AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367
Safari/531.21.10",
"creationTime" : "2018-03-31T13:10:15Z" }
```

In this example, the LDAP attribute is `sessionInfo`, and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

To purge the JSON attribute values after 24 hours, rather than the entire session entry, the plugin can be created with the following steps.

### Steps

1. Create an index on the `creationTime` field of the `sessionInfo` attribute:

```
$ bin/dsconfig create-json-attribute-constraints \
--attribute-type sessionInfo \
--set enabled:true
```

```
$ bin/dsconfig create-json-field-constraints \
--attribute-type sessionInfo \
--json-field creationTime \
--set index-values:true \
--set value-type:string
```

2. Create and enable the plugin:

```
$ bin/dsconfig create-plugin \
--plugin-name "Purge Old Session Data Plugin" \
--type purge-expired-data \
--set enabled:true \
--set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
--set datetime-attribute:sessionInfo \
--set datetime-format:custom \
--set datetime-json-field:creationTime \
--set "expiration-offset:1 d" \
--set purge-behavior:delete-json-attribute-values
```

## Configuring Uniqueness Across Attribute Sets

Attribute uniqueness can be configured across a set of attributes using the `multiple-attribute-behavior` property. The `multiple-attribute-behavior` property can take the following values:

- **unique-within-each-attribute** - If multiple attributes are specified, then uniqueness will be enforced for all values of each attribute, but the same value may appear in different attributes (in the same entry or in different entries). For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin

to have `--set "multiple-attribute-behavior:unique-within-each-attribute"` and add:

- An entry with a `telephoneNumber` value that matches the `telephoneNumber` attribute in the existing entry, then the add request will fail.
- An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then that too will fail.
- An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in the existing entry, then the add request will succeed.
- **unique-across-all-attributes-including-in-same-entry** - If multiple attributes are specified, then uniqueness will be enforced across all of those attributes, so that if a value appears in one of those attributes, that value may not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries. For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"` and add:
  - An entry with a `telephoneNumber` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then the add request will fail.
  - An entry with a `mobile` value that matches the `mobile` attribute in an existing entry, then that too will fail.
  - An entry with a `mobile` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then that will fail.
  - An entry with a `telephoneNumber` value (e.g., 123-456-7891) that matches the `mobile` attribute in an existing entry, then that too will fail.
  - An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in an existing entry, then the add request will fail.
- **unique-across-all-attributes-except-in-same-entry** - If multiple attributes are specified, then uniqueness will be enforced across all of those attributes, so that if a value appears in one of those attributes, that value may not be present in any of the listed attributes in other entries. However, the same value may appear in multiple attributes in the same entry. For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"` and add:
  - An entry with a `telephoneNumber` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then the add request will fail.
  - An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then that too will fail.
  - An entry with a `mobile` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then that will fail.
  - An entry with a `telephoneNumber` value (e.g., 123-456-7891) that matches the `mobile` attribute in an existing entry, then that will fail.
  - An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in an existing entry, then the add request will succeed.

## To Enable Uniqueness Across Attribute Sets

### Steps

- Use `dsconfig` to configure the UID Unique Attribute plugin to apply across multiple attributes. The `multiple-attribute-behavior` property is set to `"unique-within-each-attribute"`, which indicates that uniqueness will be enforced for all values of each attribute (e.g., `telephoneNumber=123-456-7890` and `mobile=123-456-7891`), but the same value (e.g., either

123-456-7890 or 123-456-7891) may appear in different attributes in the same entry or in different entries.

```
$ dsconfig create-plugin \
 --plug-in "Unique telephoneNumber and mobile" \
 --type "unique-attribute" \
 --set "enabled:true" \
 --set "type:telephoneNumber" \
 --set "type:mobile" \
 --set "multiple-attribute-behavior:unique-within-each-attribute" \
 --no-prompt
```

## Working with the Last Access Time plugin

The Last Access Time plugin is used to record the timestamp of the last activity targeting an entry. The plugin updates the `ds-last-access-time` attribute of the entry when it is accessed by an add, bind, compare, modify, modify DN, or search operation.

The plugin can be used with the Directory Server Uncached Attribute Criteria, or any application that needs to determine how recently an entry has been accessed. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The `max-search-result-entries-to-update` property also prevents mass updates of `ds-last-access-time` when searches contain many results, but may not reflect end-user access. Consider the following when using this plugin:

- The plugin should be enabled on all servers that have the same configuration.
- An updated `ds-last-access-time` attribute value is replicated like any other change to an entry.
- The `ds-last-access-time` attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The `ds-last-access-time` value format is `yyyyMMddHHmmss.SSS'Z'`, which provides millisecond-level accuracy, such as `20131207144135.821Z`.
- The `ds-last-access-time` attribute can be indexed with a local database index. The ordering index type is the most relevant, but may require a higher index entry limit (default is 4000) to accommodate searches for entries that have not been accessed in a long period of time. The ordering index type, with a short time range or high index entry limit, will result in indexed search results for requests such as `(ds-last-access-time>=20131207144135.821Z)`.

**Important:** For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

## Working with the Pass-Through Authentication plugin

The Pass-Through Authentication plugin is used to delegate bind operations to remote LDAP servers by forwarding simple bind requests to an external LDAP server, including Active Directory. The plugin can be configured to attempt a local bind, to set or update a local password, and to bypass local password policies to ensure remote passwords are migrated.

Consider the following points when using the Pass-Through Authentication plugin:

- Enable the plugin on all servers that use the same configuration.
- Remote servers that accept a forwarded bind request might require connection security, such as a secure StartTLS or LDAPS TLS connection.
- Consider the manner in which password changes and resets are handled. Updating a password in PingDirectory Server might result in divergent passwords between the local and remote server. If necessary, use PingDataSync Server to synchronize passwords between servers.
- The plugin updates local passwords only if the forwarded simple bind is successful. Expired passwords on a remote server might return an invalid credentials error and cause the overall bind operation to fail.

- Multiple remote servers can be specified. The `server-access-mode` property determines whether the servers are accessed in `round-robin`, `failover-on-unavailable`, or `failover-on-any-failure` mode. The default server access mode is `round-robin`.
- The `update-local-password` property indicates whether the local password value requires updating to the value used in the bind request, in the event that the local bind fails but the forwarded bind succeeds. To update passwords, a local entry must previously exist.
- The `allow-lax-pass-through-authentication-passwords` property indicates whether updates to the local password value accept passwords that do not meet local password policy requirements.
- The `connection-criteria` property specifies a set of connection criteria that must match the client associated with the local bind request for the bind to be forwarded to the remote server.
- The `request-criteria` property specifies a set of request criteria that must match the local bind request or a local target entry for the bind to be forwarded to the remote server.
- The `dn-map` property specifies one or more DN mappings that can be used to transform bind DN's before attempting to forward the bind to remote servers.
- The `search-base-dn` property is used when searching for a remote user entry by using a filter constructed from the pattern that the `search-filter-pattern` property defines. A DN map and search filter pattern cannot both be configured. If neither a DN map nor a search filter pattern is defined, user entries are expected to have the same DN in the local server and the remote servers.

### Pass-Through Authentication plugin for the PingOne for Customers Service

Although PingDataSync Server supports bidirectional synchronization between PingDirectory Server and the PingOne for Customers service, it can propagate password changes from the PingOne for Customers service into PingDirectory Server only when using the Pass-Through Authentication plugin for PingOne for Customers Service.

This plugin features a mandatory `try-local-bind` configuration property that enables one of the following modes of operation:

- When `try-local-bind` is `true`, the plugin attempts to authenticate locally first. It sends a request to the PingOne for Customers service only if the local bind attempt fails.
- When `try-local-bind` is `false`, the plugin attempts to authenticate with the PingOne for Customers service first.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin for PingOne for Customers Service.

| Property                         | Description                                                                                                                     | Required | Default |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------|----------|---------|
| <code>api-url</code>             | URL that PingDirectory Server uses when communicating with the PingOne for Customers service.                                   | Yes      | NA      |
| <code>auth-url</code>            | URL that PingDirectory Server uses to authenticate to the PingOne for Customers service.                                        | Yes      | NA      |
| <code>oauth-client-id</code>     | OAuth client ID that PingDirectory Server uses to authenticate to the PingOne for Customers service.                            | Yes      | NA      |
| <code>oauth-client-secret</code> | OAuth client secret that PingDirectory Server uses to authenticate to the PingOne for Customers service.                        | Yes      | NA      |
| <code>environment-id</code>      | Identifier for the PingOne for Customers environment that contains the users for whom pass-through authentication is attempted. | Yes      | NA      |

| Property                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Required | Default                                 |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-----------------------------------------|
| <b>included-local-entry-base-dn</b> | <p>Set of base DN's for local user entries for whom pass-through authentication might be attempted.</p> <p>If this value is set, only users who exist below a specified base DN allow their authentication attempts to be passed through to the PingOne for Customers service.</p>                                                                                                                                                                                                                                                                                                 | No       | All public naming contexts (if not set) |
| <b>connection-criteria</b>          | <p>Reference to a connection criteria object that can be used to identify the bind requests to pass through to the PingOne for Customers service, based on the server's knowledge of the client (predominantly expected to be the address, protocol, and security level).</p> <p>If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.</p>                                                                                                                                         | No       | NA                                      |
| <b>request-criteria</b>             | <p>Reference to a request criteria object that can be used to identify the bind requests to pass through to the PingOne for Customers service, based on the contents of the request.</p> <p>If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.</p>                                                                                                                                                                                                                             | No       | NA                                      |
| <b>try-local-bind</b>               | <p>Indicates whether PingDirectory Server tries to process the bind locally before forwarding the bind request to the PingOne for Customers service.</p> <p>If this value is set to <b>true</b> and the bind succeeds locally, PingDirectory Server does not make a request to the PingOne for Customers service. If this value is set to <b>false</b>, PingDirectory Server ignores local credentials and attempts to authenticate only to the PingOne for Customers service.</p>                                                                                                 | Yes      | <b>True</b>                             |
| <b>override-local-password</b>      | <p>Indicates whether PingDirectory Server attempts to bind to the PingOne for Customers service if the local account has a password.</p> <p>This property is used if <b>try-local-bind</b> is <b>true</b>. If it has a value of <b>false</b>, the plugin attempts to authenticate to the PingOne for Customers service only if the local user account does not have a password.</p> <p>If the local bind attempt fails while this value is set to <b>true</b>, the server tries to authenticate to the PingOne for Customers service even if the local account has a password.</p> | Yes      | <b>True</b>                             |

| Property                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Required | Default            |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|--------------------|
| <code>update-local-password</code>                           | <p>Indicates whether PingDirectory Server attempts to set the password for the local user account, regardless of whether one is already set, if the local authentication attempt fails but the attempt to authenticate with the PingOne for Customers service succeeds.</p> <p>This property is used only if <code>try-local-bind</code> is <code>true</code>.</p> <p>If the on-premise PingDirectory Server is the authoritative source for passwords, set this property to <code>false</code> and configure PingDataSync Server to synchronize password changes from PingDirectory Server into the PingOne for Customers service. If the passwords differ, either the local password or the password for the PingOne for Customers service allows the user to authenticate.</p> <p>If the PingOne for Customers service is the authoritative source for passwords, set this property to <code>true</code>. To ensure that a pass-through attempt to the PingOne for Customers service does not override local changes, make all password changes in the PingOne for Customers service.</p> | Yes      | <code>False</code> |
| <code>allow-lax-pass-through-authentication-passwords</code> | <p>Indicates whether PingDirectory Server bypasses the normal password-validation process when setting the local password from the PingOne for Customers service. This property is used only when both <code>try-local-bind</code> and <code>update-local-password</code> are <code>true</code>.</p> <p>If this value is <code>true</code> when a local bind attempt fails but the authentication attempt with the PingOne for Customers service succeeds, the user's password is updated locally even if a local attempt to change the password to the same value would be rejected because the password is considered too weak.</p> <p>If this value is <code>false</code>, pass-through authentication succeeds if the authentication with PingOne for Customers service succeeds. However, the password for the PingOne for Customers service does not replace the local password.</p>                                                                                                                                                                                                   | Yes      | <code>True</code>  |
| <code>ignored-password-policy-state-error-condition</code>   | <p>Set of zero or more password policy state error conditions that are ignored for pass-through authentication.</p> <p>For a list of values and their descriptions, see the following table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | No       | NA                 |

| Property                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Required | Default |
|--------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|---------|
| <code>user-mapping-local-attribute</code>        | <p>Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne for Customers account.</p> <p>This property must include the same number of values as the <code>user-mapping-remote-json-field</code> property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an AND search in the PingOne for Customers service to locate the user account with all the values in the corresponding fields.</p> <p>The <code>entryDN</code> attribute can be used to represent the DN of the local entry.</p> | Yes      | NA      |
| <code>user-mapping-remote-json-field</code>      | <p>The name of a PingOne for Customers field that is used to map local user entries to the corresponding PingOne for Customers account.</p> <p>This property must include the same number and order of values as the <code>user-mapping-local-attribute</code> property.</p>                                                                                                                                                                                                                                                                                                                                                                | Yes      | NA      |
| <code>additional-user-mapping-scim-filter</code> | <p>SCIM filter that is included in the search and is used to identify the PingOne for Customers account that corresponds to the local user entry.</p> <p>If a value is provided for this property, it is ANDed with the SCIM filter that was created to map the local user entry to a PingOne for Customers account. If a value is not provided for this property, no additional filter is used.</p>                                                                                                                                                                                                                                        | No       | NA      |

The following table identifies the values that can be used with the optional configuration property `ignored-password-policy-state-error-condition`, and describes the scenarios in which a user is still permitted to bind by using pass-through authentication.

| Property                                        | Scenario in which a user can still bind by using pass-through authentication                                                                              |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>temporarily-locked-due-to-failures</code> | The account is locked temporarily because of too many failed attempts.                                                                                    |
| <code>permanently-locked-due-to-failures</code> | The account is locked permanently because of too many failed attempts.                                                                                    |
| <code>locked-due-to-idle-interval</code>        | The account is locked because the user has not authenticated recently.                                                                                    |
| <code>locked-due-to-maximum-reset-age</code>    | The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame. |
| <code>password-is-expired</code>                | The password is expired.                                                                                                                                  |

## Supporting Unindexed Search Requests

By default, the Directory Server denies all unindexed search requests, except for those issued by the bind DN's that have the unindexed-search privilege. This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the unindexed-search privilege to allow any client to perform an unindexed search. To do this, set the disabled-privilege global configuration property to unindexed-search as follows:

```
$ bin/dsconfig set-global-configuration-prop \
 --set disabled-privilege:unindexed-search
```

If you choose to allow unindexed searches, you may want to cap the maximum number of concurrent unindexed search requests using the maximum-concurrent-unindexed-searches global configuration property. You configure this property using **dsconfig** as follows:

```
$ bin/dsconfig set-global-configuration-prop \
 --set maximum-concurrent-unindexed-searches:2
```

You can limit unindexed search privileges for particular clients using the allow-unindexedsearches property of the Client Connection Policy. For more information about configuring Client Connection Policies, see "Configuring Client Connection Policies".

## Sun/Oracle Compatibility

For companies that are migrating from a Sun/Oracle server to the PingDirectory Server, the PingDirectory Server provides a **dsconfig** batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to a Sun/Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the Directory Server's configuration with the necessary **dsconfig** commands. Simply uncomment the example commands listed in the file, and then run the **dsconfig** command specifying the batch file. Note that this batch file is not comprehensive and must be used together with the **migrate-sun-ds-config** tool, located in the `bin` folder (or `bat` folder for Windows systems) during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Sun/Oracle server to a Ping Identity server.

Another useful tool is the **migrate-ldap-schema** tool in the `bin` folder (or `bat` folder for Windows systems), which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server will be added to the targeted instance or written to a schema file.

### To Configure the Directory Server for Sun/Oracle Compatibility

#### Steps

1. From the Directory Server server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder. You can use a text editor to view the file.
2. Read the file completely.
3. Apply any changes to the file by removing the comment symbol at any **dsconfig** command example, and then applying the **dsconfig** command specifying the batch file.

```
$ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
 --bindPassword "password" --batch-file /path/to/dsconfig/file
```

4. Run the **migrate-ldap-schema** tool to move the schema definitions on the source server to the destination Ping Identity server.

```
$ bin/migrate-ldap-schema
```

5. Next, run the `migrate-sun-ds-config` tool to see what differences exist in the Ping Identity configuration versus the Sun/Oracle configuration. On the PingDirectory Server, run the following command:

```
$ bin/migrate-sun-ds-config
```

6. Test the server instance for further settings that may not have been set with the batch file, the `migrate-ldap-schema` tool, or the `migrate-sun-ds-config` tool.
7. If you notice continued variances in your configuration, contact your authorized support provider.

## Configuring Soft Deletes

---

The PingDirectory Server (version 3.2.4 or later) supports a *soft-delete* feature that preserves a deleted entry's attribute and uniqueness characteristics to allow it to be undeleted or permanently removed at a later date.

This chapter introduces the following topics:

### About Soft Deletes

The standard implementation of an LDAP server allows for adding, renaming, modifying, searching, comparing, and deleting one or more entries. The DELETE operation is, by specification, a destructive operation that permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. During the DELETE operation, any associations such as references and group memberships are severed to reflect the entry that is removed. Meta attributes like operational attributes, which may be unique to an entry like `entryUUID`, will be lost or be different if the same entry is re-added to the Directory Server.

There are cases, however, where a company may want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company may want to retain account and subscriber entries for their users (e.g., customers, employees, or partners) who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, may be tracked and recovered while a user is deleted or when the user returns as an active customer.

To facilitate this use case, the Directory Server supports a feature called *soft deletes*, which preserves a deleted entry's attributes and entry uniqueness characteristics to allow the entry to be undeleted or permanently removed at a later date. A delete request may result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class, `ds-soft-delete-entry`, to the entry, which saves the entry in a hidden state. All active references and group memberships are then removed. Once in this hidden state, soft-deleted entries are inaccessible to clients under normal operating conditions. Only clients with the `soft-delete-read` privilege will be allowed to interact with soft-deleted entries.

To allow soft deletes, the Directory Server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted but a different John Smith was added to the user accounts system, both entries could reside in the DIT without conflict: one in a soft-deleted state; the other, in an active state. The Directory Server extends this capability further by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an Undelete operation. However, the same uniqueness constraints that apply when adding a new user to the Directory Server are enforced when a soft-deleted entry is undeleted. Returning to the previous example, John Smith was soft deleted but a different John Smith with the same `uid` as the original John Smith was added later to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators will need to modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular DELETE operation on it. This operation, called a *hard delete*, permanently removes a soft-deleted entry from the server. Also, note that you can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The Directory Server provides tool arguments that can use the Soft Delete Request Control, a Hard Delete Request Control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating directory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, it is highly recommended that all servers in the replication cluster support Soft Deletes and have identical Soft Delete configurations.

## General Tips on Soft Deletes

There are some general tips about soft deletes that administrators should be aware of:

- **LDAP SDK and Server SDK.** The LDAP SDK and Server SDK both fully supports soft-deletes.
- **Possible Performance Impact for Searching Regular Entries and Soft-Deleted Entries.** There is little performance difference between retrieving a regular entry and a soft-deleted entry, respectively. However, there may be a performance impact when a search operation has to match criteria (such as, `uid=john.smith`) for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it may take the server a little more time to retrieve and try to match the criteria before it can return the results.
- **Soft Delete for Uncached Attributes and Entries.** The soft delete feature fully supports uncached attributes and uncached entries. See the section on [Uncached Attributes and Entries](#) for more information about the feature.
- **Soft Delete for Leaf Nodes Only.** Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- **Attempting to Soft-Delete a Soft-Deleted Entry Fails.** There are two available state options for soft-deletes: administrators can permanently delete a soft-deleted entry or undelete the entry. An administrator cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.
- **Soft-Deleted Users Have No Privileges.** Soft-deleted users do not have the ability to bind to the Directory Server or have authentication access. They cannot change their passwords and cannot undelete themselves. Also, soft-deleted entries cannot be used as an authorization identity using the proxied authorization or immediate client control. It is important to note that the soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry will retain the same privileges it originally had before being soft deleted. (One possible exception to this are those privileges assigned by virtual attributes that no longer match the newly-undeleted entry; those entries do not retain their original privileges.)
- **Soft-Deleted Entries Not Accessible by Other Means.** Soft-deleted entries may not be accessible from alternate access methods like SCIM.
- **Soft-Deleted Entries Can Be Modified but Not Renamed.** Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrators has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a MODIFY DN operation will result in an `UNWILLING_TO_PERFORM` result code.
- **Replication.** Replication will have access to the LDAP operations with Soft Delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers then replicated, this results in a replication conflict. For maximum compatibility, it is highly recommended that all servers in a replication cluster support Soft Deletes and have identical Soft Delete configuration.

- **Transactions.** Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- **Soft-Deletes Through the Directory Proxy Server .** There is no special configuration steps to configure Soft Deletes on the Directory Proxy Server. The soft-deleted entry is routed directly to the underlying Directory Server. There is one exception: in an entry-balancing deployment, the Directory Proxy Server is responsible for routing the soft-deleted entry to the Directory Server containing the originally soft-deleted item. Also, as with standard entry-balanced deployments, it is not possible to undelete (using MODDN) an entry to a different Directory Server.
- **Export-LDIF.** The default behavior is to include soft-deleted entries as part of the `export-ldif` operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- **Proxied Authorization.** The Soft Delete feature can be used with users who have proxied authorization privileges.
- **Ignored by Data Sync Server Sync Pipes.** For customers using the PingDataSync Server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular DELETE, and an actual undelete operation appears in the changelog as a regular ADD.
- **Referential Integrity Plugin Does Not Restore Membership.** References to a deleted DN are not restored by the referential integrity plugin upon undeletion of a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin will remove this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin will not add the entry back to the group.
- **Criteria-Selected or Explicitly-Requested Purging of Soft Deletes.** The Soft Delete Policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries` that performs purging of soft deleted entries. See the section on [Configuring Soft-Delete Automatic Purging](#).
- **Assigning Access to Controls to Non-Root Users Administrators.** By default, the root user account (e.g., `cn=Directory Manager`) has access to all of the controls needed to run the Soft Delete operations. For non-root users, you must grant access to these Soft Delete controls using access control rules. An example is shown in step 1 of the section, [To Configure Soft Deletes as a Global Configuration](#). The following Soft Delete Controls are available to non-root users:
  - **Soft Delete Request Control.** Allows the user to perform a soft delete operation. The OID for the control is 1.3.6.1.4.1.30221.2.5.20.
  - **Soft Delete Response Control.** Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.
  - **Hard Delete Request Control.** Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.
  - **Undelete Request Control.** Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.
  - **Soft-Deleted Entry Access Request Control.** Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24. Note that a bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the Soft-Deleted Entry Access Request Control. For example, if a user can successfully run `dump-dns` or `ldap-diff`, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents via the output of one of those tools.

## Configuring Soft Deletes on the Server

Soft deletes are configured on the Directory Server in several ways:

- **Using a Soft-Delete Policy and Global Configuration Property.** You can configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete

requests. To enter a soft delete request, the `ldapmodify` or `ldapdelete` command requires the `--useSoftDelete` option. A delete request that does not have the `--useSoftDelete` option is treated as a hard delete, which permanently removes the entry.

- **Using Connection Criteria.** You can configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria will have their deletes processed as soft deletes.
- **Using Request Criteria.** You can configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria will have their deletes processed as soft deletes. Note that you can define both connection criteria and request criteria. Both criteria are exclusive and can exist within a soft-delete policy. In this case, the connection criteria is processed first, then the request criteria.

### Configuring Soft Deletes as a Global Configuration

You can configure the soft delete feature by creating a soft-delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft-delete requests.

This configuration setting requires that the `--useSoftDelete` option be used together with the `ldapmodify` or `ldapdelete` commands to send the delete using the Soft Delete Request Control. Without the `--useSoftDelete` option, any delete will be processed as a hard delete.

### To Configure Soft Deletes as a Global Configuration

#### Steps

- Configure a soft delete policy using the `dsconfig` command. The soft delete configuration option requires a soft-delete policy, which enables the feature on the server. This is a required step.

```
$ bin/dsconfig create-soft-delete-policy \
 --policy-name default-soft-delete-policy
```

- Configure the soft delete as a global configuration property using the `dsconfig` command. The command sets up the soft-delete controls necessary to send them as a request. This is a required step.

```
$ bin/dsconfig set-global-configuration-prop \
 --set soft-delete-policy:default-soft-delete-policy
```

#### Results

After a successful modification, the server issues a warning that soft deletes are not enabled and that administrative action may be needed to prune older soft-deleted entries if resources are limited.

### Configure a User to Use Soft or Hard Delete Controls

#### About this task

To allow a user to manipulate soft deletes, the user must be able to use the appropriate controls. By default, only the Directory Manager has these controls. The user also needs to have the `soft-delete-read` privilege assigned. ACIs are required to allow this user to:

- Modify target entries.
- Use the soft delete/undelete controls.
- Use the soft deleted entry access control (to modify soft deleted entries).
- Use the hard delete request control to permanently delete an soft-deleted entry.

#### Steps

- For example, take the `uid=admin,dc=example,dc=com` user that is installed with the sample user data during setup. This user already has an ACI in place giving it access to user entries:

```
(targetattr="*") (version 3.0; aci "Grant full access for the admin user";
```

```
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

- The other ACIs need to be added to the base suffix (or other point in the DIT as required to possibly restrict the scope):

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; acl "Allow admins to use the Soft Delete Request Control and
Soft Delete Response Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com");)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; acl "Allow admins
to use the Hard Delete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com");)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; acl "Allow admins
to use the Undelete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com");)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; acl "Allow admins
to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com");)
```

- Add the **ds-privilege-name** attribute to the user with the value **soft-delete-read**. Once this is complete, the user can soft delete (and undelete) entries.

```
$./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
Successfully connected to localhost:1389.
```

```
dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete
```

```
Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
Result Code: 0 (success)
Soft Delete Response Control:
OID: 1.3.6.1.4.1.30221.2.5.21
Soft-Deleted Entry DN: entryUUID=8dbe8cb4-1aa3-41c5-88ec-
a6280eeff918+uid=user.10,ou=People,dc=example,dc=com
```

## Searching for Soft Deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent "deleted" entries. The `ldapsearch` tool has been updated to support these types of searches. If you want the option to search for soft-deleted entries, there are three ways to do so:

- **Base-Level Search on a Soft-Deleted entry by DN.** Use `ldapsearch` and specify the base DN of the specific soft-deleted entry that you are searching for.
- **Filtered Search by `ds-soft-delete-entry` object class.** To search for all soft-deleted entries, use `ldapsearch` with a filter on the `ds-soft-delete-entry` objectclass.
- **Soft-Delete-Entry-Access Control.** You can use the Soft Delete Entry Access Control with the LDAP search to return soft-deleted entries. The `ldapsearch` tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:
  - Return only soft-deleted entries.
  - Return non-deleted entries along with soft-deleted entries.
  - Return only soft-deleted entries in undeleted form.

## To Run a Base-Level Search on a Soft-Deleted Entry

### Steps

- Run `ldapsearch` using the base DN of the specified soft-deleted entry.

```
$ bin/ldapsearch \
 --baseDN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
 --searchScope base "(objectClass=*)"

Soft-deleted entry DN:
entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239

mail: user.3@maildomain.net
st: TN
```

## To Run a Filtered Search by soft-delete-entry Object Class

### Steps

- Run `ldapsearch` to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class. The following command retrieves all soft-deleted entries on the server

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
 "(objectclass=ds-soft-delete-entry)"
```

## To Run a Search using the Soft Delete Entry Access Control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the Soft Delete Entry Access Control. You could also use the `--control` option with the Soft Delete Entry Access Control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual Soft Delete Entry Access Control OID, `1.3.6.1.4.1.30221.2.5.24`.

- Return Only Soft-Deleted Entries.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries` to return only soft-deleted entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
```

```
--includeSoftDeletedEntries without-non-deleted-entries \
--searchScope sub "(objectclass=*)" "
```

- **Return Non-Deleted Entries Along with Soft-Deleted Entries.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries` to return non-deleted entries along with soft-deleted entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--includeSoftDeletedEntries with-non-deleted-entries \
--searchScope sub "(objectclass=*)" "
```

- **Return Only Soft-Deleted Entries in Undeleted Form.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form` to return only soft-deleted entries in undeleted form. Some applications require access to all entries in the server, including both active and soft-deleted entries. The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". Also, the object class, `ds-soft-delete-entry`, is not displayed.

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--includeSoftDeletedEntries deleted-entries-in-undeleted-form \
--searchScope sub "(ds-soft-delete-from-dn=*)" "

Soft-deleted entry DN:
entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c
+uid=user.14,ou=People,dc=exam-
ple,dc=com
dn: uid=user.14,ou=People,dc=example,dc=com

```

## Undeleting a Soft-Deleted Entry Using the Same RDN

To undelete a soft-deleted entry, use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the DN that the entry will be undeleted *to* and the `ds-undelete-from-dn` attribute, which is the entry that will be undeleted *from*. An undelete requires the `add changetype` so that the entry can be re-added to the server.

## To Undelete a Soft-Deleted Entry Using the Same RDN

### Steps

- Use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. The `--allowUndelete` option sends the Soft Undelete Request Control to the server. The first DN is the entry to undelete to and the `ds-undelete-from-dn` is the soft-delete entry to undelete from.

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.1,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

## Undeleting a Soft-Deleted Entry Using a New RDN

In some cases, the original RDN, `uid=user.1`, may have been allocated to a new user, which is allowed while the entry is in a soft-deleted state. To properly undelete this entry, you need to specify a new RDN value that the entry should be restored with. In this case, specifying the RDN of `uid=user.5` will undelete the original entry but with the new DN in the example below. In addition, the `uid` attribute on the entry will be updated with the new value of `user.5` as well. All other attributes of the users entry including the `entryUUID` will remain unchanged.

### To Undelete a Soft-Deleted-Entry Using a New RDN

#### Steps

- Use `ldapmodify` to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`. You will need to ensure that the DN that you are undeleting the entry to does not already exist as this will lead to an "entry already exists" error if you specify a DN that already exists in the Directory Server as a normal entry.

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.5,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

- View the results using `ldapssearch`. You will notice the RDN and the `uid` attribute has changed.

```
dn: uid=user.5,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.
uid: user.5
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
employeeNumber: 1
initials: AKA
givenName: Aartjan
pager: +1 197 025 3730
mobile: +1 890 430 9077
cn: Aartjan Aalders
sn: Aalders
telephoneNumber: +1 094 100 7524
street: 59748 Willow Street
homePhone: +1 332 432 4295
```

```
l: Green Bay
mail: user.3@maildomain.net
st: TN
entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4
```

## Modifying a Soft-Deleted Entry

You can modify a soft-deleted entry as you would a regular entry using the `ldapmodify` tool and remains hidden in its soft-deleted state after the change. The only restriction is that you cannot change the DN or run a MODDN operation on the soft-deleted entry.

To move a soft-deleted entry from one machine to another, use the `move-subtree` command and specify the DN of the soft-deleted entry. For more information, see [To Move an Entry from One Machine to Another](#).

**Note:** To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

### To Modify a Soft-Deleted Entry

#### Steps

- Soft-deleted entries can be modified like any regular entry. Use `ldapmodify` and specify the soft-deleted DN.

```
$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

## Hard Deleting a Soft-Deleted Entry

To permanently remove a soft-deleted entry from the server, you can run `ldapdelete` on the soft-deleted entry for soft-deleted entries. To hard delete a soft-deleted entry, use `ldapdelete` with the `--useHardDelete` option. The Hard Delete Request Control works with soft deletes. It mostly applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running `ldapdelete` with the Hard Delete Request Control (i.e., using the option, `--useHardDelete`) guarantees any entry will be permanently deleted.

### To Hard Delete a Soft-Deleted Entry (Global Configuration)

#### Steps

- Run `ldapdelete` on a soft-deleted entry to permanently remove it from the Directory Server. This example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
 entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
```

```
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

**Note:**

You cannot soft-delete an already soft-deleted entry. If you use the `--useSoftDelete` with the `ldapdelete` operation on a soft-deleted entry, an error message will be generated.

```
DELETE operation failed.
Result Code: 53 (Unwilling to Perform)
Diagnostic Message: DELETE operation failed.
```

### To Hard Delete a Soft-Deleted Entry (Connection or Request Criteria)

#### Steps

- Run `ldapdelete` with the `--useHardDelete` option on a soft-deleted entry to permanently remove it from the server. This example assumes that you configured soft deletes using a connection or request criteria.

```
$ bin/ldapdelete --useHardDelete \
 entryUUID=4e9b7847-edcb-3791-
 b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

## Disabling Soft Deletes as a Global Configuration

To disable soft deletes on your Directory Server, simply reset the global configuration property and the remove the soft-delete policy. From that point, all deletes will be processed as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present after the global configuration is disabled will remain in the server as latent entries.

### To Disable Soft Deletes as a Global Configuration

#### Steps

- Run `dsconfig` to reset the global configuration property. Remember to include the LDAP bind parameters for your system.

```
$ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
```

- Run `dsconfig` to delete the soft delete policy that you created. Remember to include the LDAP bind parameters for your system.

```
$ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-
policy
```

## Configuring Soft Deletes by Connection Criteria

The Directory Server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria. You can configure soft deletes by defining the connection criteria used in a client connection policy, and then configuring the soft delete connection criteria in the soft-delete policy.

### To Enable Soft Deletes by Connection Criteria

#### Steps

- Configure a soft-delete policy and global configuration as shown in “Configuring Soft Deletes as a Global Configuration”.

2. Create a simple connection criteria using `dsconfig` and name it "Internal Applications". The soft delete connection criteria is configured for a member of a Line of Business (LOB) Applications group connecting from the 10.8.1.0 network.

```
$ bin/dsconfig create-connection-criteria \
 --criteria-name "Internal Applications" \
 --type simple \
 --set included-client-address:10.8.1.0/8 \
 --set "all-included-user-group-dn:cn=LOB
Applications,ou=Groups,dc=example,dc=com"
```

3. In the soft delete policy created in step 1, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --set "auto-soft-delete-connection-criteria:Internal Applications"
```

### To Disable Soft Deletes by Connection Criteria

#### Steps

- To disable soft deletes by connection criteria, simply reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --reset auto-soft-delete-connection-criteria
```

## Configuring Soft Deletes by Request Criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria is treated as a soft delete. The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria. Both can be present in a soft-delete policy.

### To Enable Soft Deletes by Request Criteria

#### Steps

1. Configure a soft-delete policy and global configuration as shown in "Configuring Soft Deletes as a Global Configuration".
2. Configure request criteria for soft deletes. The soft delete request criteria is configured for an external delete request from a member of the Internal Applications group matching an entry with object class "inetorgperson" with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
 --criteria-name "Soft Deletes" \
 --type simple \
 --set "description:Requests for soft delete" \
 --set operation-type:delete \
 --set operation-origin:external-request \
 --set "connection-criteria:Internal Applications" \
 --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
 --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

3. In the soft delete policy created in step 1, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

```
$ bin/dsconfig create-soft-delete-policy \
 --policy-name default-soft-delete-policy \
```

```
--set "auto-soft-delete-request-criteria:Soft Deletes"
```

## To Disable Soft Deletes by Request Criteria

### Steps

- To disable soft deletes by request criteria, reset the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --reset auto-soft-delete-request-criteria
```

## Configuring Soft Delete Automatic Purging

By default, the Directory Server retains soft-deleted entries indefinitely. For companies that want to set up automatic purging of soft-deleted entries, the server provides two properties on the Soft Delete Policy that can be configured for either the maximum retention time for all soft-deleted entries and/or the retained number of soft-deleted entries. These changes take effect without requiring a server restart.

### To Configure Soft-Delete Automatic Purging

#### About this task

You can change either the retention time or the retained number of entries to enable automatic purging. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), may be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc. Once you configure the properties, the changes take effect immediately without the need for a server restart.

Note that the server will delete all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward according to the new policy.

### Steps

- Retrieve the name of the Soft Delete Policy in effect using the `dsconfig` command. For this example, the Soft Delete Policy is called `default-soft-delete-policy`.

```
$ bin/dsconfig get-global-configuration-prop \
 --property soft-delete-policy
```

- Do one or both of the following:

- Run `dsconfig` to set the retention time for soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --set "soft-delete-retention-time:52 w"
```

- Run `dsconfig` to set the retained number of soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --set soft-delete-retain-number-of-entries:1000000
```

- The Soft Delete Policy must be assigned to the global configuration if it has not been assigned yet.

```
$ bin/dsconfig set-global-configuration-prop \
 --set soft-delete-policy:default-soft-delete-policy
```

## To Disable Soft-Delete Automatic Purging

### About this task

You can disable Soft-Delete automatic purging using the `dsconfig` command. The change takes effect immediately without the need of a server restart. However, if the server is in the middle of an automatic soft-delete purging, it may continue to purge entries until the next time it evaluates the Soft Delete Policy.

### Steps

- Run `dsconfig` to reset the Soft-Delete Policy properties that control automatic purging: `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`.

```
$ bin/dsconfig set-soft-delete-policy-prop \
 --policy-name default-soft-delete-policy \
 --reset soft-delete-retention-time \
 --reset soft-delete-retain-number-of-entries
```

## Summary of Soft and Hard Delete Processed

The following table summarizes the resulting actions of a DELETE operation for soft deletes.

### If No Automatic Soft Delete Criteria is Configured

| Action                                                               | Result                                                             |
|----------------------------------------------------------------------|--------------------------------------------------------------------|
| Delete                                                               | Performs a hard delete on the entry.                               |
| Delete with the Soft Delete Request Control                          | Performs a soft delete on the entry.                               |
| Delete of a soft-deleted entry                                       | Performs a hard delete on the entry.                               |
| Delete of a soft-deleted entry with the Soft Delete Request Control  | Not allowed. Generates an <code>UNWILLING_TO_PERFORM</code> error. |
| Delete with a Hard Delete Request Control                            | Performs a hard delete on the entry.                               |
| Delete of a soft-deleted entry with the Hard Delete Request Control. | Performs a hard delete on the entry.                               |

The following table summarizes the resulting actions of a DELETE operation for soft deletes configured by connection criteria or request criteria.

### If Soft Delete Connection or Request Criteria is Configured

| Action                                               | Result                               |
|------------------------------------------------------|--------------------------------------|
| Delete not matching criteria                         | Performs a hard delete on the entry. |
| Delete matching criteria                             | Performs a soft delete on the entry. |
| Delete of a soft-deleted entry not matching criteria | Performs a hard delete on the entry. |

| Action                                                            | Result                                                |
|-------------------------------------------------------------------|-------------------------------------------------------|
| Delete of a soft-deleted entry matching criteria                  | Performs a hard delete on the entry.                  |
| Delete not matching criteria with the Hard Delete Request Control | Performs a hard delete on the entry.                  |
| Delete matching criteria with the Hard Delete Request Control     | Performs a hard delete on the entry.                  |
| Delete with Soft and Hard Delete Request Controls                 | Not allowed. Generates an UNWILLING_TO_PERFORM error. |

## Summary of Soft Delete Controls and Tool Options

The following table shows the OIDs for each soft delete control. The Soft Delete OIDs are defined in the LDAP SDK generated API documentation.

### Soft Delete OIDs

| OID Type                         | OID                      |
|----------------------------------|--------------------------|
| Soft Delete Request Control      | 1.3.6.1.4.1.30221.2.5.20 |
| Soft Delete Response Control     | 1.3.6.1.4.1.30221.2.5.21 |
| Hard Delete Request Control      | 1.3.6.1.4.1.30221.2.5.22 |
| Soft Undelete Request Control    | 1.3.6.1.4.1.30221.2.5.23 |
| Soft Delete Entry Access Control | 1.3.6.1.4.1.30221.2.5.24 |

The following table shows the new tool options available for the Soft Delete operations.

### Soft Delete Tool Options

| Action                  | Result                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldapdelete / ldapmodify | <b>--useSoftDelete/-s</b> . Process DELETE operations with the Soft Delete Request Control, whereby entries are renamed, and hidden instead of being permanently deleted. The Directory Server must be configured to allow soft deletes. Note that any entries in the LDIF file with the changetype of <code>delete</code> will be processed as a soft-delete request. |
| ldapdelete              | <b>--useHardDelete</b> . Process DELETE operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The Directory Server must be configured to allow soft deletes.                                                                      |

| Action     | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldapsearch | <p><b>--includeSoftDeletedEntries {with-non-deleted-entries   without-non-deleted-entries   deleted-entries-in-undeleted-form}</b>. Process search operations with the Soft Delete Entry Access Control. Soft delete search options are as follows:</p> <ul style="list-style-type: none"> <li>▪ <b>with-non-deleted-entries</b>. Returns all entries matching the search criteria with the results including non-deleted and soft-deleted entries.</li> <li>▪ <b>without-non-deleted-entries</b>. Returns only soft-deleted entries matching the search criteria.</li> <li>▪ <b>deleted-entries-in-undeleted-form</b>. Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form.</li> </ul> <p>Users must have access to the Soft Delete Entry Access Control to be able to search for soft-deleted entries.</p> |
| ldapmodify | <p><b>--allowUndelete</b>. Process ADD operations which include the <code>ds-undelete-from-dn</code> attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the ADD operation. The Directory Server must be configured to allow soft deletes to process any undelete requests and the client user must have the <code>soft-delete-read</code> privilege.</p>                                                                                                                                                                                                                                                                                                                                                                                         |

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

#### Soft Delete OID Symbolic Names using with the `--control/-J` Option

| Control                          | Symbolic Name         |
|----------------------------------|-----------------------|
| Soft Delete Request Control      | softdelete            |
| Hard Delete Request Control      | harddelete            |
| Soft Undelete Request Control    | undelete              |
| Soft Delete Entry Access Control | softdeleteentryaccess |

## Monitoring Soft Deletes

The Directory Server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

### New Monitor Entries

Two new monitor entries are present for a backend monitor entry. Administrators will see the following additional monitor entries on `cn=userRoot Backend, cn=monitor`:

- **ds-soft-delete-entry-operations-count**. Displays the number of soft-deletes performed on the backend since server startup.
- **ds-undelete-operations-count**. Displays the number of undeletes performed on the backend since server startup.
- **ds-backend-soft-deleted-entry-count**. Displays the current number of soft-deleted entries in the database.

- **ds-auto-purged-soft-deleted-entry-count.** Displays the current number of soft-deleted entries purged since the backend or server was restarted.

### To Monitor Soft Deletes

#### Steps

- **Run `ldapsearch` on the `cn=userRoot Backend, cn=monitor` branch.** Use a search criteria targeting the `ds-backend-monitor-entry` object class.

```
$ bin/ldapsearch --baseDN "cn=userRoot Backend,cn=monitor" \
 --searchScope sub "(objectclass=ds-backend-monitor-entry)"
```

```
dn: cn=userRoot Backend,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-backend-monitor-entry
objectClass: extensibleObject
cn: userRoot Backend
ds-backend-id: userRoot
ds-backend-base-dn: dc=example,dc=com
ds-backend-is-private: FALSE
ds-backend-entry-count: 200001
ds-backend-soft-deleted-entry-count: 1000
ds-soft-delete-operations-count: 40
ds-undelete-operations-count: 20
ds-auto-purged-soft-deleted-entry-count: 0
ds-base-dn-entry-count: 200001 dc=example,dc=com
ds-backend-writability-mode: enabled
```

### Access Logs

The access log records the LDAP operations corresponding to soft delete and undelete for DELETE, SEARCH, MODIFY, and ADD operations with the related soft-deleted values. The access log does not require any configuration for soft delete.

For DELETE (soft-delete) operations, the access log displays:

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

For SEARCH operations for soft-deleted entries, the log displays:

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

For MODIFY operations of soft-deleted entries, the log displays:

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

For ADD (soft undelete) operations, the log displays:

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

## Audit Logs

The audit log captures any MODIFY and DELETE operations of soft-deleted entries. These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry DN.

```
14/May/2012:10:57:09.054 -0500; conn=30; op=1
ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: delete
```

For any MODIFY changes made, the log displays the LDIF, the modifier's name and update time.

```
14/May/2012:10:58:33.566 -0500; conn=33; op=1
dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
 ple,dc=com
changetype: modify
replace: homePhone
homePhone: +1 003 428 0966
#-
replace: modifiersName
modifiersName: uid=admin,dc=example,dc=com
#-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time and creator's name.

```
14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
 ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
14/May/2012:11:00:14.055 -0500; conn=36; op=1
dn:
 entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
 ple,dc=com
changetype: delete
```

## To Configure the File-Based Audit Log for Soft Deletes

### Steps

1. Enable the audit log if it is disabled.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
 Logger" \
--set enabled:true
```

2. View the audit log. The `soft-delete-entry-audit-behavior` property is set to "commented" by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

```
11/May/2012:15:33:17.552 -0500; conn=13; op=1
ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: delete
```

## Change Log

The change log can be configured to capture soft-delete changes to entries, so that external clients, such as PingDataSync Server, can access these changes. The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

Two important points about soft deletes and the changelog are as follows:

- All soft-delete operations appear in the changelog and appear as a regular DELETE operation. When a soft delete occurs, the resulting changelog entry will include a `ds-soft-delete-entry-dn` operational attribute with the value of the soft-deleted entry DN. If you are using PingDataSync Server, it does recognize the `ds-soft-delete-entry-dn` attribute and does not do anything with it.
- The changelog backend's `soft-delete-entry-included-operation` property determines whether or not MODIFY or DELETE operations of soft-deleted entries appear in the changelog. By default, the property is not enabled by default.

## To Configure Soft Deletes on the Changelog Backend

### Steps

1. Configure soft deletes on the changelog backend.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.
3. View the changelog for the soft-deleted entry.

```
$ bin/ldapsearch --baseDN cn=changelog \
"(objectclass=*)" "+"
```

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863
ds-entry-checksum: 304022441
dn: changeNumber=1,cn=changelog
targetUniqueId: 94f634df-c90e-39aa-bd4a-9183c29746d0
changeTime: 20120511154141Z
ds-soft-delete-entry-dn: entryUUID=94f634df-c90e-39aa-bd4a-
9183c29746d0+uid=user.9,ou=People,dc=example,dc=com
modifyTimestamp: 20131010020345.546Z
createTimestamp: 20131010181148.630Z
localCSN: 000001373C90085200000000000003
modifiersName: uid=admin,dc=example,dc=com
entry-size-bytes: 298
subschemaSubentry: cn=schema
entryUUID: 459b06c6-89f3-307e-a515-22433eb420b6
createTimestamp: 20120511154141.431Z
modifyTimestamp: 20120511154141.431Z
```

```
ds-entry-checksum: 1157320579
```

## Importing and Exporting Data

---

The PingDirectory Server supports import or export of the database backends in LDAP Data Interchange Format (LDIF). The `bin/import-ldif` and `bin/export-ldif` tools can be used to create or export database backends for online or offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt or digitally sign the data.

This chapter presents the following topics:

### Importing Data

The PingDirectory Server provides initialization mechanisms to import database files. The `import-ldif` command-line tool imports data from an LDAP Data Interchange Format (LDIF) file. The data imported by the `import-ldif` command can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the LDIF file. The command also supports importing data that has been compressed, encrypted or digitally signed or both.

The `import-ldif` utility can be run with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, will be removed from service and data held in that backend will not be available to clients.

The `import-ldif` tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. This option must be present when performing an import into a backend with a branch that already contains entries (although the option is not needed if a branch contains just a single base entry).

### Validating an LDIF File

Prior to importing data, you can validate an import file using the Directory Server's `validate-ldif` tool. When run, the tool binds to the Directory Server, locally or remotely, and validates the LDIF file to determine whether it violates the server's schema. Those elements that do not conform to the schema will be rejected and written to standard output. You can specify the path to the output file to which the rejected entries are written and the reasons for their rejection. The `validate-ldif` tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

To process large files faster, you can also set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only. Use the `--help` option to view the arguments.

### To Validate an LDIF File

#### Steps

- Use the `validate-ldif` tool to validate an LDIF file. Make sure the server is online before running this command.

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
 --rejectFile rejectedEntries
```

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

## Computing Database Cache Estimate

After successful completion of an import, the `import-ldif` command lists detailed information about the database cache characteristics of the imported data set. The current server configuration is considered along with the capabilities of the underlying hardware to guide decisions for changing JVM size and `database-cache-percent` for the backend.

The `import-ldif` command will complete with a summary of database cache usage characteristics for the imported data set. Additional files are available in the `/logs/tools` directory that describe the database cache characteristics in more detail.

## Tracking Skipped and Rejected Entries

During import, entries can be skipped if they do not belong in the specified backend, or if they are part of an excluded base DN or filter. The `--skipFile {path}` argument can be used on the command line to indicate that any entries that are skipped should be written to a specified file. You can add a comment indicating why the entries were skipped.

Similarly, the `--rejectFile {path}` argument can be added to obtain information about which entries were rejected and why. An entry can be rejected if it violates the server's schema constraints, if its parent entry does not exist, if another entry already exists with the same DN, or if it was rejected by a plugin.

## Running an Offline Import

You can run the `import-ldif` tool offline to import LDIF data encoded with the UTF-8 character set. This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated using a MakeLDIF template. You do not need to authenticate as an administrator when performing offline LDIF imports.

### To Perform an Offline Import

#### Steps

- Use the `import-ldif` command to import data from an LDIF file. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
 --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

### To Perform an Offline LDIF Import Using a Compressed File

#### Steps

- Use the `import-ldif` command to import data from a compressed gzip formatted file. You must also use the `--isCompressed` option to indicate that the input file is compressed. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --isCompressed \
 --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
 --skipFile /path/to/skip.ldif
```

## To Perform an Offline LDIF Import Using a MakeLDIF Template

### Steps

- Use the **import-ldif** command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF`. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

The following command uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

```
$ bin/import-ldif --backendID userRoot \
 --templateFile config/MakeLDIF/example.template
```

## Running an Online LDIF Import

Administrators can run LDIF imports while the server is online from another remote server. The online import resembles the offline import, except that you must provide information about how to connect and authenticate to the target server. You can schedule the import of an LDIF file to occur at a particular time using the `--task` and `--start YYYYMMDDhhmmss` options of the **import-ldif** tool.

You can also specify email addresses for users that should be notified whenever the import process completes (regardless of success or failure, or only if the import fails). To set up SMTP notifications, see [Working with the SMTP Account Status Notification Handler](#).

### To Perform an Online LDIF Import

#### Steps

- Use the **import-ldif** tool to import data from an LDIF. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task --hostname server1 --port 389 \
 --bindDN uid=admin,dc=example,dc=com --bindPassword password \
 --backendID userRoot --ldifFile userRoot.ldif
```

### To Schedule an Online Import

#### Steps

- Use the **import-ldif** tool to import data from an LDIF file at a scheduled time. To specify a time in the UTC time zone, include a trailing "Z". Otherwise, the time will be treated as a local time in the time zone configured on the server. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task \
 --hostname server1 \
 --port 389 \
 --bindDN uid=admin,dc=example,dc=com \
 --bindPassword password \
 --backendID userRoot \
 --ldifFile /path/to/data.ldif \
 --start 20111026010000 \
 --completionNotify import-complete@example.com \
 --errorNotify import-failed@example.com
```

```
Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM CDT
```

2. Confirm that you successfully scheduled your import task using the `manage-tasks` tool to view a summary of all tasks on the system.

```
$ bin/manage-tasks --summary
```

```
ID Type Status

2011102617321510 Import Waiting on start time
```

3. Use the `manage-tasks` tool to monitor the progress of this task. Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the Directory Server.

```
$ bin/manage-tasks --info 2011102617321510
```

```
Task Details

ID 2011102617321510
Type Import
Status Waiting on start time
Scheduled Start Time Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed None
Dependency Action None
Email Upon Completion admin@example.com
Email Upon Error admin@example.com

Import Options

LDIF File /path/to/data.ldif
Backend ID userRoot
```

### To Cancel a Scheduled Import

#### Steps

- Use the `manage-tasks` tool to cancel the scheduled task.

```
$ bin/manage-tasks --cancel 2011102417321510
```

## Adding Entries to an Existing Directory Server

To add entries to an existing Directory Server while preserving operational attributes, such as `createTimestamp` or `modifiersName`, the Ignore No User Modification control must be attached to the request. The Ignore No User Modification control allows modification of certain attributes that have the No User Modification constraint. Special care should be used with this control.

The Ignore No User Modification is only applied to ADD requests. Using the control to modify an existing entry, resulting in an operational attribute change, will fail.

### To Append Entries to an Existing Directory Server

#### Steps

- Use `ldapmodify` with the Ignore No User Modification control (i.e., the OID is 1.3.6.1.4.1.30221.2.5.5).

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
--filename change-record.ldif
```

## Filtering Data Import

The `import-ldif` command provides a way to either include or exclude specific attributes or entries during an import. The arguments are summarized as follows:

### Inclusion and Exclusion Arguments for import-ldif

| Argument                          | Description                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>--includeBranch</code>      | Base DN of a branch to include in the LDIF import (can be specified multiple times)                 |
| <code>--excludeBranch</code>      | Base DN of a branch to exclude from the LDIF import (can be specified multiple times)               |
| <code>--includeAttribute</code>   | Attribute to include in the LDIF import (can be specified multiple times)                           |
| <code>--excludeAttribute</code>   | Attribute to exclude from the LDIF import (can be specified multiple times)                         |
| <code>--includeFilter</code>      | Search filter to identify entries to include in the LDIF import (can be specified multiple times)   |
| <code>--excludeFilter</code>      | Search filter to identify entries to exclude from the LDIF import (can be specified multiple times) |
| <code>--excludeOperational</code> | Exclude operational attributes from the LDIF import.                                                |
| <code>--excludeReplication</code> | Exclude replication attributes from the LDIF import.                                                |
| <code>--excludeSoftDelete</code>  | Exclude soft delete entries from the LDIF import.                                                   |

## Exporting Data

The PingDirectory Server `export-ldif` command-line tool exports data from Directory Server backend to an LDAP Data Interchange Format (LDIF) file. The tool must be run in the non-task based mode, which implies that it works outside of the server JVM process. The `export-ldif` must be run without connection or task arguments while the server is either online or offline. This tool exports a point-in-time snapshot of the backend which is guaranteed to provide a consistent state of the database, in LDIF, which can be reimported with `import-ldif` if necessary.

The data exported by `export-ldif` can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the backend. This is accomplished by specifying branches, filters, and attributes to include or exclude. The exported LDIF can be compressed, encrypted or digitally signed.

**Note:** LDIF exports can be configured as recurring tasks with `dsconfig create-recurring-task`, and then scheduled to run when added to a recurring task chain.

### To Perform an Export

#### Steps

- Use the `export-ldif` command to export data to an LDIF file.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

## To Perform an Export from Specific Branches

### Steps

- Use the `export-ldif` command to export data to an LDIF file under a specific branch from the `userRoot` backend of the local Directory Server into a compressed file. The command also excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --
compress \
 --includeBranch ou=people,dc=example,dc=com --excludeOperational \
 --wrapColumn 80
```

## Encrypting LDIF Exports and Signing LDIF Files

The Directory Server provides features to encrypt data during an LDIF export using the `export-ldif --encryptLDIF` option and to allow the encrypted LDIF file to be imported onto the same instance or another server in the same replication topology using the `import-ldif` tool. A `--doNotEncrypt` argument can be used to force an LDIF export to be unencrypted, even if automatic encryption is enabled. The `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the LDIF file may be written to disk.

The `export-ldif` tool can be used with the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to specify which key to use for encrypting the export. The `import-ldif` tool will automatically detect encryption and compression, and have `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile` options as well.

The Directory Server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the `export-ldif --sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the `import-ldif --isSigned` option.

Note that there is not much added benefit to both signing and encrypting the same data, since encrypted data cannot be altered without destroying the ability to decrypt it.

### To Encrypt an LDIF Export

#### Steps

- Run `export-ldif` tool with the `--encryptLDIF` option to encrypt the data during an export to an output LDIF file. The following command runs an offline export of the `userRoot` backend, and encrypts the file when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
 --encryptLDIF
```

### To Import an Encrypted LDIF File

#### About this task

An encrypted LDIF file can be imported into the same instance from which it was exported, or into any other server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not in some way connected to the instance from which it was exported.

#### Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from the previous example. The command imports the `data.ldif` file, decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can

automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
--overwriteExistingEntries
```

## To Sign an Export

### Steps

- Run **export-ldif** tool with the **--sign** option to digitally sign the data during an export to an output LDIF file. The following command runs an offline export of the `userRoot` backend, and signs the content when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot \
--ldifFile /path/to/data.ldif --sign
```

## To Import a Signed LDIF File

### Steps

- Run the **import-ldif** tool to import the signed LDIF file from the previous example. The command imports the `data.ldif` file, checks the signature of the contents while overwriting the existing contents to the `userRoot` backend. The command requires the **--isSigned** option, which instructs the tool that the contents of the LDIF file is signed.

```
$ bin/import-ldif --backendID userRoot \
--ldifFile /path/to/data.ldif \
--overwriteExistingEntries --isSigned
```

## Filtering Data Exports

The **export-ldif** command analogous arguments to the **import-ldif** tool to provide a way to either include or exclude specific attributes or entries during an export. The arguments are summarized as follows:

### Inclusion and Exclusion Arguments for export-ldif

| Argument                    | Description                                                                                  |
|-----------------------------|----------------------------------------------------------------------------------------------|
| <b>--includeBranch</b>      | Base DN of a branch to include in the LDIF export (can be specified multiple times)          |
| <b>--excludeBranch</b>      | Base DN of a branch to exclude from the LDIF export (can be specified multiple times)        |
| <b>--includeAttribute</b>   | Attribute to include in the LDIF export (can be specified multiple times)                    |
| <b>--excludeAttribute</b>   | Attribute to exclude from the LDIF export (can be specified multiple times)                  |
| <b>--includeFilter</b>      | Filter to identify entries to include in the LDIF export (can be specified multiple times)   |
| <b>--excludeFilter</b>      | Filter to identify entries to exclude from the LDIF export (can be specified multiple times) |
| <b>--excludeOperational</b> | Exclude operational attributes from the LDIF export.                                         |
| <b>--excludeReplication</b> | Exclude replication attributes from the LDIF export.                                         |
| <b>--excludeSoftDelete</b>  | Exclude soft delete entries from the LDIF export.                                            |

## Scrambling Data Files

The Directory Server `transform-ldif` tool provides backward compatibility with the former `scramble-ldif` tool, with additional functionality for configuring input and output files. The `transform-ldif` tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data, enables obscuring the values of certain attributes so that it is difficult to determine the original values in the source data, while also preserving the characteristics of the associated attribute syntax. This process is repeatable, so that if the same value appears multiple times, it will yield the same scrambled representation each time. Scrambling can be applied to both LDIF entries and LDIF change records.

The process of scrambling data is not the same as encryption. It should only be used to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is `userPassword` and its value starts with a scheme name surrounded by curly braces, such as "{SSHA256}XrgyNdl3fid7KYdhd/Ju47KJQ5PYZqlUlyzxQ28f/QXUnNd9fupj9g==", the scheme name will be left unchanged and the rest of the value will be treated like a generic string.
- If the attribute is `authPassword` and its value contains at least two dollar signs, such as "SHA256\$QGbHtDCi1i4=\$8/X7XRGaFCovC5mn7ATPDYIkVoocDD06Zy3lbD4AoO4=", the portion up to the first dollar sign (which represents the name of the encoding scheme) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either **TRUE** or **FALSE**. The determination to use a value of **TRUE** or **FALSE** is random, so scrambling Boolean values is not repeatable. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of RDN components for any attributes to be scrambled. For example, if the tool is configured to scramble both the `member` and `uid` attributes, and an entry has a member attribute with a value of "uid=john.doe,ou=People,dc=example,dc=com", that member value will be scrambled in a way that only obscures the "john.doe" portion but leaves the attribute names and all values of non-scrambled attributes intact.
- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization will be over a time range that is double the difference between the time the `transform-ldif` tool was launched and the timestamp to be scrambled. For values where that time difference is less than one day, one day will be added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit will be nonzero.
- If an attribute has an octet string syntax, it is scrambled as follows:
  - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each byte that represents an uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
  - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
  - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
  - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
  - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.
- If an attribute has a value that represents a valid JSON object, the resulting value will also be a JSON object. All field names will be left intact, and only the values of those fields may be scrambled. If the

`--scrambleJSONField` argument is provided, only the specified fields will have values scrambled. Otherwise, the values of all fields will be scrambled. Field values are scrambled as follows:

- Null values are not scrambled.
- Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.
- Number values will have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
- String values will be replaced with a randomly-selected generic string.
- Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
- JSON values have scrambling applied as appropriate for their fields.
- If an attribute does not match any of the previous criteria, it is scrambled as follows:
  - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
  - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
  - Each ASCII digit is replaced with a randomly-selected ASCII digit.
  - All other characters are left unchanged.

The following example reads from an LDIF file named `original.ldif`, scrambles the values of the `telephoneNumber`, `mobile`, and `homeTelephoneNumber` attributes, and writes the results to `scrambled.ldif`:

```
$ bin/transform-ldif --sourceLDIF original.ldif \
 --targetLDIF scrambled.ldif \
 --scrambleAttribute telephoneNumber \
 --scrambleAttribute mobile \
 --scrambleAttribute homeTelephoneNumber \
 --randomSeed 0
```

## Backing Up and Restoring Data

---

The PingDirectory Server provides efficient **backup** and **restore** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler.

This chapter presents the following topics:

### Backing Up and Restoring Data

Administrators should have a comprehensive backup strategy and schedule that comprise of daily, weekly, and monthly backups including incremental and full backups of the directory server data, configuration, and backends. Administrators should also have a backup plan for the underlying file system. This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

**Note:** Backups can be configured as recurring tasks with `dsconfig create-recurring-task`, and then scheduled to run when added to a recurring task chain.

The PingDirectory Server provides efficient **backup** and **restore** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler. The Directory Server can run backups with the server online while processing other requests, so that there is no need to shut down the server or place it in read-only mode prior to starting a backup.

If you back up more than one backend, the **backup** tool creates a subdirectory below a specified backup directory for each backend. If you back up only a single backend, then the backup files will be placed in

the specified directory. A single directory can only contain files from one backend, so that you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including the server product name, the server version, the backend ID, the set of base DNs for the backend, and the Java class used to implement the backend logic. For JE backends, the backup descriptor also includes information about the Berkeley DB JE version and information about the attribute and VLV indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors. The administrator can choose to ignore the warnings with the `ignoreCompatibilityWarnings` option to the `restore` tool, whereas errors will always cause the restore to fail. For example, when restoring a *newer* backup into an older version of the server, a warning will be generated. When restoring an *older* backup into a new version of the server, no warning will be generated, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly (major, minor, point, and patch version numbers).

Both the `backup` and `restore` tools provide encryption options `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` that can be used to specify which key to use for encrypting the backup. For backups encrypted with an encryption settings definition or an internal topology key, the server will automatically determine the correct key. Or, the `--doNotEncrypt` argument can be used to force a backup to be unencrypted even if automatic encryption is enabled.

If needed, the `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the backup may be written to disk.

## Retaining Backups

The backup tool can be used with either the `--retainPreviousFullBackupCount` or `--retainPreviousFullBackupAge` arguments to identify which previous backups should be preserved. Any other backups in that directory will be removed. A new backup will always be preserved. If the new backup is an incremental backup, then any other backups it depends on will also be preserved. However, older backups in the same directory are eligible to be removed.

If the `--retainPreviousFullBackupCount` argument is provided, that number of the most recent previous full backups will be preserved (along with any incremental backups that depend on them). Any other previous full backups (and their dependent incremental backups) can be removed. If the `--retainPreviousFullBackupAge` argument is provided, its value must be a duration represented as an integer followed by a time unit. Any full backups (and their dependent incremental backups) created longer ago than that duration will be eligible to be removed. If both the `--retainPreviousFullBackupCount` and `--retainPreviousFullBackupAge` arguments are provided, then only backups that don't satisfy either condition will be deleted. A value of zero can be specified for the `--retainPreviousFullBackupCount` argument so that only the most recent backup is preserved (along with its dependencies), and all previous backups will be removed.

**Note:** The `remove-backup` tool also supports the `--retainFullBackupCount` and `--retainFullBackupAge` arguments to delete any backups outside the provided retention criteria.

## To List the Available Backups on the System

### Steps

- Use the **restore** tool to list the backups in a backup directory.

```
$ bin/restore --listBackups --backupDirectory /mybackups
```

```
[13:26:21] The console logging output is also available in '/ds/PingDirectory/logs/tools/restore.log'
```

```
Backup ID: 20120212191715Z
Backup Date: 12/Feb/2012:13:17:19 -0600
Is Incremental: false
Is Compressed: false
Is Encrypted: false
Has Unsigned Hash: false
Has Signed Hash: false
Dependent Upon: none
Backup ID: 20120212192411Z
Backup Date: 12/Feb/2012:13:24:16 -0600
Is Incremental: true
Is Compressed: false
Is Encrypted: false
Has Unsigned Hash: false
Has Signed Hash: false
Dependent Upon: 20120212191715Z
```

## To Back Up All Backends

### Steps

- Use **backup** to save all of the server's backends. The optional `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

```
$ bin/backup --backUpAll --compress --backupDirectory /path/to/backup
```

## To Back Up a Single Backend

### Steps

- Go to the server root directory, and use the **backup** tool to save the single backend, `userRoot`.

```
$ bin/backup --backendID userRoot --compress --backupDirectory /path/to/backup
```

## To Perform an Offline Restore

### Steps

- Use the **restore** command to restore the `userRoot` backend. Only a single backend can be restored at a time. The Directory Server must be shut down before performing an offline restore.

```
$ bin/restore --backupDirectory /path/to/backup/userRoot
```

 **Note:** The server root directory should never be restored from a file system backup or snapshot.

## To Assign an ID to a Backup

### Steps

- Go to the server root directory, and use the backup tool to save the single backend, userRoot. The following command assigns the backup ID "weekly" to the userRoot backup. The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

```
$ bin/backup --backupDirectory /path/to/backups/userRoot \
 --backendID userRoot --backupID weekly
```

## To Run an Incremental Backup on All Backends

### About this task

The Directory Server provides support for incremental backups, which backs up only those items that have changed since the last backup (whether full or incremental) on the system, or since a specified earlier backup. Incremental backups must be placed in the same backup directory as the full backup on which they are based.

Not all backends support incremental backups. If a backend does not support incremental backups, use of the `--incremental` option will have no effect, and a full backup will be taken.

### Steps

- The following command runs an incremental backup on all backends based on the most recent backup:

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
```

## To Run an Incremental Backup on a Single Backend

### Steps

- Go to the server root directory, and use `backup` to save the single backend, userRoot.

```
$ bin/backup --backendID userRoot --incremental --backupDirectory /path/to/
backup
```

## To Run an Incremental Backup based on a Specific Prior Backup

### Steps

- You can run an incremental backup based on a specific prior backup that is not the most current version on the system. To get the backup ID, use the `restore --listBackups` command (see below).

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup \
 --incrementalBaseID backup-ID
```

## To Restore an Incremental Backup

### About this task

The process for restoring an incremental backup is exactly the same as the process for restoring a full backup for both the online and offline restore types. The `restore tool` will automatically ensure that the full backup and any intermediate incremental backups are restored first before restoring the final incremental backup. The tool will not restore any files in older backups that are no longer present in the final data set.

## To Schedule an Online Backup

### About this task

You can schedule a backup to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

For online (remote) backups, the backup operation can be conducted while PingDirectory Server is online if you provide information about how to connect and to authenticate to the target Directory Server.

### Steps

- You can schedule the backup to occur at a specific time using the Task-based `--start YYYYMMDDhhmmss` option. To specify a time in the UTC time zone format, add a trailing "Z" to the time. Otherwise, the time will be treated as a local time in the time zone configured on the server.

```
$ bin/backup --backUpAll --task --start 20111025010000 \
 --backupDirectory /path/to/backup --completionNotify admin@example.com \
 --errorNotify admin@example.com
```

```
Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM CDT
```

## To Schedule an Online Restore

### About this task

By providing connection and authentication information (and an optional start time), the restore can be performed via the Tasks subsystem while the server is online. The Tasks subsystem allows you to schedule certain operations, such as `import-ldif`, `backup`, `restore`, `start-server`, and `stop-server`. You can schedule a restore to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

### Steps

- The backend that is being restored will be unavailable while the restore is in progress. To specify a time in the UTC time zone, add a trailing "Z" to the time. Otherwise, the time will be treated as a local time in the configured time zone on the server.

```
$ bin/restore --task --start 20111025010000 \
 --backupDirectory /path/to/backup/userRoot \
 --completionNotify admin@example.com --errorNotify admin@example.com
```

## To Encrypt a Backup

### Steps

- Go to the server root directory, and use the `backup` tool to backup up the single backend, `userRoot` and encrypt it with the `--encrypt` option.

```
$ bin/backup --encrypt --backendID userRoot --compress --backupDirectory /
path/to/backup
```

## To Sign a Hash of the Backup

### Steps

- Go to the server root directory, and use the **backup** tool to backup up the single backend, userRoot. Use the **-signHash** option to generate a hash of the backup contents and digitally sign the hash of the backup contents. If you want to generate only a hash of the backup contents, run backup with the **--hash** option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID
userRoot \
--backupDirectory /path/to/backup
```

## To Restore a Backup

### Steps

- Go to the server root directory, and use the **restore** tool to restore a backup. The **backup** tool uses a descriptor file to access property information used for the backup, indicating if the backup was compressed, signed and/or encrypted.

```
$ bin/restore --backupDirectory /path/to/backup
```

## Moving or Restoring a User Database

Part of any disaster recovery involves the restoration of the user database from one server to another. You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. The plan is the best insurance against significant downtime or data loss in the event of unrecoverable database issue.

**Note:** The server root directory should never be restored from a file system backup or snapshot. External backup methods (for example, VM snapshots) are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

- Regular Backup from Local Replicated Directory Server** . Take a backup from a local replicated directory server and restore to the failed server. This will be more recent than any other backup you have.
- Restore the Most Recent Backup**. Restore the most recent backup from a local server. In some cases, this may be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it will take longer for replication to play back changes.
- Contact Support**. If all else fails, contact your authorized support provider and they can work with you (and possibly in cooperation with the Oracle Berkeley DB JE engineers) to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

## Comparing the Data in Two Directory Servers

The PingDirectory Server provides an **ldap-diff** tool to compare the data on two LDAP servers to determine any differences that they may contain. The differences are identified by first issuing a subtree search on both servers under the base DN using the default search filter (`objectclass=*`) to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format that could be used to modify the content of the source server, so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a `^` character to the attribute. (On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`.) The `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.

The `ldap-diff` tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives due to replication delays. By default, it will re-check each entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it will list any exceptions in comments in the output file.

The Directory Server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the Directory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For Directory Servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by the `ldap-diff` tool can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

If you do not want to use a subtree search filter, you can use an input file of DNs for the source, target, or both. The format of the file can accept various syntaxes for each DN:

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHROaW5ncyB0byBkbyB0aGFuIHN1ZSB3aGF0IHROaXMgc2F55cw==
There was a blank line above dn: cn=this is the final entry.
```

**i CAUTION:** Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation, because manual updates to the servers risk introducing additional replication conflicts.

## To Compare Two Directory Servers Using ldap-diff

### Steps

1. Use `ldap-diff` to compare the entries in two Directory Server instances. Ignore the `userpassword` attribute due to the one-way password hash used for the password storage scheme.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
"^userpassword"
```

2. Open the output file in a text editor to view any differences. The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and then adds from the perspective of the source server as the authoritative source.

```
This file contains the differences between two LDAP servers.
#
The format of this file is the LDIF changes needed to bring server
ldap://server1.example.com:1389 in sync with server
ldap://server2.example.com:2389.
#
These differences were computed by first issuing an LDAP search at both
servers under base DN dc=example,dc=com using search filter
(objectclass=*)
and search scope SUB to first retrieve the DNs of all entries. And then
each
entry was retrieved from each server and attributes: [^userpassword] were
compared. # # Any entries that were out-of-sync were compared a total of 3
times
waiting a minimum of 2 seconds between each attempt to account for
replication
delays.
#
Comparison started at [24/Feb/2010:10:34:20 -0600]
The following entries were present only on ldap://server2.example.com:2389
and
need to be deleted. This entry existed only on ldap://
server1.example.com:1389
Note: this entry might be incomplete. It only includes attributes:
[^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
st: DC
dn: uid=user.200,ou=people,dc=example,dc=com
changetype: delete

The following entries were present on both servers but were out of sync.

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999
-
delete: mobile
mobile: +1 009 471 1808

The following entries were missing on ldap://server2.example.com:2389 and
need
to be added. This entry existed only on ldap://server2.example.com:2389
Note: this entry might be incomplete. It only includes attributes:

[^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
Comparison completed at [24/Feb/2010:10:34:25 -0600]
```

## To Compare Configuration Entries Using `config-diff`

### Steps

- Use `config-diff` to compare Directory Server configurations and produce a `dsconfig` batch file needed to bring the source inline with the target.

The following example compares the current configurations of `server1` and `server2`. The changes necessary to bring `server1`'s configuration inline with `server2` are written to the console. The same credentials are used to connect to both servers.

```
$ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory Manager" \
\
--sourceBindPassword password --targetHost server2
```

For more information about runtime options, see the *Command Line Tool Reference* or the `config-diff` tool help.

## To Compare Entries Using Source and Target DN Files

### Steps

- Use `ldap-diff` to compare the entries in two Directory Server instances. In the following example, the utility uses a single DN input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute due to the password storage scheme that uses a one-way hashing algorithm.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
--targetDNsFile input-file.ldif "^userpassword"
```

## To Compare Directory Servers for Missing Entries Only Using `ldap-diff`

### Steps

- Use `ldap-diff` to compare two Directory Servers and return only those entries that are missing on one of the servers using the `--missingOnly` option, which can significantly reduce the runtime for this utility.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
"^userpassword" \
--missingOnly
```

## Revert or Replay Changes

The PingDirectory Server provides support for an audit logger that records information about the changes to data within the server. The data is formatted as LDIF, and it can be replayed with tools such as `ldapmodify` or `parallel-update`. The data also includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can also log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made (for example, by a malicious or defective client), it can be used to obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export (for example, concurrent database corruption across all instances), it can be used to recover changes that may not otherwise be available.
- It can be useful for automating the process of identifying changes made in one topology that can be replayed into another topology (for example, to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem).
- It can be useful for analytics and reporting purposes.

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the **extract-data-recovery-log-changes** tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

### The Data Recovery Log

The **setup** tool automatically creates an audit logger for data recovery purposes in **logs/data-recovery**. The log is always compressed, and it will be encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the **logs/data-recovery** directory so that they are isolated from other log files. The active log file is named **data-recovery.gz.encrypted**, while rotated files are named **data-recovery.{timestamp}.gz.encrypted**.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.
- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file will easily fit into the **extract-data-recovery-log-changes** tool's memory.
- The server will retain rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server will also retain no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which may provide information about the downstream client.

### The extract-data-recovery-log-changes Tool

The **extract-data-recovery-log-changes** tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the **ldapmodify** or **parallel-update**. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The **extract-data-recovery-log-changes** tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes will be converted to a form that will revert the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin,

content type, or alterations. The following is a sample command to revert all changes by user `uid=malicious,ou=People,dc=example,dc=com` between noon and 2 pm on October 15, 2018:

```
$ bin/extract-data-recovery-log-changes \
 --auditLogFile logs/data-recovery/data-
 recovery.201810161234.567.gz.encrypted \
 --outputFile revert-malicious-user-changes.ldif \
 --direction revert \
 --startTime 201810151200.000 \
 --endTime 201810151359.999 \
 --includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

## Working with Indexes

---

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server.

This chapter presents topics related to indexes:

### Overview of Indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server. The Directory Server automatically creates index files when you first initialize a base DN or when you use the `dsconfig` tool to create a local DB backend. During modify operations, the Directory Server updates the database index files. If encryption is enabled on the server, indexes will be encrypted.

The PingDirectory Server comes with the following types of indexes:

- **Default system indexes** to ensure that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.
- **Default Local DB indexes** that are created for each database suffix. Modify the index to meet your system's requirements using the `dsconfig` tool.
- **Local DB VLV indexes** that allow a client to request the server to send search results using the Virtual List View control.
- **Filtered Indexes** that provide the ability to index an attribute but only for entries that match a specified filter based on an equality index. The filtered index can only be used for searches containing that filter. The filtered index can be maintained independently of the equality index for that attribute and even if a normal equality index is not maintained for that attribute.

### General Tips on Indexes

Administrators should keep the following tips in mind when working with indexes:

- **Important Critical Indexes.** The Directory Server has several built-in indexes on the Local DB Backend that are critical to internal server processing and should never be removed.

```
aci, ds-entry-unique-id, objectClass
```

- **Built-in Indexes for Efficient Queries.** The Directory Server has built-in indexes on the Local DB Backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. The `mail` and `uid` indexes can be removed, but these attributes are referenced from the Password Modify Extended Operation and will cause problems with components such as the Exact Match Identity Mapper. If the `mail` or `uid` indexes are removed, additional configuration

changes may be necessary to ensure that the server starts properly. The `cn`, `givenName`, `mail`, `sn`, and `telephoneNumber` indexes can be safely removed if clients do not query on these attributes. This will reduce the size of the database both on disk and in memory.

- **Online Rebuilds.** Whenever an online index rebuild is in progress, the data in that backend will be available and writable although the index being rebuilt will not be used; therefore, searches which attempt to use that attribute might be unindexed.
- **Index Rebuild Administrative Alert.** The Directory Server generates an administrative alert when the rebuild process begins and ends. It will have a degraded-alert-type of "index-rebuild-in-progress" so that a Directory Proxy Server, such as the Directory Server can avoid using that server while the rebuild is in progress.
- **System Indexes Cannot be Rebuilt.** The contents of the backend must be exported and re-imported in order to rebuild system indexes. See the table below for the list of system indexes.
- **Indexing Certain Attributes.** You should ensure that the following recommendations are used when setting up the indexes.
  - Equality and substring indexes should not be used for attributes that contain binary data.
  - Approximate indexes should be avoided for attributes containing numbers, such as telephone numbers.
- **Unindexed Searches.** Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, applications should be prevented from performing unindexed searches, so that searches that are not indexed would be rejected rather than tying up a worker thread. The ways to achieve this include:
  - Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.
  - To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user will only be permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search` privilege allows a client to request an unindexed search without this control.
  - The Reject Unindexed Search request control can be used to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of privileges. See the LDAP SDK for information about these controls. These capabilities are also available with the `ldapsearch` tool.
  - Make sure that `allow-unindexed-searches` property is set to `false` in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow unindexed searches, set the `allow-unindexed-searches-with-control` property to `true`. If `allow-unindexed-searches` is `false` but, `allow-unindexed-searches-with-control` is `true`, the policy will only permit an unindexed search if the request includes the Permit Unindexed Search request control. See the LDAP SDK and the `ldapsearch` tool for more information.
  - Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them will be active at any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

To change the maximum number of concurrent unindexed searches, use the `dsconfig` tool to set a value for the number. A value of "0" (default) represents no limit on the number of concurrent unindexed searches.

```
$ bin/dsconfig set-global-configuration-prop \
 --set maximum-concurrent-unindexed-searches:2
```

- **Index Entry Limit.** The Directory Server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must

rebuild the indexes using the `rebuild-index` tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JE backend index entry limit configuration (i.e., 4000).

To change the default index entry limit, use the `dsconfig` tool as seen in the following example:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
 --index-name cn --set index-entry-limit:5000
```

- **Rebuild Index vs Full Import.** You can expect a limited amount of database growth due to the existence of old data when running `rebuild-index` versus doing a full import of your database.

## Index Types

The PingDirectory Server supports several types of indexes to quickly find entries that match search criteria in LDAP operations. The Directory Server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs. Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files (`id2entry`, `dn2id`, `dn2uri`, `id2children`, `id2subtree`).

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the `uid` attribute has an equality matching rule defined in the schema, and thus, has an equality index maintained by the Directory Server. The following table describes the index types:

### Directory Server Index Types

| Index Type  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Approximate | Used to efficiently locate entries that match the approximate search filter. It is used to identify which entries are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.                                                                                                                                                                                                           |
| Equality    | Used to efficiently locate entries that match the equality search filter. It is used to identify which entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule. An offshoot of the equality index is the filtered index, which uses a defined search filter for a specific attribute. The filtered index can be maintained independently of the equality index for a specific attribute. |
| Ordering    | Used to efficiently locate entries that match the ordering search filter. It is used to identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.                                                                                                                                                                                                                |
| Presence    | Used to efficiently locate entries that match the presence search filter. It is used to identify which entries have at least one value for a specified attribute. There is only one presence index key per attribute.                                                                                                                                                                                                                                                                |
| Substring   | Used to efficiently locate entries that match the substring search filter. It is used to identify which entries contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.                                                                                                                                                                                                             |

## System Indexes

The PingDirectory Server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

## System Indexes

| Index       | Description                                                                                                                                                                                                                                                 |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dn2id       | Allows quick retrieval of DNs. The DN database, or <code>dn2id</code> , has one record for each entry. The key is the normalized entry DN and the value is the entry ID.                                                                                    |
| id2entry    | Allows quick retrieval of entries. The <code>id2entry</code> database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.                                                                                      |
| referral    | Allows quick retrieval of referrals. The referral database called <code>dn2uri</code> contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the <code>ref</code> attribute for that entry. |
| id2children | Allows quick retrieval of an entry and its children. The <code>id2children</code> database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.                                  |
| id2subtree  | Allows quick retrieval of an entry's subtree. The <code>id2subtree</code> database provides a mapping between an entry's unique identifier and its unique identifiers in its subtree.                                                                       |

### To View the System Indexes

#### Steps

Use the `dbtest` command to view the system and user indexes. The index status indicates if it is a trusted index or not. An index is either trusted or untrusted. An untrusted index requires rebuilding.

```
$ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID userRoot
```

## Managing Local DB Indexes

You can modify the local DB indexes to meet your system's requirements using the `dsconfig` tool. If you are using the `dsconfig` tool in interactive command-line mode, you can access the **Local DB Index** menu from the Basic object menu.

### To View the List of Local DB Indexes

#### Steps

- Use `dsconfig` with the `list-local-db-indexes` option to view the default list of indexes.

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

```
Local DB Index : Type : index-type

aci : generic : presence
cn : generic : equality, substring
ds-entry-unique-id : generic : equality
givenName : generic : equality, substring
mail : generic : equality
member : generic : equality
objectClass : generic : equality
sn : generic : equality, substring
telephoneNumber : generic : equality
uid : generic : equality
uniqueMember : generic : equality
```

## To View a Property for All Local DB Indexes

### Steps

- Use `dsconfig` with the `--property` option to view a property assigned set for all local DB indexes. Repeat the option for each property that you want to list. In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

```
$ bin/dsconfig list-local-db-indexes --property index-entry-limit \
--property prime-index --backend-name userRoot
```

## To View the Configuration Parameters for Local DB Index

### Steps

- To view the configuration setting of a local DB index, use `dsconfig` with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. If you want to view the advanced properties, add the `--advanced` option to your command.

```
$ bin/dsconfig get-local-db-index-prop --index-name aci \
--backend-name userRoot
```

## To Modify the Configuration of a Local DB Index

### About this task

You can easily modify an index using the `dsconfig` tool. Any modification or addition of an index requires the indexes to be rebuilt. In general, an index only needs to be built once after it has been added to the configuration.

If you add an index, then import the data using the `import-ldif` tool, then the index will be automatically rebuilt. If you add an index, then add the data using some other method than `import-ldif`, you must rebuild the index using the `rebuild-index` tool.

### Steps

- Use `dsconfig` with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `prime-index` property, which loads the index at startup. This command requires the `--advanced` option to access this property.

```
$ bin/dsconfig set-local-db-index-prop --index-name uid \
--backend-name userRoot --set prime-index:true
```

- View the index to verify the change.

```
$ bin/dsconfig get-local-db-index-prop --index-name uid \
--backend-name userRoot
```

- Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in [General Tips on Indexes](#).

```
$ bin/stop-server
```

- Run the `rebuild-index` tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index uid
```

- Restart the Directory Server if shutdown.

```
$ bin/start-server
```

## To Create a New Local DB Index

### Steps

1. To create a new local DB index, use **dsconfig** with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type: <value>` options.

```
$ bin/dsconfig create-local-db-index \
 --index-name roomNumber --backend-name userRoot \
 --set index-type:equality
```

2. View the index.

```
$ bin/dsconfig get-local-db-index-prop \
 --index-name roomNumber --backend-name userRoot
```

3. Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in [General Tips on Indexes](#) on page 148.

```
$ bin/stop-server
```

4. Rebuild the index using the **rebuild-index** tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
```

5. Restart the Directory Server.

```
$ bin/start-server
```

## To Delete a Local DB Index

### About this task

You can delete an index using the **dsconfig** tool. Check that no plugin applications are using the index before deleting it. When the index is deleted, the corresponding index database will also be deleted. The disk space is reclaimed once the cleaner threads begin.

### Steps

- Use **dsconfig** with the `delete-local-db-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-index \
 --index-name roomNumber --backend-name userRoot
```

## Working with Composite Indexes

The PingDirectory Server composite index can be generated from multiple pieces of information (a combination of multiple filter components, or a combination of filter components and a base DN). A composite index can also be based on only a single piece of information.

To improve searches over a large number of entries, equality composite indexes can be used to combine a mandatory equality filter pattern with an optional base DN pattern to improve the performance of searches in directories with a very large number of entries, and in particular with a very large number of non-leaf entries. Equality composite indexes offer two advantages over existing equality attribute indexes in these types of deployments.

**Base DN Pattern** - If a directory environment has many branches, but searches are often done that are within specific individual branches, the base DN pattern can be used to make search processing more efficient. The server will only need to search entries within a target branch.

For example, if the directory contains an `"ou=Customers,dc=example,dc=com"` branch, with a separate branches below that for sets of customers, like `"ou=ACME,ou=Customers,dc=example,dc=com"`, and

"ou=SHOPCO,ou=Customers,dc=example,dc=com", a composite index with a filter pattern of "(sn=\*)" and a base DN pattern of "ou=?,ou=Customers,dc=example,dc=com" can be defined. Then a search with a filter of "(sn=Smith)" and a base DN of "ou=ACME,ou=Customers,dc=example,dc=com" can be used to narrow the search to the Smiths in the ACME branch.

**Index Pages** - If many entries have the same value for a specific attribute, composite indexes can break large ID sets up across multiple pages, unlike the traditional attribute index. Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index will return either one Smith record whose value is a block that contains all 50,000 of the matching entry IDs (if the index isn't exploded), or 50,000 Smith records that each have a value of the matching entry ID (when the index is exploded). The non-exploded form is efficient for searching because all of the entry IDs are returned in a single read, but it's expensive for writing because if a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten. The exploded form is efficient for writing (adding or removing a Smith involves just that one entry ID), but it's expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

Composite indexes break up the block of entry IDs across multiple pages (a page size of up to 5000). If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, ten blocks of 5,000 IDs are returned. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value (such as givenName or sn), not for an attribute with very few entries with the same value (such as id or mail). For attributes in which all of the values match a small number of entries, it's better to use an equality attribute index.

When configuring a composite index, define the following properties:

### Composite Index Properties

| Composite Index Properties | Description                                                                                                                                                                                                               |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| index-filter-pattern       | Specifies a single-valued filter property used to identify a portion of the index criteria. This can only be specified at the time that the index definition is created and is required.                                  |
| index-base-dn-pattern      | Specifies a single-valued DN property that may indicate that the index should be scoped to a specific subtree or subtree pattern. This can only be specified at the time the index definition is created and is optional. |

## Working with JSON Indexes

JSON indexing is similar to general attribute indexing. Where an attribute can be indexed several ways and requires a separate database for each index type, there is only a single database for each JSON field that can be used for different JSON filter types. This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field, and the corresponding database entry value is an list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator (based on the data type for the target field) that enables iterating through values in a logical order to facilitate inequality and subinitial searches.

JSON indexes are automatically created when the JSON Field constraint indicates that a JSON field should be indexed. Indexes can be viewed with the following command:

```
$ bin/dbtest list-index-status \
 --backendID userRoot \
 --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

- `equals`. Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. However, depending on the nature of the search filter, the ID list may contain references to entries that don't actually match the filter (such as if the field is a string, and the filter is configured to use case-sensitive matching).
- `equalsAny`. Identifies entries that have any of a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.
- `greaterThan/lessThan`. Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, except that it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.
- `substring`. Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component, and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes the following:

- Add, delete, modify, and modify DN operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The `rebuild-index` tool and corresponding backend code to make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The `verify-index` tool should also work with JSON indexes to make it possible to check their validity.
- Matching entry count control and `debugsearchindex` return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

**Note:** Exploded indexes and the entry balancing global index do not support JSON objects.

## Working with Local DB VLV Indexes

Local DB VLV indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter. The client can navigate through the list by passing a context back to the server with the virtual list view control. The Local DB VLV index can be used only when the client request contains the virtual list view (VLV) control and the client has been authorized with an ACI with a `targetcontrol` of **2.16.840.1.113730.3.4.9**.

**Note:** A client request, which includes a virtual list view control, can be successfully processed without a matching Local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV, since the server has to retrieve each entry twice.

### To View the List of Local DB VLV Indexes

#### Steps

- Use `dsconfig` with the `list-local-db-indexes` option to view the default list of indexes. In the example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-vlv-indexes --backend-name userRoot
```

## To Create a New Local DB VLV Index

### Steps

1. Use **dsconfig** with the `create-local-db-ylv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options. If you do not set any property values, the default values are assigned.

```
$ bin/dsconfig create-local-db-ylv-index \
 --index-name givenName --backend-name userRoot --set base-
dn:dc=example,dc=com \
 --set scope:whole-subtree --set filter:"(objectclass=*)" \
 --set sort-order:givenName
```

2. Rebuild the index using the **rebuild-index** tool. You must add the "ylv." prefix to the index name to rebuild the VLV index. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index ylv.givenName
```

## To Modify a VLV Index's Configuration

### Steps

1. Use **dsconfig** with the `set-local-db-ylv-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `base-dn` property.

```
$ bin/dsconfig set-local-db-ylv-index-prop --index-name givenName \
 --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
```

2. Rebuild the index using the **rebuild-index** tool. You must add the prefix "ylv." to the index name. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index ylv.givenName
```

## To Delete a VLV Index

### About this task

You can delete a VLV index using the **dsconfig** tool. Check that the index is not being used in any plugin applications before deleting it.

### Steps

1. Use **dsconfig** with the `delete-local-db-ylv-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-ylv-index --index-name givenName \
 --backend-name userRoot
```

2. Verify the deletion by trying to view the ylv index.

```
$ bin/dsconfig get-local-db-ylv-index-prop --index-name givenName \
 --backend-name userRoot
```

## Working with Filtered Indexes

The PingDirectory Server filtered index is useful when client search requests consisting of a compound &-filter with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

For example, assume a database contains several thousand company profiles and each company profile is represented by many entries. The "(objectClass=company)" filter matches a small set of entries per company, and therefore may exceed the index entry limit since there are many companies. Also assume that the "(companyDomain=example.com)" filter matches many of the entries for the company with domain `example.com` and can also result in an unindexed search. The more narrow filter "(&(objectClass=company)(companyDomain=example.com))" also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the `companyDomain` attribute with a static filter of "(objectClass=company)" in the `equality-index-filter` property of the index.

Filtered indexing is primarily useful for cases in which clients frequently issue searches with AND filters that meet the following criteria:

- The AND filter itself matches a relatively small number of entries, but each of the individual components may match a very large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that doesn't change.
- The filter must be narrowed to a base DN, for data structures with many branches, or if indexed attribute values appear in a very large number of entries.

The filtered index can be maintained independently from the equality filter for that attribute. Further, the filtered index will be used only for searches containing the equality component with the associated attribute type ANDed with this filter. When configuring a filtered index, be aware of the `equality-index-filter` and `maintain-equality-index-without-filter` properties of the index.

Once configured and built with the `rebuild-index` tool or `import-ldif`, searches with filters based on the above example will be processed with the index:

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)
(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))(&(objectClass=company)
(companyDomain=example.org)))
```

When configuring a filtered index, define the following properties:

### Filtered Index Properties

| Filtered Index Properties                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>equality-index-filter</code>                  | Specifies a search filter that may be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index will be maintained for the associated attribute, but only for entries that match the provided filter. Further, the index will be used only for searches containing an equality component with the associated attribute type ANDed with this filter. |
| <code>maintain-equality-index-without-filter</code> | Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute will not be indexed for equality by itself but only in conjunction with the defined equality index filters.                                                                                                         |

## To Create a Filtered Index

### Steps

1. Use the `dsconfig` tool to create a filtered index. The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined `"(objectclass=company)"`. After you have created the index, you must rebuild the indexes.

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
 --index-name companyDomain --set maintain-equality-index-without-
filter:true \
 --set index-type:equality --set equality-index-
filter:"(objectclass=company)"
```

2. Stop the Directory Server using `bin/stop-server`.
3. Run the `rebuild-index` tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
```

4. Start the Directory Server using `bin/start-server`.

## Tuning Indexes

The PingDirectory Server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system. The server now supports an optional expanded index database using an *exploded* format to process high write load operations. To view the current state of the server's indexes and make adjustments to the index databases, the Directory Server automatically generates an Index Summary Statistics Table after each LDIF import or index rebuild. The `dbtest` tool also includes an Index Histogram to determine the key datasize for the indexes. This section provides descriptions of each of these tools.

### About the Exploded Index Format

The `index-entry-limit` Backend configuration property specifies the maximum number of entries kept in an index record, before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search. If any index keys have already reached this limit, indexes must be rebuilt before they can be allowed to use a new limit. If `index-entry-limit` is configured to be larger than 50000, then any keys that match more than 50000 entries will be stored in a separate database in an expanded (or "exploded") format.

All keys whose entry count is less than 50000 continue to be stored in one database in a consolidated format, such that changes to the key require rewriting all the entry IDs matching the key. All keys whose entry count is greater than 50000 and less than the `index-entry-limit` are stored in a separate database in an exploded format, such that changes to the key require writing only to the updated entry ID.

If the `index-entry-limit` is increased to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it will be stored in a separate database where each key is stored with its entry ID individually. The consolidated format is very efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is far more efficient for high volumes of write operations since it avoids large on-disk growth.

### Monitoring Index Entry Limits

Index keys that have reached their limit require indexes to be rebuilt before they can be allowed to use a new limit. There are several ways to monitor index limits to avoid a potentially costly rebuild. There are cases in which it is acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and also because applications frequently need to find entries of a specific type. However, it doesn't make sense for the "top" `objectClass` key to be indexed, because it appears in every entry in the server.

Choose an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `verify-index` tool `--listKeysNearestIndexEntryLimit` argument lists a specified number of keys that are closest to the limit without having exceeded it. The index entry limit should be larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if the index entry limit needs to be adjusted.

The `verify-index` tool also provides the `--listKeysExceedingIndexEntryLimit` argument to list all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has already exceeded but that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key (with additional room for future growth) and run the `rebuild-index` tool (or export to LDIF and re-import).

The server provides other ways to determine if index keys have exceeded, or are close to exceeding, the index entry limit. Some of these include:

- When performing an LDIF import, the tool includes an "Index Summary Statistics" section that provides usage information for each index, including the number of keys for which the index entry limit has been exceeded, and also the number of keys for which the number of matching entries falls within a number of predefined buckets (such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries).
- If, during a search operation, the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation will include an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- If, during a search operation, the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are more than 80 percent to reaching that limit, the access log message for that operation will include an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80 percent of the index entry limit.
- If a search operation requests either includes the `debugsearchindex` attribute, or the matching entry count request control with debugging enabled, the debug information will include any indexes accessed that have exceeded the index entry limit, or that are within 80 percent of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered (since the backend was brought online, or since the index entry limit was changed) in a number of different categories. These monitor attributes include:
  - `ds-index-exceeded-entry-limit-count-since-db-open` — The number of index keys for which the number of matching entries has crossed the index entry limit due to a write operation.
  - `ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80 percent of the index entry limit.
  - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.
  - `ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80 percent of the index entry limit.
  - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

## About the Index Summary Statistics Table

The Directory Server now automatically generates an Index Summary Statistics Table, which can be used to determine the optimal configuration for your system's indexes. This table is only generated when the `rebuild-index` tool is run in offline mode. The table is generated after any LDIF import or an index rebuild, and is written to system out and to `logs/tools/rebuild-index-summary.txt`. The table lists the current index entry limit (set by the `index-entry-limit` property on the local DB configuration), the number of keys whose entry count exceeds this limit if any, and the maximum entry count for any key in the index. The table then displays a histogram of the number of keys whose entry falls within a range of values. An example of the Index Summary Statistics table is show below for the `sn.equality` and the `sn.substring` indexes.

The following figure shows that there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```

--- Index Summary Statistics ---
Index : Limit : >Limit : Max : 1-9 : 10-99 : 100-999 : 1000-9999 : 10000-99999

dc_example_dc_com_sn.equality : 4000 : 2 : 100000 : : : : :
dc_example_dc_com_sn.substring : 4000 : 7 : 13419 : 150814 : 7109 : 407 : 36 : 6

```

## MY TITLE Example of an Index Summary Statistics Table

### About the dbtest Index Status Table

The `dbtest` tool has a `list-all --analyze` option that generates the current status of all of the databases on your system, including all index databases. The table shows the type, entry count (i.e., the number of records in the database), index status (TRUSTED to indicate that the indexes are up-to-date, or UNTRUSTED if the index needs rebuilding), the total data size for each key, the average data size for each key and the maximum data size for each key. Note also that any indexes that are in exploded format are listed on this table.

| Index Name                        | Index Type | JE Database Name                                    | Index Status |
|-----------------------------------|------------|-----------------------------------------------------|--------------|
| id2children                       | Index      | dc_example_dc_com_id2children                       | TRUSTED      |
| id2subtree                        | Index      | dc_example_dc_com_id2subtree                        | TRUSTED      |
| uid.equality                      | Index      | dc_example_dc_com_uid.equality                      | TRUSTED      |
| aci.presence                      | Index      | dc_example_dc_com_aci.presence                      | TRUSTED      |
| ds-soft-delete-timestamp.ordering | Index      | dc_example_dc_com_ds-soft-delete-timestamp.ordering | TRUSTED      |
| ds-soft-delete-from-dn.equality   | Index      | dc_example_dc_com_ds-soft-delete-from-dn.equality   | TRUSTED      |
| givenName.equality                | Index      | dc_example_dc_com_givenName.equality                | TRUSTED      |
| givenName.substring               | Index      | dc_example_dc_com_givenName.substring               | TRUSTED      |
| objectClass.equality              | Index      | dc_example_dc_com_objectClass.equality              | TRUSTED      |
| member.equality                   | Index      | dc_example_dc_com_member.equality                   | TRUSTED      |
| uniqueMember.equality             | Index      | dc_example_dc_com_uniqueMember.equality             | TRUSTED      |
| cn.equality                       | Index      | dc_example_dc_com_cn.equality                       | TRUSTED      |
| cn.substring                      | Index      | dc_example_dc_com_cn.substring                      | TRUSTED      |
| sn.equality                       | Index      | dc_example_dc_com_sn.equality                       | TRUSTED      |
| sn.substring                      | Index      | dc_example_dc_com_sn.substring                      | TRUSTED      |
| telephoneNumber.equality          | Index      | dc_example_dc_com_telephoneNumber.equality          | TRUSTED      |
| mail.equality                     | Index      | dc_example_dc_com_mail.equality                     | TRUSTED      |
| ds-entry-unique-id.equality       | Index      | dc_example_dc_com_ds-entry-unique-id.equality       | TRUSTED      |

## MY TITLE dbtest Output Including Index Databases

### Configuring the Index Properties

By default, the `index-entry-limit` is set to 4000, which means the server will stop maintaining index values for keys that match more than 4000 entries. This can be changed with the `dsconfig` tool.

## To Configure the Index Properties

### About this task

Before running the following commands, be aware that you will need to do an index rebuild on the system, which requires a system shutdown, unless the command is run as a task.

### Steps

1. Run `dsconfig` and set the `index-entry-limit` to 5000. By default, the value is set to 4000. Remember to include the bind parameters for your system. Once you enter the command, confirm that you want to apply the changes.

```
$ bin/dsconfig set-backend-prop \
 --backend-name userRoot \
 --set index-entry-limit:5000 \
One or more configuration property changes require administrative action
or confirmation/notification. Those properties include:
* index-entry-limit: If any index keys have already reached this limit,
indexes must be rebuilt before they will be allowed to use the new limit.
Setting a large limit (greater than 10,000) could have a big impact on
write performance and database growth on disk.
Continue? Choose 'no' to return to the previous step (yes / no) [yes]: yes
```

2. Stop the server.

```
$ bin/stop-server
```

3. Rebuild the index.

```
$ bin/rebuild-index --baseDN dc=example,dc=com \
 --index cn --index givenName --index objectClass \
 --index sn --maxThreads 10
```

4. View the Index Summary Statistics table, which is automatically displayed to system out after running the `rebuild-index` command. You can also access the table at `logs/tools/rebuild-index-summary.txt`. Repeat the last three steps to make more adjustments to your indexes.

```
--- Index Summary Statistics ---
Index : Limit : >Limit : Max : 1-9 : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
-----:-----:-----:-----:-----:-----:-----:-----:-----:-----
dc_example_dc_com_cn.equality : 5000 : : 1 : 100001 : : : : :
dc_example_dc_com_cn.substring : 5000 : 9 : 15401 : 131746 : 22372 : 545 : 39 : 3 :
dc_example_dc_com_givenName.equality : 5000 : : 16 : 3788 : 4817 : : : : :
dc_example_dc_com_givenName.substring : 5000 : 8 : 23809 : 7039 : 12062 : 483 : 42 : 3 :
dc_example_dc_com_objectClass.equality : 5000 : 4 : 100003 : 3 : : : : : : 4
dc_example_dc_com_sn.equality : 5000 : : 8 : 13419 : : : : : :
dc_example_dc_com_sn.substring : 5000 : 9 : 15401 : 33967 : 7055 : 459 : 39 : 3 :

The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
(2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
maximum entry count for any key in the index. The remaining columns provide the number of keys
whose entry count falls in the range indicated in the column heading
```

5. Restart the server.

```
$ bin/start-server
```

## Managing Entries

The Directory Server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

This chapter presents the following topics:

### Searching Entries

The Directory Server provides an `ldapsearch` tool to search for entries or attributes within your server. The tool requires the LDAP connection parameters needed to bind to the server, including the

`baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search:

- `base` (search only the entry specified)
- `one` (search only the children of the entry and not the entry itself)
- `sub` (search the entry and its descendents)

The `ldapsearch` tool provides basic functionality as specified by the RFC 2254 but provides additional features that takes advantage of the Directory Server's control mechanisms. For more information, run the `ldapsearch --help` function.

## To Search the Root DSE

About this task

The Root DSE is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls. Specifically, the root DSE entry provides information about the supported LDAPv3 controls, SASL mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

**Note:** The Directory Server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. Once this property is set, the associated attribute types are re-created and re-registered as user attributes in the schema (in memory, not on disk). Once you set the property, you can use `ldapsearch` without "+" to view the root DSE.

Use the `dsconfig` tool to set the `show-all-attributes` property to TRUE, as follows:

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

Steps

- Use `ldapsearch` to view the root DSE entry on the Directory Server. Be sure you include the "+" to display the operational attributes in the entry.

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

## To Search All Entries in the Directory Server

Steps

- Use `ldapsearch` to search all entries in the Directory Server. The filter `"(objectclass=*)"` matches all entries. If the `--searchScope` option is not specified, the command defaults to a search scope of `sub`:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--searchScope sub "(objectclass=*)" "
```

## To Search for an Access Control Instruction

### Steps

- Use `ldapsearch` to search the `dc=example,dc=com` base DN entry. The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an ACI.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci

dn: dc=example,dc=com
aci: (targetattr!="userPassword")
 (version 3.0; acl "Allow anonymous read access for anyone";
 allow (read,search,compare) userdn="ldap:///anyone");
aci: (targetattr="*")
 (version 3.0; acl "Allow users to update their own entries";
 allow (write) userdn="ldap:///self");
aci: (targetattr="*")
 (version 3.0; acl "Grant full access for the admin user";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

## To Search for the Schema

### Steps

- Use `ldapsearch` to search the `cn=schema` entry. The base DN is specified as `cn=schema`, and the filter `"(objectclass=*)"` matches all entries. The command uses a special attribute `"+"` to return all operational attributes:

```
$ bin/ldapsearch --baseDN cn=schema \
 --searchScope base "(objectclass=*)" "+"
```

## To Search for a Single Entry using Base Scope and Base DN

### Steps

- Use `ldapsearch` to search for a single entry by specifying the base scope and DN:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
 --searchScope base "(objectclass=*)" "
```

## To Search for a Single Entry Using the Search Filter

### Steps

- Search for a single entry by specifying the `sub` scope and a search filter that describes a single entry:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
 --searchScope sub "(uid=user.14) "
```

## To Search for All Immediate Children for Restricted Return Values

### Steps

- Search for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn` and `givenName`. The special attribute `"+"` returns all operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
 --searchScope one '(objectclass=*)' sn givenName "+"
```

## To Search for All Children of an Entry in Sorted Order

### Steps

- Search for all children of the `ou=People,dc=example,dc=com` subtree. The resulting entries are sorted by the server in ascending order by `sn` and then in descending order by `givenName`:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
--searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

## To Limit the Number of Returned Search Entries and Search Time

### Steps

- Search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree by specifying a compound filter. No more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
--searchScope sub --sizeLimit 200 --timeLimit 5 \
"(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
```

## To Get Information about How Indexes are used in a Search Operation

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Information about the can be obtained about the server's use of indexes in the course of processing a search operation. The following are two basic ways to accomplish this.

Issue a search request with the desired base DN, scope, and filter, and request that the server return the special `debugsearchindex` attribute. Users will need to be granted access to the `debugsearchindex` operational attribute and the `cn=debugsearch` portion of the DIT with the following command:

```
$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetattr=\"debugsearchindex\") (target=\"ldap:///
cn=debugsearch\")
(version 3.0; acl \"Allow members of the Index Debugging Users group
to request the debugsearchindex operational attribute \"; allow
(read,search,compare) groupdn=\"ldap:///cn=Index Debugging
Users,ou=Groups,dc=example,dc=com\");"
```

To issue a search request for the server return the special `debugsearchindex` attribute, use the `ldapsearch` command such as:

```
$ bin/ldapsearch --hostname ds.example.com \
--port 389 --bindDN uid=admin,dc=example,dc=com \
--bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
dn: cn=debugsearch
debugsearchindex: 0.040 ms - Beginning index processing for search
request with base DN 'dc=example,dc=com', scope wholeSubtree,
and filter (&(givenName=John)(sn=Doe)).
debugsearchindex: 0.067 ms - Unable to optimize the AND filter
beyond what the client already provided.
debugsearchindex: 0.834 ms - Candidate set obtained for single-key
filter (givenName=John) from index dc example dc com givenName.equality.
Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2, originalFilter=(givenName=John),
remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.030 ms - Final candidate set for filter (givenName=John)
```

```

 obtained from an unexploded index key in
dc_example_dc_com_givenName.equality.
 Since the scope of the search includes the entire entry container, there
is
 no need to attempt to further pare down the results based on the search
scope.
 Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true,
 size=2, originalFilter=(givenName=John), remainingFilter=null,
 matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.020 ms - Short-circuiting index processing for AND filter
 (&(givenName=John)(sn=Doe)) after evaluating single-key component
 (givenName=John) because the current ID set size of 2 is within the
 short-circuit threshold of 5.
debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for AND
filter
 (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even though
there is still more of the filter to evaluate, the current candidate set
is
 within the short-circuit threshold of 5, so no additional index
processing will
 be performed to try to pare down the results based on the remaining
filter or the
 search scope. Candidate set: CandidateSet(isDefined=true,
isExploded=false,
 isResolved=true, size=2, originalFilter=(&(givenName=John)(sn=Doe)),
 remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
debugsearchindex: 0.016 ms - Completed all index processing. Candidate set:
CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
 originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
 matchingEntryCountType=UPPER_BOUND)

```

The second way would be to issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to `true`. To do this with `ldapsearch`, use a command such as:

```

$ bin/ldapsearch --hostname ds.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub --matchingEntryCountControl examineCount=0:debug
"(&(givenName=John)(sn=Doe))"
Upper Bound on Matching Entry Count: 2
Matching Entry Count Debug Messages:
* naw-desktop:1389 - 0.104 ms - Beginning index processing for search request
with
 base DN 'dc=example,dc=com', scope wholeSubtree, and filter
 (&(givenName=John)(sn=Doe)).
* naw-desktop:1389 - 0.105 ms - Unable to optimize the AND filter beyond what
the client already provided.
* naw-desktop:1389 - 0.614 ms - Candidate set obtained for single-key filter
(givenName=John) from index
 dc_example_dc_com_givenName.equality. Candidate set:
 CandidateSet(isDefined=true, isExploded=false, isResolved=true,
 size=2, originalFilter=(givenName=John), remainingFilter=null,
 matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.090 ms - Final candidate set for filter
 (givenName=John) obtained from an unexploded index key in
 dc_example_dc_com_givenName.equality. Since the scope of the search
 includes the entire entry container, there is no need
 to attempt to further pare down the results based on the search scope.
 Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true,

```

```

 size=2, originalFilter=(givenName=John), remainingFilter=null,
 matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.045 ms - Short-circuiting index processing for AND
filter
 (&(givenName=John)(sn=Doe)) after evaluating single-key component
 (givenName=John) because the current ID set size of 2 is within the short-
circuit threshold of 5.
* naw-desktop:1389 - 0.111 ms - Obtained a candidate set of size 2 for AND
filter
 (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even though
there is
 still more of the filter to evaluate, the current candidate set is within
 the short-circuit threshold of 5, so no additional index processing will
be performed
 to try to pare down the results based on the remaining filter or the
search scope.
 Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2,
 originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
 matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - 0.040 ms - Completed all index processing. Candidate
set:
 CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
 originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
 matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - The search is partially indexed
(candidatesAreInScope=true,
 unindexedFilterPortion=(sn=Doe))
* naw-desktop:1389 - Constructing an UPPER_BOUND response with a count of 2

```

## Working with the Matching Entry Count Control

The `ldapsearch` command can be used with the `--matchingEntryCountControl` option to determine the count of entries that match a search filter. Users will need to be granted access to this control by its OID `1.3.6.1.4.1.30221.2.5.36` with the following command:

```

$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
 (version 3.0; acl \"Allow members of the Index Debugging Users group to
 use the matching entry count request control \"; allow (read)
 groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com\");"

```

An `examineCount` control can be used for searches that are at least partially indexed, in order to determine whether to return an examined count, an unexamined count, or an upper bound count. The factors that determine what is returned are:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. Indexes can also be used to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if indexes can be used to identify the entry IDs for all entries that match the search criteria, but the candidate list may potentially also include entries that either don't match the filter or are outside the scope of the search.
- A search is unindexed if it is not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count, except that all of the candidate entries are examined to determine whether they would have been returned to the client. An examined count may be less than an unexamined count if the set of matching entries includes those that would be removed by access control evaluation, or special entries like LDAP sub-entries, replication conflict entries, or soft-deleted entries.

- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it did not do.
- If a search is fully indexed, the result is an examined count or an unexamined count. If **alwaysExamine** is true and **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If **alwaysExamine** is false, or if the number of candidates exceeds **examineCount**, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count. The **alwaysExamine** flag isn't relevant in this case. If **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.
- If a search is unindexed, the result is either an examined count or an unknown count. If **allowUnindexed** is true, the unindexed search is processed, which can be very expensive. Instead of getting the matching entries back, the examined count is returned. If **allowUnindexed** is false, an unknown count is returned. If **allowUnindexed** is true, the requester needs to have the **unindexed-search** privilege to get the exact count.

The following is a sample `ldapsearch` with the `--matchingEntryCountControl` option:

```

$./ldapsearch \
 --bindDN "cn=directory manager" \
 --bindPassword password \
 --baseDN dc=example,dc=com \
 --matchingEntryCountControl
examineCount=100:alwaysExamine:allowUnindexed:debug \
 "(objectclass=*)"

```

## Adding Entries

Depending on the number of entries that you want to add to your Directory Server, you can use the `ldapmodify` tool for small additions. The `ldapmodify` tool provides two methods for adding a single entry: using a LDIF file or from the command line. The attributes must conform to your schema and contain the required object classes.

Adding requests with the **ignore-no-user-modification** control enable a client to include attributes that are not normally allowed from external sources. For example, the **userPassword** attribute is a user-modifiable attribute. An add request with the **ignore-no-user-modification** control allows a one-time exception to the password policy, even if the requesting client does not have the **bypass-pw-policy** privilege. This exception enables specifying pre-encoded passwords.

**Note:** When adding an entry, the server can ensure that the entry's RDN is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated entryUUID value. An LDAP client written with the LDAP SDK for Java can use the **NameWithEntryUUIDRequestControl** to explicitly indicate which add requests should be named in this way, or the `ldapmodify` tool with the `--nameWithEntryUUID` argument. Also, the **auto-name-with-entry-uuid-connection-criteria** and **auto-name-with-entry-uuid-request-criteria** global configuration properties can be used to identify which add requests should be automatically named this way.

The uniqueness request control can also be used with `ldapmodify` for enforcing uniqueness on a per-request basis. Provide at least one of the **uniquenessAttribute** or **uniquenessFilter** arguments with the request. For more information about this control, see the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control.

## To Add an Entry Using an LDIF File

### Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password. The Directory Server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563 postalCode:
 50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. Use the `ldapmodify` tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. If the command is successful, you will see generated success messages with the `#` symbol.

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

```
Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
ADD operation successful for DN uid=user.2000,ou=People,dc=example,dc=com
```

## To Add an Entry Using the Changetype LDIF Directive

### About this task

RFC 2849 specifies LDIF directives that can be used within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine adds and modifies in one file.

### Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user2.ldif`. Note the use of the `changetype` directive in the second line.

```
dn: uid=user.2001,ou=People,dc=example,dc=com
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
```

```
postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Seely Dorm.
uid: user.2001
userPassword: pleasantry
employeeNumber: 2001
initials: SPD
givenName: Seely pager: +1 596 665 3344
mobile: +1 039 686 4949
cn: Seely Dorm
sn: Dorm
telephoneNumber: +1 097 257 7542
street: 100 Apple Street
homePhone: +1 214 521 4883
l: Cincinnati
mail: user.2001@maildomain.net
st: OH
```

2. Use the `ldapmodify` tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

```
$ bin/ldapmodify --filename add-user2.ldif
```

## To Add Multiple Entries in a Single File

### About this task

You can have multiple entries in your LDIF file by simply separating each DN and its entry with a blank line from the next entry.

### Steps

1. Open a text editor and create a couple of entries that conform to your schema. For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

```
dn: uid=user.2003,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass:
organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...

dn: uid=user.2004,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...
```

2. Use the `ldapmodify` tool to add the entries specified in the LDIF file. In this example, we use the short form arguments for the `ldapmodify` tool.

The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype will be treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those beginning with "#") for each addition.

```
$ bin/ldapmodify -h server.example.com -p 389 \
```

```
-D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif

Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
ADD operation successful for DN uid=user.2003,ou=People,dc=example,dc=com
Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
ADD operation successful for DN uid=user.2004,ou=People,dc=example,dc=com
```

## Deleting Entries Using `ldapdelete`

You can delete an entry using the `ldapdelete` tool. You should ensure that there are no child entries below the entry as that could create an orphaned entry. Also, make sure that you have properly backed up your system prior to removing any entries.

### To Delete an Entry Using `ldapdelete`

#### Steps

Use `ldapdelete` to delete an entry. The following example deletes the `uid=user.14` entry.

```
$ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
```

### To Delete Multiple Entries Using an LDIF File

#### Steps

1. You can generate a file of DNs that you would like to delete from the Directory Server.

The following command searches for all entries in the `ou=Accounting` branch and returns the DNs of the subentries.

```
$ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
 "ou=Accounting,ou=People,dc=example,dc=com" --
outputFile /usr/local/entry_dns.txt
```

2. Run the `ldapdelete` command with the file to delete the entries. The command uses the `--continueError` option, which will continue deleting through the whole list even if an error is encountered for a DN entry.

```
$ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueError
```

## Deleting Entries Using `ldapmodify`

You can use the LDIF `changetype` directive to delete an entry from the Directory Server using the `ldapmodify` tool. You can only delete leaf entries.

### To Delete an Entry Using `ldapmodify`

#### Steps

- From the command line, use the `ldapmodify` tool with the `changetype:delete` directive. Enter the DN, press **Enter** to go to the next line, then enter the `changetype` directive. Press **Control-D** twice to enter the EOF sequence (UNIX) or **Control-Z** (Windows).

```
$ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN
"uid=admin,dc=example,dc=com" --bindPassword password
dn:uid=user.14,ou=People,dc=example,dc=com
changetype: delete
```

## Modifying Entries Using ldapmodify

You can use the `ldapmodify` tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value. If you have more than one change, you can separate them using the `-` (dash) symbol.

### To Modify an Attribute from the Command Line

#### Steps

1. Use the `ldapsearch` tool to locate a specific entry.

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the `ldapmodify` command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changed using the `replace` directive. In this example, we change the telephone number of a specific user entry. When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

### To Modify Multiple Attributes in an Entry from the Command Line

#### Steps

1. Use the `ldapsearch` tool to locate a specific entry.

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the `ldapmodify` command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changes using the `add` and `replace` directive.

In this example, we add the `postOfficeBox` attribute, change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-"). When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postOfficeBox
postOfficeBox: 111
-
replace: mobile
mobile: +1 039 831 3737
-
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

## To Add an Attribute from the Command Line

### Steps

- Use the `ldapmodify` command from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be added using the `add` directive. In this example, we add another value for the `cn` attribute, which is multi-valued. When you are done typing, you can press **CTRL-D** (UNIX EOF escape sequence) twice to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
cn: Sally Tea Tree
```

An error could occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's objectclass requirements. Also, make sure there are no trailing spaces after the attribute value.

## To Add an Attribute Using the Language Subtype

### About this task

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

### Steps

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

## To Add an Attribute Using the Binary Subtype

### About this task

The Directory Server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that could be stored in an entry. The operation must specifically match the subtype for successful operation. The version directive with a value of "1" must be used for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

### Steps

- Use the `ldapmodify` command to add an attribute with a binary subtype. The attribute points to the file path of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
```

```
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

## To Delete an Attribute

### Steps

Use `ldapmodify` with the LDIF `delete` directive to delete an attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: employeeNumber
```

## To Delete One Value from an Attribute with Multiple Values

### About this task

You can use the LDIF `delete` directive to delete a specific attribute value from an attribute. For this example, assuming you have multiple values of `cn` in an entry (e.g., `cn: Sally Tree, cn: Sally Tea Tree`).

### Steps

- Use `ldapmodify` to delete a specific attribute of a multi-valued pair, then specify the attribute pair that you want to delete. In this example, we keep `cn:Sally Tree` and delete the `cn: Sally Tea Tree`.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: cn
cn: Sally Tea Tree
```

## To Rename an Entry

### About this task

Renaming an entry involves changing the relative distinguished name (RDN) of an entry. You cannot rename a RDN if it has children entries as this violates the LDAP protocol.

### Steps

- Use the `ldapmodify` tool to rename an entry. The following command changes `uid=user.14` to `uid=user.2014` and uses the `changetype`, `newrdn`, and `deleteoldrdn` directives.

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype: moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

## To Move an Entry Within a Directory Server

### About this task

You can use `ldapmodify` to move an entry from one base DN to another base DN. Before running the `ldapmodify` command, you must assign access control instructions (ACIs) on the parent entries. The source parent entry must have an ACI that allows export operations: `allow(export)`. The target parent entry must have an ACI that allows import operations: `allow(import)`. For more information on access control instructions, see [Working with Access Control](#).

### Steps

- Use the `ldapmodify` command to move an entry from the Contractor branch to the `ou=People` branch.

```
$ bin/ldapmodify
dn: uid=user.14,ou=contractors,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 0
newsuperior: ou=People,dc=example,dc=com
```

## To Move an Entry from One Machine to Another

### About this task

The Directory Server provides a tool, `move-subtree`, to move a subtree or one entry on one machine to another. The subtree or entry must exist on the source server and must not be present on the target server. The source server must also support the 'real attributes only' request control. The target server must support the Ignore NO-USER-MODIFICATION request control.

**Note:** The `move-subtree` tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. Once the entries are moved, they are no longer present on the source server.

### Steps

- Use the `move-subtree` tool to move an entry (e.g., `uid=test.user,ou=People,dc=example,dc=com`) from the source host to the target host.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
--sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
--targetHost target.example.com --targetPort 389 \
--targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
--entryDN uid=test.user,ou=People,dc=example,dc=com
```

## To Move Multiple Entries from One Machine to Another

### About this task

The `move-subtree` tool provides the ability to move multiple entries listed in a DN file from one machine to another. Empty lines and lines beginning with the octothorpe character (#) will be ignored. Entry DNs may optionally be prefixed with `dn:` , but long DNs cannot be wrapped across multiple lines.

## Steps

1. Open a text file, enter a list of DNs, one DN per line, and then save the file. You can also use the `ldapsearch` command with the special character "1.1" to create a file containing a list of DNs that you want to move. The following example searches for all entries that match `(department=Engineering)` and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
 --searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

2. Run the `move-subtree` tool with the `--entryDNFile` option to specify the file of DNs that will be moved from one machine to another.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
 --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
 --targetHost target.example.com --targetPort 389 \
 --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
 --entryDNFile /path/to/file/test-dns.ldif
```

3. If an error occurs with one of the DNs in the file, the output message shows the error. The `move-subtree` tool will continue processing the remaining DNs in the file.

```
An error occurred while communicating with the target server: The entry
uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry with
that name
already exists
Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
```

## Working with the Parallel-Update Tool

The PingDirectory Server provides a `parallel-update` tool, which reads change information (add, delete, modify, and modify DN) from an LDIF file and applies the changes in parallel. This tool is a multi-threaded version of the `ldapmodify` tool that is designed to process a large number of changes as quickly as possible.

The `parallel-update` tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries (for example, modifying an entry after it has been added, or adding a child after its parent). The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file (for example, the change to add a parent entry is provided later in the LDIF file than a change to add a child entry).

After the tool has applied the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table

### Parallel-Update Tool Result Statistics

| Processing Statistic | Description                            |
|----------------------|----------------------------------------|
| Attempts             | Number of update attempts              |
| Successes            | Number of successful update attempts   |
| Rejects              | Number of rejected updates             |
| ToRetry              | Number of updates that will be retried |

| Processing Statistic | Description                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------|
| AvgOps/S             | Average operations per second                                                                      |
| RctOps/S             | Recent operations per second. Total number of operations from the last interval of change updates. |
| AvgDurMS             | Average duration in milliseconds                                                                   |
| RctDurMS             | Recent duration in milliseconds. Total duration from the last interval of change updates.          |

## To Run the Parallel-Update Tool

### Steps

1. Create an LDIF file with your changes. The third change will generate a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

```
dn:uid=user.2,ou=People,dc=example,dc=com
changetype: delete

dn:uid=user.99,ou=People,dc=example,dc=com
changetype: moddn
newrdn: uid=user.100
deleteoldrdn: 1

dn:uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

dn:uid=user.100,ou=People,dc=example,dc=com
changetype: modify
replace: st
st: TX
-
replace: employeeNumber
employeeNumber: 100
```

2. Use `parallel-update` to apply the changes in the LDIF file to a target server. In this example, we use ten concurrent threads. The optimal number of threads depends on your underlying system. The `--ldifFile` and `--rejectFile` options are also required.

```
$ bin/parallel-update --hostname 127.0.0.1 \
 --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS

 4 3 1 0 3 3 26 26
All processing complete Attempted 4 operations in 1 seconds
```

### 3. View the rejects file for any failed updates.

```
ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed
for
the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

## Working with the Watch-Entry Tool

The PingDirectory Server provides a **watch-entry** tool, which demonstrates replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can also be directly modified with this tool as well.

### To Run the Watch-Entry Tool

#### Steps

- Perform the following to connect to **server.example.com** as **uid=admin,dc=example,dc=com** and watch entry **uid=kate,ou=people,dc=example,dc=com** for changes:

```
$ bin/watch-entry --hostname server.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--entryDN uid=user,ou=people,dc=example,dc=com
```

## Working with LDAP Transactions

The PingDirectory Server provides support for *batched transactions*, which are processed all at once at commit time. Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes are not actually processed until the commit request is received. Therefore, the client cannot know whether the changes will be successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations (add, delete, modify, modify DN, and password modify) that are processed as a single atomic unit when the commit request is received. If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It is not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple Directory Server backends.

Directory servers may limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that the following controls may be used in conjunction with the transaction specification request control: assertion request control, manageDsaIT request control, pre-read request control, and post-read request control. The proxied authorization v1 and v2 controls cannot be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory Server supports the following additional controls in conjunction with operations included in a transaction: account usable request control, hard delete request control, intermediate client request control, password policy request control, replication repair request control, soft delete request control, soft deleted entry access request control, subtree delete request control, and undelete request control.

## To Request a Batched Transaction Using `ldapmodify`

### Steps

1. Use the `ldapmodify` tool's `--useTransaction` option. It provides a mechanism for processing multiple operations as part of a single batched transaction. Create a batch text file with the changes that you want to apply as a single atomic unit:

```
dn:uid=user.3,ou=People,dc=example,dc=com
changetype: delete
dn:uid=user.1,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 383 288 1090
```

2. Use `ldapmodify` with the `--useTransaction` and `--filename` options to run the batched transaction.

```
$ bin/ldapmodify --useTransaction --filename test.ldif
```

```
#Successfully created a transaction with transaction ID 400
#Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
#DELETE operation successful for DN uid=user.3,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
#MODIFY operation successful for DN uid=user.1,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Successfully committed transaction 400
```

## Working with Virtual Attributes

---

The PingDirectory Server provides mechanisms to support virtual attributes in an entry. Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend. While most virtual attributes are operational attributes, providing processing-related information that the server requires, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your directory server requirements.

This chapter presents the following topics:

### Overview of Virtual Attributes

The PingDirectory Server allows its entries to hold virtual attributes. Virtual attributes are dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend. Most virtual attributes are operational attributes, providing processing-related information that the server requires. However, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

#### Viewing the List of Default Virtual Attributes

The Directory Server has a default set of virtual attributes that can be viewed using the `dsconfig` tool. Some virtual attributes are enabled by default and are useful for most applications. You can easily enable or disable each virtual attribute using the `dsconfig` tool.

The default set of virtual attributes are described in the table below. You can enable or disable these attributes using the `dsconfig` tool.

## Virtual Attributes

| Virtual Attributes             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ds-entry-checksum              | Generates a simple checksum of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ds-instance-name               | Generates the name of the Directory Server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| entryDN                        | Generates an <code>entryDN</code> operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| hasSubordinates                | Creates an operational attribute that has a value of TRUE if the entry has subordinate entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| isMemberOf                     | Generates an <code>isMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| numSubordinates                | Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested. Note that this operational attribute only returns the number of immediate children of the node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| subschemaSubentry              | <p>A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree.</p> <ul style="list-style-type: none"> <li>▪ <code>ldapSyntaxes</code> - set of attribute syntaxes</li> <li>▪ <code>matchingRules</code> - set of matching rules</li> <li>▪ <code>matchingRuleUse</code> - set of matching rule uses</li> <li>▪ <code>attributeTypes</code> - set of attribute types</li> <li>▪ <code>objectClasses</code> - set of object classes</li> <li>▪ <code>nameForms</code> - set of name forms</li> <li>▪ <code>dITContentRules</code> - set of DIT content rules</li> <li>▪ <code>dITStructureRules</code> - set of DIT structure rules</li> </ul> |
| User Defined Virtual Attribute | Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Virtual Static Member          | Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the <code>Virtual Static Member</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.                                                                                                                                                                                                                                                                                                                     |
| Virtual Static Uniquemember    | Generates a <code>uniqueMember</code> attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the <code>Virtual Static Uniquemember</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.                                                                                                                                                                                                                                                                                            |

## To View the List of Default Virtual Attributes Using dsconfig Non-Interactive Mode

### Steps

- Use `dsconfig` to view the virtual attributes.

```
$ bin/dsconfig list-virtual-attributes
```

## Viewing Virtual Attribute Properties

Each virtual attribute has basic properties that you can view using the `dsconfig` tool. The complete list of properties is described in the *PingDirectory Server Configuration Reference*. Some basic properties are as follows:

- Description.** A description of the virtual attribute.
- Enabled.** Specifies whether the virtual attribute is enabled for use.
- Base-DN.** Specifies the base DN's for the branches containing entries that are eligible to use this virtual attribute. If no values are given, the server generates virtual attributes anywhere in the server.
- Group-DN.** Specifies the DN's of the groups whose members can use this virtual attribute. If no values are given, the group membership is not taken into account when generating the virtual attribute. If one or more group DN's are specified, then only members of those groups are allowed to have the virtual attribute.
- Filter.** Specifies the filters that the server applies to entries to determine if they require virtual attributes. If no values are given, then any entry is eligible to have a virtual attribute value generated.

### To View Virtual Attribute Properties

#### Steps

- Use `dsconfig` to view the properties of a virtual attribute.

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

## Enabling a Virtual Attribute

You can enable a virtual attribute using the `dsconfig` tool. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

### To Enable a Virtual Attribute using dsconfig Interactive Mode

#### Steps

- Use `dsconfig` to enable a virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.

```
bin/dsconfig
```

- On the Directory Server main menu, type `o` to change the object menu, and then type the number corresponding to **Standard**.
- On the Directory Server main menu, type the number corresponding to virtual attributes.
- On the **Virtual Attribute management** menu, type the number to view and edit an existing virtual attribute.
- From the list of existing virtual attributes on the system, select the virtual attribute to work with. For this example, type the number corresponding to the `numSubordinates` virtual attribute.
- On the **numSubordinates Virtual Attribute Properties** menu, type the number to enable the virtual attribute. On the **Enabled Property** menu for the `numSubordinates` virtual attribute, type the number to change the value to TRUE.

7. On the **numSubordinates Virtual Attribute Properties** menu, type `f` to apply the changes.
8. Verify that the virtual attribute is enabled. Note that this example assumes you have configured the group entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
```

```
dn: ou=People,dc=example,dc=com
numSubordinates: 1000
```

### To Enable a Virtual Attribute Using dsconfig Non-Interactive Mode

#### Steps

- Use **dsconfig** to enable the `numSubordinates` virtual attribute.

```
$ bin/dsconfig set-virtual-attribute-prop \
 --name numSubordinates --set enabled:true
```

## Creating User-Defined Virtual Attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute. There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, otherwise you will see an error message when you configure it.

You can define your virtual attributes using the **dsconfig** tool on the Standard object menu. Only the value property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following:

- **enabled** -- Indicates whether the virtual attribute should be used.
- **attribute-type** -- The attribute type for the virtual attribute that will be generated.
- **base-dn, group-dn, filter** -- May be used to select which entries are eligible to contain the virtual attribute.
- **client-connection-policy** -- May be used to configure who can see the virtual values.
- **conflict-behavior** -- Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry. The server can either return only the real value(s), only the virtual value(s), or merge both real and virtual values.
- **require-explicit-request-by-name** -- Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
- **multiple-virtual-attribute-evaluation-order-index, multiple-virtual-attribute-merge-behavior** -- Used to control the behavior the server should exhibit if multiple virtual attributes may be used to contribute values to the same attribute.

### To Create a User-Defined Virtual Attribute in Interactive Mode

#### About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter `"(employeeType=employee)"`.

#### Steps

1. Run **dsconfig** to configure the user-defined virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.
2. On the Directory Server main menu, type `o` to change the object menu, and then type the number to select Standard.
3. On the Directory Server main menu, type the number corresponding to virtual attributes.

4. On the **Virtual Attribute management** menu, type the number to create a new virtual attribute.
5. Next, you can use an existing virtual attribute as a template for your new attribute, or you can create a new attribute from scratch. In this example, type `n` to create a new Virtual Attribute from scratch.
6. On the **Virtual Attribute Type** menu, enter a number corresponding to the type of virtual attribute that you want to create. In this example, type the number corresponding to User Defined Virtual Attribute.
7. Next, enter a name for the new virtual attribute. In this example, enter "Employee Password Policy Assignment."
8. On the **Enabled Property** menu, enter the number to set the property to true (enable).
9. On the **Attribute-Type Property** menu, type the `attribute-type` property for the new virtual attribute. You can enter the OID number or attribute name. The `attribute-type` property must conform to your schema. For this example, type "ds-pwp-password-policy-dn".
10. Enter the value for the virtual attribute, and then press Enter or Return to continue. In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type Enter or Return to continue.
11. On the **User Defined Virtual Attributes** menu, enter a description for the virtual attribute. Though optional, this step is useful if you plan to create a lot of virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, enter: `Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee)`.
12. On the **User Defined Virtual Attribute** menu, type the number corresponding to the filter.
13. On the **Filter Property** menu, enter the option to add one or more filter properties, type the filter, and then press **Enter** to continue. In this example, type `(employeeType=employee)`. Press the number to use the filter value entered.
14. On the **User Defined Virtual Attribute** menu, type `f` to finish creating the virtual attribute.
15. Verify that the attribute was created successfully. Add the `employeeType=employee` attribute to an entry (e.g., `uid=user.0`) using `ldapmodify`. Add the `employeeType=contractor` attribute to another entry (e.g., `uid=user.1`).
16. Use `ldapsearch` to search for the user with the `employeeType=employee` attribute (e.g., `uid=user.0`). You will notice the `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
 ds-password-policy-dn
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn=Password
Policies,cn=config
```

17. Run `ldapsearch` again using the filter `"(uid=user.1)"`, the `ds-pwp-password-policy-dn` attribute will not be present in the entry, because the entry has the attribute, `employeeType=contractor`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
 ds-password-policy-dn
```

```
dn: uid=user.1,ou=People,dc=example,dc=com
```

## To Create a User-Defined Virtual Attribute Using dsconfig in Non-Interactive Mode

### Steps

- You can also use `dsconfig` in non-interactive command-line mode to create a virtual attribute. The following command sets up the Employee Password Policy Assignment virtual attribute introduced in the previous section:

```
$ bin/dsconfig create-virtual-attribute \
--name "Employee Password Policy Assignment" \
--type user-defined \
--set enabled:true \
--set attribute-type:ds-pwp-password-policy-dn \
--set "filter:(employeeType=employee)" \
--set "value:cn=Employee Password Policy,cn>Password Policies,cn=config"
```

## Creating Mirror Virtual Attributes

The PingDirectory Server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry. For example, given a DIT where users have a manager attributed with a value of the DN of the employee as follows:

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute, so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute as follows:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

## To Create a Mirror Virtual Attribute in Non-Interactive Mode

### About this task

You can also use `dsconfig` in non-interactive command-line mode to create a mirror virtual attribute. The following example sets up the `managerName` virtual attribute introduced in the previous section:

### Steps

- Update the schema to define the `managerName` attribute. In a text editor, create a file with the following schema definition for the attribute and save it as `98-myschema.ldif`, for example, in the `<server-root>/config/schema` folder. You can optionally add the attribute to an object class.

```
dn: cn=schema
```

```
objectClass: top
objectClass: ldapSubentry
objectClass: subschema attributeTypes: (1.3.6.1.4.1.32473.3.1.9.4 NAME
 'managerName'
 EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
 1.3.6.1.4.1.1466.115.121.1.44{256}
 X-ORIGIN 'Directory Server Example')
```

## 2. Restart the Directory Server.

```
$ bin/stop-server --restart
```

## 3. Use `dsconfig` to create the virtual attribute.

```
$ bin/dsconfig create-virtual-attribute \
 --name "managerName" \
 --type mirror \
 --set "description:managerName from manager cn" \
 --set enabled:true \
 --set attribute-type:managerName \
 --set source-attribute:cn \
 --set source-entry-dn-attribute:manager
```

## 4. Verify the mirror virtual attribute by searching for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

## Editing a Virtual Attribute

You can edit virtual attributes by using the `dsconfig` tool. Ensure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

### To Edit a Virtual Attribute Using `dsconfig` in Non-Interactive Mode

#### Steps

- Use `dsconfig` to change a property's value.

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
 --set "value:111"
```

## Deleting a Virtual Attribute

You can delete virtual attributes using the `dsconfig` tool. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

### To Delete a Virtual Attribute

#### Steps

- Use `dsconfig` to delete an existing virtual attribute.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

## Working with Groups

---

LDAP groups are special types of entries that represent collections of users. Groups are often used by external clients, for example, to control who has access to a particular application or features. They may also be used internally by the server to control its behavior. For example, groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. In general, there are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group.
- To determine the set of groups in which a specified user is a member.
- To determine the set of all users that are members of a particular group.

This chapter provides an overview of Directory Server groups concepts and provides procedures on setting up and querying groups in the Directory Server.

### Overview of Groups

The Directory Server provides the following types of groups:

- **Static Groups.** A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its particular structural object class. Static groups are ideal for relatively small, infrequently changing elements. Once the membership list grows, static groups become more difficult to manage as any change in a member base DN must also be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

The Directory Server also supports nested groups, in which a parent group entry contains child attributes whose DNs reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughout, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.

- **Dynamic Groups.** A dynamic group has its membership list determined by search criteria using a LDAP URL. Dynamic groups solve the scalability issues encountered for static groups as searches are efficient, constant-time operations. However, if searches range over a very large set of data, performance could be affected.
- **Virtual Static Groups.** A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Virtual static groups are not good for applications that need to retrieve the entire membership list as the process for constructing the entire membership list can be expensive.

### About the `isMemberOf` and `isDirectMemberOf` Virtual Attribute

The existence of both static, nested, dynamic, and virtual static groups can make it unnecessarily complex to work with groups in the server, particularly because the ways you interact with them are so different. And the fact that static groups can use three different structural object classes (not counting the auxiliary class for virtual static groups) does not make things any easier.

To make group operations simpler, the PingDirectory Server provides the ability to generate either an `isMemberOf` and `isDirectMemberOf` virtual attributes in user entries. These attributes dramatically simplify the process for making group-related determinations in a manner that is consistent across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of DNs of all groups (including static, nested, dynamic, and virtual static groups) in which the associated user is a member. The value of the

`isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because the `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who specifically have been granted the privilege can see it. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. It is always a best practice to restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

To determine whether a user is a member of a specified group using the `isMemberOf` virtual attribute, simply perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this simple base-level search:

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| Base DN              | <code>uid=john.doe,ou=People,dc=example,dc=com</code>               |
| Scope                | base                                                                |
| Filter               | <code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code> |
| Requested Attributes | 1.1                                                                 |

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

To determine the set of all groups in which a user is a member, simply retrieve the user's entry with a base-level search and include the `isMemberOf` attribute:

|                      |                                                       |
|----------------------|-------------------------------------------------------|
| Base DN              | <code>uid=john.doe,ou=People,dc=example,dc=com</code> |
| Scope                | base                                                  |
| Filter               | <code>(objectclass=*)</code>                          |
| Requested Attributes | <code>isMemberOf</code>                               |

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries:

|                      |                                                                     |
|----------------------|---------------------------------------------------------------------|
| Base DN              | <code>ou=People,dc=example,dc=com</code>                            |
| Scope                | sub                                                                 |
| Filter               | <code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code> |
| Requested Attributes | <code>cn, mail</code>                                               |

The `isDirectMemberOf` virtual attribute can be used in the examples above in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

Note that if this filter targets a dynamic group using an unindexed search, then this may be an expensive operation. However, it will not be any more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries, whereas it would otherwise be required to retrieve the static group and then perform a separate search for each member's entry.

## Using Static Groups

A static group contains an explicit membership list where each member is represented as a DN-valued attribute. There are three types of static groups supported for use in the Directory Server:

- groupOfNames.** A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members. RFC 4519 requires that the `member` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

- groupOfUniqueNames.** A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members. RFC 4519 requires that the `uniquemember` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Test Group
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
uniquemember: uid=user.3,ou=People,dc=example,dc=com
```

- groupOfEntries.** A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members. This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the Directory Server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfEntries
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

### Creating Static Groups

You can configure a static group by adding it using an LDIF file. Static groups contain a membership list of explicit DNs specified by the `uniquemember` attribute.

#### To Create a Static Group

##### Steps

- Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniquenames` object class and `uniquemember` attributes. If you did not have `ou=groups` set up in your server, then you can add it in the same file. When done, save the file as `static-group.ldif`. The following example LDIF file creates two groups, `cn=Development` and `cn=QA`.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
```

```

objectclass: organizationalunit
ou: groups

dn: cn=Development,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Development
ou: groups
uniquemember: uid=user.14,ou=People,dc=example,dc=com
uniquemember: uid=user.91,ou=People,dc=example,dc=com
uniquemember: uid=user.180,ou=People,dc=example,dc=com

dn: cn=QA,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: QA
ou: groups
uniquemember: uid=user.0,ou=People,dc=example,dc=com
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com

```

2. Use **ldapmodify** to add the group entries to the server.

```
$ bin/ldapmodify --defaultAdd --filename static-group.ldif
```

3. Verify the configuration by using the virtual attribute `isDirectMemberOf` that checks membership for a non-nested group. By default, the virtual attribute is disabled by default, but you can enable it using **dsconfig**.

```
$ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set
enabled:true
```

4. Use **ldapsearch** to specifically search the `isDirectMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isDirectMemberOf
```

```

dn: uid=user.14,ou=People,dc=example,dc=com
isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com

```

5. Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an `aci` attribute in an LDIF file, and save the file as `dev-group-aci.ldif`. Add the file using the **ldapmodify** tool. You can create a similar ACI for the QA group, which is not shown in this example.

```

dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
 (targetattr != "cn || sn || uid")
 (targetfilter ="(ou=Development)")
 (version 3.0; acl "Dev Group Permissions";
 allow (write) (groupdn = "ldap:///
cn=Development,ou=groups,dc=example,dc=com");)

```

6. Add the file using the **ldapmodify** tool.

```
$ bin/ldapmodify --filename dev-group-aci.ldif
```

## To Add a New Member to a Static Group

### Steps

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the user to be added. The following example adds a new `uniquemember`, `user.4`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
add: uniquemember
uniquemember: uid=user.4,ou=People,dc=example,dc=com
```

## To Remove a Member from a Static Group

### Steps

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute. The following example removes the DN of `user.1`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

## Searching Static Groups

The following sections describe how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group.

### To Determine if a User is a Static Group Member

#### About this task

To determine whether a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the DN of the specified user.

For best performance, you will want to include a specific attribute list (just `"cn"`, or `"1.1"` request that no attributes be returned) so that the entire member list is not returned. For example, to determine whether the user `"uid=john.doe,ou=People,dc=example,dc=com"` is a member of the `groupOfNames` static group `"cn=Test Group,ou=Groups,dc=example,dc=com"`, issue a search with the following criteria:

#### Search Criteria for a Single User's Membership in a Static Group

|                      |                                                                |
|----------------------|----------------------------------------------------------------|
| Base DN              | <code>cn=Test Group,ou=Groups,dc=example,dc=com</code>         |
| Scope                | <code>base</code>                                              |
| Filter               | <code>(member=uid=john.doe,ou=People,dc=example,dc=com)</code> |
| Requested Attributes | <code>1.1</code>                                               |

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group. If you do not know the membership attribute for the specified group (it could be either a `member` or `uniqueMember` attribute), then you may want to revise the filter so that it allows either one as follows:

```
(| (member=uid=john.doe,ou=People,dc=example,dc=com)
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com))
```

## Steps

- Run a base-level search to retrieve the group entry with an equality filter looking for the membership attribute.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
--searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com)"
"1.1"
```

## To Determine the Static Groups to Which a User Belongs

### About this task

To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the DIT. The search filter must be configured to match any type of static group in which the specified user is a member.

For example, the following criteria may be used to determine the set of all static groups in which the user, `uid=john.doe,ou=People,dc=example,dc=com`, is a member:

### Search Criteria for Determining All the Static Groups for a User

|                      |                                                                                                                                                                                                                                                                            |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Base DN              | dc=example,dc=com                                                                                                                                                                                                                                                          |
| Scope                | sub                                                                                                                                                                                                                                                                        |
| Filter               | (( (&(objectClass=groupOfNames)<br>(member=uid=john.doe,ou=People,dc=example,dc=com))<br>&(objectClass=groupOfUniqueNames)(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com))<br>&(objectClass=groupOfEntries)<br>(member=uid=john.doe,ou=People,dc=example,dc=com))) |
| Requested Attributes | 1.1                                                                                                                                                                                                                                                                        |

Every entry returned from the search represents a static group in which the specified user is a member.

## Steps

- Run a sub-level search to retrieve the static groups to which a user belongs.

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
"(|(&(objectClass=groupOfNames)
(member=uid=john.doe,ou=People,dc=example,dc=com)) \
&(objectClass=groupOfUniqueNames) \
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com)) \
&(objectClass=groupOfEntries) \
(member=uid=john.doe,ou=People,dc=example,dc=com))" "1.1"
```

**Note:** A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes will give the same results. You can also use the virtual attributes with virtual static groups.

## To Determine the Members of a Static Group

### About this task

To determine all of the members for a static group, simply retrieve the group entry including the membership attribute. The returned entry will include the DNs of all users that are members of that group. For example, the following criteria may be used to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`:

## Search Criteria for All of the Static Group's Members

|                      |                                           |
|----------------------|-------------------------------------------|
| Base DN              | cn=Test Group,ou=Groups,dc=example,dc=com |
| Scope                | base                                      |
| Filter               | (objectClass=*)                           |
| Requested Attributes | member uniqueMember                       |

If you want to retrieve additional information about the members, such as attributes from member entries, you must issue a separate search for each member to retrieve the user entry and the desired attributes.

### Steps

- Run a base-level search to retrieve all of the members in a static group.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
 --searchScope base "(objectclass=*)" uniqueMember
```

**Note:** If you want to retrieve attributes from member entries, it is more efficient to search all users whose `isMemberOf` attribute contains the group DN, returning the attributes desired.

## Using Dynamic Groups

Dynamic groups contain a set of criteria used to identify members rather than maintaining an explicit list of group members. If a new user entry is created or if an existing entry is modified so that it matches the membership criteria, then the user will be considered a member of the dynamic group. Similarly, if a member's entry is deleted or if it is modified so that it no longer matches the group criteria, then the user will no longer be considered a member of the dynamic group.

In the Directory Server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL will be used in the process of making the determination, and any other elements present in the URL will be ignored. For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of `contractor` will be considered members of the group:

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that less than 80,000 entries have the `employeeType` of `contractor`, you need to create the following index definition to evaluate the dynamic group:

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
 --index-name employeeType --set index-entry-limit:80000 \
 --set index-type:equality
```

### Creating Dynamic Groups

You can configure a dynamic group in the same manner as static groups using an LDIF file. Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

## To Create a Dynamic Group

### Steps

1. Assume that `uid=user.15` is not part of any group. Use `ldapsearch` to verify that `uid=user.15` is not part of any group. In a later step, we will add the user to the dynamic group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" ou
```

```
dn: uid=user.15,ou=People,dc=example,dc=com
```

2. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the Engineering department.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.0)"
ou isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ou: Engineering
```

3. Open a text editor, and then create a dynamic group entry in LDIF. The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute. When done, save the file as `add-dynamic-group.ldif`.

```
dn: cn=eng-staff,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfURLs
ou: groups
cn: eng-staff
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
```

4. Use `ldapmodify` to add the group entry to the server.

```
$ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
```

5. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

6. If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For very large databases, it is not practical to run a database-wide search for all users as there can be a performance hit on the Directory Server. The following command returns the DNs of entries that are part of the `cn=eng-staff` dynamic group and sorts them in ascending order by the `sn` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
"(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

7. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry. This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry will be automatically added to the `eng-staff` dynamic group.

```
$ bin/ldapmodify
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: modify
add: ou
ou: Engineering
```

**8. Use `ldapsearch` to check if the user is part of the `cn=eng-staff` dynamic group.**

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" isMemberOf
```

```
dn: uid=user.15,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

**Searching Dynamic Groups**

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

**To Determine if a User is a Dynamic Group Member**

About this task

To determine whether a user is a member of a specific dynamic group, you must verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL. You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side can be more complicated. While possible, particularly in clients that are able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

For example, to determine whether the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the above member URL, issue a search with the following criteria:

**Search Criteria for a Single User's Membership in a Dynamic Group**

|                      |                                                       |
|----------------------|-------------------------------------------------------|
| Base DN              | <code>uid=john.doe,ou=People,dc=example,dc=com</code> |
| Scope                | <code>base</code>                                     |
| Filter               | <code>(ou=Engineering)</code>                         |
| Requested Attributes | <code>1.1</code>                                      |

Note that the search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member. If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

**To Determine the Dynamic Groups to Which a User Belongs**

About this task

To determine the set of all dynamic groups in which a user is a member, first perform a search to find all dynamic group entries defined in the server. You can do this using a subtree search with a filter of `(objectClass=groupOfURLs)`.

You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups. For example, to find the set of all dynamic groups defined in the `dc=example,dc=com` tree, issue a search with the following criteria:

**Search Criteria for Determining All of the Dynamic Groups for a User**

|         |                                        |
|---------|----------------------------------------|
| Base DN | <code>dc=example,dc=com</code>         |
| Scope   | <code>sub</code>                       |
| Filter  | <code>(objectClass=groupOfURLs)</code> |

|                      |           |
|----------------------|-----------|
| Requested Attributes | memberURL |
|----------------------|-----------|

Each entry returned will be a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

### To Determine the Members of a Dynamic Group

#### About this task

To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL. The set of requested attributes should reflect the attributes desired from the member user entries, or "1.1" if no attributes are needed.

For example, to retrieve the `cn` and `mail` attributes from the group described above, use the following search:

#### Search Criteria for Determining the Members of a Dynamic Group

|                      |                           |
|----------------------|---------------------------|
| Base DN              | dc=example,dc=com         |
| Scope                | sub                       |
| Filter               | (employeeType=contractor) |
| Requested Attributes | cn, mail                  |

**CAUTION:** Note that this search may be expensive if the associated filter is not indexed or if the group contains a large number of members.

### Using Dynamic Groups for Internal Operations

You can use dynamic groups for internal operations, such as ACI or component evaluation. The Directory Server performs the `memberurl` parsing and internal LDAP search; however, the internal search operation may not be performed with access control rules applied to it.

For example, the following dynamic group represents an organization's employees within the same department:

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
(&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example,dc=com` entry. For example:

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
(version 3.0; acl "Grant write access to employeeType" ;
allow (all) groupdn="ldap:///cn=department
202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example,dc=com`.

## Using Virtual Static Groups

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. The Directory Server provides a third type of group that makes it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with it as a static group. A *virtual static group* is a type of group that references another group and provides access to the members of that group as if it was a static group.

To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`. It should also include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members. For example, the following will create a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group:

```
dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
objectClass: ds-virtual-static-group
cn: Virtual Static Sales Group
ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
```

Note that you must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group. A configuration object for this virtual attribute does exist in the server configuration, but is disabled by default. To enable it, issue the following change:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
 --set enabled:true
```

If you want to use virtual static groups with the `groupOfUniqueNames` object class, then you will also need to enable the `Virtual Static uniqueMember` virtual attribute in the same way.

### Creating Virtual Static Groups

If your application only supports static groups but has scalability issues, then using a virtual static group could be a possible solution. A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. It is not a good solution if an application accesses the full list of group members due to the performance expense at constructing the list. If you have a small database and an application that requires that the full membership list be returned, you must also enable the `allow-retrieving-membership` property for the `Virtual Static uniqueMember` virtual attribute using the `dsconfig` tool.

### To Create a Virtual Static Group

#### Steps

1. Open a text editor, and then create a group entry in LDIF. The entry contains the `groupOfUniqueNames` object class, but in place of the `uniqueMember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class. When done, save the file as `add-virtual-static-group.ldif`.

```
dn: cn=virtualstatic,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
objectclass: ds-virtual-static-group
ou: groups
cn: virtual static
```

```
ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
```

2. Use `ldapmodify` to add the virtual static group entry to the server.

```
$ bin/ldapmodify -h server1.example.com -p 389 -D
"uid=admin,dc=example,dc=com" \
-w password -a -f add-virtual-static-group.ldif
```

3. Use `dsconfig` to enable the Virtual Static `uniqueMember` attribute, which is disabled by default.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. In the previous section, we set up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. Use `ldapsearch` with the `isMemberOf` virtual attribute to determine if `uid=user.0` is part of the virtual static group.

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager" \
-w secret -b dc=example,dc=com "(uid=user.0) isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

5. Use `ldapsearch` to determine if `uid=user.0` is a member of the virtual static group. You should see the returned `cn=virtualstatic` entry if successful.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.0,ou=People,dc=example,dc=com))"
```

6. Next, try searching for a user that is not part of the `cn=eng-staff` dynamic group (e.g., `uid=user.20`), nothing will be returned.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.20,ou=People,dc=example,dc=com))"
```

## Searching Virtual Static Groups

Because virtual static groups behave like static groups, the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group. Similarly, the process for determining all virtual static groups in which a user is a member is basically the same as the process as that of real static groups in which a user is a member. In fact, the query provided in the static groups discussion returns virtual static groups in addition to real static groups, because the structural object class of a virtual static group is the same as the structural object class for a static group.

You can also retrieve a list of all members of a virtual static group in the same way as a real static group: simply retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default. The virtual attribute used to expose membership can be updated to allow this with a configuration change such as the following:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
--set allow-retrieving-membership:true
```

Because this can be an expensive operation, we recommend that the option to allow retrieving virtual static group membership be left disabled unless it is required.

## Creating Nested Groups

The PingDirectory Server supports nested groups, where the DN of an entry that defines a group is included as a member in the parent entry. For example, the following example shows a nested static group (e.g., `cn=Engineering Group`) that has `uniquemember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=Groups,dc=example,dc=com
uniquemember: cn=QA,ou=Groups,dc=example,dc=com
```

Nested group support is enabled by default on the Directory Server. To support nested groups without the performance hit, the Directory Server uses a group cache, which is also enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The Directory Server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for several reasons. LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them. Supporting nested groups in LDAP clients is not trivial, and many directory server-enabled applications that can interact with groups do not provide any support for nesting. If nesting support is not needed in your environment, or if nesting support is only required for clients but is not needed for server-side evaluation (such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server may need to make a membership determination), then this support should be disabled.

### To Create Nested Static Groups

#### Steps

1. The following example shows how to set up a nested static group, which is a static group that contains `uniquemember` attributes whose values contain other groups (static, virtual static, or dynamic). Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniqueNames` object class and `uniquemember` attributes. If you did not have `ou=groups` set up in your server, then you can add it in the same file. When done, save the file as `nested-group.ldif`. Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. Use `ldapmodify` to add the group entry.

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. Verify the configuration by using the `isMemberOf` virtual attribute that checks the group membership for an entry. By default, the virtual attribute is enabled. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf
dn: uid=user.14,ou=People,dc=example,dc=com
```

```
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

- Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an ACI in LDIF, and save the file as `eng-group-aci.ldif`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target = "ldap:///ou=People,dc=example,dc=com")
 (targetattr != "cn || sn || uid")
 (targetfilter = "(ou=Engineering Group)")
 (version 3.0; acl "Engineering Group Permissions";
 allow (write) (groupdn = "ldap:///cn=Engineering
 Group,ou=groups,dc=example,dc=com");)
```

- Add the file using the `ldapmodify` tool.

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

**Note:** When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support "nesting" by including the members of another group with a filter in the member URL. For example, if you have two groups `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL as follows:

```
cn=dynamic1,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
memberURL: ldap:///dc=example,dc=com??sub?
(isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
```

The members included from the other group using this method are not considered "nested" members and will be returned even when using `isDirectMemberOf` when retrieving the members.

## Maintaining Referential Integrity with Static Groups

The Directory Server can automatically update references to an entry whenever that entry is removed or renamed in a process called *referential integrity*. For example, if a user entry is deleted, then referential integrity plugin will remove that user from any static groups in which the user was a member (this is not necessary for dynamic groups, since no explicit membership is maintained). Similarly, if a modify DN operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

Referential integrity support is disabled by default, but may be enabled using the `dsconfig` tool as follows:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
 --set enabled:true
```

Other configuration attributes of note for this plugin include:

- attribute-type.** This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the `member` and `uniqueMember` attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
- base-dn.** This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. If no values are provided (which is the default behavior), then entries within all public naming contexts will be included.

- **log-file.** This attribute specifies the path to a log file that may be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.
- **update-interval.** This attribute specifies the maximum length of time that a background thread may sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

In the default configuration, where referential integrity processing is performed synchronously, the throughput and response time of delete and modify DN operations may be adversely impacted because the necessary cleanup work must be completed before the response to the original operation can be returned. Changing the configuration to use a non-zero update interval alleviates this performance impact because referential integrity processing uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

However, performing referential integrity processing in a background thread may introduce a race condition that may adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. If referential integrity processing has not yet been completed for the delete, then newly-established group memberships may be removed along with those that already existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then attempts by the client to re-establish those memberships may fail if referential integrity processing has not yet removed the previous membership. For this reason, we recommend that the default synchronous behavior be maintained unless the performance impact associated with it is unacceptable and clients are not expected to operate in a manner that may be adversely impacted by delayed referential integrity processing.

**Note:** The internal operations of the referential integrity plugin are not replicated. So, in a replicated topology, you must enable the referential integrity plugin consistently on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see Chapter 6, “Configuring the Directory Server” in the *PingDirectory Server Administration Guide*.

## Monitoring the Group Membership Cache

The Directory Server logs information at startup about the memory consumed by the group membership cache. This hard-coded cache contains information about all of the group memberships for internal processing, such as ACIs. The group membership cache is enabled by default.

The information about this cache is logged to the standard output log (`server.out`) and the standard error log. When using groups, you can use the log information to tune the server for best performance. For example, at startup the server logs a message like the following to the `server.out` log:

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The error log will contain something like the following:

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE
msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and
1000002
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently
consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

## Using the Entry Cache to Improve the Performance of Large Static Groups

The PingDirectory Server provides an entry cache implementation, which allows for fine-grained control over the kinds of entries that may be held in the cache. You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

Under most circumstances, we recommend that the Directory Server be used *without* an entry cache. The Directory Server is designed to efficiently retrieve and decode entries from the database in most cases. The database cache is much more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

However, if the Directory Server contains very large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, then you may want to enable an entry cache that holds only large static groups.

In servers containing large static groups, you can define an entry cache to hold only those large static groups. This entry cache should have an include filter that matches only group entries (for example, "(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfEntries))"). The filter contains a minimum value count so that only groups with a large number of members (such as those with at least 100 `member` or `uniqueMember` values) will be included. The Directory Server provides an entry cache implementation with these settings although it is disabled by default.

### To Enable the Entry Cache

#### Steps

- Run `dsconfig` to enable the entry cache.

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry Cache" \
 --set enabled:true
```

### To Create Your Own Entry Cache for Large Groups

#### Steps

- You can create your own entry cache for large groups using the `dsconfig create-entry-cache` subcommand.

```
bin/dsconfig create-entry-cache --type fifo \
 --set enabled:true \
 --set cache-level:10 \
 --set max-entries:175000 \
 --set "include-filter:(objectClass=groupOfUniqueNames)" \
 --set min-cache-entry-value-count:10000 \
 --set min-cache-entry-attribute:uniquemember
```

### Monitoring the Entry Cache

You can monitor the memory consumed by your entry cache using the `entry-cache-info` property in the periodic stats logger. You can retrieve the monitor entry over LDAP by issuing a search on `baseDN="cn=monitor" using filter="(objectClass=ds-fifo-entry-cache-monitor-entry)"`. For example, the entry might appear as follows:

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
objectClass: extensibleObject
```

```

cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory.
 Entries can be
 added to the cache until the overall JVM memory usage reaches the configured
 limit of
 75%. Cache has 174999 remaining entries before reaching the configured limit
 of 175000.

```

By default, the entry cache memory is set to 75%, with a maximum of 90%.

## Tuning the Index Entry Limit for Large Groups

The Directory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the DIT. You can specify an index entry limit property, which defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (which is 4000 by default), then you must rebuild the indexes using the **rebuild-index** tool as follows:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
```

In the majority of Directory Server environments, the default index entry limit value of 4000 entries should be sufficient. However, group-related processing, it may be necessary to increase the index entry limit. For directories containing more than 4000 groups with the same structural object class (i.e., more than 4000 entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries), then you may want to increase the index entry limit for the `objectClass` attribute so that it has a value larger than the maximum number of group entries of each type. Set `index-entry-limit` property using a command line like the following:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
 --index-name objectClass --set index-entry-limit:175000
```

As an alternative, a separate backend may be created to hold these group entries, so that an unindexed search in that backend yields primarily group entries. If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type may be very expensive.

For directories in which any single user may be a member of more than 4000 static groups of the same type, you may need to increase the index entry limit for the `member` and/or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member. If you do not increase the limit, then searches to retrieve the set of all static groups in which the user is a member may be unindexed and therefore very expensive.

## Summary of Commands to Search for Group Membership

The following summary of commands show the fastest way to retrieve direct or indirect member DN's for groups.

- To retrieve direct member (non-nested) DN's of group "cn=group.1,ou=groups,dc=example,dc=com".

```
$ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com"
"(objectClass=*)" uniqueMember member
```

- To retrieve direct member entries (non-nested) under "dc=example,dc=com" of group "cn=group.1,ou=groups,dc=example,dc=com". This is useful when attributes from member entries are used in the filter or being returned.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
"(isDirectMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

- To retrieve group DN's in which user "uid=user.2,ou=people,dc=example,dc=com" is a direct member (non-nested, static groups).

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
"(objectClass=*)" isDirectMemberOf
```

- To retrieve all member entries under ou=people,dc=example,dc=com of group "cn=group.1,ou=groups,dc=example,dc=com".

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
"(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

- To retrieve the group DN's in which user "uid=user.2,ou=people,dc=example,dc=com" is a member.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
"(objectClass=*)" isMemberOf
```

## Migrating Sun/Oracle Groups

You can migrate Sun/Oracle static and dynamic groups to PingDirectory Server groups. The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups. For information about the differences in access control evaluation between Sun/Oracle and the PingDirectory Server, see [Migrating ACIs from Sun/Oracle to PingDirectory Server](#).

### Migrating Static Groups

The PingDirectory Server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, static groups may be imported without modification.

A FIFO entry cache can be enabled to cache group-to-user mappings, which improves performance when accessing very large entries, though at the expense of greater memory consumption. The PingDirectory Server provides an out-of-the-box FIFO entry cache object for this purpose. This object must be explicitly enabled using `dsconfig` as described in [Using the Entry Cache to Improve the Performance of Large Static Groups](#).

### To Migrate Static Groups

#### Steps

1. Run the `migrate-ldap-schema` tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.

2. Run the `migrate-sun-ds-config` tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the `import-ldif` tool.
5. From the PingDirectory Server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder using a text editor.
6. Find the **FIFO Entry Cache** section and, after reading the accompanying comments, enable the corresponding `dsconfig` command by removing the comment character ("`#`").

```
$ bin/dsconfig set-entry-cache-prop \
 --cache-name "Static Group Entry Cache" --set enabled:true
```

7. To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --set
enabled:true
```

If this Directory Server is part of a replication topology, you should enable the Referential Integrity plugin for each replica.

### Migrating Static Groups to Virtual Static Groups

In many cases, electing to use virtual static groups in place of static groups can produce marked performance gains without any need to update client applications. The specifics of a migration to virtual static groups varies depending on the original DIT, but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

In the following example, the common membership trait for all members of the All Users group is the parent DN `ou=People,dc=example,dc=com`. In other cases, a common attribute may need to be used. For example, groups based on the location of its members could use the `l` (location) or `st` (state) attribute.

#### To Migrate DSEE Static Groups to Virtual Static Groups

About this task

In the following example, consider the common case of an "All Users" group, which contains all entries under the parent DN `"ou=People,dc=example,dc=com"`. When implemented as a virtual static group, this group may have a large membership set without incurring the overhead of a static group.

Steps

1. First, create a dynamic group.

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

2. Next, create a virtual static group that references the dynamic group.

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
objectClass: ds-virtual-static-group
cn: All Users
ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
```

3. Finally, the `Virtual Static uniqueMember` virtual attribute must be enabled to populate the All Users group with `uniqueMember` virtual attributes.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. Confirm that the virtual static group is correctly configured by checking a user's membership in the group.

```
$ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
--searchScope base "(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)"
1.1
```

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
```

5. The ability to list all members of a virtual static group is disabled by default. You may enable this feature, but only if specifically required by a client application.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set allow-retrieving-membership: true
```

**Note:** The virtual static group may also be implemented using the `groupOfNames` object class instead of `groupOfUniqueNames`. In that case, you must update the `Virtual Static member` configuration object instead of the `Virtual Static uniqueMember` configuration object.

## Migrating Dynamic Groups

The PingDirectory Server supports dynamic groups with the `groupofURLs` object class. In general, dynamic groups may be imported without modification.

### To Migrate Dynamic Groups

#### Steps

1. Run the `migrate-ldap-schema` tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.
2. Run the `migrate-sun-ds-config` tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the `import-ldif` tool.

## Encrypting Sensitive Data

The Directory Server provides several ways that you can protect sensitive information in the server. If not enabled during server setup, you can enable on-disk encryption for data in backends as well as in the changelog and the replication databases, and you can also protect sensitive attributes by limiting the ways that clients may interact with them.

This chapter presents the following topics:

- [Encrypting and Protecting Sensitive Data](#) on page 679
- [Backing Up and Restoring the Encryption-Settings Definitions](#) on page 684
- [Configuring Sensitive Attributes](#) on page 687
- [Configuring Global Sensitive Attributes](#) on page 689
- [Excluding a Global Sensitive Attribute on a Client Connection Policy](#) on page 689

## Encrypting and Protecting Sensitive Data

The Directory Server provides an encryption-settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data in backends as well as in the changelog and the replication databases. You can also protect sensitive attributes by limiting the ways that clients may interact with them.

### About the Encryption-Settings Database

The encryption-settings database is a repository that the server uses to hold information for encrypting and decrypting data. The database contains any number of *encryption-settings definitions* that specifies information about the cipher transformation and encapsulates the key used for encryption and decryption.

Before data encryption can be enabled, you first need to create an encryption-settings definition. An encryption-settings definition specifies the cipher transformation that should be used to encrypt the data, and encapsulates the encryption key. The `encryption-settings` command-line tool can be used to manage the encryption settings database, including creating, deleting, exporting, and importing encryption-settings definitions, listing the available definitions, and indicating which definition should be used for subsequent encryption operations.

Although the encryption-settings database can have multiple encryption-settings definitions, only one of them can be designated as the *preferred* definition. The preferred encryption-settings definition is the one that will be used for any subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten (e.g., as a result of a modify or modify DN operation, or if the data is exported to LDIF and re-imported). Similarly, if you introduce a new preferred encryption-settings definition, then any existing encrypted data will continue to use the previous definition until it is rewritten. If you do change the preferred encryption-settings definition for the server, then it is important to retain the previous definitions until you are confident that no remaining data uses those older keys.

### Supported Encryption Ciphers and Transformations

The set of encryption ciphers that are supported by the Directory Server is limited to those ciphers supported by the JVM in which the server is running. For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the following:

- Java Cryptography Architecture Reference Guide
- Java Cryptography Architecture Standard Algorithm Name Documentation

When configuring encryption, the cipher to be used must be specified using a key length (in bits) and either a cipher algorithm name (e.g., "AES") or a full cipher transformation which explicitly specifies the mode and padding to use for the encryption (e.g., "AES/CBC/PKCS5Padding"). If only a cipher algorithm is given, then the default mode and padding for that algorithm will be automatically selected.

The following cipher algorithms and key lengths have been tested using the Sun/Oracle JVM:

#### Cipher Algorithms

| Cipher Algorithm | Key Length (bits) |
|------------------|-------------------|
| AES              | 128               |
| Blowfish         | 128               |
| DES              | 64                |
| DESede           | 192               |
| RC4              | 128               |

**Note:** By default, some JVM implementations may come with limited encryption strength, which may restrict the key lengths that can be used. For example, the Sun/Oracle JVM does not allow AES with 192-bit or 256-bit keys unless the unlimited encryption strength policy files are downloaded and installed.

The Directory Server supports four Cipher Stream Providers, which are used to obtain cipher input and output streams to read and write encrypted data.

### Cipher Stream Providers

| Cipher Stream Providers | Description                                                                                                                                                                                                                        |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default                 | Default cipher stream provider using a hard-coded default key.                                                                                                                                                                     |
| File-Based              | Used to read a specified file in order to obtain a password used to generate cipher streams for reading and writing encrypted data.                                                                                                |
| Third-Party             | Used to provide cipher stream provider implementations created in third-party code using the Server SDK.                                                                                                                           |
| Wait-for-Passphrase     | Causes the server to wait for an administrator to enter a passphrase that will be used to derive the key for cipher streams. You can supply the passphrase to the server by running <b>encryption-settings supply-passphrase</b> . |

### Using the encryption-settings Tool

The **encryption-settings** tool provides a mechanism for interacting with the server's encryption-settings database. It may be used to list the available definitions, create new definitions, delete existing definitions, and indicate which definition should be the preferred definition. It may also be used to export definitions to a file for backup purposes and to allow them to be imported for use in other Directory Server instances.

#### To List the Available Encryption Definitions

##### Steps

- Use the **encryption-settings** tool with the **list** subcommand to display the set of available encryption settings definitions. This subcommand does not take any arguments. For each definition, it will include the unique identifier for the definition, as well as the cipher transformation and key length that will be used for encryption and whether it is the preferred definition.

```
$ bin/encryption-settings list
```

```
Encryption Settings Definition ID: 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
Cipher Transformation: DESede
Key Length (bits): 192
```

```
Encryption Settings Definition ID: F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

### Creating Encryption-Settings Definitions

To create a new encryption-settings definition, use the **create** subcommand. This subcommand takes the following arguments:

- cipher-algorithm {algorithm}**. Specifies the base cipher algorithm that should be used. This should just be the name of the algorithm (e.g., "AES", "DES", "DESede", "Blowfish", "RC4", etc.). This argument is required.

- **--cipher-transformation {transformation}**. Specifies the full cipher transformation that should be used, including the cipher mode and padding algorithms (e.g., "AES/CBC/ PKCS5Padding"). This argument is optional, and if it is not provided, then the JVM-default transformation will be used for the specified cipher algorithm.
- **--key-length-bits {length}**. Specifies the length of the encryption key in bits (e.g., 128). This argument is required.
- **--set-preferred**. Indicates that the new encryption-settings definition should be made the preferred definition and therefore should be used for subsequent encryption operations in the server. When creating the first definition in the encryption-settings database, it will automatically be made the preferred definition.

### To Create an Encryption-Settings Definition

#### Steps

- Use the **encryption-settings** tool with the `create` subcommand to specify the definition.

```
$ bin/encryption-settings create --cipher-algorithm AES \
 --key-length-bits 128 --set-preferred
```

```
Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

### Changing the Preferred Encryption-Settings Definition

To change the preferred encryption-settings definition, use the **encryption-settings** tool with the `set-preferred` subcommand. This subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be exported. This argument is required.

### To Change the Preferred Encryption-Settings Definition

#### Steps

- Use the **encryption-settings** tool with the `set-preferred` subcommand to change a definition to a preferred definition.

```
$ bin/encryption-settings set-preferred --id
4D86C7922F71BB57B8B5695D2993059A26B8FC01
```

```
Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01 was
successfully set as the preferred definition for subsequent encryption
operations
```

### Deleting an Encryption-Settings Definition

To delete an encryption-settings definition, use the **encryption-settings** tool with the `delete` subcommand. The subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be deleted. This argument is required.

Never delete an encryption-settings definition if data in the server is still encrypted using the settings contained in that definition. Any data still encrypted with a definition that has been removed from the database will be inaccessible to the server and will cause errors for any attempt to access it. This includes the replicationChanges and changelog databases, which the **re-encode-entries** tool will not re-encode with the new encryption-settings definition. Therefore, wait for the amount of time defined in the **replication-purge-delay**, of the Replication Server, and **changelog-maximum-age** of the changelog Backend (if enabled) before removing previous encryption-settings definitions. To safely delete a compromised encryption-settings definition, see the [Dealing with a Compromised Encryption Key](#) section.

To stop using a definition for encryption and use a different definition, make sure that the desired definition exists in the encryption-settings database and set it to be the preferred definition. As long as the encryption key has not been compromised, there is no harm in having old encryption-settings definitions available to the server, and it is recommended that they be retained just in case they are referenced by something.

The preferred encryption-settings definition cannot be deleted unless it is the only one left. To delete the currently-preferred definition when one or more other definitions are available, make one of the other definitions preferred as described in the previous section.

### To Delete an Encryption-Settings Definition

#### Steps

- Use the **encryption-settings** command with the `delete` subcommand. Make sure to include the `--id` argument to specify the definition.

```
$ bin/encryption-settings delete --id
F635E109A8549651025D01D9A6A90F7C9017C66D
```

```
Successfully deleted encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D
```

### Configuring the Encryption-Settings Database

Because the encryption-settings database contains the encryption keys used to protect server data, the contents of the encryption-settings database is itself encrypted. By default, the server will derive a key to use for this purpose, but it is recommended that you customize the logic used to access the encryption-settings database with a cipher stream provider. The Server SDK provides an API that can be used to create custom cipher stream provider implementations, but the server also comes with one that will obtain the key from a PIN file that you create (see the example procedure below).

### To Configure the Encryption-Settings Database

#### Steps

1. Use **dsconfig** to configure the server so that the encryption-settings database is encrypted with a PIN contained in the file `config/encryption-settings.pin`.

```
$ bin/dsconfig create-cipher-stream-provider \
--provider-name "Encryption Settings PIN File" \
--type file-based \
--set enabled:true \
--set password-file:config/encryption-settings.pin
```

2. Use **dsconfig** to set the global configuration property for the cipher stream provider, which sets the on-disk encryption.

```
$ bin/dsconfig set-global-configuration-prop \
--set "encryption-settings-cipher-stream-provider:Encryption Settings PIN
File"
```

3. Use the **encryption-settings** tool to create a new encryption-settings definition. This command automatically generates a new 256-bit encryption key for use with AES encryption, and mark it as the preferred definition for future encryption operations in the server. Note that this command will fail if you do not have the unlimited encryption strength policy installed as described in the previous section (if you do not have that policy installed, then you are restricted to a 128-bit key for AES encryption).

```
$ bin/encryption-settings create \
--cipher-algorithm AES \
--key-length-bits 256 \
--set-preferred
```

#### 4. Obtain a list of the definitions in the encryption-settings database.

```
$ bin/encryption-settings list
```

#### 5. You can export an encryption-settings definition from the database using a command like the following where the encryption-settings ID should be changed as necessary to suit your deployment:

```
$ bin/encryption-settings export \
 --id DA39A3EE5E6B4B0D3255BF95601890AFD80709 \
 --output-file /tmp/exported-key \
 --pin-file /tmp/exported-key.pin
```

#### 6. If no PIN file is specified, then you will be interactively prompted to provide it. To import an encryption-settings definition into the database on another server.

```
$ bin/encryption-settings import \
 --input-file /tmp/exported-key \
 --pin-file /tmp/exported-key.pin \
 --set-preferred
```

### Encrypt Passphrase Files

Using an encrypted passphrase or `tools.properties` file enables you to have credentials available for use by the server and command-line tools, but not stored in the clear. These files should be encrypted with the `encrypt-file` tool, including:

- Certificate keystore and truststore PIN files. When setting up an instance with encryption enabled and at least one of SSL or StartTLS enabled, the installer will automatically encrypt the PIN files for the `config/keystore`, `config/truststore`, and `config/ads-truststore` certificate databases.
- Passphrase files specified by command-line arguments. For example, most LDAP tools offer `--bindPasswordFile`, `--keystorePasswordFile`, and `--truststorePasswordFile` arguments.
- The `config/tools.properties` file, which will automatically be used to obtain a default set of arguments for most command-line tools. Alternately, the `--propertiesFilePath` argument can be used to specify an alternate properties file.

These files should be encrypted with the following considerations:

- If the file is encrypted with a key obtained from the server's encryption settings database, then the server and associated command-line tools should be able to retrieve the appropriate key from the encryption settings database so that the clear-text contents of the file can be accessed without any interaction (although if the cipher stream provider configured to protect the contents of the encryption settings database requires interaction, like the wait for passphrase cipher stream provider, then command-line tools may require interaction to unlock the encryption settings database).
- If the file is encrypted with a passphrase that the user specifies rather than one obtained from the encryption settings database, then the user will be interactively prompted for that passphrase when running the tool. This option cannot be used for keystore and truststore PIN files that need to be accessed by the server.

To encrypt a file with the server's preferred encryption settings definition, use a command such as:

```
$ bin/encrypt-file --input-file password.txt \
 --output-file password.txt.encrypted
```

To use a key from an encryption settings definition that isn't the default, use the `--encryption-settings-id` argument to specify the ID of the desired encryption settings definition (which can be obtained with `encryption-settings list`), such as:

```
$ bin/encrypt-file --input-file password.txt \
 --output-file password.txt.encrypted \
 --encryption-settings-id 4B6899D6716FC3AFFD71F7B447EB135063A0E724
```

To encrypt the file with a passphrase rather than a key from an encryption settings definition, use either the `--prompt-for-passphrase` argument to interactively prompt for the passphrase, or use the `--passphrase-file` argument to specify the path to a file containing the clear-text passphrase. For example:

```
$ bin/encrypt-file --input-file password.txt \
 --output-file password.txt.encrypted \
 --prompt-for-passphrase
```

## Backing Up and Restoring the Encryption-Settings Definitions

If using data encryption in a Directory Server instance, do not lose the encryption-settings definitions used to encrypt data in the server. If an encryption-settings definition is lost, any data encrypted with that definition will be completely inaccessible. Make sure the encryption-settings definitions are backed up regularly.

The Directory Server provides two different mechanisms for backing up and restoring encryption-settings definitions. One or more encryption-settings definitions can be exported and imported using the `encryption-settings` tool. Or, the entire encryption-settings database can be backed up and restored using the Directory Server's `backup` and `restore` tools.

If a pin file is used to define a passphrase to the encryption-settings database, the passphrase must be backed up and kept secure independently of the userRoot and encryption-settings database backups. The passphrase in the pin file is needed if the encryption-settings database is to be restored into a different server root.

### Exporting Encryption-Settings Definitions

To back up an individual definition (or to export it from one server so that you can import it into another), use the `export` subcommand to the `encryption-settings` command. The subcommand takes the following arguments:

- `--id {id}`. Specifies the ID for the encryption-settings definition to be exported. This argument can be specified multiple times. If it is omitted, all definitions are exported.
- `--output-file {path}`. Specifies the path to the output file to which the encryption-settings definition will be written. This argument is required.
- `--pin-file {path}`. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.

### To Export an Encryption-Settings Definition

#### Steps

- Use the `encryption-settings` tool with the `export` subcommand to export the definition to a file.

```
$ bin/encryption-settings export --id
F635E109A8549651025D01D9A6A90F7C9017C66D \
 --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
```

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

### Importing Encryption-Settings Definitions

To import an encryption-settings definition that has been previously exported, use the `encryption-settings` tool with the `import` subcommand. The subcommand takes the following arguments:

- **--input-file {path}**. Specifies the path to the file containing the exported encryption-settings definition. This argument is required.
- **--pin-file {path}**. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.
- **--set-preferred**. Specifies that the newly-imported encryption-settings definition should be made for the preferred definition for subsequent encryption-settings.

## To Import an Encryption-Settings Definition

### Steps

- Use the **encryption-settings** tool with the `import` subcommand to import the definition to a file.

```
$ bin/encryption-settings import --input-file /tmp/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
```

```
Successfully imported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
```

## Enabling Data Encryption in the Server

Encryption can be enabled during server setup, by defining an encryption key and passphrase. This configuration should be used across all servers in a topology. On legacy systems or post setup, data encryption can be configured by having at least one encryption-settings definition available for use. Then, set the value of the `encrypt-data` global configuration property to true.

Setting the global configuration property will automatically enable data encryption for all types of backends that support it (including the changelog backend and indexes), as well as for the replication server database. All subsequent write operations will cause the corresponding records written into any of these locations to be encrypted. Any existing data will remain unencrypted until it is rewritten by a write operation. If you wish to have existing data encrypted, then you will need to export that data to LDIF and re-import it. This will work for both the data backends, the changelog, and indexes, but it is not an option for the replication database, so existing change records will remain unencrypted until they are purged. If this is not considered acceptable in your environment, then follow the steps in [Dealing with a Compromised Encryption Key](#) to safely purge the replication database.

Configuration for backups and LDIF exports can be done with the following global properties:

- **automatically-compress-encrypted-ldif-exports**. Indicates whether to automatically compress LDIF exports that are also encrypted. If set to true, any LDIF export that is encrypted (either explicitly with `--encryptLDIF`, or implicitly with the `encrypt-ldif-exports-by-default` configuration property) will automatically be gzip-compressed. If this is false, encrypted LDIF exports can still be manually compressed using the `--compress` command-line argument.
- **backup-encryption-settings-definition-id**. The unique identifier for the encryption settings definition to use to generate the encryption key for encrypted backups by default. If this property is given a value, then a definition with that ID must exist in the server's encryption settings database. If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used. If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. Regardless of this property's value, it can be overridden with the `backup` command-line tool. Providing one of the `--promptForEncryptionPassphrase` or `--encryptionPassphraseFile` arguments will generate the encryption key from the provided passphrase. Or, the `--encryptionSettingsDefinitionID` argument can be used to generate the key from the specified encryption settings definition.
- **encrypt-backups-by-default**. Indicates whether the server should encrypt backups by default. If set to true, a defined `backup-encryption-settings-definition-id` value will be used to generate the encryption key for the backup. If this property is true, and if a `backup-encryption-settings-definition-id` value is not specified, the server will try to use the preferred encryption

settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used. Regardless of this property's value, it can be overridden with the `backup` command-line tool's `--encrypt` argument, even if this property is set to false. The `--doNotEncrypt` argument will always cause the backup to be unencrypted, even if this property has a value of true.

- `encrypt-ldif-exports-by-default`. Indicates whether the server should encrypt LDIF exports by default. If set to true, and an `ldif-export-encryption-settings-definition-id` value is specified, then that encryption settings definition is used to generate the encryption key for the export. If this property is true, and an `ldif-export-encryption-settings-definition-id` value is not specified, the server will first try to use the preferred encryption settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, then an internal key that is shared among instances in the topology is used. Regardless of this property's value, the default behavior can be overridden with the `export-ldif` command-line tool. The tool's `--encryptLDIF` argument will always encrypt the export, and the `--doNotEncryptLDIF` argument will always create an unencrypted export.

### To Enable Data Encryption in the Server

#### Steps

- Use `dsconfig` to set the global configuration property for data encryption to true.

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

### Using Data Encryption in a Replicated Environment

Data encryption is only used for the on-disk storage for data within the server. Whenever clients access that data, it is presented in unencrypted form (although the communication with those clients may itself be encrypted using SSL or StartTLS). Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server may apply data encryption in a completely independent manner and have different sets of encryption-settings definitions. It is also possible to have a replication topology containing some servers with data encryption enabled and others with it disabled.

However, when initializing the backend of one server from another server with data encryption enabled, then the server being initialized must have access to all encryption-settings definitions that may have been used for data contained in that backend. To do this, perform an export of the encryption-settings database on the source server using `bin/encryption-settings export` and import it on the target server using `bin/encryption-settings import`.

### Dealing with a Compromised Encryption Key

If an encryption-settings definition becomes compromised such that an unauthorized individual obtains access to the encryption key, then any data encrypted with that definition is also vulnerable because it can be decrypted using that key. It is very important that the encryption-settings database be protected (for example, using file permissions or file system ACLs) to ensure that its contents remain secure.

In the event that an encryption-settings definition is compromised, stop using the definition immediately. Any data encrypted with the compromised key should be re-encrypted with a new definition or purged from the server. This can be done on one server at a time to avoid an environment-wide downtime, but it should be completed as quickly as possible on all servers that had used that definition at any point in the past in order to minimize the risk of that data becoming exposed.

### To Deal with a Compromised Encryption Key

#### About this task

The recommended process for responding to a compromised encryption settings definition is as follows:

## Steps

1. Create a new encryption-settings definition and make it the preferred definition for new writes.
2. Ensure that client traffic is routed away from the server instance to be updated. For example, if the Directory Server is accessed through a Directory Proxy Server, then you may set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to have a value of `unavailable`.
3. Ensure that external clients are not allowed to write operations in the directory server instance. This may be accomplished by setting the `writability-mode` global configuration property to have a value of `internal-only`.
4. Wait for all outstanding local changes to be replicated out to other servers. This can be accomplished by looking at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.
5. Stop the directory server instance.
6. Delete the replication server database by removing all files in the `changeLogDb` directory below the server root. As long as all local changes have been replicated out to other servers, this will not result in any data loss in the replication environment.
7. Export the contents of all local DB and changelog backends to LDIF. Then, re-import the data from LDIF, which will cause it to be encrypted using the new preferred encryption settings definition.
8. Export the compromised key from the encryption settings database to back it up in case it may be needed again in the future (e.g., if some remaining data was later found to have been encrypted with the key contained in that definition). Then, delete it from the encryption settings database so that it can no longer be used by that directory server instance.
9. Start the directory server instance.
10. Allow replication to bring the server back up-to-date with any changes processed while it was offline.
11. Re-allow externally-initiated write operations by changing the value of the global `writability-mode` configuration property back to `enabled`.
12. Re-configure the environment to allow client traffic to again be routed to that server instance (e.g., by changing the value of the "health-check-state" property in the corresponding LDAP external instance definitions in the Directory Proxy Server instances back to "dynamically-determined").

## Configuring Sensitive Attributes

Data encryption is only applied to the on-disk storage for a Directory Server instance. It does not automatically protect information accessed or replicated between servers, although the server offers other mechanisms to provide that protection (i.e., SSL, StartTLS, SASL). Ensuring that all client communication uses either SSL or StartTLS encryption and ensuring that all replication traffic uses SSL encryption ensures that the data is protected from unauthorized individuals who may be able to eavesdrop on network communication. This communication security may be enabled independently of data encryption (although if data encryption is enabled, then it is strongly recommended that secure communication be used to protect network access to that data).

However, for client data access, it may not be as simple as merely enabling secure communication. In some cases, it may be desirable to allow insecure access to some data. In other cases, it may be useful to have additional levels of protection in place to ensure that some attributes are even more carefully protected. These kinds of protection may be achieved using sensitive attribute definitions.

Each sensitive attribute definition contains a number of configuration properties, including:

- **`attribute-type`** . Specifies the set of attribute types whose values may be considered sensitive. At least one attribute type must be provided, and all specified attribute types must be defined in the server schema.
- **`include-default-sensitive-operational-attributes`** . Indicates whether the set of sensitive attributes should automatically be updated to include any operational attributes maintained by the Directory Server itself that may contain sensitive information. At present, this includes the `ds-`

`sync-hist` operation attribute, which is used for data required for replication conflict resolution and may contain values from other attributes in the entry.

- **allow-in-filter** . Indicates whether sensitive attributes may be used in filters. This applies not only to the filter used in search requests, but also filters that may be used in other places, like the assertion and join request controls. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be used in filters over both secure and insecure connections)
  - `Reject` (reject any request which includes a filter targeting one or more sensitive attributes over both secure and insecure connections)
  - `Secure-only` (allow sensitive attributes to be used in filters over secure connections, but reject any such requests over insecure connections)
- **allow-in-add** . Indicates whether sensitive attributes may be included in entries created by LDAP add operations. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be included in add requests over both secure and insecure connections)
  - `Reject` (reject any add request containing sensitive attributes over both secure and insecure connections)
  - `Secure-only` (allow sensitive attributes to be included in add requests received over a secure connection, but reject any such requests over an insecure connection)
- **allow-in-compare** . Indicates whether sensitive attributes may be targeted by the assertion used in a compare operation. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be targeted by requests over both secure and insecure connections)
  - `Reject` (reject any compare request targeting a sensitive attribute over both secure and insecure connections)
  - `Secure-only` (allow compare requests targeting sensitive attributes over a secure connection, but reject any such requests over an insecure connection)
- **allow-in-modify** . Indicates whether sensitive attributes may be updated using modify operations. The value of this property must be one of:
  - `Allow` (allow sensitive attributes to be modified by requests over both secure and insecure connections)
  - `Reject` (reject any modify request updating a sensitive attribute over both secure and insecure connections)
  - `Secure-only` (only modify requests updating sensitive attributes over a secure connection, but reject any such request over an insecure connection)

The `allow-in-returned-entries`, `allow-in-filter`, `allow-in-add`, `allow-in-compare`, and `allow-in-modify` properties all have default values of `secure-only`, which prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

If a client connection policy references a sensitive attribute definition, then any restrictions imposed by that definition will be enforced for any clients associated with that client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, then the server will use the most restrictive combination of all of those sets.

Note that sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and may only be used to enforce additional restrictions on clients. Sensitive attribute definitions may never be used to grant a client additional access to information that it would not have already had through other means. For example, if the `employeeSSN` attribute is declared to be a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute will only be returned to those clients that have both been granted permission by the access control rules defined in the server and are communicating with the server over a secure connection. The `employeeSSN` attribute will be stripped out of entries returned to clients normally authorized to see it if they are using insecure connections, and it will also be stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

## To Create a Sensitive Attribute

### Steps

1. To create a sensitive attribute, you must first create one or more sensitive attribute definitions.

For example, to create a sensitive attribute definition that will only allow access to the `employeeSSN` attribute by clients using secure connections, the following configuration changes may be made:

```
$ bin/dsconfig create-sensitive-attribute \
 --attribute-name "Employee Social Security Numbers" \
 --set attribute-type:employeeSSN \
 --set include-default-sensitive-operational-attributes:true \
 --set allow-in-returned-entries:secure-only \
 --set allow-in-filter:secure-only \
 --set allow-in-add:secure-only \
 --set allow-in-compare:secure-only \
 --set allow-in-modify:secure-only
```

2. Associate those sensitive attribute definitions with the client connection policies for which you want them to be enforced.

```
$ bin/dsconfig set-client-connection-policy-prop --policy-name default \
 --set "sensitive-attribute:Employee Social Security Numbers"
```

## Configuring Global Sensitive Attributes

Administrators can assign one or more sensitive attribute definitions to a client connection policy. However, in an environment with multiple client connection policies, it could be easy to add a sensitive attribute definition to one policy but overlook it in another. The Directory Server supports the ability to define sensitive attributes as a global configuration option so that they will automatically be used across all client connection policies.

### To Configure a Global Sensitive Attribute

#### Steps

- Run `dsconfig` to add a global sensitive attribute across all client connection policies. The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-attribute:employeeSSN"
```

## Excluding a Global Sensitive Attribute on a Client Connection Policy

Administrators can set a global sensitive attribute across all client connection policies. However, there may be cases when a specific directory server must exclude the sensitive attribute as it may not be needed for client connection requests. For example, in most environments it is good to declare the `userPassword` attribute to be a sensitive attribute in a manner that prevents it from being read by external clients. Further, this solution is more secure than protecting the `password` attribute using the server's default global ACI, which only exists for backwards compatibility purposes. If the Data Sync Server is installed, then it does need to be able to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the Data Sync Server. The Directory Server provides an `exclude-global-sensitive-attribute` property for this purpose.

## To Exclude a Global Sensitive Attribute on a Client Connection Policy

### Steps

1. Run `dsconfig` to remove the global ACI that limits access to the `userPassword` or `authPassword` attribute. This is present for backwards compatibility.

```
$ bin/dsconfig set-access-control-handler-prop \
 --remove 'global-aci:(targetattr="userPassword || authPassword")
 (version 3.0; acl "Prevent clients from retrieving passwords from the
 server";
 deny (read,search,compare) userdn="ldap:///anyone";) '
```

2. Run `dsconfig` to add the `userPassword` attribute as a global sensitive attribute, which is applied to all client connection policies. Do this by adding the built-in "Sensitive Password Attributes" Sensitive Attribute definition to the Global Configuration.

```
$ bin/dsconfig set-global-configuration-prop \
 --add "sensitive-attribute:Sensitive Password Attributes"
```

3. If the server is designated to synchronize passwords with a Sync Server, then it is necessary to configure a client connection policy for the Sync User to exclude the global sensitive attribute. The following is an example on how to create a new policy if the Data Sync Server binds with the default DN of `cn=Sync User,cn=Root DNs,cn=config`.

```
$ bin/dsconfig create-connection-criteria \
 --criteria-name "Requests by Sync Users" \
 --type simple \
 --set user-auth-type:internal \
 --set user-auth-type:sasl \
 --set user-auth-type:simple \
 --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

$ bin/dsconfig create-client-connection-policy \
 --policy-name "Data Sync Server Connection Policy" \
 --set enabled:true \
 --set evaluation-order-index:9998 \
 --set "connection-criteria:Requests by Sync Users" \
 --set "exclude-global-sensitive-attribute:Sensitive Password Attributes"
```

## Working with the LDAP Changelog

---

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

This chapter will present the following topics related to the LDAP Changelog:

### Overview of the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services. For example, you can install the Data Sync Server that monitors the LDAP changelog for any updates that occur on a source directory server and synchronizes these changes to a target DIT or database server. The Directory Server provides an additional feature in that the LDAP changelog supports virtual attributes.

**Note:** The LDAP Changelog should not be confused with the Replication Changelog. The main distinction is as follows:

- The LDAP Changelog (i.e., the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication Changelog Backend (i.e., the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

### Key Changelog Features

As of version 3.2, the Directory Server supports two new Changelog Backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries. External client applications can change the contents of attributes they can see in the targeted entry based on the access control rules applied to the associated base DN.

- **apply-access-controls-to-changelog-entry-contents.** Indicates whether the contents of changelog entry attributes (i.e., `changes`, `deletedEntryAttrs`, `ds-changelog-entry-key-attr-values`, `ds-changelog-before-values`, and `ds-changelog-after-values`) are subject to access control and/or sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations will be suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry will also be suppressed. This property only applies to standard LDAP searches of the `cn=changelog` branch.
- **report-excluded-changelog-attributes.** Indicates whether to include additional information about any attributes that may have been removed due to access control filtering. This property only applies to content removed as a result of processing performed by the `apply-access-controls-to-changelog-entry-contents` property. Possible values are:
  - **none** - Indicates that changelog entries should not include any information about attributes that have been removed.
  - **attribute-counts** - Indicates that changelog entries should include a count of user and/or operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, the number of the excluded user attributes will be reported in the `ds-changelog-num-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes will be reported in the `ds-changelog-num-excluded-operational-attributes` attribute of the changelog entry. Both the `ds-changelog-num-excluded-user-attributes` and `ds-changelog-num-excluded-operational-attributes` are operational and must be explicitly requested by clients (or all operational attributes requested using "+") to be returned.
  - **attribute-names** - Indicates that changelog entries should include the names of user and/or operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes will be reported in the `ds-changelog-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes will be reported in the `ds-change-log-excluded-operational-attribute` attribute of the changelog entry. Both the `ds-changelog-excluded-user-attribute` and `ds-changelog-excluded-operational-attribute` attributes are operational and must be explicitly requested by clients (or all operational attributes requested via "+") to be returned.

## To Enable Access Control Filtering in the LDAP Changelog

About this task

To set up access control to the LDAP Changelog, use the `dsconfig` tool to enable the properties to the Changelog Backend. Only admin users with the `bypass-acl` privilege can read the changelog.

Steps

1. Enable the `apply-access-control-to-changelog-entry-contents` property to allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
 --set "apply-access-controls-to-changelog-entry-contents:true"
```

Access control filtering will be applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the Changelog Backend is servicing requests from an PingDataSync Server that has the `filter-changes-by-user` Sync Pipe property set.

2. Optional. Set the `report-excluded-changelog-attributes` property to include a count of users that have been removed through access control filtering. The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
 --set "report-excluded-changelog-attributes:attribute-counts"
```

### Useful Changelog Features

The Directory Server provides two useful changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

- **changelog-max-before-after-values.** Setting this property to a non-zero value causes all of the old values and all of the new values (up to the specified maximum) for each changed attribute to be stored in the changelog entry. The values will be stored in the `ds-change-log-before-values` and `ds-changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

**Note:** The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before/after values will be stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute whose format is:

```
attr=attributeName,beforeCount=100,afterCount=101
```

where "attributeName" is the name of the attribute and the "beforeCount" and "afterCount" are the total number of values for that attribute before and after the change, respectively. This attribute indicates that you need to reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert will be generated.

**Note:** If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values will not be stored.

- **changelog-include-key-attribute.** This property is used for correlation attributes that need to be synchronized across servers, such as `uid`. It causes the current (after-change) value of the specified attributes to be recorded in the `ds-changelog-entry-key-attr-values` attribute on the

changelog entry. This applies for all change types. On a DELETE operation, the values are from the entry before they were deleted.

The key values will be recorded on every change and override the settings configured in `changelog-include-attribute`, `changelog-exclude-attribute`, `changelog-deleted-entry-include-attribute`, or `changelog-deleted-entry-exclude-attribute`.

### Example of the Changelog Features

After the `changelog-max-before-after-values` property is set, the before-and-after values of any change attribute will be recorded in the LDAP Changelog. For example, given a simple entry with two multi-valued mail attributes:

```
dn: uid=test,dc=example,dc=com
objectclass: inetorgperson
cn: test user
sn: user
description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
```

Then, apply the following changes to the entry:

```
dn: uid=test,dc=example,dc=com
changetype: modify
add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
```

The resulting changelog would record the following attribute values:

```
dn: changeNumber=1,cn=changelog
objectClass: top
objectClass: changeLogEntry
targetDN: uid=test,dc=example,dc=com
changeType: modify
changes::
YWRkOiBtYWlsCmlhaWw6IHRlc3RAaG90bWFpbC5jb20KLQpkZWxl dGU6IG1haWwKbWFpbDogdGVzdEB5YWWh

ds-changelog-entry-key-attr-values:: dWlkOiB0ZXN0Cg==
changenumber: 1
```

You can run the `bin/base64 decode -d` command-line tool to view the decoded value for the `changes`, `ds-changelog-before-values`, `ds-changelog-after-values` attributes:

After base64 decoding, the `changes` attribute reads:

```

add: mail
mail: test@hotmail.com
-
delete: mail
mail: test@yahoo.com
-
replace: description
description: newDescription
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
-

```

After base64 decoding, the `ds-changelog-before-values` attribute reads:

```

description: oldDescription
mail: test@yahoo.com
mail: test@gmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

After base64 decoding, the `ds-changelog-after-values` attribute reads:

```

description: newDescription
mail: test@gmail.com
mail: test@hotmail.com
modifyTimestamp: 20131010020345.546Z
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config

```

## Viewing the LDAP Changelog Properties

You can view the LDAP changelog properties by running the `dsconfig get-backend-prop` command and specifying the changelog backend.

### To View the LDAP Changelog Properties Using dsconfig Non-Interactive Mode

#### Steps

- Use `dsconfig` to view the changelog properties on the Directory Server. To view "advanced" properties that are normally hidden, add the `--advanced` option when running the command. For a specific description of each property, see the *PingDirectory Server Configuration Reference*.

```
$ bin/dsconfig get-backend-prop --backend-name changelog
```

```

Property : Value(s)

backend-id : changelog
description : -
enabled : false
writability-mode : disabled
base-dn : cn=changelog
set-degraded-alert-when-disabled : false
return-unavailable-when-disabled : false
db-directory : db
db-directory-permissions : 700
changelog-maximum-age : 2 d
db-cache-percent : 1
changelog-include-attribute : -
changelog-exclude-attribute : -

```

```

changelog-deleted-entry-include-attribute : -
changelog-deleted-entry-exclude-attribute : -
changelog-include-key-attribute : -
changelog-max-before-after-values : 0
changelog-write-batch-size : 100
changelog-purge-batch-size : 1000
changelog-write-queue-capacity : 100
write-lastmod-attributes : true
use-reversible-form : false
je-property : -

```

## Enabling the LDAP Changelog

By default, the LDAP changelog is disabled on the Directory Server. If you are using the `dsconfig` tool in interactive mode, the changelog appears in the Backend configuration as a Standard object menu item.

**Note:** You can enable the feature using the `dsconfig` tool only if required as it can significantly affect LDAP update performance.

### To Enable the LDAP Changelog Using dsconfig Non-Interactive Mode

#### Steps

- Use `dsconfig` to enable the changelog property on the Directory Server.

```

$ bin/dsconfig set-backend-prop \
 --backend-name changelog --set enabled:true

```

### To Enable the LDAP Changelog Using Interactive Mode

#### Steps

- Use `dsconfig` to enable the changelog on each server in the network. Then, authenticate to the server by entering the host name, LDAP connection, port, bindDN and bind password.

```
$ bin/dsconfig
```

- On the Directory Server main menu, type `o` to change from the Basic object level to the Standard object level.
- Enter the option to select the Standard Object level.
- On the Directory Server main menu, type the number corresponding to Backend.
- On the **Backend Management** menu, enter the option to view and edit an existing backend.
- Next, you should see a list of the accessible backends on your system. For example, you may see options for the `changelog` and `userRoot` backends. Enter the option to work with the changelog backend.
- On the **Changelog Backend properties** menu, type the number corresponding to the Enabled property.
- On the **Enabled Property** menu, type the number to change the `Enabled` property to `TRUE`.
- On the **Backend Properties** menu, type `f` to apply the change. If you set up the server in a server group, type `g` to update all of the servers in the group. Otherwise, repeat steps 1-10 on the other servers.
- Verify that changes made to the data are recorded in the changelog.

## Changing the LDAP Changelog Database Location

In cases where disk space issues arise, you can change the on-disk location of the LDAP Change Log database. The changelog backend supports a `db-directory` property that specifies the absolute or

relative path (relative to the local server root) to the file system directory that is used to hold the Oracle Berkeley DB Java Edition database files containing the data for this backend.

If you change the changelog database location, you must stop and then restart the Directory Server for the change to take effect. If the changelog backend is already enabled, then the database files must be manually moved or copied to the new location while the server is stopped.

### To Change the LDAP Changelog Location Using dsconfig Non-Interactive Mode

#### Steps

1. Use **dsconfig** to change the database location for the LDAP Changelog, which by default is at `<server-root>/db`. The following command sets the LDAP changelog backend to `<server-root>/db2`. Remember to include the LDAP connection parameters (for example, host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
 --set "db-directory:db2" --set "enabled:true"
```

The database files are stored under `<server-root>/db2/changelog`. The files for this backend are stored in a sub-directory named after the `backend-id` property.

2. Stop and restart the server. Since the LDAP changelog backend was previous disabled, there is no need to manually relocate any existing database files.

```
$ bin/stop-server
$ bin/start-server
```

### To Reset the LDAP Changelog Location Using dsconfig Non-Interactive Mode

#### Steps

1. If you have changed the LDAP Changelog location, but want to reset it to its original location, use **dsconfig** to reset it. The following command resets the LDAP changelog backend to `<server-root>/db` location. Remember to include the LDAP connection parameters (for example, host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
 --reset "db-directory"
```

2. The server attempts to use whatever it finds in the configured location when it starts. If there is nothing there, it will create an empty database. If the LDAP changelog backend at the previous location is enabled at the time, stop the server, manually copy the database files to the new LDAP changelog location, and then restart the server.

## Viewing the LDAP Changelog Parameters in the Root DSE

The Root DSE is a special entry that holds operational information about the server. The entry provides information about the LDAP controls, extended operations, and SASL mechanisms available in the server as well as the state of the data within the changelog. For changelog parameters, the attributes of interest include:

- **firstChangeNumber**. Change number for the first (oldest) change record contained in the LDAP changelog.
- **lastChangeNumber**. Change number for the last (most recent) change record contained in the LDAP changelog.
- **lastPurgedChangeNumber**. Change number for the last change that was purged from the LDAP changelog. It can be 0 if no changes have yet been purged.

- **firstReplicaChange.** Information about the first (oldest) change record for a change received from the specified replica. This is a multi-valued attribute and should include a value for each server in the replication topology.
- **lastReplicaChange.** Information about the last (most recent) change record for a change received from the specified replica.

The `firstReplicaChange` and `lastReplicaChange` attributes use the following syntax:

```
serverID:CSN:changeNumber
```

where:

- **serverID.** Specifies the unique identifier for the server updating the change log.
- **CSN.** Specifies the Change Sequence Number, which is the time when the update was made to the given replica.
- **changeNumber.** Specifies the order of the change that is logged to the LDAP changelog.

The `firstReplicaChange` and `lastReplicaChange` attributes can be used to correlate information in the local LDAP Change Log with data in the LDAP Change Log of other servers in the replication topology. The order of the individual changes in the LDAP Change Log can vary between servers based on the order in which they were received from a replica.

### To View the LDAP Changelog Parameters

Steps

- Use `ldapsearch` to view the Root DSE.

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

## Viewing the LDAP Changelog Using `ldapsearch`

All records in the changelog are immediate children of the `cn=changelog` entry and are named with the `changeNumber` attribute. You can view changelog entries using `ldapsearch`. Changes are represented in the form documented in the *draft-good-ldap-changelog* specification with the `targetDN` attribute providing the DN of the updated entry, the `changeType` attribute providing the type of operation (add, delete, modify, or modDN), and the `changes` attribute providing a base64-encoded representation of the attributes included in the entry (for add operations) or the changes made (for modify operations) in LDIF form. You can view the changes by decoding the encoded value using the `base64 decode` utility. The LDAP SDK for Java also provides support for parsing changelog entries.

### To View the LDAP Changelog Using `ldapsearch`

Steps

1. Grant access to the `cn=changelog` backend to the `uid=admin` account using access control rules. By default, only the root user has access to this backend.

```
$ bin/ldapmodify
dn: cn=changelog
changetype: modify
add: aci
aci: (targetattr="*|+")(
 (version 3.0; acl "Access to the changelog backend for the admin
 account";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

## 2. Use `ldapsearch` to view the changelog.

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)"

dn: cn=changelog
objectClass: top
objectClass: untypedObject
cn: changelog

dn: changeNumber=1,cn=changelog
objectClass: changeLogEntry
objectClass: top
targetDN: uid=user.0,ou=People,dc=example,dc=com
changeType: modify
changes::
 cmVwbGFjZTogbW9iaWxlCmlvYmlsZTogKzEgMDIwIDE1NCA5Mzk4Ci0KcmVwbGFjZToga
 G9tZVBob25lCmhvbWVQaG9uZTogKzEgMjI1IDIxNiA0OTQ5Ci0KcmVwbGFjZTogZ2l2ZW50YW1lCm

 zYwNDA5MzAwMDAwMDAyCgo=
changenumber: 2
```

### To View the LDAP Change Sequence Numbers

#### Steps

- The changelog displays the server state information, which is important for failover between servers during synchronization operations. The server state information is exchanged between the servers in the network (LDAP servers and replication servers) as part of the protocol start message. It also helps the client application determine which server is most up-to-date. Make sure that the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

```
$ bin/ldapsearch --baseDN cn=changelog --dontWrap "(objectclass=*)" "+"

dn: cn=changelog

dn: changeNumber=1,cn=changelog
entry-size-bytes: 182
targetUniqueId: 68147342-1f61-3465-8489-3de58c532130
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184D9E303000000001
replicationCSN: 0000011D27184D9E303000000001
replicaIdentifier: 12336

dn: changeNumber=2,cn=changelog
entry-size-bytes: 263
targetUniqueId: 4e9b7847-edcb-3791-b11b-7505f4a55af4
changeTime: 20111023002624Z
lastReplicaCSN: 0000011D27184F2E303000000002
replicationCSN: 0000011D27184F2E303000000002
replicaIdentifier: 12336
```

## To View LDAP Changelog Monitoring Information

### About this task

The changelog contains a monitor entry that you can access over LDAP, JConsole, the Administrative Console, or SNMP. Make sure that the `uid=admin` account has the necessary access rights to the `cn=changelog` backend.

### Steps

- Use `ldapsearch` to view the changelog monitor entry.

```
$ bin/ldapsearch --baseDN cn=changelog,cn=monitor "(objectclass=*)"

dn: cn=changelog,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: extensibleObject
cn: changelog
changelog: cn=changelog
firstchangenumber: 1
lastchangenumber: 8
lastpurgedchangenumber: 0
firstReplicaChange: 16225:0000011D0205237F3F6100000001:5
firstReplicaChange: 16531:0000011CFF334C60409300000002:1
lastReplicaChange: 16225:0000011D02054E8B3F6100000002:7
lastReplicaChange: 16531:0000011CFF334C60409300000002:1
oldest-change-time: 20081015063104Z
...(more data)...
```

## Indexing the LDAP Changelog

The Directory Server supports attribute indexing in the Changelog Backend to allow Get Changelog Batch requests to filter results that include only changes involving specific attributes. Normally, the directory server that receives a request must iterate over the whole range of changelog entries and then match entries based on search criteria for inclusion in the batch. The majority of this processing also involves determining whether the changelog entry includes changes to a particular attribute or set of attributes, or not. Using changelog indexing, client applications can dramatically speed up throughput when targeting the specific attributes.

Administrators can configure attribute indexing using the `index-include-attribute` and `index-exclude-attribute` properties on the Changelog Backend. The properties can accept the specific attribute name or special LDAP values `"*"` to specify all user attributes or `"+"` to specify all operational attributes.

To determine if the directory server supports this feature, administrators can view the Root DSE for the following entry:

```
supportedFeatures: 1.3.6.1.4.1.30221.2.12.3
```

### To Index a Changelog Attribute

#### Steps

1. Use `dsconfig` to set attribute indexing on an attribute in the Changelog Backend.

The following command enables the Changelog Backend and sets the backend to include all user attributes (`"*"`) for ADD or MODIFY operations using the `changelog-include-attribute` property. The `changelog-deleted-entry-include-attribute` property is set to all attributes (`"*"`) to specify a set of attribute types that should be included in a changelog entry for DELETE operations. Attributes specified in this list will be recorded in the `deletedEntryAttrs` attribute on the changelog

entry when an entry is deleted. The attributes `displayName` and `employeeNumber` are indexed using the `index-include-attribute` property.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
--set "enabled:true" \
--set "changelog-include-attribute:*" \
--set "changelog-deleted-entry-include-attribute:*" \
--set "index-include-attribute:displayName" \
--set "index-include-attribute:employeeNumber"
```

2. Add another attribute to index using the `dsconfig --add` option, which adds the attribute to an existing configuration setting.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
--add "index-include-attribute:cn"
```

## To Exclude Attributes from Indexing

### Steps

- Use `dsconfig` to set attribute indexing on all user attributes in the Changelog Backend. The following command includes all user attributes except the description and location attributes.

```
$ bin/dsconfig set-backend-prop --backend-name changelog \
--set "index-include-attribute:*" \
--set "index-exclude-attribute:description" \
--set "index-exclude-attribute:location"
```

## Tracking Virtual Attribute Changes in the LDAP Changelog

While the LDAP Changelog primarily tracks changes to real attributes, it can also provide information about virtual attributes included in created, updated, or deleted entries. The `include-virtual-attributes` property controls the virtual attribute information to include in changelog entries, and this property may include any or all of the following values:

### add-attributes

Indicates that changelog entries for add operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was created.

### deleted-entry-attributes

Indicates that changelog entries for delete operations should include a `ds-changelog-virtual-attributes` attribute that lists the virtual attribute values generated for the entry at the time it was deleted.

### before-and-after-values

Indicates that changelog entries for modify and modify DN operations should include `ds-changelog-before-virtual-values` and `ds-changelog-after-virtual-values` attributes that contain the values of virtual attributes that have been updated.

### key-attribute-values

Indicates that changelog entries should include a `ds-changelog-entry-key-virtual-values` attribute that holds the values for any virtual attributes included in the set of key attributes, as defined by the `changelog-include-key-attribute` property.

The `add-attributes` and `before-and-after-values` options are selected by default.

## To Track Virtual Attribute Changes in the LDAP Changelog

### Steps

- Use `dsconfig` to enable virtual attribute change tracking in the LDAP Changelog.

The following command enables the LDAP changelog and sets `include-virtual-attributes` to `add-attributes`, which indicates that virtual attribute be included in the set of attributes listed for an add operation. The `delete-entry-attributes` option indicates that virtual attributes should be included in the set of deleted entry attributes listed for a delete operation. The `before-and-after-values` option indicates that virtual attributes should be included in the set of before and after values for attributes targeted by the changes. The `key-attribute-values` option indicates that virtual attributes should be included in the set of entry key attribute values.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
 --set "enabled:true" \
 --set "include-virtual-attributes:add-attributes" \
 --set "include-virtual-attributes:deleted-entry-attributes" \
 --set "include-virtual-attributes:before-and-after-values" \
 --set "include-virtual-attributes:key-attribute-values"
```

## Managing Access Control

---

The PingDirectory Server provides a fine-grained access control model to ensure that users are able to access the information they need, but are prevented from accessing information that they should not be allowed to see. It also includes a privilege subsystem that provides even greater flexibility and protection in many key areas.

This chapter presents the access control model and provides examples that illustrate the use of key access control functionality.

### Overview of Access Control

The access control model uses access control instructions (ACIs), which are stored in the `aci` operational attribute, to determine what a user or a group of users can do with a set of entries, down to the attribute level. The operational attribute can appear on any entry and affects the entry or any subentries within that branch of the directory information tree (DIT).

Access control instructions specifies four items:

- **Resources.** *Resources* are the targeted items or objects that specifies the set of entries and/or operations to which the access control instruction applies. For example, you can specify access to certain attributes, such as the `cn` or `userPassword` password.
- **Name.** *Name* is the descriptive label for each access control instruction. Typically, you will have multiple access control instructions for a given branch of your DIT. The access control name helps describe its purpose. For example, you can configure an access control instructions labelled "ACI to grant full access to administrators."
- **Clients.** *Clients* are the users or entities to which you grant or deny access. You can specify individual users or groups of users using an LDAP URL. For example, you can specify a group of administrators using the LDAP URL: `groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com."`
- **Rights.** *Rights* are permissions granted to users or client applications. You can grant or deny access to certain branches or operations. For example, you can grant `read` or `write` permission to a `telephoneNumber` attribute.

### Key Access Control Features

The PingDirectory Server provides important access control features that provide added security for the Directory Server's entries.

## Improved Validation and Security

The Directory Server provides an access control model with strong validation to help ensure that invalid ACIs are not allowed into the server. For example, the Directory Server ensures that all access control rules added over LDAP are valid and can be fully parsed. Any operation that attempts to store one or more invalid ACIs are rejected. The same validation is applied to ACIs contained in data imported from an LDIF file. Any entry containing a malformed `aci` value will be rejected.

As an additional level of security, the Directory Server examines and validates all ACIs stored in the data whenever a backend is brought online. If any malformed ACIs are found in the backend, then the server generates an administrative alert to notify administrators of the problem and places itself in lockdown mode. While in lockdown mode, the server only allows requests from users who have the `lockdown-mode` privilege. This action allows administrators to correct the malformed ACI while ensuring that no sensitive data is inadvertently exposed due to an access control instruction not being enforced. When the problem has been corrected, the administrator can use the `leave-lockdown-mode` tool or restart the server to allow it to resume normal operation.

## Global ACIs

Global ACIs are a set of ACIs that can apply to entries anywhere in the server (although they can also be scoped so that they only apply to a specific set of entries). They work in conjunction with access control rules stored in user data and provide a convenient way to define ACIs that span disparate portions of the DIT.

In the PingDirectory Server, global ACIs are defined within the server configuration, in the `global-aci` property of configuration object for the access control handler. They can be viewed and managed using configuration tools like `dsconfig` and the Administrative Console.

The global ACIs available by default in the PingDirectory Server include:

- Allow anyone (including unauthenticated users) to access key attributes of the root DSE, including: `namingContexts`, `subschemaSubentry`, `supportedAuthPasswordSchemes`, `supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedLDAPVersion`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`.
- Allow anyone (including unauthenticated users) to access key attributes of the subschema subentry, including: `attributeTypes`, `dITContentRules`, `dITStructureRules`, `ldapSyntaxes`, `matchingRules`, `matchingRuleUse`, `nameForms`, and `objectClasses`.
- Allow anyone (including unauthenticated users) to include the following controls in requests made to the server: authorization identity request, manage DSA IT, password policy, real attributes only, and virtual attributes only.
- Allow anyone (including unauthenticated users) to request the following extended operations: get symmetric key, password modify request, password policy state, StartTLS, and Who Am I?

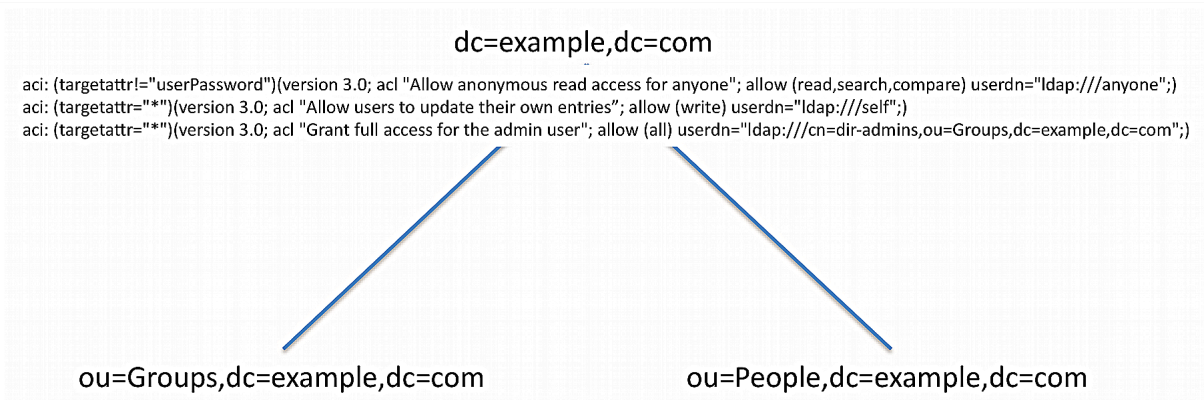

## Access Controls for Public or Private Backends

The PingDirectory Server classifies backends as either public or private, depending on their intended purpose. A private backend is one whose content is generated by the Directory Server itself (for example, the root DSE, monitor, and backup backends), is used in the operation of the server (for example, the configuration, schema, task, and trust store backends), or whose content is maintained by the server (for example, the LDAP changelog backend). A public backend is intended to hold user-defined content, such as user accounts, groups, application data, and device data.

The PingDirectory Server access control model also supports the distinction between public backends and private backends. Many private backends do not allow writes of any kind from clients, and some of the private backends that do allow writes only allow changes to a specific set of attributes. As a result, any access control instruction intended to permit or restrict access to information in private backends should be defined as global ACIs, rather than attempting to add those instructions to the data for that private backend.

## General Format of the Access Control Rules

Access control instructions (ACIs) are represented as strings that are applied to one or more entries within the Directory Information Tree (DIT). Typically, an ACI is placed on a subtree, such as `dc=example,dc=com`, and applies to that base entry and all entries below it in the tree. The Directory Server iterates through the DIT to compile the access control rules into an internally-used list of denied and allowed targets and their permissible operations. When a client application, such as `ldapsearch`, enters a request, the Directory Server checks that the user who binds with the server has the necessary access rights to the requested search targets. ACIs are cumulatively applied, so that a user who may have an ACI at an entry, may also have other access rights available if ACIs are defined higher in the DIT and are applicable to the user. In most environments, ACIs are defined at the root of a main branch or a subtree, and not on individual entries unless absolutely required.

## MY TITLE ACI

An access control rule has a basic syntax as follows:

```

aci : (targets) (version 3.0; acl "name";
 permissions
 bind rules
 ;)

```

## Access Control Components

| Access Control Component | Description                                                                                                                                                                                                                  |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| targets                  | Specifies the set of entries and/or attributes to which an access control rule applies. Syntax: <i>(target keyword =    != expression)</i>                                                                                   |
| name                     | Specifies the name of the ACI.                                                                                                                                                                                               |
| permissions              | Specifies the type of operations to which an access control rule might apply. Syntax: <i>allow//deny (permission)</i>                                                                                                        |
| bind rules               | Specifies the criteria that indicate whether an access control rule should apply to a given requestor. Syntax: <i>bind rule keyword =    != expression;. The bind rule syntax requires that it be terminated with a ";".</i> |

## Summary of Access Control Keywords

This section provides an overview of the keywords supported for use in the PingDirectory Server access control implementation.

## Targets

A target expression specifies the set of entries and/or attributes to which an access control rule applies. The *keyword* specifies the type of target element. The *expression* specifies the items that is targeted by the access control rule. The operator is either the equal ("=") or not-equal ("!="). Note that the "!=" operator cannot be used with `targattrfilters` and `targetscope` keywords. For specific examples on each target keyword, see the section [Working with Targets](#).

```
(keyword [=|!]=expression)
```

The following keywords are supported for use in the target portion of ACIs:

### Summary of Access Control Target Keywords

| Target Keyword  | Description                                                                                                                                                                  | Wildcards |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|
| extop           | Specifies the OIDs for any extended operations to which the access control rule should apply.                                                                                | No        |
| target          | Specifies the set of entries, identified using LDAP URLs, to which the access control rule applies.                                                                          | Yes       |
| targattrfilters | Identifies specific attribute values based on filters that may be added to or removed from entries to which the access control rule applies.                                 | Yes       |
| targetattr      | Specifies the set of attributes to which the access control rule should apply.                                                                                               | Yes       |
| targetcontrol   | Specifies the OIDs for any request controls to which the access control rule should apply.                                                                                   | No        |
| targetfilter    | Specifies one or more search filters that may be used to indicate the set of entries to which the access control should apply.                                               | Yes       |
| targetscope     | Specifies the scope of entries, relative to the defined target entries or the entry containing the ACI if there is no target, to which the access control rule should apply. | No        |

## Permissions

Permissions indicate the types of operations to which an access control rule might apply. You can specify if the user or group of users are allowed or not allowed to carry out a specific operation. For example, you would grant read access to a targeted entry or entries using "allow (read)" permission. Or you can specifically deny access to the target entries and/or attributes using the "deny (read)" permission. You can list out multiple permissions as required in the ACI.

```
allow (permission1 ...,
 permission2
 ,...permissionN)
```

```
deny (permission1 ...,
 permission2
 ,...permissionN)
```

The following keywords are supported for use in the permissions portion of ACIs:

### Summary of Access Control Permissions

| Permission | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| add        | Indicates that the access control should apply to add operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| compare    | Indicates that the access control should apply to compare operations, as well as to search operations with a base-level scope that targets a single entry.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| delete     | Indicates that the access control should apply to delete operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| export     | Indicates that the access control should only apply to modify DN operations in which an entry is moved below a different parent by specifying a new superior DN in the modify DN request. The requestor must have the <code>export</code> permission for operations against the entry's original DN. The requestor must have the <code>import</code> permission for operations against the entry's new superior DN. For modify DN operations that merely alter the RDN of an entry but keeps it below the same parent (i.e., renames the entry), only the <code>write</code> permission is required. This is true regardless of whether the entry being renamed is a leaf entry or has subordinate entries. |
| import     | See the description for the <code>export</code> permission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| proxy      | Indicates that the access control rule should apply to operations that attempt to use an alternate authorization identity (for example, operations that include a proxied authorization request control, an intermediate client request control with an alternate authorization identity, or a client that has authenticated with a SASL mechanism that allows an alternate authorization identity to be specified).                                                                                                                                                                                                                                                                                        |
| read       | Indicates that the access control rule should apply to search result entries returned by the server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| search     | Indicates that the access control rule should apply to search operations with a non-base scope.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| selfwrite  | Indicates that the access control rule should apply to operations in which a user attempts to add or remove his or her own DN to the values for an attribute (for example, whether users may add or remove themselves from groups).                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| write      | Indicates that the access control rule should apply to modify and modify DN operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| all        | An aggregate permission that includes all other permissions except "proxy." This is equivalent to providing a permission of "add, compare, delete, read, search, selfwrite, write, export, and import."                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

### Bind Rules

The Bind Rules indicate whether an access control rule should apply to a given requester. The syntax for the target keyword is shown below. The *keyword* specifies the type of target element. The expression specifies the items that is targeted by the access control rule. The operator is either equals ("=") or not-equals ("!="). The semi-colon delimiter symbol (";") is required after the end of the final bind rule.

```
keyword [=|!=] expression;
```

Multiple bind rules can be combined using Boolean operations (AND, OR, NOT) for more access control precision. The standard Boolean rules for evaluation apply: innermost to outer parentheses first, left to right expressions, NOT before AND or OR. For example, an ACI that includes the following bind rule targets all users who are not `uid=admin,dc=example,dc=com` and use simple authentication.

```
(userdn!="ldap:///uid=admin,dc=example,dc=com" and authmethod="simple");
```

The following bind rule targets the `uid=admin,dc=example,dc=com` and authenticates using SASL EXTERNAL or accesses the server from a loopback interface.

```
(userdn="ldap:///uid=admin,dc=example,dc=com and (authmethod="SSL" or ip="127.0.0.1"));
```

The following keywords are supported for use in the bind rule portion of ACIs:

### Summary of Bind Rule Keywords

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| authmethod        | <p>Indicates that the requester's authentication method should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. The keyword's syntax is as follows:</p> <pre style="text-align: center;"><b>authmethod</b> = <i>method</i></pre> <p>where <i>method</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ none</li> <li>▪ simple. Indicates that the client is authenticated to the server using a bind DN and password.</li> <li>▪ ssl. Indicates that the client is authenticated with an SSL/TLS certificate (for example, via SASL EXTERNAL), and not just over a secure connection to the server.</li> <li>▪ sasl {sasl_mechanism}. Indicates that the client is authenticated to the server using a specified SASL Mechanism.</li> </ul> <p>The following example allows users who authenticate with an SSL/TLS certificate (for example, via SASL EXTERNAL) to update their own entries:</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow users to update their own entries";    allow (write) (userdn="ldap:///self" and authmethod="ssl");)</pre> |

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dayofweek         | <p>Indicates that the day of the week should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are not allowed in this expression. Multiple day of week values may be separated by commas. The keyword's syntax is as follows:</p> <pre style="text-align: center;"><b>dayofweek</b> = <i>day1, day2, ...</i></pre> <p>where <i>day</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ sun</li> <li>▪ mon</li> <li>▪ tues</li> <li>▪ wed</li> <li>▪ thu</li> <li>▪ fri</li> <li>▪ sat</li> </ul> <p>The following example allows users who authenticate with an SSL/TLS certificate (for example., via SASL EXTERNAL) on weekdays to update their own entries:</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow users to update their own entries";    allow (write) (dayofweek!="sun,sat" and userdn="ldap:///self"     and authmethod="ssl");)</pre> |
| dns               | <p>Indicates that the requester's DNS-resolvable host name should be taken into account when determining whether the access control rule should apply to an operation. Wildcards are allowed in this expression. Multiple DNS patterns may be separated by commas. The keyword's syntax is as follows:</p> <pre style="text-align: center;"><b>dns</b> = <i>dns-host-name</i></pre> <p>The following example allows users on host name <code>server.example.com</code> to update their own entries:</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow users to update their own entries";    allow (write) (dns="server.example.com" and userdn="ldap:///self");)</pre>                                                                                                                                                                                                                                                                                     |

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| userattr          | <p>Indicates that the requester's relation to the value of the specified attribute should be taken into account when determining whether the access control rule should apply to an operation. A bindType value of <code>USERDN</code> indicates that the target attribute should have a value which matches the DN of the authenticated user. A bindType value of <code>GROUPDN</code> indicates that the target attribute should have a value which matches the DN of a group in which the authenticated user is a member. A bindType value of <code>LDAPURL</code> indicates that the target attribute should have a value that is an LDAP URL whose criteria matches the entry for the authenticated user. Any value other than <code>USERDN</code>, <code>GROUPDN</code>, or <code>LDAPURL</code> is expected to be present in the target attribute of the authenticated user's entry. The keyword's syntax is as follows:</p> <pre>userattr = attrName# [ bindType    attrValue ]</pre> <p>where:</p> <ul style="list-style-type: none"> <li>▪ <i>attrName</i> = name of the attribute for matching</li> <li>▪ <i>bindType</i> = <code>USERDN</code>, <code>GROUPDN</code>, <code>LDAPURL</code></li> <li>▪ <i>attrValue</i> = an attribute value. Note that the <i>attrVALUE</i> of the attribute must match on both the bind entry and the target of the ACI.</li> </ul> <p>The following example allows a manager to change employee's entries. If the bind DN is specified in the <i>manager</i> attribute of the targeted entry, the bind rule is evaluated to TRUE.</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow a manager to change employee   entries";    allow (write) userattr="manager#USERDN");</pre> <p>The following example allows any member of a group to change employee's entries. If the bind DN is a member of the group specified in the <i>allowEditors</i> attribute of the targeted entry, the bind rule is evaluated to TRUE.</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow allowEditors to change employee   entries";    allow (write) userattr="allowEditors#GROUPDN");</pre> <p>The following example allows a user's manager to edit that user's entry and any entries below the user's entry up to two levels deep. You can specify up to five levels (0, 1, 2, 3, 4) below the targeted entry, with zero (0) indicating the targeted entry.</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow managers to change employees entries   two levels below";    allow (write) userattr="parent[0,1,2].manager#USERDN");</pre> <p>The following example allows any member of the engineering department to update any other member of the engineering department at or below the specified ACI.</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow any member of Eng Dept to update any   other member of the   engineering department at or below the ACI";    allow (write) userattr="department#ENGINEERING");</pre> <p>The following example allows an entry to be updated by any user whose entry matches the criteria defined in the LDAP URL contained in the <i>allowedEditorCriteria</i> attribute of the target entry.</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow a user that matches the filter to   change entries";    allow (write) userattr="allowedEditorCriteria#LDAPURL");</pre> |

| Bind Rule Keyword | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| userdn            | <p>Indicates that the user's DN should be taken into account when determining whether the access control rule should apply to an operation. The keyword's syntax is as follows:</p> <pre>userdn [ =    != ] "ldap:///value [    "ldap:///value ..."]</pre> <p>where <i>value</i> is one of the following representations:</p> <ul style="list-style-type: none"> <li>▪ The DN of the target user</li> <li>▪ A value of <code>anyone</code> to match any client, including unauthenticated clients.</li> <li>▪ A value of <code>all</code> to match any authenticated client.</li> <li>▪ A value of <code>parent</code> to match the client authenticated as the user defined in the immediate parent of the target entry.</li> <li>▪ A value of <code>self</code> to match the client authenticated as the user defined in the target entry.</li> </ul> <p>If the value provided is a DN, then that DN may include wildcard characters to define patterns. A single asterisk will match any content within the associated DN component, and two consecutive asterisks may be used to match zero or more DN components.</p> <p>The following example allows users to update their own entries:</p> <pre>aci: (targetattr="*")   (version 3.0; acl "Allow users to update their own entries";    allow (write) userdn="ldap:///self");</pre> |

## Working with Targets

The following section presents a detailed look and examples of the target ACI keywords: `target`, `targetattr`, `targetfilter`, `targetattrfilters`, `targetscope`, `targetcontrol`, and `extop`.

### target

The `target` keyword indicates that the ACI should apply to one or more entries at or below the specified distinguished name (DN). The target DN must be equal or subordinate to the DN of the entry in which the ACI is placed. For example, if you place the ACI at the root of `ou=People,dc=example,dc=com`, you can target the DN, `uid=user.1,ou=People,dc=example,dc=com` within your ACI rule. The DN must meet the string representation specification of distinguished names, outlined in RFC 4514, and requires that special characters be properly escaped.

The `target` clause has the following format, where DN is the distinguished name of the entry or branch:

```
(target = ldap:///
 DN
)
```

For example, to target a specific entry, you would use a clause such as the following:

```
(target = ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

Note that, in general, specifying a target DN is not recommended. It is better to have the ACI defined in that entry and omit the `target` element altogether. For example, although you can have `(target="ldap:///uid=john.doe,ou=People,dc=example,dc=com)` in any of the `dc=example,dc=com` or `ou=People` entries, it is better for it to be defined in the `uid=john.doe` entry and not explicitly include the `target` element.

The expression allows for the "not equal" (!=) operator to indicate that all entries within the scope of the given branch that do NOT match the expression be targeted for the ACI. Thus, the following expression targets all entries within the subtree that do not match `uid=john.doe`.

```
(target != ldap:///uid=john.doe,ou=People,dc=example,dc=com)
```

The `target` keyword also supports the use of asterisk (\*) characters as wildcards to match elements within the distinguished name. The following target expression matches all entries that contains and begins with "john.d," so that entries like "john.doe,ou=People,dc=example,dc=com," and "john.davies,ou=People,dc=example,dc=com" would match.

```
(target = ldap:///uid=john.d*,ou=People,dc=example,dc=com)
```

The following target expression matches all entries whose DN begins with "john.d," and matches the `ou` attribute. Entries like "john.doe,ou=People,dc=example,dc=com," and "john.davies,ou=asia-branch,dc=example,dc=com" would match.

```
(target = ldap:///uid=john.d*,ou=*,dc=example,dc=com)
```

Another example of a complete ACI targets the entries in the `ou=People,dc=example,dc=com` branch and the entries below it, and grants the users the privilege to modify all of their user attributes within their own entries.

```
aci: (target="ldap:///ou=People,dc=example,dc=com")
 (targetattr="*")
 (version 3.0; acl "Allow all the ou=People branch to modify their own
 entries";
 allow (write) userdn="ldap:///self";)
```

### targetattr

The `targetattr` keyword targets the attributes for which the access control instruction should apply. There are four general forms that it can take in the PingDirectory Server:

- **(targetattr="\*")**. Indicates that the access control rule applies to all user attributes. Operational attributes will not automatically be included in this set.
- **(targetattr="+")**. Indicates that the access control rule applies to all operational attributes. User attributes will not automatically be included in this set.
- **(targetattr="attr1|attr2|attr3|...|attrN")**. Indicates that the access control rule applies only to the named set of attributes.
- **(targetattr!="attr1|attr2|attr3|...|attrN")**. Indicates that the access control rule applies to all user attributes except the named set of attributes. It will not apply to any operational attributes.

The targeted attributes can be classified as user attributes and operational attributes. User attributes define the actual data for that entry, while operational attributes provide additional metadata about the entry that can be used for informational purposes, such as when the entry was created, last modified and by whom. Metadata can also include attributes specifying which password policy applies to the user, or overridden default constraints like size limit, time limit, or look-through limit for that user.

The PingDirectory Server distinguishes between these two types of attributes in its access control implementation. The Directory Server does not automatically grant any access at all to operational attributes. For example, the following clause applies only to user attributes and not to operational attributes:

```
(targetattr="*")
```

You can also target multiple attributes in the entry. The following clause targets the common name (cn), surname (sn) and state (st) attribute:

```
(targetattr="cn||sn||st")
```

You can use the "+" symbol to indicate that the rule should apply to all operational attributes, as follows:

```
(targetattr="+")
```

To include all user and all operational attributes, you use both symbols, as follows:

```
(targetattr="*||+")
```

If there is a need to target a specific operational attribute rather than all operational attributes, then it can be specifically included in the values of the `targetattr` clause, as follows:

```
(targetattr="ds-rlim-size-limit")
```

Or if you want to target all user attributes and a specific operational attribute, then you can use them in the `targetattr` clause, as follows:

```
(targetattr="*||ds-rlim-size-limit")
```

The following ACIs are placed on the `dc=example,dc=com` tree and allows any user anonymous read access to all entries except the `userPassword` attribute. The second ACI allows users to update their own contact information. The third ACI allows the `uid=admin` user full access privileges to all user attributes in the `dc=example,dc=com` subtree.

```
aci: (targetattr!="userPassword") (version 3.0; acl "Allow anonymous
 read access for anyone"; allow (read,search,compare) userdn="ldap:///
 anyone");
aci: (targetattr="telephonenumber||street||homePhone||l||st")
 (version 3.0; acl "Allow users to update their own contact info";
 allow (write) userdn="ldap:///self");
aci: (targetattr="*") (version 3.0; acl "Grant full access for the admin
 user";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com");
```

An important note must be made when assigning access to user and operational attributes, which can be outlined in an example to show the implications of the Directory Server not distinguishing between these attributes. It can be easy to inadvertently create an access control instruction that grants far more capabilities to a user than originally intended. Consider the following example:

```
aci: (targetattr!="uid||employeeNumber")
 (version 3.0; acl "Allow users to update their own entries";
 allow (write) userdn="ldap:///self");
```

This instruction is intended to allow a user to update any attribute in his or her own entry with the exception of `uid` and `employeeNumber`. This ACI is a very common type of rule and seems relatively harmless on the surface, but it has very serious consequences for a Directory Server that does not distinguish between user attributes and operational attributes. It allows users to update operational attributes in their own entries, and could be used for a number of malicious purposes, including:

- A user could alter password policy state attributes to become exempt from password policy restrictions.
- A user could alter resource limit attributes and bypass size limit, time limit, and look-through-limit constraints.
- A user could add access control rules to his or her own entry, which could allow them to make their entry completely invisible to all other users including administrators granted full rights by access control rules, but excluding users with the `bypass-acl` privilege, allow them to edit any other attributes in their own entry including those excluded by rules like `uid` and `employeeNumber` in the example above, or add, modify, or delete any entries below his or her own entry.

Because the PingDirectory Server does not automatically include operational attributes in the target attribute list, these kinds of ACIs do not present a security risk for it. Also note that users cannot add ACIs to any entries unless they have the `modify-acl` privilege.

Another danger in using the `(targetattr!="x")` pattern is that two ACIs within the same scope could have two different `targetattr` policies that cancel each other out. For example, if one ACI has `(targetattr!="cn|sn")` and a second ACI has `(targetattr!="userPassword")`, then the net effect is `(targetattr="*")`, because the first ACI inherently allows `userPassword`, and the second allows `cn` and `sn`.

### targetfilter

The `targetfilter` keyword targets all attributes that match results returned from a filter. The `targetfilter` clause has the following syntax:

```
(targetfilter =
 ldap_filter
)
```

For example, the following clause targets all entries that contain "ou=engineering" attribute:

```
(targetfilter = "(ou=engineering)")
```

You can only specify a single filter, but that filter can contain multiple elements combined with the OR operator. The following clause targets all entries that contain "ou=engineering," "ou=accounting," and "ou=marketing."

```
(targetfilter = "(|(ou=engineering)(ou=accounting)(ou=marketing)")
```

The following example allows the user, `uid=eng-mgr`, to modify the `departmentNumber`, `cn`, and `sn` attributes for all entries that match the filter `ou=engineering`.

```
aci:(targetfilter="(ou=engineering)")
 (targetattr="departmentNumber|cn|sn")
 (version 3.0; acl "example"; allow (write)
 userdn="ldap:///uid=eng-mgr,dc=example,dc=com";)
```

### targattrfilters

The `targattrfilters` keyword targets specific attribute *values* that match a filtered search criteria. This keyword allows you to set up an ACI that grants or denies permissions on an attribute value if that value meets the filter criteria. The `targattrfilters` keyword applies to individual values of an attribute, not to the whole attribute. The keyword also allows the use of wildcards in the filters.

The keyword clause has the following formats:

```
(target = "add=attr1:Filter1 && attr2:Filter2... && attrn:FilterN,
del=attr1:Filter1 && attr2:Filter2 ... && attrn:FilterN")
```

where

- **add** represents the operation of adding an attribute value to the entry
- **del** represents the operation of removing an attribute value from the entry
- **attr1, attr2... attrN** represents the targeted attributes
- **filter1, filter2 ... filterN** represents filters that identify matching attribute values

The following conditions determine when the attribute must satisfy the filter:

- When adding or deleting an entry containing an attribute targeted a `targattrfilters` element, each value of that attribute must satisfy the corresponding filter.
- When modifying an entry, if the operation adds one or more values for an attribute targeted by a `targattrfilters` element, each value must satisfy the corresponding filter. If the operation deletes one or more values for a targeted attribute, each value must satisfy the corresponding filter.
- When replacing the set of values for an attribute targeted by a `targattrfilters` element, each value removed must satisfy the delete filters, and each value added must satisfy the add filters.

The following example allows any user who is part of the `cn=directory server admins` group to add the `soft-delete-read` privilege.

```
aci: (targetattrfilter="add=ds-privilege-name:(ds-privilege-name=soft-delete-read)")
 (version 3.0; acl "Allow members of the directory server admins group to grant the soft-delete-read privilege"; allow (write) groupdn="ldap:///cn=directory server admins,ou=group,dc=example,dc=com";)
```

### targetscope

The `targetscope` keyword is used to restrict the scope of an access control rule. By default, ACIs use a subtree scope, which means that they are applied to the target entry (either as defined by the target clause of the ACI, or the entry in which the ACI is defined if it does not include a target), and all entries below it. However, adding the `targetscope` element into an access control rule can restrict the set of entries to which it applies.

The following `targetscope` keyword values are allowed:

- **base**. Indicates that the access control rule should apply only to the target entry and not to any of its subordinates.
- **onelevel**. Indicates that the access control rule should apply only to entries that are the immediate children of the target entry and not to the target entry itself, nor to any subordinates of the immediate children of the target entry.
- **subtree**. Indicates that the access control rule should apply to the target entry and all of its subordinates. This is the default behavior if no `targetscope` is specified.
- **subordinate**. Indicates that the access control rule should apply to all entries below the target entry but not the target entry itself.

The following ACI targets all users to view the operational attributes (`supportedControl`, `supportedExtension`, `supportedFeatures`, `supportedSASLMechanisms`, `vendorName`, and `vendorVersion`) present in the root DSE entry. The `targetscope` is `base` to limit users to view only those attributes in the root DSE.

```
aci: (target="ldap:///") (targetscope="base")
 (targetattr="supportedControl||supportedExtension||supportedFeatures||supportedSASLMechanisms||vendorName||vendorVersion")
 (version 3.0; acl "Allow users to view Root DSE Operational Attributes"; allow (read,search,compare) userdn="ldap:///anyone")
```

### targetcontrol

The `targetcontrol` keyword is used to indicate whether a given request control can be used by those users targeted in the ACI. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying control OIDs.

The following ACI example shows the controls required to allow an administrator to use and manage the Soft-Delete feature. The Soft Delete Request Control allows the user to soft-delete an entry, so that it could be undeleted at a later time. The Hard Delete Request Control allows the user to permanently remove an entry or soft-deleted entry. The Undelete Request Control allows the user to undelete a currently soft-deleted entry. The Soft-Deleted Entry Access Request Control allows the user to search for any soft-deleted entries in the server.

```
aci: (targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.22||1.3.6.1.4.1.30221.2.5.23||1.3.6.1.4.1.30221.2.5.24")
 (version 3.0; acl "Allow admins to use the Soft Delete Request Control, Hard Delete Request Control, Undelete Request Control, and Soft-deleted entry access request control"; allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

## extOp

The `extop` keyword can be used to indicate whether a given extended request operation can be used. Multiple OIDs can be provided by separating them with the two pipe characters (optionally surrounded by spaces). Wildcards are not allowed when specifying extended request OIDs.

The following ACI allows the `uid=user-mgr` to use the Password Modify Request (i.e., `OID=1.3.6.1.4.1.4203.1.11.1`) and the StartTLS (i.e., `OID=1.3.6.1.4.1.1466.20037`) extended request OIDs.

```
aci: (extop="1.3.6.1.4.1.4203.1.11.1 || 1.3.6.1.4.1.1466.20037")
 (version 3.0; acl "Allows the mgr to use the Password Modify Request and
 StartTLS;
 allow(read) userdn="ldap:///uid=user-mgr,ou=people,dc=example,dc=com";)
```

## Examples of Common Access Control Rules

This section provides a set of examples that demonstrate access controls that are commonly used in your environment. Note that to be able to alter access control definitions in the server, a user must have the `modify-acl` privilege as discussed later in this chapter.

### Administrator Access

The following ACI can be used to grant any member of the `"cn=admins,ou=groups,dc=example,dc=com"` group to add, modify and delete entries, reset passwords and read operational attributes such as `isMemberOf` and password policy state:

```
aci: (targetattr="+") (version 3.0; acl "Administrators can read, search or
 compare operational attributes";
 allow (read,search,compare) groupdn="ldap:///
 cn=admins,ou=groups,dc=example,dc=com";)
aci: (targetattr="*") (version 3.0; acl "Administrators can add, modify and
 delete entries";
 allow (all) groupdn="ldap:///cn=admins,ou=groups,dc=example,dc=com";)
```

### Anonymous and Authenticated Access

The following ACI allow anonymous read, search and compare on select attributes of `inetOrgPerson` entries while authenticated users can access several more. The authenticated user will inherit the privileges of the anonymous ACI. In addition, the authenticated user can change `userPassword`:

```
aci: (targetattr="objectclass || uid || cn || mail || sn || givenName")
 (targetfilter="(objectClass=inetorgperson)")
 (version 3.0; acl "Anyone can access names and email addresses of entries
 representing people";
 allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="departmentNumber || manager || isMemberOf")
 (targetfilter="(objectClass=inetorgperson)")
 (version 3.0; acl "Authenticated users can access these fields for entries
 representing people";
 allow (read,search,compare) userdn="ldap:///all";)
aci: (targetattr="userPassword") (version 3.0; acl "Authenticated users can
 change password";
 allow (write) userdn="ldap:///all";)
```

If no unauthenticated access should be allowed to the Directory Server, the preferred method for preventing unauthenticated, or anonymous access is to set the Global Configuration property `reject-unauthenticated-requests` to `true`.

### Delegated Access to a Manager

The following ACI can be used to allow an employee's manager to edit the value of the employee's `telephoneNumber` attribute. This ACI uses the `userattr` keyword with a bind type of `USERDN`, which

indicates that the target entry's manager attribute must have a value equal to the DN of the authenticated user:

```
aci: (targetattr="telephoneNumber")
(version 3.0; acl "A manager can update telephone numbers of her direct
reports";
allow (read,search,compare,write) userattr="manager#USERDN";)
```

### Proxy Authorization

The following ACIs can be used to allow the application "cn=OnBehalf,ou=applications,dc=example,dc=com" to use the proxied authorization v2 control to request that operations be performed using an alternate authorization identity. The application user is also required to have the `proxied-auth` privilege as discussed later in this chapter:

```
aci: (version 3.0;acl "Application OnBehalf can proxy as another entry";
allow (proxy) userdn="ldap:///cn=OnBehalf,ou=applications,dc=example,dc=com";)
```

## Validating ACIs Before Migrating Data

Many directory servers allow for less restrictive application of their access control instructions, so that they accept invalid ACIs. For example, if Sun/Oracle encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, the PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server.

To validate an access control instruction, the PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. The tool can examine access control rules contained in either an LDIF file or an LDAP directory and write its result in LDIF with comments providing information about any problems that were identified. Each entry in the output will contain only a single ACI, so if an entry in the input contains multiple ACIs, then it may be present multiple times in the output, each time with a different ACI value. The entries contained in the output contains only ACI values, and all other attributes will be ignored.

### To Validate ACIs from a File

About this task

The `validate-acis` tool can process data contained in an LDIF file. It will ignore all attributes except `aci`, and will ignore all entries that do not contain the `aci` attribute, so any existing LDIF file that contains access control rules may be used.

Steps

1. Run the `bin/validate-acis` tool (UNIX or Linux systems) or `bat\validate-acis` (Windows systems) by specifying the input file and output file. If the output file already exists, the existing contents will be re-written. If no output file is specified, then the results will be written to standard output.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif
```

```
Processing complete # Total entries examined: 1
Entries found with ACIs: 1
Total ACI values found: 3
Malformed ACI values found: 0
Other processing errors encountered: 0
```

- Review the results by opening the output file. For example, the `validated-acis.ldif` file that was generated in the previous step reads as follows:

```
The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr!="userPassword")
 (version 3.0; acl "Allow anonymous read access for anyone";
 allow (read,search,compare) userdn="ldap:///anyone";)

The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
 (version 3.0; acl "Allow users to update their own entries";
 allow (write) userdn="ldap:///self";)

The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
 (version 3.0; acl "Grant full access for the admin user";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

- If the input file has any malformed ACIs, then the generated output file will show what was incorrectly entered. For example, remove the quotation marks around `userPassword` in the original `test-acis.ldif` file, and re-run the command. The following command uses the `--onlyReportErrors` option to write any error messages to the output file only if a malformed ACI syntax is encountered.

```
$ bin/validate-acis --ldifFile test-acis.ldif --outputFile validated-
acis.ldif \
 --onlyReportErrors
```

```
Processing complete
Total entries examined: 1
Entries found with ACIs: 1
Total ACI values found: 3
Malformed ACI values found: 0
Other processing errors encountered: 0
```

The output file shows the following message:

```
The following access control rule is malformed or contains an unsupported
syntax: The provided string '(targetattr!=userPassword)(version 3.0; acl
"Allow anonymous read access for anyone"; allow (read,search,compare)
userdn="ldap:///anyone";)' could not be parsed as a valid Access Control
Instruction (ACI) because it failed general ACI syntax evaluation
dn: dc=example,dc=com
aci: (targetattr!=userPassword)
 (version 3.0; acl "Allow anonymous read access for anyone";
 allow (read,search,compare) userdn="ldap:///anyone";)

The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
 (version 3.0; acl "Allow users to update their own entries";
 allow (write) userdn="ldap:///self";)

The following access control rule is valid
dn: dc=example,dc=com
aci: (targetattr="*")
 (version 3.0; acl "Grant full access for the admin user";
 allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

## To Validate ACIs in Another Directory Server

About this task

The `validate-acis` tool also provides the ability to examine ACIs in data that exists in another Directory Server that you are planning to migrate to the PingDirectory Server. The tool helps to determine whether the Ping Identity Server accepts those ACIs.

Steps

- To use it in this manner, provide arguments that specify the address and port of the target Directory Server, credentials to use to bind, and the base DN of the subtree containing the ACIs to validate.

```
$ bin/validate-acis

Processing complete # Total entries examined: 1
Entries found with ACIs: 1
Total ACI values found: 3
Malformed ACI values found: 0
Other processing errors encountered: 0
```

## Migrating ACIs from Sun/Oracle to PingDirectory Server

This section describes the most important differences in access control evaluation between Sun/Oracle and the PingDirectory Server.

### Support for Macro ACIs

Sun/Oracle provides support for macros ACIs, making it possible to define a single ACI that can be used to apply the same access restrictions to multiple branches in the same basic structure. Macros ACIs are infrequently used and can cause severe performance degradation, so support for macros ACIs is not included in the PingDirectory Server. However, you can achieve the same result by simply creating the same ACIs in each branch.

### Support for the roleDN Bind Rule

Sun/Oracle roles are a proprietary, non-standard grouping mechanism that provide little value over standard grouping mechanisms. The PingDirectory Server does not support DSEE roles and does not support the use of the `roleDN` ACI bind rule. However, the same behavior can be achieved by converting the DSEE roles to standard groups and using the `groupDN` ACI bind rule.

### Targeting Operational Attributes

The Sun/Oracle access control model does not differentiate between user attributes and operational attributes. With Sun/Oracle, using `targetattr="*"` will automatically target both user and operational attributes. Using an exclusion list like `targetattr!="userPassword"` will automatically target all operational attributes in addition to all user attributes except `userPassword`. This behavior is responsible for several significant security holes in which users are unintentionally given access to operational attributes. In some cases, it allows users to do things like exempt themselves from password policy restrictions.

In the PingDirectory Server, operational attributes are treated differently from user attributes and operational attributes are never automatically included. As such, `targetattr="*"` will target all user attributes but no operational attributes, and `targetattr!="userPassword"` will target all users attributes except `userPassword`, but no operational attributes. Specific operational attributes can be targeted by including the names in the list, like `targetattr="creatorsName|modifiersName"`. All operational attributes can be targeted using the "+" character. So, `targetattr="+"` targets all operational attributes but no user attributes and `targetattr="*|+"` targets all user and operational attributes.

## Specification of Global ACIs

Both DSEE and PingDirectory Server support global ACIs, which can be used to define ACIs that apply throughout the server. In servers with multiple naming contexts, this feature allows you to define a rule once as a global ACI, rather than needing to maintain an identical rule in each naming context.

In DSEE, global ACIs are created by modifying the root DSE entry to add values of the `aci` attribute. In the PingDirectory Server, global ACIs are managed with `dsconfig` referenced in the `global-aci` property of the Access Control Handler.

## Defining ACIs for Non-User Content

In DSEE, you can write to the configuration, monitor, changelog, and tasks backends to define ACIs. In the PingDirectory Server, access control for private backends, like configuration, monitor, schema, changelog, tasks, encryption settings, backups, and alerts, should be defined as global ACIs.

## Limiting Access to Controls and Extended Operations

DSEE offers limited support for restricting access to controls and extended operations. To the extent that it is possible to control such access with ACIs, DSEE defines entries with a DN such as `"oid={oid},cn=features,cn=config"` where `{oid}` is the OID of the associated control or extended operation. For example, the following DSEE entry defines ACIs for the persistent search control: `"oid=2.16.840.1.113730.3.4.3,cn=features,cn=config"`.

In the PingDirectory Server, the `"targetcontrol"` keyword can be used to define ACIs that grant or deny access to controls. The `"extop"` keyword can be used to define ACIs that grant or deny access to extended operation requests.

## Tolerance for Malformed ACI Values

In DSEE, if the server encounters a malformed access control rule, it simply ignores that rule without any warning. If this occurs, then the server will be running with less than the intended set of ACIs, which may prevent access to data that should have been allowed or, worse yet, may grant access to data that should have been restricted.

The PingDirectory Server is much more strict about the access control rules that it will accept. When performing an LDIF import, any entry containing a malformed or unsupported access control rule will be rejected. Similarly, any add or modify request that attempts to create an invalid ACI will be rejected. In the unlikely event that a malformed ACI does make it into the data, then the server immediately places itself in lockdown mode, in which the server terminates connections and rejects requests from users without the `lockdown-mode` privilege. Lockdown mode allows an administrator to correct the problem without risking exposure to user data.

**Note:** Consider running the `import-ldif` tool with the `--rejectFile` option so that you can review any rejected ACIs.

## About the Privilege Subsystem

In DSEE, only the root user is exempt from access control evaluation. While administrators can create ACIs that give "normal" users full access to any content, they can also create ACIs that would make some portion of the data inaccessible even to those users. In addition, some tasks can only be accomplished by the root user and you cannot restrict the capabilities assigned to that root user.

The PingDirectory Server offers a privilege subsystem that makes it possible to control the capabilities available to various users. Non-root users can be granted limited access to certain administrative capabilities, and restrictions can be enforced on root users. In addition, certain particularly risky actions (such as the ability to interact with the server configuration, change another user's password, impersonate another user, or shutdown and restart the server) require that the requester have certain privileges in addition to sufficient access control rights to process the operation.

## Identifying Unsupported ACIs

The PingDirectory Server provides a `validate-acis` tool that can be used to examine content in an LDIF file or data in another directory server (such as a DSEE instance) to determine whether the access control rules contained in that data are suitable for use in the PingDirectory Server instance. When migrating data from a DSEE deployment into a PingDirectory Server instance, the `validate-acis` tool should first be used to determine whether ACIs contained in the data are acceptable. If any problems are identified, then the data should be updated to correct or redefine the ACIs so that they are suitable for use in the PingDirectory Server.

For more information about using this tool, see [Validating ACIs Before Migrating Data](#).

## Working with Privileges

In addition to the access control implementation, the PingDirectory Server includes a privilege subsystem that can also be used to control what users are allowed to do. The privilege subsystem works in conjunction with the access control subsystem so that privileged operations are only allowed if they are allowed by the access control configuration and the user has all of the necessary privileges.

Privileges can be used to grant normal users the ability to perform certain tasks that, in most other directories, would only be allowed for the root user. In fact, the capabilities extended to root users in the PingDirectory Server are all granted through privileges, so you can create a normal user account with the ability to perform some or all of the same actions as root users.

Administrators can also remove privileges from root users so that they are unable to perform certain types of operations. Multiple root users can be defined in the server with different sets of privileges so that the capabilities that they have are restricted to only the tasks that they need to be able to perform.

### Available Privileges

The following privileges are defined in the PingDirectory Server.

### Summary of Privileges

| Privilege           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| audit-data-security | This privilege is required to initiate a data security audit on the server, which is invoked by the <code>audit-data-security</code> tool.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| backend-backup      | This privilege is required to initiate an online backup through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                                                                                                                                     |
| backend-restore     | This privilege is required to initiate an online restore through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                                                                                                                                    |
| bypass-acl          | This privilege allows a user to bypass access control evaluation. For a user with this privilege, any access control determination made by the server immediately returns that the operation is allowed. Note, however, that this does not bypass privilege evaluation, so the user must have the appropriate set of additional privileges to be able to perform any privileged operation (for example, a user with the <code>bypass-acl</code> privilege but without the <code>config-read</code> privilege is not allowed to access the server configuration). |
| bypass-pw-policy    | This privilege allows a user entry to bypass password policy evaluation. This privilege is intended for cases where external synchronization might require passwords that violate the password validation rules. The privilege is not evaluated for bind operations so that password policy evaluation will still occur when binding as a user with this privilege.                                                                                                                                                                                              |

| Privilege         | Description                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bypass-read-acl   | This privilege allows the associated user to bypass access control checks performed by the server for bind, search, and compare operations. Access control evaluation may still be enforced for other types of operations.                                                                                                                                       |
| config-read       | This privilege is required for a user to access the server configuration. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to see.                                                                                                                                             |
| config-write      | This privilege is required for a user to alter the server configuration. The user is also required to have the <code>config-read</code> privilege. Access control evaluation is still performed and can be used to restrict the set of configuration objects that the user is allowed to alter.                                                                  |
| disconnect-client | This privilege is required for a user to request that an existing client connection be terminated. The connection is terminated through the disconnect client task. The server's access control configuration must also allow the user to add the corresponding entry to the tasks backend.                                                                      |
| jmx-notify        | This privilege is required for a user to subscribe to JMX notifications generated by the Directory Server. The user is also required to have the <code>jmx-read</code> privilege.                                                                                                                                                                                |
| jmx-read          | This privilege is required for a user to access any information provided by the Directory Server via the Java Management Extensions (JMX).                                                                                                                                                                                                                       |
| jmx-write         | This privilege is required for a user to update any information exposed by the Directory Server via the Java Management Extensions (JMX). The user is also required to have the <code>jmx-read</code> privilege. Note that currently all of the information exposed by the server over JMX is read-only.                                                         |
| ldif-export       | This privilege is required to initiate an online LDIF export through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, you can set up a global ACI that allows access to members of an Administrators group.                    |
| ldif-import       | This privilege is required to initiate an online LDIF import through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the Tasks backend. To allow access to the Tasks backend, configure the global ACI as shown in the previous description of the <code>ldif-export</code> privilege. |
| lockdown-mode     | This privilege allows the associated user to request that the server enter or leave lockdown mode, or to perform operations while the server is in lockdown mode.                                                                                                                                                                                                |
| modify-acl        | This privilege is required for a user to add, modify, or remove access control rules defined in the server. The server's access control configuration must also allow the user to make the corresponding change to the <code>aci</code> operational attribute.                                                                                                   |
| password-reset    | This privilege is required for one user to be allowed to change another user's password. This privilege is not required for a user to be allowed to change his or her own password. The user must also have the access control instruction privilege to write the <code>userPassword</code> attribute to the target entry.                                       |

| Privilege        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| privilege-change | This privilege is required for a user to change the set of privileges assigned to a user, including the set of privileges, which are automatically granted to root users. The server's access control configuration must also allow the user to make the corresponding change to the <code>ds-privilege-name</code> operational attribute.                                                                                                              |
| proxied-auth     | This privilege is required for a user to request that an operation be performed with an alternate authorization identity. This privilege applies to operations that include the proxied authorization v1 or v2 control operations that include the intermediate client request control with a value set for the client identity field, or for SASL bind requests that can include an authorization identity different from the authentication identity. |
| server-restart   | This privilege is required to initiate a server restart through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                            |
| server-shutdown  | This privilege is required to initiate a server shutdown through the tasks interface. The server's access control configuration must also allow the user to add the corresponding entry in the tasks backend.                                                                                                                                                                                                                                           |
| soft-delete-read | This privilege is required for a user to access a soft-deleted-entry.                                                                                                                                                                                                                                                                                                                                                                                   |
| stream-values    | This privilege is required for a user to perform a stream values extended operation, which obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.                                                                                                                                                                                                                                                       |
| unindexed-search | This privilege is required for a user to be able to perform a search operation in which a reasonable set of candidate entries cannot be determined using the defined index and instead, a significant portion of the database needs to be traversed to identify matching entries. The server's access control configuration must also allow the user to request the search.                                                                             |
| update-schema    | This privilege is required for a user to modify the server schema. The server's access control configuration must allow the user to update the operational attributes that contain the schema elements.                                                                                                                                                                                                                                                 |

### Privileges Automatically Granted to Root Users

The special abilities that root users have are granted through privileges. Privileges can be assigned to root users in two ways:

- By default, root users may be granted a specified set of privileges. Note that it is possible to create root users which are not automatically granted these privileges by including the `ds-cfg-inherit-default-root-privileges` attribute with a value of `FALSE` in the entries for those root users.
- Individual root users can have additional privileges granted to them, and/or some automatically-granted privileges may be removed from that user.

The set of privileges that are automatically granted to root users is controlled by the `default-root-privilege-name` property of the Root DN configuration object. By default, this set of privileges includes:

- `audit-data-security`
- `backend-backup`
- `backend-restore`
- `bypass-acl`
- `config-read`
- `config-write`
- `disconnect-client`
- `ldif-export`

- lockdown-mode
- manage-topology
- metrics-read
- modify-acl
- password-reset
- permit-get-password-policy-state-issues
- privilege-change
- server-restart
- server-shutdown
- soft-delete-read
- stream-values
- unindexed-search
- update-schema

The privileges not granted to root users by default includes:

- bypass-pw-policy
- bypass-read-acl
- jmx-read
- jmx-write
- jmx-notify
- permit-externally-processed-authentication
- permit-proxied-mschapv2-details
- proxied-auth

The set of default root privileges can be altered to add or remove values as necessary. Doing so will require the `config-read`, `config-write`, and `privilege-change` privileges, as well as either the `bypass-acl` privilege or sufficient permission granted by the access control configuration to make the change to the server's configuration.

### Assigning Additional Privileges for Administrators

To allow access to the Tasks backend, set up a global ACI that allows access to members of an Administrators group as follows:

```
$ dsconfig set-access-control-handler-prop \
 --add 'global-aci:(target="ldap:///cn=tasks") (targetattr="*|+")(
 version 5.0; acl "Access to the tasks backend for administrators";
 allow (all) groupdn="ldap:///
 cn=admin,ou=groups,dc=example,dc=com";) '
```

### Assigning Privileges to Normal Users and Individual Root Users

Privileges can be granted to normal users on an individual basis. This can be accomplished by adding the `ds-privilege-name` operational attribute to that user's entry with the names of the desired privileges. For example, the following change will grant the `proxied-auth` privilege to the `uid=proxy,dc=example,dc=com` account:

```
dn: uid=proxy,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: proxied-auth
```

The user making this change will be required to have the `privilege-change` privilege, and the server's access control configuration must also allow the requester to write to the `ds-privilege-name` attribute in the target user's entry.

This same method can be used to grant privileges to root users that they would not otherwise have through the set of default root privileges. You can also remove default root privileges from root users by prefixing the name of the privilege to remove with a minus sign. For example, the following change grants a root user the `jmx-read` privilege in addition to the set of default root privileges, and removes the `server-restart` and `server-shutdown` privileges:

```
dn: cn=Sync Root User,cn=Root DNs,cn=config
changetype: modify
add: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: -server-restart
ds-privilege-name: -server-shutdown
```

Note that because root user entries exist in the configuration, this update requires the `config-read` and `config-write` privileges in addition to the `privilege-change` privilege.

### Disabling Privileges

Although the privilege subsystem in the PingDirectory Server is a very powerful feature, it might break some applications if they expect to perform some operation that requires a privilege that they do not have. In the vast majority of these cases, you can work around the problem by simply assigning the necessary privilege manually to the account used by that application. However, if this workaround is not sufficient, or if you need to remove a particular privilege (for example, to allow anyone to access information via JMX without requiring the `jmx-read` privilege), then privileges can be disabled on an individual basis.

The set of disabled privileges is controlled by the `disabled-privilege` property in the global configuration object. By default, no privileges are disabled. If a privilege is disabled, then the server behaves as if all users have that privilege.

## Working with Proxied Authorization

The Directory Server supports the Proxied Authorization Control (RFC 4370) to allow an authorized LDAP client to authenticate to the server as another user. Typically, LDAP servers are deployed as backend authentication systems that store user credentials and authorization privileges necessary to carry out an operation. Single sign-on (SSO) systems can retrieve user credentials from the Directory Server and then issue permissions that allow the LDAP client to request operations under the identity as another user. The use of the proxied authorization control provides a means for client applications to securely process requests without the need to bind or re-authenticate to the server for each and every operation.

The Directory Server supports the proxied authorization V1 and V2 request controls. The proxied authorization V1 request control is based on early versions of the draft-weltman-ldapv3-proxy Internet draft and is available primarily for legacy systems. It is recommended that deployments use the proxied authorization V2 request control based on RFC 4370.

The proxied authorization V2 control is used to request that the associated operation be performed as if it has been requested by some other user. This control may be used in conjunction with `add`, `delete`, `compare`, `extended`, `modify`, `modify DN`, and `search` requests. In that case, the associated operation will be processed under the authority of the specified authorization identity rather than the identity associated with the client connection (i.e., the user as whom that connection is bound). The target authorization identity for this control is specified as an "authzid" value, which should be either "dn:" followed by the distinguished name of the target user, or "u:" followed by the user name.

Note that because of the inherent security risks associated with the use of the proxied authorization control, most directory servers that support its use enforce strict restrictions on the users that are allowed to request this control. If a user attempts to use the proxied authorization V2 request control and does not have sufficient permission to do so, then the server will return a failure response with the `AUTHORIZATION_DENIED` result code.

## Configuring Proxied Authorization

Configuring proxied authorization requires a combination of access control instructions and the `proxied-auth` privilege to the entry that will perform operations as another user.

**Note:** You cannot use the `cn=Directory Manager` root DN as a proxying DN.

### To Configure Proxied Authorization

#### Steps

1. Open a text editor and create a user entry, such as `uid=clientApp`, which is the user entry that will request operations as another user, `uid=admin,dc=example,dc=com`. The client application entry also requires the `proxied-auth` privilege to allow it to run proxied authorization requests. Save the file as `add-user.ldif`.

```
dn: ou=Applications,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
objectClass: extensibleObject
ou: Admins
ou: Applications

dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
givenName: Client
uid: clientApp
cn: Client App
sn: App
userPassword: password
ds-privilege-name: proxied-auth
```

2. Add the file using `ldapmodify`.

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

3. The client application targets a specific subtree in the Directory Information Tree (DIT) for its operations. For example, some client may need access to an accounts subtree to retrieve customer information. Another client may need access to another subtree, such as a subscriber subtree. In this example, we want the client application to target the `ou=People,dc=example,dc=com` subtree. To allow the target, open a text editor and create an LDIF file to assign an ACI to that branch so that the client app user can access it as a proxy auth user. Note that the ACI should be on a single line of text. The example shows the ACI over multiple lines for readability. Add the file using the `ldapmodify`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
 userdn="ldap:///uid=clientApp,ou=Applications,dc=example,dc=com");)
```

4. Run a search to test the configuration using the bind DN `uid=clientApp` and the `proxyAs` option, which requires that you prefix `"dn:"` to the proxying entry or `"u:"` to the user name. The `uid=clientApp` binds to the server and proxies as `uid=admin` to access the `ou=People,dc=example,dc=com` subtree.

```
$ bin/ldapsearch --port 1389 \
 --bindDN "uid=clientApp,ou=Applications,dc=example,dc=com" \
 --bindPassword password \
 --proxyAs "dn:uid=admin,dc=example,dc=com" \
```

```
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)" "
```

## Restricting Proxy Users

The Directory Server provides a set of operational attributes that restricts the proxied authorization capabilities of a client application and its proxyable target entry. When present in an entry, the Directory Server evaluates each operational attribute together to form a whitelist of potential users that can be proxied. If none of those attributes is present, then the user may potentially proxy as anyone.

The Directory Server supports a two-tier provision system that, when configured, can restrict specific users for proxied authorization. The first tier is a set of `ds-auth-may-proxy-as-*` operational attributes on the client entry that will bind to the server and carry out operations under the identity of another user. The second tier is a set of `ds-auth-is-proxyable-*` operational attributes on the user entry that defines whether access is allowed, prohibited, or required by means of proxied authorization. If allowed or required, the attributes define which client entries can proxy as the user.

## MY TITLE Proxying Operational Attributes

For example, if a client application, such as `uid=clientApp`, is requesting to search the `ou=People,dc=example,dc=com` branch as the user `uid=admin`, the command would look like this:

```
ldapsearch --bindDN uid=clientApp,dc=example,dc=com \
--bindPassword password \
--proxyAs uid=admin,dc=example,dc=com \
--baseDN ou=People,dc=example,dc=com \
"(object-class=*)" "
```

At bind, the Directory Server evaluates the list of users in the `uid=clientApp` entry based on the presence of any `ds-auth-may-proxy-as-*` attributes. In the figure below, the `uid=clientApp` entry has a `ds-auth-may-proxy-as` attribute with a value, `uid=admin`, which means that the client app user may proxy only as the `uid=admin` account. Next, the server confirms that `uid=admin` is in the list of proxyable users and then evaluates the `ds-auth-is-proxyable-*` attributes present in the `uid=admin` entry. These attributes determine the list of restricted users that either are allowed, prohibited, or required to proxy as the `uid=admin` entry. In this case, the `uid=admin` entry has the `ds-auth-is-proxyable` attribute with a value of "required", which indicates that the entry can only be accessed by means of proxied authorization. The `uid=admin` entry also has the `ds-auth-is-proxyable-by` attribute with a value of `uid=clientApp`, which indicates it can only be requested by the `uid=clientApp` entry. Once both sets of attributes have been confirmed, the `uid=clientApp` can bind to the server as the authenticated user. From this point, the Directory Server performs ACL evaluation on the branch to determine if the requested user has access rights to the branch. If the branch is accessible by the `uid=clientApp` entry, and then the search request is processed.

## MY TITLE Proxying Operational Attributes Examples

### About the `ds-auth-may-proxy-as-*` Operational Attributes

The Directory Server first evaluates the list of potential users that can be proxied for the authenticated user based on the presence of the `ds-auth-may-*` operational attributes in the entry. These operational attributes are multi-valued and are evaluated together if all are present in an entry:

- `ds-auth-may-proxy-as`.** Specifies the user DNs that the associated user is allowed to proxy as. For instance, based on the previous example, you could specify in the `uid=clientApp` entry that it can proxy operations as `uid=admin` and `uid=agent1`.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as: uid=admin,dc=example,dc=com
ds-auth-may-proxy-as: uid=agent1,ou=admins,dc=example,dc=com
```

- `ds-auth-may-proxy-as-group`.** Specifies the group DNs and its group members that the associated user is allowed to proxy as. For instance, you could specify that the potential users that the `uid=clientApp` entry can proxy as are those members who are present in the group `cn=Agents,ou=Groups,dc=example,dc=com`. This attribute is multi-valued, so that more than one group can be specified. Nested static and dynamic groups are also supported.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-group: cn=Agents,ou=Groups,dc=example,dc=com
```

- `ds-auth-may-proxy-as-url`.** Specifies the DNs that are returned based on the criteria defined in an LDAP URL that the associated user is allowed to proxy as. For instance, the attribute specifies that the client can proxy as those entries that match the criteria in the LDAP URL. This attribute is multi-valued, so that more than one LDAP URL can be specified.

```
dn: uid=clientApp,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
ds-auth-may-proxy-as-url: ldap:///ou=People,dc=example,dc=com??sub?
(l=austin)
```

### About the `ds-auth-is-proxyable-*` Operational Attributes

After the Directory Server has evaluated the list of users that the authenticated user can proxy as, the server checks to see if the requested authorized user is in the list. If the requested authorized user is present in the list, then the server continues processing the proxable attributes in the entry. If the requested authorized user is not present in the list, the bind will fail.

The operational attributes on the proxying entry are as follows:

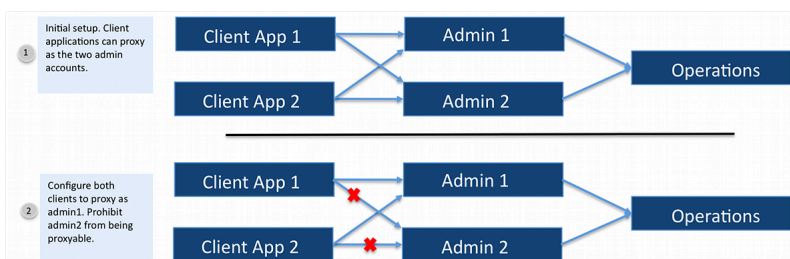

- `ds-auth-is-proxyable`.** Specifies whether the entry is proxyable or not. Possible values are: "allowed" (operation may be proxied as this user), "prohibited" (operations may not be proxied as this

user), "required" (indicates that the account will not be allowed to authenticate directly but may only be accessed by some form of proxied authorization).

- **ds-auth-is-proxyable-as**. Specifies any users allowed to use this entry as a target of proxied authorization.
- **ds-auth-is-proxyable-as-group**. Specifies any groups allowed to use this entry as a target of proxied authorization. Nested static and dynamic groups are also supported.
- **ds-auth-is-proxyable-as-url**. Specifies the LDAP URLs that are used to determine any users that are allowed to use this entry as a target of proxied authorization.

### Restricting Proxied Authorization for Specific Users

To illustrate how the proxied authorization operational attributes work, it is best to set up a simple example where two LDAP clients, `uid=clientApp1` and `uid=clientApp2` can freely proxy two administrator accounts, `uid=admin1` and `uid=admin2`. We will add the `ds-auth-may-proxy-as-*` and the `ds-auth-is-proxyable-*` attributes to these entries to restrict how each account can use proxied authorization. For example, the two client applications will continue to proxy the `uid=admin1` account but the `uid=admin2` account will no longer be able to be used as a proxied entry.

### MY TITLE Proxy Users Example Scenario

#### To Restrict Proxied Authorization for Specific Users

##### Steps

1. For this example, set up two user entries, `uid=clientApp1` and `uid=clientApp2`, which will be proxying the `uid=admin1` and `uid=admin2` accounts to access the `ou=People,dc=example,dc=com` subtree. Both entries have the `proxied-auth` privilege assigned to it. Open a text editor and create an LDIF file. Add the file using the `ldapmodify` tool. Note that `"..."` indicates that other attributes present in the entry are not included in the example for readability purposes.

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth

dn: uid=clientApp2,ou=Applications,dc=example,dc=com
objectClass: top
...
ds-privilege-name: proxied-auth
```

2. Next, assign the ACL for each client application to the subtree, `ou=People,dc=example,dc=com`. Note that the ACLs should be on one line of text. The example displays the ACLs over multiple lines for readability.

```
dn: ou=People,dc=example,dc=com
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
 userdn="ldap:///uid=clientApp1,ou=Applications,dc=example,dc=com");)
aci: (version 3.0; acl "People Proxy Access"; allow(proxy)
 userdn="ldap:///uid=clientApp2,ou=Applications,dc=example,dc=com");)
```

3. Run a search for each entry. In this example, assume that there are two admin accounts: `admin1` and `admin2` that have full access rights to user attributes. You should be able to proxy as the `uid=admin1` and `uid=admin2` entries to access the subtree for both clients.

```
$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin1,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"

$ bin/ldapsearch --port 1389 \
--bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
--bindPassword password \
--proxyAs "dn:uid=admin2,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)"
```

4. Next, limit the proxied authorization capabilities for each client application. Update the `uid=clientApp1` entry to add the `ds-auth-may-proxy-as` attribute. In this example, the `ds-auth-may-proxy-as` attribute specifies that `uid=clientApp1` can proxy as the `uid=admin1` entry. Open a text editor, create the following LDIF file, save it, and add it using `ldapmodify`. Note that `ds-auth-may-proxy-as` is multi-valued:

```
dn: uid=clientApp1,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as
ds-auth-may-proxy-as: uid=admin1,dc=example,dc=com
```

5. Repeat the previous step for the `uid=clientApp2` entry, except specify the `ds-auth-may-proxy-as-url`. The client entry may proxy as any DN that matches the LDAP URL.

```
dn: uid=clientApp2,ou=Applications,dc=example,dc=com
changetype: modify
add: ds-auth-may-proxy-as-url
ds-auth-may-proxy-as-url: ldap:///dc=example,dc=com??sub?(uid=admin*)
```

6. Next, we want to create a group of client applications that has `uid=clientApp1` and `uid=clientApp2` as its `uniquemembers` to illustrate the use of the `ds-auth-proxyable-by-group` attribute. In this example, set up a static group using the `groupOfUniqueNames` object class.

```
dn: ou=Groups,dc=example,dc=com
objectClass: top
objectClass: organizationalunit
ou: groups

dn: cn=Client Applications,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Client Applications
ou: groups
uniquemember: uid=clientApp1,ou=Applications,dc=example,dc=com
uniquemember: uid=clientApp2,ou=Applications,dc=example,dc=com
```

7. Update the `uid=admin1` entry to provide the DN that it may be proxied as. Add the `ds-auth-is-proxyable` and the `ds-auth-is-proxyable-by` attributes. For instance, we make the `uid=admin1` a required proxyable entry, which means that it can only be accessed by some form of proxied authorization. Then, specify each DN that can proxy as `uid=admin1` using the `ds-auth-is-proxyable-by`. Open a text editor, create the following LDIF file, save it, and add it using `ldapmodify`. Note that the example includes all three types of `ds-auth-is-proxyable-by`

attributes as an illustration, but, in an actual deployment, only one type of attribute is necessary if they all target the same entries.

```
dn: uid=admin1,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: required
-
add: ds-auth-is-proxyable-by
ds-auth-is-proxyable-by: ou=clientApp1,ou=Applications,dc=example,dc=com
ds-auth-is-proxyable-by: ou=clientApp2,ou=Applications,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-group
ds-auth-is-proxyable-by-group: cn=Client
Applications,ou=Groups,dc=example,dc=com
-
add: ds-auth-is-proxyable-by-url
ds-auth-is-proxyable-by-url: ldap:///ou=Applications,dc=example,dc=com??sub?
(uid=clientApp*)
```

8. Next, prohibit proxying for the `uid=admin2` entry by setting the `ds-auth-is-proxyable` to prohibited. Open a text editor, create the following LDIF file, save it, and add it using `ldapmodify`.

```
dn: uid=admin2,dc=example,dc=com
changetype: modify
add: ds-auth-is-proxyable
ds-auth-is-proxyable: prohibited
```

9. Run a search using the proxied account. For example, run a search first with `uid=clientApp1` or `uid=clientApp2` that proxies as `uid=admin1` to return a successful operation. However, if you run a search for `uid=clientApp1` that proxies as `uid=admin2`, as seen below, you will see an "authorization denied" message due to `uid=admin2` not matching the list of potential entries that can be proxied. The `ds-auth-may-proxy-as-*` attributes specify that the client can only proxy as `uid=admin1`:

```
$ bin/ldapsearch --port 1389 \
 --bindDN "uid=clientApp1,ou=Applications,dc=example,dc=com" \
 --bindPassword password \
 --proxyAs "dn:uid=admin2,dc=example,dc=com" \
 --baseDN ou=People,dc=example,dc=com \
 "(objectclass=*)" "
```

One of the operational attributes (`ds-auth-may-proxy-as`, `ds-auth-may-proxy-as-group`, `ds-auth-may-proxy-as-url`) in user entry `'uid=clientApp1,ou=Applications,dc=example,dc=com'` does not allow that user to be proxied as user `'uid=admin2,dc=example,dc=com'`

Result Code: 123 (Authorization Denied)

Diagnostic Message: One of the operational attributes (`ds-auth-may-proxy-as`, `ds-auth-may-proxy-as-group`, `ds-auth-may-proxy-as-url`) in user entry `'uid=clientApp1,ou=Applications,dc=example,dc=com'` does not allow that user to be proxied as user `'uid=admin2,dc=example,dc=com'`

10. Run another search using `uid=clientApp2`, which attempts to proxy as `uid=admin2`. You will see an "authorization denied" message due to the presence of the `ds-auth-is-proxyable:prohibited` operational attribute, which states that `uid=admin2` is not available for proxied authorization.

```
$ bin/ldapsearch --port 1389 \
 --bindDN "uid=clientApp2,ou=Applications,dc=example,dc=com" \
 --bindPassword password \
```

```
--proxyAs "dn:uid=admin2,dc=example,dc=com" \
--baseDN ou=People,dc=example,dc=com \
"(objectclass=*)" "
```

The 'ds-auth-is-proxyable' operational attribute in user entry 'uid=admin2,dc=example,dc=com' indicates that user may not be accessed via proxied authorization

Result Code: 123 (Authorization Denied)

Diagnostic Message: The 'ds-auth-is-proxyable' operational attribute in user entry 'uid=admin2,dc=example,dc=com' indicates that user may not be accessed via proxied authorization

## Working with Parameterized ACIs

The Directory Server supports the use of parameterized ACIs to control access to subtrees with homogenous administrative group or user patterns, which can be used in multi-tenant deployments. A single parameterized ACI can take the place of specifying identical ACIs on each tenant's subtree. For example, the following parameterized ACI:

```
(target="ldap:///o=($1),dc=example,dc=com") (version 3.0; aci \
"Subtree Admin Group members may search for and read entries in their
subtree."; allow \
(search, read) groupdn="ldap:///cn=Subtree Admin
Group,ou=groups,o=($1),dc=example,dc=com";)
```

Enables:

- Members of a group with DN "**cn=Subtree Admin Group,ou=groups,o=Customers,dc=example,dc=com**" to search for and read entries in the "**o=Customers,dc=example,dc=com**" subtree.
- Members of a group with DN "**cn=Subtree Admin Group,ou=groups,o=Partners,dc=example,dc=com**" to search for and read entries in the "**o=Partners,dc=example,dc=com**" subtree

The same access is granted for any substitution value for the **(\$1)** parameter variable. If an operation tried to read the **uid=user.1,o=acme,dc=example,dc=com** entry, this ACI would be considered. This ACI would allow a read action, if the operation's user is a member of the **cn=Subtree Admin Group,ou=groups,o=acme,dc=example,dc=com** group.

Attribute values from the target DN can be replaced with different variables (**(\$#)**) and then reference those variables in the group DN or user DN. The string representation of a parameter variable is constructed as follows:

- an open parenthesis
- a dollar sign
- a positive integer
- a closing parenthesis

In another example:

```
"population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme"
```

The **(\$2)** variable is the population ID in the DN of the target entry, and **(\$1)** is the environment ID in the DN of the target entry. Those values from the target entry's DN are then substituted into the group DN or user DN value.

Parameter variables present in a parameterized ACI's target will be associated with the actual values from the resource DN. Each actual value will be substituted for its respective parameter variable in the ACI's target, and group bind rule DN's when performing access control on the resource entry. Parameter

variables can be used in multiple RDNs in a parameterized target. A given RDN may have at most one parameter variable as its attribute value, and a given parameter variable may appear only once in the parameterized target.

The following values are examples of valid parameterized target DN's:

- `ou=($1),dc=example,dc=com`
- `population=($2),ou=Populations,environment=($1),ou=Environments,o=Acme`
- `o=($1)` (for a global ACI)

An ACI on an entry can only apply to that entry's subtree. If an ACI with a parameterized target is stored on an entry, that entry's DN must appear in a non-parameterized form as the rightmost RDNs of the parameterized target's DN. For example, if an ACI with a parameterized target were stored on the `dc=example,dc=com` entry, that parameterized target must end in `dc=example,dc=com` in a non-parameterized form. Global ACIs do not have this restriction. Each global ACI can have parameter variables in any or all of its parameterized target's RDNs. Additional restrictions for parameterized targets include:

- They may not be pattern ACIs. That is, they may not contain wildcards (\*).
- RDNs that are parameterized must be single-valued. For example, a given parameterized RDN may not consist of two or more type-value pairs joined by '+'.

## Managing the Schema

---

This chapter presents a basic summary of the supported schema components on the PingDirectory Server and procedures to extend the schema with new element definitions. The chapter presents the following topics:

### About the Schema

A schema is the set of directory server rules that define the structures, contents, and constraints of a Directory Information Tree (DIT). The schema guarantees that any new data entries or modifications meet and conform to these predetermined set of definitions. It also reduces redundant data definitions and provides a uniform method for clients or applications to access its Directory Server objects.

The PingDirectory Server ships with a default set of read-only schema files that define the core properties for the Directory Server. The Administrative Console provides a Schema Editor that administrators can use to view existing schema definitions and add new custom schema elements to their DIT. Any attempt to alter a schema element defined in a read-only file or add a new schema element to a read-only file will result in an "Unwilling to Perform" result.

### About the Schema Editor

The Administrative Console Management Console provides a user-friendly graphical editor with tabs to manage any existing schema component related to the DIT: object classes, attributes, matching rules, attribute syntaxes, and schema utilities. The **Object Classes** and **Attribute Types** tabs enable viewing existing definitions as well as adding, modifying, or removing custom schema elements.

The **Matching Rules** and **Attribute Syntaxes** tabs are read-only and provide a comprehensive listing of all of the elements necessary to define new schema elements. The **Schema Utilities** tab provides a schema validator that allows you to load a schema file or perform a cut-and-paste operation on the schema definition to verify that it meets the proper schema and ASN.1 formatting rules. The **Utilities** tab also supports schema file imports by first checking for proper syntax compliance and generating any error message if the definitions do not meet specification.

### MY TITLE Example Schema Editor Screen

The Schema Editor provides two views for each definition: **Properties View** and **LDIF View**. The **Properties View** breaks down the schema definition by its properties and shows any inheritance relationships among the attributes. The **LDIF View** shows the equivalent schema definition in ASN.1 format, which includes the proper text spacing required for each schema element.

### Default Directory Server Schema Files

The PingDirectory Server stores its schema as a set of LDIF files for a Directory Server instance in the `<server-root>/config/schema` directory. The Directory Server reads the schema files in alphanumeric order at startup, so that the `00-core.ldif` file is read first, then `01-pwppolicy.ldif`, and then the rest of the files. Custom schema files should be named so that they are loaded in last. For example, custom schema elements could be saved in a file labelled `99-user.ldif`, which loads after the default schema files are read at startup.

The Directory Server then uses the schema definitions to determine any violations that may occur during add, modify, or import requests. Clients applications check the schema (i.e., matching rule definitions) to determine the assertion value algorithm used in comparison or search operations.

The default set of schema files are present at installation and should not be modified. Modifying the default schema files could result in an inoperable server.

The schema files have the following descriptions:

#### Default Schema Files

| Schema Files      | Description                                                                  |
|-------------------|------------------------------------------------------------------------------|
| 00-core.ldif      | Governs the Directory Server's core functions.                               |
| 01-pwppolicy.ldif | Governs password policies.                                                   |
| 02-config.ldif    | Governs the Directory Server's configuration.                                |
| 03-changelog.ldif | Governs the Directory Server's change log.                                   |
| 03-rc2713.ldif    | Governs Java objects.                                                        |
| 03-rc2714.ldif    | Governs Common Object Request Broker Architecture (CORBA) object references. |

| Schema Files       | Description                                                               |
|--------------------|---------------------------------------------------------------------------|
| 03-rfc2739.ldif    | Governs calendar attributes for vCard.                                    |
| 03-rfc2926.ldif    | Governs Server Location Protocol (SLP) mappings to and from LDAP schemas. |
| 03-rfc2985.ldif    | Governs PKCS #9 public-key cryptography.                                  |
| 03-rfc3112.ldif    | Governs LDAP authentication passwords.                                    |
| 03-rfc3712.ldif    | Governs printer services.                                                 |
| 03-uddiv3.ldif     | Governs web services registries of SOA components.                        |
| 04-rfc2307bis.ldif | Governs mapping entities from TCP/IP and UNIX into X.500 entries.         |

## Extending the Directory Server Schema

The PingDirectory Server stores its schema as LDIF files in the `<server-root>/config/schema` directory. At startup, the Directory Server reads the schema files once in alphanumeric order starting with `00-core.ldif` and ending with any custom schema definition files, such as `99-user.ldif` if present.

You can extend the schema to include additional customizations necessary for your Directory Server data using one of the following methods:

- **Using the Schema Editor.** This method is the easiest and quickest way to set up a schema definition and have it validated for the correct ASN.1 formatting. The Editor lets you define your schema properties, load your custom file, or perform a cut-and-paste operation on a new schema element. If any errors exist in the file, the Schema Editor generates an error message if the schema definitions do not pass compliance.
- **Using a Custom Schema File.** You can create a custom schema file with your new definitions using a text editor, save it as `99-user.ldif`, and then import the file using the Schema Editor or the `ldapmodify` tool. You must name the custom LDIF file with a high two-digit number prefix, so that the Directory Server will read the file AFTER the core schema files are read at startup. For example, you can name the file, `99-myschema.ldif`, etc. See the next section, [General Tips on Extending the Schema](#) to see the requirements for naming each file.
- **Using the Command Line.** If you have a small number of additions, you can extend the schema over LDAP and from the command line using the `ldapmodify` tool. The Directory Server writes the new schema changes to a file `99-user.ldif` in the `<server-root>/config/schema` directory. However, this method can be cumbersome as schema definitions require strict adherence to text spacing and white space characters.

### General Tips on Extending the Schema

You should consider the following points when extending the schema:

- Never modify the default schema files as doing so could damage the Directory Server's processing capabilities.
- Define all attributes first before they can be used in an object class. If you are using the Schema Editor to add new schema elements, then you can use the Quick Add Attributes option when defining new objectclasses.
- Define the parent object class first before creating object classes that inherit from the parent.
- The schema file naming syntax requires that custom schema files must begin with exactly two digits followed by a non-digit character, followed by a zero or more characters and ending with ".ldif". Note that the two digits do not need to be followed by a dash ("-"). Any files that do not meet this criteria will be ignored and either a NOTICE or SEVERE\_WARNING message will be logged.

Any file in the `<server-root>/config/schema` directory with a name that starts with "." or with a name that ends with a tilde (~), ".swp", or ".tmp" will generate a NOTICE message indicating that

temporary files will be ignored. Any other file that does not meet the naming criteria will generate a SEVERE\_WARNING message indicating that it will be ignored.

- Define custom attributes and object classes in one file. Typically, this file will be the `99-user.ldif`. You can specify a different file name to which the Directory Server writes using the X-SCHEMA-FILE element and the file name in the definition. For example:

```
add: attributeTypes attributeTypes: (1.3.6.1.4.1.32473.3.1.9.1
 NAME 'contractorStatus'
 EQUALITY booleanMatch
 SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
 SINGLE-VALUE
 USAGE userApplications
 X-ORIGIN 'Directory Server Example'
 X-SCHEMA-FILE '99-custom.ldif')
```

- Pay special attention to the white space characters in the schema definitions, where WSP means zero or more space characters, and SP means one or more space characters. The LDIF specification states that LDIF parsers should ignore exactly one space at the beginning of each continuation line, since continuation lines must begin with a space character. Thus, if you define a new schema definition with each keyword on a separate continuation line, you should add two spaces before an element keyword to be safe. For example, the following attribute definition has two spaces before the keywords: NAME, SUP, and X-ORIGIN.

```
attributeTypes: (2.5.4.32 NAME 'owner' SUP distinguishedName X-ORIGIN 'RFC
 4519')
```

- In a replicated topology, any new schema additions will be replicated to other replication servers to their respective Schema backend. The additions will be written to the file specified by the X-SCHEMA-FILE extension or written to `99-user.ldif` if no file is specified.

## Managing Attribute Types

An attribute type determines the important properties related to an attribute, such as specifying the matching and syntax rules used in value comparisons. An attribute description consists of an attribute type and a set of zero or more options. Options are short, case-insensitive text strings that differentiate between attribute descriptions. For example, the LDAPv3 specification defines only one type of option, the tagging option, which can be used to tag language options, such as `cn;lang-de;lang-sp` or binary data, such as `userCertificate;binary`. You can also extend the schema by adding your own attribute definitions.

Attributes have the following properties:

- Attributes can be user attributes that hold information for client applications, or operational attributes that are used for administrative or server-related purposes. You can specify the purpose of the attribute by the USAGE element.
- Attributes are multi-valued by default. Multi-valued means that attributes can contain more than one value within an entry. Include the SINGLE-VALUE element if the attribute should contain at most one value within an entry.
- Attributes can inherit properties from a parent attribute as long as they both have the same USAGE, and the child attribute has the same SYNTAX or its SYNTAX allows values which are a subset of the values allowed by the SYNTAX of the parent attribute. For example, the surname (`sn`) attribute is a child of the name attribute.

### Attribute Type Definitions

New attribute types do not require server code extensions if the provided matching rules and attribute syntaxes are used in the definitions. Administrators can create new attributes using the Schema Editor, which stores the definition in a file in the `<server-root>/config/schema` directory. See [Extending the Directory Server Schema](#) for more information.

The formal specification for attribute types is provided in RFC 4512, section 4.1.2 as follows:

```

AttributeTypeDescription = "(" wsp; Left parentheses followed by a white space
numericoid ; Required numeric object identifier
[sp "NAME" sp qdescrs] ; Short name descriptor as alias for the OID
[sp "DESC" sp qdstring] ; Optional descriptive string
[sp "OBSOLETE"] ; Determines if the element is active
[sp "SUP" sp oid] ; Specifies the supertype
[sp "EQUALITY" sp oid] ; Specifies the equality matching rule
[sp "ORDERING" sp oid] ; Specifies ordering matching rule
[sp "SUBSTR" sp oid] ; Specifies substrings matching rule
[sp "SYNTAX" sp oidlen] ; Numeric attribute syntax with minimum
upper bound

[sp "SINGLE-VALUE"] ; length expressed in {num}
valued in ; Specifies if the attribute is single

 ; the entry
[sp "COLLECTIVE"] ; Specifies if it is a collective attribute
[sp "NO-USER-MODIFICATION"] ; Not modifiable by external clients
[sp "USAGE" sp usage] ; Application usage
extensions wsp ")" ; Extensions followed by a white space and
")"

usage = "userApplications" / ; Stores user data
"directoryOperation" / ; Stores internal server data
"distributedOperation" / ; Stores operational data that must be
synchronized ; across servers
"dSAOperation" ; Stores operational data specific to a
server and ; should not be synchronized across servers

```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```

extensions = /
"X-ORIGIN" / ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-APPROX" / ; Specifies the approximate matching rule
"X-ALLOWED-VALUE" / ; Explicitly specifies the set of allowed values
"X-VALUE-REGEX" / ; Specifies the set of regular expressions to compare
against
 ; attribute values to determine acceptance
"X-MIN-VALUE-LENGTH" / ; Specifies the minimum character length for
attribute values
"X-MAX-VALUE-LENGTH" / ; Specifies the maximum character length for
attribute values
"X-MIN-INT-VALUE" / ; Specifies the minimum integer value for the
attribute
"X-MAX-INT-VALUE" / ; Specifies the maximum integer value for the
attribute
"X-MIN-VALUE-COUNT" / ; Specifies the minimum number of allowable values
for the
 ; attribute
"X-MAX-VALUE-COUNT" / ; Specifies the maximum number of allowable values
for the
 ; attribute
"X-READ-ONLY" ; True or False. Specifies if the file that contains
the
 ; schema element is marked as read-only in the
server
 ; configuration.

```

### Basic Properties of Attributes

The Basic Properties section displays the standard elements in schema definition.

## Basic Properties of Attributes

| Attributes         | Description                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name               | Specifies the globally unique name.                                                                                                                                                                              |
| Description        | Specifies an optional definition that describes the attribute and its contents. The analogous LDIF equivalent is "DESC".                                                                                         |
| OID                | Specifies the object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.            |
| Syntax             | Specifies the attribute syntax used. For example, the <code>userPassword</code> attribute uses the User Password Syntax whereas the <code>authPassword</code> attribute uses the Authentication Password Syntax. |
| Parent             | Specifies the schema definition's parent or supertype if any. The analogous LDIF equivalent is "SUP".                                                                                                            |
| Multivalued        | Specifies if the attribute can appear more than once in its containing object class.                                                                                                                             |
| Required By Class  | Specifies any object classes that require the attribute.                                                                                                                                                         |
| Allowed By Class   | Specifies any object classes that can optionally use the attribute.                                                                                                                                              |
| Value Restrictions | Specifies any restriction on the value of the attribute.                                                                                                                                                         |

The Extra Properties section provides additional auxiliary information associated with the attribute.

## Basic Properties of Attributes

| Attributes      | Description                                                                                                                                                                                                                                                                            |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aliases         | Specifies any shortform alias names, if any. In theory, you could have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the NAME element. For example, NAME ( 'sn' 'surname' ).                       |
| Origin          | Specifies the origin of the schema definition. Typically, it could refer to a specific RFC or company.                                                                                                                                                                                 |
| Stored in File  | Specifies the schema file that stores the definition in the <code>&lt;server-root&gt;/config/schema</code> folder.                                                                                                                                                                     |
| Usage           | Specifies the intended use of the attribute. Choices are the following: <ul style="list-style-type: none"> <li>▪ <code>userApplications</code></li> <li>▪ <code>directoryOperation</code></li> <li>▪ <code>distributedOperation</code></li> <li>▪ <code>dSAOperation</code></li> </ul> |
| User-Modifiable | Specifies if the attribute can be modified by an authorized user.                                                                                                                                                                                                                      |
| Obsolete        | Specifies if the schema definition is obsolete or not.                                                                                                                                                                                                                                 |
| Matching Rules  | Specifies the associated matching rules for the attribute.                                                                                                                                                                                                                             |

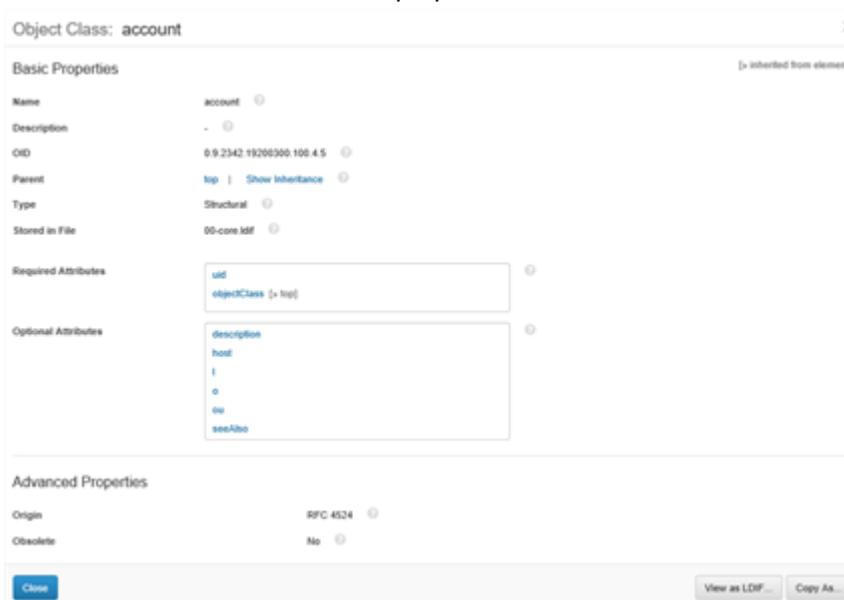

## Viewing Attributes

The Schema Editor displays all of the attribute types on your directory server instance. It shows the basic properties that are required elements plus the extra properties that are allowed within the attribute definition.

## To View Attribute Types Using the Schema Editor

### Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is also running.
2. On the main menu, click **Schema**.
3. In the Administrative Console **Schema Editor**, click the **Attribute Types** tab.
4. Click a specific attribute to view its definition. In this example, click the `account` attribute. In the **Object Class** window, view the attribute properties.

5. Click the **View as LDIF** button to see the equivalent attribute definition in ASN.1 format.

## To View Attribute Types over LDAP

### Steps

- Use `ldapsearch` to view a multi-valued operational attribute `attributeTypes`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
 "(objectclass=*)" attributeTypes
```

## To View a Specific Attribute Type over LDAP

### Steps

- Use `ldapsearch` with the `--dontWrap` option and use the `grep` command to search for a specific attribute.

```
$ bin/ldapsearch --baseDN cn=schema \
 --searchScope base --dontWrap "(objectclass=*)" \
 attributeTypes | grep 'personalTitle'
```

## Creating a New Attribute over LDAP

The following section shows how you can add the schema element from the previous section over LDAP. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting.

## To Add an New Attribute to the Schema over LDAP

### Steps

1. Create an LDIF file with the new attribute definition using a text editor. Save the file as `myschema.ldif`.

```
dn: cn=schema
changetype: modify
add: attributeTypes
attributeTypes: (contractorStatus-OID NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ALLOWED-VALUES 'Y' 'N' 'y' 'n'
X-ORIGIN 'PingDirectory Server Example')
```

2. Use `ldapmodify` to add the attribute.

```
$ bin/ldapmodify --filename myschema.ldif
```

3. Verify the addition by displaying the attribute using `ldapsearch`.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontwrap "(objectclass=*)" attributeTypes | grep 'contractorStatus'
```

4. You can view the custom schema file at `<server-root>/config/schema/99-user.ldif`. You should see the following:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: (contractorStatus-OID
NAME 'contractorStatus'
EQUALITY booleanMatch
SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'PingDirectory Server Example')
```

## To Add Constraints to Attribute Types

### Steps

- The Directory Server provides attribute type extensions that constrain the values for the associated attribute using the `DirectoryString` attribute syntax. The following schema definition includes two `attributeType` definitions for `myAttr1` and `myAttr2`. The first definition constrains the values for the attribute `myAttr1` to 'foo', 'bar', 'baz'. The second definition constrains the minimum allowable length for `myAttr2` to 1 and the maximum allowable length to 5.

```
attributeTypes: (1.2.3.4
NAME 'myAttr1'
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
X-ALLOWED-VALUES ('foo' 'bar' 'baz')
attributeTypes: (1.2.3.5
NAME 'myAttr2'
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
X-MIN-VALUE-LENGTH '1'
X-MAX-VALUE-LENGTH '5')
```

## Managing Object Classes

Object classes are sets of related information objects that form entries in a Directory Information Tree (DIT). The Directory Server uses the schema to define these entries, to specify the position of the entries in a DIT, and to control the operation of the server. You can also extend the schema by adding your own schema definitions.

Object classes have the following general properties:

- Object classes must have a globally unique name or identifier.
- Object classes specify the required and allowed attributes in an entry.
- Object classes can inherit the properties and the set of allowed attributes from its parent object classes, which may also be part of a hierarchical chain derived from the top abstract object class.
- Object classes that are defined in the PingDirectory Server can be searched using the `objectClasses` operational attribute. The Directory Server also has a special entry called the subschema subentry, which provides information about the available schema elements on the server.

### Object Classes Types

Based on RFC 4512, object classes can be a combination of three different types:

- **Abstract object classes** are used as the base object class, from which structural or auxiliary classes inherit its properties. This inheritance is a one-way relationship as abstract object classes cannot be derived from structural or auxiliary classes. The most common abstract object class is `top`, which defines the highest level object class in a hierarchical chain of object classes.
- **Structural object classes** define the basic attributes in an entry and define where an entry can be placed in a DIT. All entries in a DIT belong to one structural object class. Structural object classes can inherit properties from other structural object classes and from abstract object classes to form a chain of inherited classes. For example, the `inetOrgPerson` structural object class inherits properties from the `organizationalPerson` structural class, which inherits from another object class, `person`.
- **Auxiliary object classes** are used together with structural object classes to define additional sets of attributes required in an entry. The auxiliary object class cannot form an entry alone but must be present with a structural object class. Auxiliary object classes cannot derive from structural object classes or vice-versa. They can inherit properties from other auxiliary classes and from abstract classes.

### Object Class Definition

New object classes can be specified with existing schema components and do not require additional server code extensions for their implementation. Administrators can create new object classes using the Schema Editor, which manages schema in the `<server-root>/config/schema` directory. See [Extending the Directory Server Schema](#) for more information.

The object class definition is defined in RFC 4512, section 4.1.1, as follows::

```
ObjectClassDescription = "(" wsp; Left parenthesis followed by a white space
numericoid ; Required numeric object identifier
[sp "NAME" sp qdescrs] ; Short name descriptor as alias for the OID
[sp "DESC" sp qdstring] ; Optional descriptive string
[sp "OBSOLETE"] ; Determines if the element is inactive
[sp "SUP" sp oid] ; Specifies the direct superior object class
[sp kind] ; abstract, structural (default), auxiliary
[sp "MUST" sp oids] ; Required attribute types
[sp "MAY" sp oids] ; Allowed attribute type
extensions wsp ")" ; Extensions followed by a white space and
")"

usage = "userApplications" / ; Stores user data
 "directoryOperation" / ; Stores internal server data
 "distributedOperation" / ; Stores operational data that must be
synchronized
```

```

"dsaOperation" ; across servers
server and ; Stores operational data specific to a
 ;
 ; should not be synchronized across
servers

```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```

extensions = /
"X-ORIGIN" / ; Specifies where the object class is defined
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-READ-ONLY" ; True or False. Specifies if the file that contains
 ; the schema element is marked as read-only
 ; in the server configuration.

```

**Note:** Although RFC 4512 allows multiple superior object classes, the PingDirectory Server allows at most one superior object class, which is defined by the SUP element in the definition.

### Basic Object Class Properties

The Basic Properties section displays the standard elements in schema definition.

#### Basic Properties of Attributes

| Attributes          | Description                                                                                                                                                                                                                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name                | Specifies the globally unique name.                                                                                                                                                                                                                                                                            |
| Description         | Specifies an optional definition that describes the object class and its contents. The analogous LDIF equivalent is "DESC".                                                                                                                                                                                    |
| OID                 | Specifies the object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI.                                                                                                          |
| Parent              | Specifies the schema definition's hierarchical parent or superior object class if any. An object class can have one parent. The analogous LDIF equivalent                                                                                                                                                      |
| Type                | Specifies the type of schema definition: abstract, structural, or auxiliary. The analogous LDIF equivalent is "ABSTRACT", "STRUCTURAL", or "AUX"                                                                                                                                                               |
| Required Attributes | Specifies any required attributes with the object class. The Schema Editor also marks any inherited attributes from another object class. You can double-click an attribute value to take you to the Properties View for that particular attribute. The analogous LDIF equivalent is "MUST".                   |
| Optional Attributes | Specifies any optional attributes that could be used with the object class. The Schema Editor also marks any inherited attributes from another object class. You can double-click an attribute value to take you to the Properties View for that particular attribute. The analogous LDIF equivalent is "MAY". |

The Extra Properties section provides additional auxiliary information associated with the object class.

#### Basic Properties of Attributes

| Attributes | Description                                                                                                                                                                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aliases    | Specifies any shortform alias names, if any. In theory, you could have any number of shortform names as long as they are all unique. The analogous LDIF equivalent appears as the secondary element with the NAME element although most object classes do not have aliases. |

| Attributes     | Description                                                                                            |
|----------------|--------------------------------------------------------------------------------------------------------|
| Origin         | Specifies the origin of the schema definition. Typically, it could refer to a specific RFC or company. |
| Obsolete       | Specifies if the schema definition is obsolete or not.                                                 |
| Stored in File | Specifies the schema file that stores the definition in the <server-root>/config/schema folder.        |

### Viewing Object Classes

You can view the object classes on your Directory Server by using the Administrative Console Schema Editor, over LDAP using the `ldapsearch` tool, or some third party tool. The Schema Editor displays all of the object classes on the directory server instance. It shows the basic properties that are required elements and the extra properties that are allowed within the object class.

#### To View Object Classes over LDAP

##### Steps

- Use `ldapsearch` tool to view a multi-valued operational attribute, `objectClasses`, which publishes the object class definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
--dontWrap "(objectclass=*)" objectClasses
```

```
dn: cn=schema
objectClasses: (2.5.6.0 NAME 'top' ABSTRACT MUST objectClass X-ORIGIN 'RFC
4512')
objectClasses: (2.5.6.1 NAME 'alias' SUP top STRUCTURAL MUST
aliasedObjectName
X-ORIGIN 'RFC 4512')
objectClasses: (2.5.6.2 NAME 'country' SUP top STRUCTURAL MUST c
MAY (searchGuide $ description) X-ORIGIN 'RFC 4519')
...(more output)...
```

### Managing an Object Class over LDAP

The following section shows how you can manage an object class schema element over LDAP by adding a new attribute element to an existing object class. You can create your own schema file or type the schema from the command line. In either case, you must pay special attention to text spacing and ASN.1 formatting. The following example procedure adds an attribute, `contractorAddress`, to the custom schema file, then adds it to the `contractor` objectclass.

#### To Manage an Object Class over LDAP

##### Steps

- Assume that you have defined the `contractorAddress` attribute, create an LDIF file called `contractorAddress-attr.ldif` with the following content:

```
dn: cn=schema
changetype: modify

add: attributeTypes attributeTypes: (contractor-OID NAME
'contractorAddress'
SYNTAX 1.3.6.1.4.1.1466.115.121.1.15
SINGLE-VALUE
USAGE userApplications
X-ORIGIN 'user defined'
X-SCHEMA-FILE '98-custom-schema.ldif')
```

```
X-ORIGINS 'user defined'
X-SCHEMA-FILE '98-custom-schema.ldif')
```

2. Add the attribute using `ldapmodify`.

```
$ bin/ldapmodify --filename contractorAddress-attr.ldif
```

3. Next, create an LDIF file to modify the contractor objectclass to allow this attribute. When doing this, you are just re-adding the updated `objectClass` and the Directory Server will handle the proper replacement of the existing object class with the new one. Create a file called `contractor-oc.ldif`. Make sure that the lines are not wrapped, the `objectClasses` line should be one continuous line.

```
dn:cn=schema
changetype: modify
add: objectClasses
objectClasses: (contractor-OID NAME 'contractor'
DESC 'Contractor status information
SUP top
AUXILIARY MAY (contractorStatus $ contractorAgency $ contractorAddress)
X-ORIGIN 'Directory Server Example'
X-SCHEMA-FILE '98-custom-schema.ldif')
```

4. Update the `objectClass` using `ldapmodify` as follows:

```
$ bin/ldapmodify --filename contractor-oc.ldif
```

5. These schema changes will be replicated to all servers in the replication topology. Verify the change by looking at the `config/schema/98-custom-schema.ldif` file on the other servers in the replication topology to ensure that the changes are present.
6. If you need to add an index for this attribute, you can do so by using the `dsconfig` command-line utility. You will need to do this on each server in your topology unless you have server configuration groups set up. See [Configuring Server Groups](#) for more information.

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
--index-name contractorAddress --set index-type:equality
```

7. Rebuild the index online. This will not affect other indexes or entries since there is no currently existing data for this attribute on any entry.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index contractorAddress
```

## Creating a New Object Class Using the Schema Editor

The procedures to create a new object class are similar to that of creating a new attribute. Make sure that any attributes that are part of the new object class are defined prior to defining the object class.

### To Create a New Object Class Using the Schema Editor

#### Steps

1. Start the Administrative Console.
2. On the main menu, click **LDAP Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab, and then click **New** located in the bottom left of the window.
4. Enter the properties for the new objectclass. In the **Attributes** box, filter the types of attributes required for the new object class. Click the right arrow to move it into the **Required** or the **Optional** box. All custom attributes appear at the bottom of the list in the **Attributes** box.

## Extending the Schema Using a Custom Schema File

You can add new attributes and object classes to your Directory Server schema by creating a custom schema file. You can import the file using the Schema Editor, over LDAP using the `ldapmodify` tool, or from the command line. Make sure to define the attributes first, then define the object classes.

### To Extend the Schema Using a Custom Schema File

#### Steps

1. Create an LDIF file with the new attribute extensions using a text editor.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
attributeTypes: (contractorStatus-OID NAME 'contractorStatus'
 EQUALITY booleanMatch
 SYNTAX 1.3.6.1.4.1.1466.115.121.1.7
 SINGLE-VALUE
 USAGE userApplications
 X-ORIGIN 'Directory Server Example')
attributeTypes: (contractorAgency-OID NAME 'contractorAgency'
 EQUALITY caseIgnoreMatch
 SUBSTR caseIgnoreSubstringsMatch
 SYNTAX 1.3.6.1.4.1.1466.115.121.1.44{256}
 SINGLE-VALUE
 USAGE userApplications
 X-ORIGIN 'PingDirectory Server Example')
```

2. In the same LDIF file, add a new object class definition after the attribute types. In this example, create an auxiliary object class, `contractor`, that alone cannot be used as an entry. The object class will be used to add supplemental information to the `inetOrgPerson` structural object class. The attributes are all optional for the new object class.

```
objectClasses: (contractor-OID
 NAME 'contractor'
 DESC 'Contractor status information'
 SUP top
 AUXILIARY
 MAY (contractorStatus $ contractorAgency)
 X-ORIGIN 'PingDirectory Server Example')
```

3. Save the file as `99-auxobjclass.ldif`, and place it in the `<server-root>/config/schema` directory.
4. At this stage, the schema extensions are not loaded into the Directory Server yet. You have four options to load them:
  - Create a task that loads the new extensions into the schema. We create a task labelled with the ID "add-schema-99-auxobjclass" and add it using `ldapmodify`. The server does not need to be restarted using this method.

```
dn: ds-task-id=add-schema-99-auxobjclass,cn=Scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-add-schema-file
ds-task-id: add-schema-99-auxobjclass
ds-task-class-name:
 com.unboundid.directory.server.tasks.AddSchemaFileTask
```

```
ds-task-schema-file-name: 99-auxobjclass.ldif
```

- Import the schema file using the Administrative Console Schema Editor. You do not need to restart the server when using this method.
- Place the `99-auxobjclass.ldif` file in the `<server-root>/config/schema` directory and restart the Directory Server. The schema file is read at startup.
- Add the schema file using `load-ldap-schema-file`. You do not need to restart the server when using this method.

```
$ bin/load-ldap-schema-file --schemaFile config/schema 99-auxobjclass.ldif
```

##### 5. Verify the addition by displaying the attribute using `ldapsearch`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.9)" contractorStatus
```

```
dn: uid=user.9,ou=People,dc=example,dc=com
contractorStatus: TRUE
```

## Managing Matching Rules

Matching rules determine how clients and servers compare attribute values during LDAP requests or operations. They are also used in evaluating search filter elements including distinguished names and attributes. Matching rules are defined for each attribute based on EQUALITY (e.g., two attributes are equal based on case, exact match, etc.), SUBSTR (e.g., assertion value is a substring of an attribute), and ORDERING (e.g., greater than or equal, less than or equal, etc.) properties.

**Note:** The PingDirectory Server supports an APPROXIMATE matching rule that compares similar attributes based on fuzzy logic. Thus, attributes that are similar or "sound-like" each other are matched. For example, "petersen" would match "peterson".

### Matching Rule Definition

New matching rules require additional server code extensions to be implemented on the PingDirectory Server. If you need new matching rules, contact your authorized support provider for assistance.

The formal specification for attribute types is provided in RFC 4512, section 4.1.3 as follows:

```
MatchingRuleDescription = "(" wsp ; Left parentheses followed by a white
 space
 numericoid ; Required numeric object identifier
 identifying
 [sp "NAME" sp qdescrs ; this matching rule
 [sp "DESC" sp qdstring ; Short name descriptor
 [sp "OBSOLETE"] ; Description
 [sp "OBSOLETE"] ; Specifies if the rule is inactive
 sp "SYNTAX" sp numericoid ; Assertion syntax
 extensions wsp ")" ; Extensions followed by a white space
 and ")"
```

### Default Matching Rules

The PingDirectory Server provides a large set of matching rules, which support a variety of applications. The default matching rules available for the Directory Server are listed in the table below for each matching rule type: Equality, Substring, Ordering, and Approximate matches.

**Default Matching Rules**

| Matching Rule/OID                                           | Attribute Syntax/OID                                      | Description                                                                                                                                                                                     |
|-------------------------------------------------------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| uuidMatch/ 1.3.6.1.1.16.2                                   | UUID/ 1.3.6.1.1.16.1                                      | Compares an asserted UUID with a stored UUID attribute value for equality. RFC 4530.                                                                                                            |
| uuidOrderingMatch/ 1.3.6.1.1.16.3                           | UUID/ 1.3.6.1.1.16.1                                      | Compares the collation order of an asserted UUID with a stored UUID attribute value for ordering RFC 4530.                                                                                      |
| caseExactIA5Match/<br>1.3.6.1.4.1.1466.109.114.1            | IA5 String/<br>1.3.6.1.4.1.1466.115.121.1.26              | Compares an asserted value with an attribute value of International Alphabet 5 syntax. RFC 4517.                                                                                                |
| caselgnoreIA5Match/<br>1.3.6.1.4.1.1466.109.114.2           | IA5 String/<br>1.3.6.1.4.1.1466.115.121.1.26              | Compares an asserted value with an attribute value of International Alphabet 5 syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517. |
| caselgnoreIA5SubstringsMatch/<br>1.3.6.1.4.1.1466.109.114.3 | Substring Assertion/<br>1.3.6.1.4.1.1466.115.121.1.58     | Compares an asserted substring with an attribute value of IA5 string syntax. Case, leading, and trailing spaces are ignored. Multiple spaces are treated as a single space. RFC 4517.           |

RFC 4517.                                                                                                                                                                                                      |
| objectIdentifierFirstComponentMatch/OID/<br>2.5.13.30             | 1.3.6.1.4.1.1466.115.121.1.38                      | Equality matching rules for subschema attributes between an OID syntax and the value syntax. RFC 4517.                                                                                                                                                                                                          |
| directoryStringFirstComponentMatch/Directory String/<br>2.5.13.31 | 1.3.6.1.4.1.1466.115.121.1.15                      | Compares an asserted Directory String value with an attribute value of type SEQUENCE whose first component is mandatory and of type Directory String. Returns true if the attribute value has a first component whose value matches the asserted Directory String using the rules of caseIgnoreMatch. RFC 3698. |
| wordMatch/ 2.5.13.32                                              | Directory String/<br>1.3.6.1.4.1.1466.115.121.1.15 | Compares an asserted word with any word in the attribute value for equality RFC 3698.                                                                                                                                                                                                                           |
| keywordMatch/ 2.5.13.33                                           | Directory String/<br>1.3.6.1.4.1.1466.115.121.1.15 | Compares an asserted value with any keyword in the attribute value for equality. RFC 3698.                                                                                                                                                                                                                      |

### Basic Matching Rule Properties

The Properties section displays the standard elements in a matching rule schema definition.

### Basic Properties of Matching Rules

| Attributes  | Description                                                                                                                                                                                                           |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name        | Specifies the descriptive and unique name of the element.                                                                                                                                                             |
| Description | Specifies an optional definition that describes the matching rule. The analogous LDIF equivalent is "DESC".                                                                                                           |
| OID         | Specifies the globally unique object identifier assigned to the schema definition. You can obtain a specific OID for your company that allows you to define your own object classes and attributes from IANA or ANSI. |
| Type        | Specifies the type of type of matching rule: Equality, Ordering, Substring, or Approximate.                                                                                                                           |

| Attributes         | Description                                                        |
|--------------------|--------------------------------------------------------------------|
| Syntax             | Specifies the matching rule syntax.                                |
| Used by Attributes | Specifies any attributes that use the corresponding matching rule. |

### Viewing Matching Rules

You can view the matching rules on your Directory Server by using the Schema Editor on the Administrative Console, over LDAP using the `ldapsearch` tool, or some third party tool.

The Schema Editor displays all of the matching rules on your Directory Server instance. It shows the basic properties that are allowed within the matching rule.

### To View Matching Rules Over LDAP

#### Steps

- Use `ldapsearch` to view a multi-valued operational attribute, `matchingRules`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
 "(objectclass=*)" matchingRules
```

## Managing Attribute Syntaxes

The attribute type definition has a `SYNTAX` element, or attribute syntax, that specifies how the data values for the attribute are represented. The syntax can be used to define a large range of data types necessary for client applications. An attribute syntax uses the Abstract Syntax Notation One (ASN.1) format for its definitions.

### Attribute Syntax Definition

New attribute syntaxes require additional code to be implemented on the PingDirectory Server. If you need new syntax definitions, contact your authorized support provider for assistance.

The formal specification for attribute types is provided in RFC 4512, section 4.1.5 as follows:

```
SyntaxDescription = "(" wsp
numericoid ; Object identifier
[sp "DESC" sp qdstring] ; Description
extensions wsp ")" ; Extensions followed by a white space and ")"
```

### Default Attribute Syntaxes

The PingDirectory Server supports a large set of Attribute Syntax rules for applications. The default Attribute Syntax rules available for the directory server are listed in the table below.

#### Default Attribute Syntaxes

| LDAP Syntax                | OID                          | Description                                                                                                                                                         |
|----------------------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UUID                       | 1.3.6.1.1.16.1               | 128-bit (16 octets) Universally Unique Identifier (UUID) used for Uniform Resource Names as defined in RFC 4122. For example, a4028c1a-f36e-11da-ba1a-04112154bd1e. |
| Attribute Type Description | 1.3.6.1.4.1.1466.115.121.1.3 | Syntax for the AttributeTypeDescription rule based on RFC 4517.                                                                                                     |

| LDAP Syntax                    | OID                           | Description                                                                                                                                                    |
|--------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Binary                         | 1.3.6.1.4.1.1466.115.121.1.5  | Strings based on Basic Encoding Rules (BER) or Distinguished Encoding rules (DER). For example, an X.509 digital certificate or LDAP messages are BER encoded. |
| Bit String                     | 1.3.6.1.4.1.1466.115.121.1.6  | Sequence of binary digits based on RFC 4517. For example, '0010111'B.                                                                                          |
| Boolean                        | 1.3.6.1.4.1.1466.115.121.1.7  | TRUE or FALSE.                                                                                                                                                 |
| Certificate                    | 1.3.6.1.4.1.1466.115.121.1.8  | BER/DER-encoded octet strings based on an X.509 public key certificate as defined in RFC 4523.                                                                 |
| Certificate List               | 1.3.6.1.4.1.1466.115.121.1.9  | BER/DER-encoded octet string based on an X.509 certificate revocation list as defined in RFC 4523.                                                             |
| Certificate Pair               | 1.3.6.1.4.1.1466.115.121.1.10 | BER/DER-encoded octet string based on an X.509 public key certificate pair as defined in RFC 4523.                                                             |
| Country String                 | 1.3.6.1.4.1.1466.115.121.1.11 | Two character country code specified in ISO 3166. For example, US, CA, etc.                                                                                    |
| DN                             | 1.3.6.1.4.1.1466.115.121.1.12 | Distinguished name of an entry as defined in RFC4514.                                                                                                          |
| Delivery Method                | 1.3.6.1.4.1.1466.115.121.1.14 | Sequence of services in preference order by which an entity receives messages as defined in RFC4517. For example, videotext \$ telephone.                      |
| Directory String               | 1.3.6.1.4.1.1466.115.121.1.15 | String of one or more characters from the Universal Character Set (UCS) using UCS Transformation Format 8 (UTF-8) encoding of the string.                      |
| DIT Content Rule Description   | 1.3.6.1.4.1.1466.115.121.1.16 | DITContentRuleDescription as defined in RFC4517.                                                                                                               |
| DIT Structure Rule Description | 1.3.6.1.4.1.1466.115.121.1.17 | DITStructureRuleDescription as defined in RFC4517.                                                                                                             |
| Enhanced Guide                 | 1.3.6.1.4.1.1466.115.121.1.21 | Combination of attribute types and filter operators to be used to construct search filters as defined in RFC4517. For example, person#(sn\$EQ)#oneLevel.       |
| Facsimile Telephone Number     | 1.3.6.1.4.1.1466.115.121.1.22 | Fax telephone number on the public switched telephone network as defined in RFC4517.                                                                           |
| Fax                            | 1.3.6.1.4.1.1466.115.121.1.23 | Image generated using Group 3 fax process as defined in RFC4517.                                                                                               |

| LDAP Syntax                   | OID                           | Description                                                                                                                                                                                                |
|-------------------------------|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generalized Time              | 1.3.6.1.4.1.1466.115.121.1.24 | String representing data and time as defined in RFC4517. YYYYMMDDHHMMSS[.fraction][(+ -HHMM)]Z] For example, 201103061032, 201103061032-0500, or 201103061032Z ("Z" indicates Coordinated Universal Time). |
| Guide                         | 1.3.6.1.4.1.1466.115.121.1.25 | Attribute types and filter operators as defined in RFC4517.                                                                                                                                                |
| IA5 String                    | 1.3.6.1.4.1.1466.115.121.1.26 | String of zero or more characters from the International Alphabet 5 (IA5) character set as defined in RFC4517.                                                                                             |
| Integer                       | 1.3.6.1.4.1.1466.115.121.1.27 | String representations of integer values. For example, the character string "1234" represents the number 1234 as defined in RFC4517.                                                                       |
| JPEG                          | 1.3.6.1.4.1.1466.115.121.1.28 | Image in JPEG File Interchange Format (JFIF) as defined in RFC4517.                                                                                                                                        |
| Matching Rule Description     | 1.3.6.1.4.1.1466.115.121.1.30 | MatchingRuleDescription as defined in RFC4512.                                                                                                                                                             |
| Matching Rule Use Description | 1.3.6.1.4.1.1466.115.121.1.31 | Attribute types to which a matching rule is applied in an extensibleMatch search filter (RFC4511).                                                                                                         |
| Name and Optional UID         | 1.3.6.1.4.1.1466.115.121.1.34 | Distinguished name and an optional unique identifier that differentiates identical DNs as defined in RFC4517. For example, uid=jsmith,ou=People,dc=example,dc=com#0111'B                                   |
| Name Form Description         | 1.3.6.1.4.1.1466.115.121.1.35 | NameFormDescription as defined in RFC4512.                                                                                                                                                                 |
| Numeric String                | 1.3.6.1.4.1.1466.115.121.1.36 | Sequence of one or more numerals and spaces as defined in RFC4517. For example, 14 848 929 102.                                                                                                            |
| Object Class Description      | 1.3.6.1.4.1.1466.115.121.1.37 | ObjectClassDescription as defined in RFC 4512.                                                                                                                                                             |
| OID                           | 1.3.6.1.4.1.1466.115.121.1.38 | Object identifier as defined in RFC 4512.                                                                                                                                                                  |
| Other Mailbox                 | 1.3.6.1.4.1.1466.115.121.1.39 | Specifies an electronic mailbox as defined in RFC 4517. For example, otherMailbox = google \$ user@gmail.com                                                                                               |
| Octet String                  | 1.3.6.1.4.1.1466.115.121.1.40 | Sequence of zero or more octets (8-bit bytes) as defined in RFC4517.                                                                                                                                       |
| Postal Address                | 1.3.6.1.4.1.1466.115.121.1.41 | Strings of characters that form a multi-line address in a physical mail system. Each component is separated by a "\$". For example, 1234 Main St.\$Austin, TX 78744\$USA.                                  |
| Protocol Information          | 1.3.6.1.4.1.1466.115.121.1.42 | Undefined.                                                                                                                                                                                                 |

| LDAP Syntax                    | OID                           | Description                                                                                                                                                                                                                                           |
|--------------------------------|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Presentation Address           | 1.3.6.1.4.1.1466.115.121.1.43 | String encoded OSI presentation address as defined in RFC 1278. For example, TELEX +00728722+RFC-1006+03+10.0.0.6                                                                                                                                     |
| Printable String               | 1.3.6.1.4.1.1466.115.121.1.44 | String of one or more printable ASCII alphabetic, numeric, and punctuation characters as defined in RFC 4517.                                                                                                                                         |
| RFC3672 Subtree Specification  | 1.3.6.1.4.1.1466.115.121.1.45 | Syntax based on subtree specification as defined as RFC 3672.                                                                                                                                                                                         |
| Supported Algorithm            | 1.3.6.1.4.1.1466.115.121.1.49 | Octet string based on the LDAP-encoding for a supported algorithm value that results from the BER encoding of a SupportedAlgorithm ASN.1 value.                                                                                                       |
| Telephone Number               | 1.3.6.1.4.1.1466.115.121.1.50 | String of printable international telephone number representations in E.123 format as defined in RFC 4517. For example, +1 512 904 5525.                                                                                                              |
| Teletex Terminal Identifier    | 1.3.6.1.4.1.1466.115.121.1.51 | Identifier and telex terminal as defined in RFC 4517.                                                                                                                                                                                                 |
| Telex Number                   | 1.3.6.1.4.1.1466.115.121.1.52 | String representing the telex number, country code, and answerback code as defined in RFC 4517. For example, 812374, ch, ehg.                                                                                                                         |
| UTC Time                       | 1.3.6.1.4.1.1466.115.121.1.53 | Character string representing the data and time in UTC Time format as defined as RFC 4517: YYMMDDHHMM[SS][(+ -HHMM)]Z], where Z is the coordinated universal time. For example, 0903051035Z, 0903051035-0500.                                         |
| LDAP Syntax Description        | 1.3.6.1.4.1.1466.115.121.1.54 | SyntaxDescription as defined in RFC4512.                                                                                                                                                                                                              |
| Substring Assertion            | 1.3.6.1.4.1.1466.115.121.1.58 | Syntax for assertion values in an extensible match as defined in RFC 4517.                                                                                                                                                                            |
| Authentication Password Syntax | 1.3.6.1.4.1.4203.1.1.2        | Encoded password storage syntax as defined in RFC 3112. For example, the syntax specifies the storage scheme in brackets as follows: <storage-scheme> \$<auth component>\$<auth value> For example: SSHA\$xdEZWRRqgyJk=\$egDEFDXvdeeEnXUEIDPnd39dkpe= |
| User Password Syntax           | 1.3.6.1.4.1.30221.1.3.1       | Encoded password storage syntax as defined in RFC 2307. For example, the syntax specifies the storage scheme in brackets as follows: {SSHA}XaljOF0ii3fOwCrU1klgBpWFayqSYs +5W1pMnw==                                                                  |
| Relative Subtree Specification | 1.3.6.1.4.1.30221.1.3.2       | Similar to the RFC 3672 subtree specification except it uses an LDAP search filter as the specification filter.                                                                                                                                       |

| LDAP Syntax                            | OID                     | Description                                                                      |
|----------------------------------------|-------------------------|----------------------------------------------------------------------------------|
| Absolute Subtree Specification         | 1.3.6.1.4.1.30221.1.3.3 | Syntax for a subset of entries in a subtree based on RFC 3672.                   |
| Sun-defined Access Control Information | 1.3.6.1.4.1.30221.1.3.4 | Syntax for access control instructions used in Sun Directory Servers.            |
| Compact Timestamp                      | 1.3.6.1.4.1.30221.2.3.1 | Syntax based on compact timestamp ISO 8601 format. For example, 20110306T102532. |

### Basic Attribute Syntax Properties

The Properties section displays the standard elements in an attribute syntax.

### Basic Properties of Attribute Syntaxes

| Attributes         | Description                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| Name               | Specifies the descriptive and unique name of the element.                                                      |
| Description        | Indicates an optional definition that describes the attribute syntax. The analogous LDIF equivalent is "DESC". |
| OID                | Specifies the globally unique object identifier assigned to the schema definition.                             |
| Used by Attributes | Indicates any attributes that use the corresponding attribute syntax.                                          |

### Viewing Attribute Syntaxes

You can view the attribute syntaxes on your Directory Server by using the Schema Editor on the Administrative Console, over LDAP using the `ldapsearch` tool, or some third party tool.

The Schema Editor displays all of the attribute syntaxes on your Directory Server instance. It shows the properties that are allowed within the attribute syntax.

#### To View Attribute Syntaxes Over LDAP

##### Steps

- Use `ldapsearch` to view the Directory Server's published list of attribute syntaxes using the multi-valued operational attribute, `ldapSyntaxes`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema \
--searchScope base "(objectclass=*)" ldapSyntaxes
```

### Using the Schema Editor Utilities

The Schema Editor provides a **Schema Utilities** tab that enables importing new schema elements from a file and to checking schema compliance. If importing a schema file, the system automatically checks for compliance prior to the import. If the definition does not meet schema compliance, the system will display an error message. However, it is good practice to first check if your file is compliant with your schema prior to importing it.

#### To Check Schema Compliance Using the Schema Editor

##### Steps

1. Start the Administrative Console.

2. On the main menu, click **LDAP Schema**.
3. On the Schema Editor, click the **Schema Utilities** tab.
4. Click **Import Schema Elements** to read in an LDIF file, or copy-and-paste a new schema definition, and then click **Validate Entries**. If there is a problem, an error will be generated.

## Modifying a Schema Definition

The Directory Server only allows schema definitions that are read-write to be edited. Schema elements indicated by the **Modifiable** column in the Schema Editor's tables can be modified.

### To Modify a Schema Definition

#### Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is running.
2. On the main menu, click **Schema**.
3. On the Schema Editor, click the **Object Classes** tab.
4. Select the object class that you want to modify, and then click **Actions -> Edit**. The Edit dialog box appears.
5. Make your changes, and then click **OK**.

## Deleting a Schema Definition

The Directory Server only allows schema definitions that are read-write to be deleted. In general, those schema definitions in the **Custom** folder of the Schema Editor can be removed from the system. You should make sure that the schema element is not currently in use.

### To Delete a Schema Definition

#### Steps

1. Start the Administrative Console. Check that the Directory Server instance associated with the console is also running.
2. On the main menu, click **Schema**.
3. On the **Schema Editor**, click the **Object Classes** tab.
4. Select the object class that you want to remove, and then click **Actions -> Delete**.
5. On the **Confirmation** dialog, click **Yes** if you are sure that you want to delete the schema element.

## Schema Checking

The PingDirectory Server provides full support for parsing all schema elements and provides access to all of its components. By default, the Directory Server enables schema checking for all operations, especially when importing data to the server or when modifying entries using the `ldapmodify` tool. Any schema violations will generate an error message to standard output.

### To View the Schema Checking Properties

#### Steps

- Use `dsconfig` to view the schema checking property.

```
$ bin/dsconfig get-global-configuration-prop \
 --property check-schema
```

## To Disable Schema Checking

### About this task

Although not recommended, you can use the `dsconfig` tool to disable the schema checking. This feature only applies to public backends. Schema checking is enforced on private backends, such as changes to the Configuration, Schema, Task, and others. An admin action alert will be generated when attempting to disable schema checking using `dsconfig` interactive or non-interactive mode. The alert provides alternatives to disabling schema checking.

### Steps

Run the `dsconfig` command and specify the `set-global-configuration-prop` subcommand to disable the `check-schema` property.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
 --set check-schema:false
```

The system generates an admin action alert providing alternate options to disabling schema checking. Press **Enter** to continue the process or following one of the suggested tasks:

```
One or more configuration property changes require administrative action or
confirmation/notification.
```

Those properties include:

- \* `check-schema`: Schema checking should only be disabled as a last resort since disabling schema checking harms performance and can lead to unexpected behavior in the server as well as the applications that access it. There are less severe options for addressing schema issues:
  1. Update the data to conform to the server schema.
  2. Modify the server schema to conform to the data. Contact support before modifying the server's default schema.
  3. Change the `single-structural-objectclass-behavior` property to allow entries to have no structural object class or multiple structural object classes.
  4. Change the `invalid-attribute-syntax-behavior` property to allow attribute values to violate their attribute syntax.
  5. Change the `allow-zero-length-values` property of the Directory String Attribute Syntax configuration to allow attributes with this syntax to have a zero length value.

```
Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

## Managing Matching Rule Uses

Matching Rule Use definitions map certain attribute types with a matching rule definition for extensible match filters. Extensible match filters allows clients to search using DN components, for example, `(ou:dn:=engineering)` or using an OID number, for example, `(cn:1.2.3.4:=Sam Carter)`. The matching rule use attribute publishes those attribute types and matching rule combinations, which can be used in extensible match assertions.

Typically, you define a matching rule use that is not normally specified in the attribute type definition. You can create new matching rule uses from the existing schema definitions by adding a custom schema file in the `<server-root>/config/schema` directory.

### Matching Rule Use Definitions

Matching Rule Use can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.4 as follows:

```
MatchingRuleUseDescription = "(" wsp
numericoid ; Object identifier
[sp "NAME" sp qdescrs] ; Short name descriptor
[sp "DESC" sp qdstring] ; Description
[sp "OBSOLETE"] ; Specifies if the rule use is inactive
sp "APPLIES" sp oid ; Attribute types
extensions wsp ")" ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-READ-ONLY" ; True or False. Specifies if the file that contains
 ; the schema element is marked as read-only in the
 ; server configuration.
```

### To View Matching Rule Uses

About this task

A matching rule use lists the attribute types that are suitable for use with an `extensibleMatch` search filter.

Steps

- Use `ldapsearch` to view the Directory Server's published list of matching rule uses using the multi-valued operational attribute, `matchingRuleUse`, which publishes the definitions on the Directory Server if any. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
"(objectclass=*)" matchingRuleUse
```

## Managing DIT Content Rules

DIT Content Rules provide a way to precisely define what attributes may be present in an entry, based on its structural object class, without specifically creating a new object class definition. The DIT content rules can define the mandatory and optional attributes that entries contain, the set of auxiliary object classes that entries may be part of, and any optional attributes from the structural and auxiliary object classes that are prohibited from being present in the entries.

### DIT Content Rule Definitions

DIT Content Rules can be specified with existing schema components and do not require additional code for its implementation. On the PingDirectory Server, only one DIT Content Rule may be defined for an entry in the structural object class.

The formal specification for attribute types is provided in RFC 4512, section 4.1.6 as follows:

```
DITContentRuleDescription = "(" wsp
numericoid ; Object identifier of the structural object class
the rule applies to
```

```
[sp "NAME" sp qdescrs] ; Short name descriptor
[sp "DESC" sp qdstring] ; Description
[sp "OBSOLETE"] ; Specifies if the rule is inactive
[sp "AUX" sp oids] ; List of allowed auxiliary object classes
[sp "MUST" sp oids] ; List of required attributes
[sp "MAY" sp oids] ; List of allowed attributes in the entry
[sp "NOT" sp oids] ; List of prohibited attributes in the entry
extensions wsp ")" ; Extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" / ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-READ-ONLY" ; True or False. Specifies if the file that contains
; the schema element is marked as read-only in
; the server configuration.
```

## To View DIT Content Rules

### Steps

- Use `ldapsearch` to view a multi-valued operational attribute `dITContentRules`, which publishes the definitions on the Directory Server if any. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
 "(objectclass=*)" dITContentRules
```

## Managing Name Forms

Name Forms define how entries can be named based on their structural object class. Specifically, name forms specify the structural object class to be named, as well as the mutually-exclusive set of required and allowed attributes to form the Relative Distinguished Names (RDNs) of the entries. Each structural object class may be associated with at most one name form definition.

### Name Form Definitions

Name Forms can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.7.2 as follows:

```
NameFormDescription = "(" wsp
numericoid ; object identifier
[sp "NAME" sp qdescrs] ; short name descriptor
[sp "DESC" sp qdstring] ; description
[sp "OBSOLETE"] ; not active
sp "OC" sp oid ; structural object class
sp "MUST" SP oids ; attribute types
[sp "MAY" sp oids] ; attribute types
extensions wsp ")" ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" / ; Specifies where the attribute type is defined
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-READ-ONLY" ; True or False. Specifies if the file that contains
; the schema element is marked as read-only in
; the server configuration.
```

## To View Name Forms

### Steps

- Use **ldapsearch** to view a multi-valued operational attribute `nameForms`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base "(objectclass=*)"
nameForms
```

## Managing DIT Structure Rules

DIT Structure Rules define which entries may be superior or subordinate to other entries in the DIT. Together with name forms, DIT Structure Rules determine how RDNs are added together to make up distinguished names (DNs). Because DITs do not have a global standard and are specific to a company's implementation, each DIT structure rule associates a name form with an object class and specifies each structure rule with an integer rule identifier, instead of an OID number. The identifier defines its relationship, either superior or subordinate, to another object class. If no superior rules are specified, then the DIT structure rule applies to the root of the subtree.

### DIT Structure Rule Definition

DIT Structure Rules can be specified with existing schema components and do not require additional code for its implementation.

The formal specification for attribute types is provided in RFC 4512, section 4.1.7.1 as follows:

```
DITStructureRuleDescription = "(" wsp
ruleid ; object identifier
[sp "NAME" sp qdescrs] ; short name descriptor
[sp "DESC" sp qdstring] ; description
[sp "OBSOLETE"] ; specifies if the rule is inactive
sp "FORM" sp oid ; OID or name form with which the rule is
associated
[sp "SUP" ruleids] ; Superior rule IDs
extensions wsp ")" ; extensions followed by a white space and ")"
```

The following extensions are specific to the PingDirectory Server and are not defined in RFC 4512:

```
extensions = /
"X-ORIGIN" / ; Specifies where the rule is defined
"X-SCHEMA-FILE" / ; Specifies which schema file contains the definition
"X-READ-ONLY" ; True or False. Specifies if the file that contains
 ; the schema element is marked as read-only in
 ; the server configuration.
```

## To View DIT Structure Rules

### Steps

- Use **ldapsearch** to view a multi-valued operational attribute `dITStructureRules`, which publishes the definitions on the Directory Server. The attribute is stored in the subschema subentry.

```
$ bin/ldapsearch --baseDN cn=schema --searchScope base \
"(objectclass=*)" dITStructureRules
```

## Managing JSON Attribute Values

The PingDirectory Server supports a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. The following is an example schema definition:

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema
cn: schema
attributeTypes: (jsonAttr1-OID NAME 'jsonAttr1' DESC 'test json attribute
support' EQUALITY jsonObjectExactMatch SYNTAX 1.3.6.1.4.1.30221.2.3.4 USAGE
userApplications)
objectClasses: (jsonObjectClass-OID NAME 'jsonObjectClass' AUXILIARY MAY
jsonAttr1)
```

**Note:** The EQUALITY matching rule should always be specified as `jsonObjectExactMatch` in the schema definition. Using the `jsonObjectFilterExtensibleMatch` is not valid in this case.

The `jsonObjectExactMatch` and `jsonObjectFilterExtensibleMatch` matching rules are provided to filter equality matching rule JSON object syntax. The following three additional matching rules are used in conjunction with the `jsonObjectExactMatch` and provide support for customizing the way that the server treats case sensitivity in JSON field names and in string values:

- `jsonObjectCaseSensitiveNamesCaseSensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseInsensitiveValues`
- `jsonObjectCaseInsensitiveNamesCaseSensitiveValues`

The `jsonObjectExactMatch` equality matching rule is used in evaluating equality filters in search operations, and for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. The order of elements in arrays is considered significant. Substring or approximate matching is not supported.

The `jsonObjectFilterExtensibleMatch` matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation for the LDAP SDK for Java. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.

The following are example searches using the `jsonObjectFilterExtensibleMatch` rule with available filter types.

Equals field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com -D "cn=Directory Manager"
-w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"equals", "field" : ["stuff", "onetype", "name"], "value" : "John Doe" })'
```

Contains field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com -D "cn=Directory Manager"
-w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"containsField", "field" : "age", "expectedType" : "number" })'
```

Greater than field filter type:

```
$ bin/ldapsearch -p 1389 -b dc=example,dc=com -D "cn=Directory Manager"
-w password '(jsonAttr1:jsonObjectFilterExtensibleMatch:={ "filterType" :
"greaterThan", "field" : "age", "value" : 26, "allowEquals" : true})'
```

## Configuring JSON Attribute Constraints

The PingDirectory Server can define a number of constraints for the fields included in JSON objects stored in values of a specified attribute type. Constraints that can be placed on a JSON field include:

- Requiring values of the field to have a specified data type.
- Indicating whether the field is required or optional.
- Indicating whether the field can have multiple values in an array. If a field is permitted to have array values, restrictions can also be placed on the number of elements that can be present in the array.
- Indicating whether the field can have a value that is the null primitive as an alternative to values of the indicated data type.
- Restricting values of string fields to a predefined set of values, that match a given regular expression, or a specified length.
- Restricting values of numeric fields with upper and lower bounds.

Any existing data that doesn't match newly-defined JSON constraints can still be decoded and managed by the server. Only new entries are subject to the new constraints. Attempts to alter existing entries with non-compliant JSON objects may require fixing those objects to make them conform to the new constraints.

The two global configuration properties that define schema constraints for JSON objects are `create-json-attribute-constraints` and `create-json-field-constraints` in `dsconfig`. In `dsconfig` interactive under advanced settings, the menu options are JSON Attribute Constraints and JSON Field Constraints. Configuration properties for each include:

- **attribute-type.** The name or object identifier of the attribute type with which the definition is associated. This attribute type must have the JSON object syntax. This property will be the naming attribute for the configuration entry.
- **allow-unnamed-fields.** A boolean value that indicates whether JSON objects, used as the values of attributes of the associated type, can include fields that are not referenced in the `attribute-value-constraints` object. If this is `false`, JSON objects will only be permitted to have the defined fields. If this is `true` (which is the default behavior), JSON objects are permitted to have fields that are not referenced, and no constraints are imposed on those fields.

Unless a schema definition is configured with `allow-unnamed-fields` set to `false`, it is only necessary to include information about fields whose values should be indexed or tokenized. However, it may be desirable to define other fields that are expected in order to ensure that clients will not be permitted to store invalid values. See the [Working with JSON Indexes](#) for information about indexing JSON attributes.

As with standard LDAP schema, JSON schema constraints are enforced for any changes made after the constraints are defined. If there are already JSON values in the data before a JSON schema is defined for that attribute type (or before changes are made), values that already exist may violate those constraints. JSON schema constraints will also be enforced for data provided in an LDIF import, so that entries containing JSON objects that violate these constraints will be rejected.

### JSON Field Constraints

| Property           | Description                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>field</code> | Specifies the path to the target field as a string, with periods to separate levels of hierarchy. If any field name in the hierarchy itself includes a period, that period should be escaped with a backslash. |

| Property                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>value-type</code>         | <p>Specifies the expected data type for the target field. Values can include:</p> <ul style="list-style-type: none"> <li>▪ <code>any</code>. The target field can have any value.</li> <li>▪ <code>boolean</code>. The target field must have a value of <code>true</code> or <code>false</code>.</li> <li>▪ <code>integer</code>. The target field must have a number that can be exactly represented as an integer.</li> <li>▪ <code>null</code>. The target field must have a value of <code>null</code>.</li> <li>▪ <code>number</code>. The target field must have a value that represents a valid JSON number</li> <li>▪ <code>object</code>. The target field must have a value that represents a valid JSON object. The <code>allowed-fields</code> array may contain additional elements that define constraints for the fields that may be present in the object.</li> <li>▪ <code>string</code>. The target field must have a value that represents a valid JSON string.</li> </ul> |
| <code>is-required</code>        | <p>Specifies whether the target field is required to be present. If it is present, its value must be either <code>true</code> or <code>false</code>. If it is absent, a default of <code>false</code> is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>is-array</code>           | <p>Indicates whether the target field can be an array. If the value can be an array, all of the elements of the array must be of the type specified in the <code>value-type</code> field. It can be present with a value that is one of the single strings listed below. If it is absent, a value of <code>prohibited</code> is assumed. Values include:</p> <ul style="list-style-type: none"> <li>▪ <code>required</code>. The target field must be an array with zero or more values of the specified type, and must not be a single value of the specified type.</li> <li>▪ <code>optional</code>. The target field may be an array with zero or more values of the specified type, or it may be a single value of the specified type.</li> <li>▪ <code>prohibited</code>. The target field must not be an array and may only be a single value of the specified type.</li> </ul>                                                                                                          |
| <code>allow-null-value</code>   | <p>Specifies whether the target field can have a value of <code>null</code> as an alternative to the specified <code>value-type</code>. If present, its value must be either <code>true</code> or <code>false</code>. If it is absent, a default of <code>false</code> is assumed. This has no effect if the <code>value-type</code> is <code>null</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>allow-empty-object</code> | <p>If the value of the target field is a JSON object (or an array of JSON objects), specifies whether empty objects are permitted. If present, the value must be either <code>true</code> (the object may have zero or more fields) or <code>false</code> (the object may have one or more fields). If it is absent, a default of <code>false</code> is assumed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>index-values</code>       | <p>Specifies whether values of the target field should be indexed in backends. If present, the value must be either <code>true</code> (the field should be indexed) or <code>false</code> (the field should not be indexed). If it is absent, a default of <code>false</code> is assumed. If <code>true</code>, the <code>value-type</code> must be <code>boolean</code>, <code>integer</code>, <code>null</code>, or <code>string</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>index-entry-limit</code>  | <p>Specifies the maximum number of entries in which a particular value may appear before the entry ID list for that value is no longer maintained. If present, the value must be an integer greater than or equal to one. If it is absent, the server will use the default index entry limit for the associated backend. This is only applicable if <code>index-values</code> is <code>true</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>prime-index</code>        | <p>Specifies whether backends should prime the contents of the JSON index database into memory when they are opened. This is ignored if the backend's <code>prime-all-indexes</code> property has a value of <code>true</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Property                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cache-mode</code>                       | Specifies the cache mode to use for the contents of the JSON index database. If the value is not specified, the backend's default cache mode will be used. If a cache mode of <code>cache-keys-only</code> is configured, priming will only load the internal nodes into memory for the index. If <code>no-caching</code> is configured, no priming is performed for the index.                                                                                                                                |
| <code>tokenize-values</code>                  | Specifies whether values of the target field should be tokenized in backends. If present, the value is either <code>true</code> (field values should be tokenized) or <code>false</code> . If it is absent, a value of <code>false</code> is assumed. If <code>true</code> , the <code>value-type</code> must be <code>string</code> .                                                                                                                                                                         |
| <code>allowed-values</code>                   | Specifies an explicit set of values that the target field is permitted to have. If present, the value must be an array of strings. Any attempt to use a value not in this array for the associated field is rejected. This can only be used with a <code>value-type</code> of <code>string</code> . If not present, any value can be used as long as it satisfies all other defined constraints.                                                                                                               |
| <code>allowed-value-regular-expression</code> | Specifies a regular expression that the target field will be required to match. If present, the value must be a single string or an array of strings representing valid regular expressions (which may require escaping to represent in JSON). Any attempt to use a value that does not match one of the provided regular expressions will be rejected. This can only be used with a <code>value-type</code> of <code>string</code> . If not present, values are not required to match any regular expression. |
| <code>minimum-numeric-value</code>            | Specifies the lower bound for values of the target field. If present, the value must be a single number (it can be an integer). Any attempt to use a value that is less than this number is rejected. This can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code> . If not present, no minimum numeric value applies.                                                                                                                                                  |
| <code>maximum-numeric-value</code>            | Specifies the upper bound for values of the target field. If present, the value must be a single number (it can be an integer). Any attempt to use a value that is more than this number is rejected. This can only be used with a <code>value-type</code> of <code>integer</code> or <code>number</code> . If not present, no maximum numeric value applies.                                                                                                                                                  |
| <code>minimum-value-length</code>             | Specifies the minimum number of characters allowed for values of the target field. If present, the value must be an integer. Any attempt to use a value with fewer characters than this number is rejected. This can only be used with a <code>value-type</code> of <code>string</code> . If not present, no minimum length applies.                                                                                                                                                                           |
| <code>maximum-value-length</code>             | Specifies the maximum number of characters allowed for values of the target field. If present, the value must be an integer. Any attempt to use a value with more characters than this number is rejected. This can only be used with a <code>value-type</code> of <code>string</code> . If not present, no maximum length applies.                                                                                                                                                                            |
| <code>minimum-value-count</code>              | Specifies the minimum number of elements that must be present in an array. If present, the value must be an integer. Any attempt to use an array with fewer elements is rejected. This can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code> . If not present, no minimum array value count applies.                                                                                                                                                          |
| <code>maximum-value-count</code>              | Specifies the maximum number of elements that must be present in an array. If present, the value must be an integer. Any attempt to use an array with more elements is rejected. This can only be used with an <code>is-array</code> value of <code>required</code> or <code>optional</code> . If not present, no maximum array value count applies.                                                                                                                                                           |

**Note:** When writing JSON objects in a local DB backend, field names and JSON primitive values of `null`, `true`, and `false` are always tokenized. Integers are either tokenized or compacted using their two's complement representation (other numbers are stored using string representations). Array and object sizes are compacted, and their contents are compacted based on their data types. String values are tokenized that match a recognizable format, including:

- Dates and times in common generalized time and ISO 8601 formats.
- UUIDs in which the alphabetic characters are either all uppercase or all lowercase.
- Strings of at least 12 bytes that are a valid base64 encoding.
- Strings of at least 6 bytes that are a valid hexadecimal encoding, in which the alphabetic characters are either all uppercase or all lowercase.

## To Add Constraints to JSON Attributes

### Steps

- Use the `dsconfig` tool (interactive or command line) to create and configure JSON attribute constraints. The following is a sample command:

```
$ bin/dsconfig create-json-attribute-constraints \
 --attribute-type appjson \
 --set enabled:true \
 --set allow-unnamed-fields:false
```

```
$ bin/dsconfig create-json-field-constraints \
 --attribute-type appjson \
 --json-field email.verified \
 --set value-type:boolean \
 --set is-required:true \
 --set index-values:true \
 --set tokenize-values:false \
 --set allow-null-value:true
```

```
$ bin/dsconfig create-json-field-constraints \
 --attribute-type appjson \
 --json-field email.type \
 --set value-type:string \
 --set is-required:true \
 --set index-values:true \
 --set tokenize-values:true \
 --set allowed-value:home \
 --set allowed-value:other \
 --set allowed-value:work \
 --set allow-null-value:false \
 --set minimum-value-length:1
```

```
$ bin/dsconfig create-json-field-constraints \
 --attribute-type appjson \
 --json-field email.value \
 --set value-type:string \
 --set is-required:true \
 --set index-values:true \
 --set tokenize-values:true \
 --set prime-index:true \
 --set allow-null-value:true \
 --set maximum-value-length:256 \
 --set minimum-value-length:1 \
 --set allowed-value-regular-expression:[-_+|\.\w\d]+@\w+\.\w{2,5}
```

## Managing Password Policies

The PingDirectory Server provides a flexible password policy system to assign, manage, or remove password policies for root and non-root users. The password policy contains configurable properties for password expiration, failed login attempts, account lockout and other aspects of password and account maintenance on the Directory Server. The Directory Server also provides a global configuration option and a per-user privilege feature that disables parts of the password policy evaluation for production environments that do not require a password policy.

This chapter presents the following topics:

### Viewing Password Policies

Password policies enforce a set of rules that ensure that access to data is not compromised through negligent password practices. The PingDirectory Server provides mechanisms to create and maintain password policies that determine whether passwords should expire, whether users are allowed to modify their own passwords, or whether too many failed authentication attempts should result in an account lockout. Many other options are available to fully configure a password policy for your PingData Platform system.

The Directory Server provides three out-of-the-box password policies that can be applied to your entries or as templates for configuring customized policies. The Default Password Policy is automatically applied to all users although it is possible to use an alternate password policy on a per-user basis. The Root Password Policy is enforced for the default root user, which uses a stronger password storage scheme (PBKDF2 rather than the salted 256-bit SHA-2 scheme) and also requires that a root user provide his or her current password to select a new password.

The Secure Password Policy provides a more secure option than the default policy that makes use of a number of features, including password expiration, account lockout, last login time and last login IP address tracking, password history, and a number of password validators.

#### CAUTION:

Using the Secure Password policy as-is may notably increase write load in the server by requiring updates to password policy state attributes in user entries and/or requiring users to change passwords more frequently. In environments in which write throughput is a concern (including environments spread across multiple data centers requiring replication over a WAN), it may be useful to consider whether the policy should be updated to reduce the number of entry updates that may be required.

### To View Password Policies

#### Steps

- You can view the list of password policies configured on the Directory Server using the `dsconfig` tool, in either interactive or non-interactive mode, or the Administrative Console. The following example demonstrates the process for obtaining a list of defined password policies in non-interactive mode:

```
$ bin/dsconfig list-password-policies
```

```
Password Policy : Type : password-attribute : default-password-storage-
scheme
-----:-----:-----:-----
Default Password Policy : generic : userpassword : Salted 256-bit SHA-2
Root Password Policy : generic : userpassword : PBKDF2
Secure Password Policy : generic : userpassword : PBKDF2
```

## To View a Specific Password Policy

### Steps

- Use `dsconfig` or the Administrative Console to view a specific password policy. In this example, view the Default Password Policy that applies to all uses for which no specific policy has been configured.

```
$ bin/dsconfig get-password-policy-prop \
 --policy-name "Default Password Policy"
```

```
Property : Value(s)

description : -
password-attribute : userpassword
default-password-storage-scheme : Salted SHA-1
deprecated-password-storage-scheme : -
password-validator : -
account-status-notification-handler : -
allow-user-password-changes : true
password-change-requires-current-password : false
force-change-on-add : false
force-change-on-reset : false
password-generator : Random Password Generator
require-secure-authentication : false
require-secure-password-changes : false
min-password-age : 0s
max-password-age : 0s
max-password-reset-age : 0s
password-expiration-warning-interval : 5d
expire-passwords-without-warning : false
allow-expired-password-changes : false
grace-login-count : 0s
lockout-failure-count : 0s
lockout-duration : 0s
lockout-failure-expiration-interval : 0s
require-change-by-time : -
last-login-time-attribute : ds-pwp-last-login-time
last-login-time-format : -
previous-last-login-time-format : -
idle-lockout-interval : 0s
password-history-count : 0s
password-history-duration : 0s
```

## About the Password Policy Properties

The Directory Server provides a number of configurable properties that can be used to control password policy behavior.

**Note:** To view a description of each of the password policy properties, see the *Ping Identity Directory Server Configuration Reference* that is bundled with the PingDirectory Server.

Some of the most notable properties include:

- allow-user-password-changes.** Specifies whether users can change their own passwords. If a user attempts to change his/her own password, then the server will consult this property for the user's password policy, and will also ensure that the access control handler allows the user to modify the configured password attribute.
- default-password-storage-scheme.** Specifies the names of the password storage schemes that are used to encode clear-text passwords for this password policy.

- **enable-debug.** When enabled, is used to debug password policy interaction. This property should be used in addition to the server's debug framework with a relevant debug target.
- **force-change-on-add.** Specifies whether users are required to change their passwords upon first authenticating to the Directory Server after their account has been created.
- **force-change-on-reset.** Specifies whether users are required to change their passwords after they have been reset by an administrator. An administrator is a user who has the `password-reset` privilege and the appropriate access control instruction to allow modification of other users' passwords.
- **idle-lockout-interval.** Specifies the maximum length of time that an account may remain idle (the associated user does not authenticate to the server) before that user is locked out. For accounts that do not have a last login time value, the password changed time or the account creation time will be used. If that information is not available, then the user will not be allowed to authenticate. It is strongly recommended that the server be allowed to run for a period of time with last login time tracking enabled (i.e., values for both `last-login-time-attribute` and `last-login-time-format` properties) to ensure that users have a last login time before enabling idle account lockout.
- **lockout-duration.** Specifies the length of time that an account is locked after too many authentication failures. The value of this attribute is an integer followed by a unit of seconds, minutes, hours, days, or weeks. A value of 0 seconds indicates that the account must remain locked until an administrator resets the password.
- **lockout-failure-count.** Specifies the maximum number of times that a user may be allowed to attempt to bind with the wrong password before that user's account becomes locked either temporarily (in which case the account will automatically be unlocked after a configurable length of time) or permanently (in which case an administrator must reset the user's password before the account may be used again). For example, if the value is set to 3, the user is locked out after three failed attempts, even if a fourth attempt is made with the correct password.
- **max-password-age.** Specifies the maximum length of time that a user can continue to use the same password before he or she is required to choose a new password. The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w). A minimum length of time can also be specified before the user is allowed to change the password.
- **password-change-requires-current-password.** Specifies whether users must include their current password when changing their password. This applies for both password changes made with the password modify extended operation as well as simple modify operations targeting the password attribute. In the latter case, if the current password is required then the password modification must remove the current value and add the desired new value (providing both the current and new passwords in the clear rather than using encoded representations).
- **password-expiration-warning-interval.** Specifies the length of time before a user's password expires that he or she receives notification about the upcoming expiration (either through the password policy or password expiring response controls). The value can be expressed in seconds (s), minutes (m), hours (h), days (d), or weeks (w).
- **password-retirement-behavior.** Specifies the behavior of a password that is allowed a retirement period before becoming invalid. This setting may be used by application service accounts that require a transition period while updating passwords. This is disabled by default.
- **password-validator.** Specifies the names of the password validators that are used with the associated password storage scheme. The password validators are invoked when a user attempts to provide a new password, to determine whether the new password is acceptable.
- **require-secure-authentication.** Indicates whether users with the associated password policy are required to authenticate in a secure manner. This might mean either using a secure communication channel between the client and the server, or using a SASL mechanism that does not expose the credentials.
- **require-secure-password-changes.** Indicates whether users with the associated password policy are required to change their password in a secure manner that does not expose the credentials.

**Note:** As an alternative to account lockout, a `failed-bind-response-delay` configuration property can be set on the LDAP Connection handler to instruct the server to introduce a delay (such as one second) into the process of returning a response to an unsuccessful bind operation. Delaying the

response to a failed bind only affects the connection on which the bind was attempted, and still limits the rate at which a malicious client can try to guess a user's password. However, it will not affect other attempts to authenticate as that user on other connections, so the legitimate user can still authenticate with the correct password.

## Modifying an Existing Password Policy

You can modify an existing password policy to suit your company's requirements.

**Note:** Password policies should be kept synchronized across all PingDirectory Server and Directory Proxy Server instances.

### To Modify an Existing Password Policy

#### Steps

- Use **dsconfig** (in interactive or non-interactive mode) or the Administrative Console to modify the configuration for any defined password policy. The following example sets some of the properties presented in the previous section for the default password policy using **dsconfig** in non-interactive mode:

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "max-password-age:90 days" \
 --set "password-expiration-warning-interval:14 days" \
 --set "lockout-failure-count:3" \
 --set "password-history-count:6"
```

## Creating a New Password Policy

You can create any number of password policies in the Directory Server using either the **dsconfig** tool (in interactive or non-interactive mode) or the Administrative Console.

### To Create a New Password Policy

#### Steps

- Use **dsconfig** (in interactive or non-interactive mode) or the Administrative Console to create a new password policy. The following example demonstrates the process for creating a new policy using **dsconfig** in non-interactive mode.

```
$ bin/dsconfig create-password-policy \
 --policy-name "Demo Password Policy" \
 --set "password-attribute:userpassword" \
 --set "default-password-storage-scheme:Salted SHA-256" \
 --set "force-change-on-add:true" \
 --set "force-change-on-reset:true" \
 --set "password-expiration-warning-interval:2 weeks" \
 --set "max-password-age:90 days" \
 --set "lockout-duration:24 hours" \
 --set "lockout-failure-count:3" \
 --set "password-change-requires-current-password:true"
```

### To Assign a Password Policy to an Individual Account

#### About this task

To indicate that a user should be subject to a particular password policy (rather than automatically inheriting the default policy), include the `ds-pwp-password-policy-dn` operational attribute in that

user's entry with a value equal to the DN of the desired password policy for that user. This attribute can be explicitly included in a user's entry, or it can be generated by a virtual attribute, which makes it easy to apply a custom password policy to a set of users based on a flexible set of criteria.

### Steps

1. Create a file (`assign.ldif`) with the following contents:

```
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
Policies,cn=config
```

2. Use `ldapmodify` to apply the modification to the user's entry.

```
$ bin/ldapmodify --filename assign.ldif
```

### To Assign a Password Policy Using a Virtual Attribute

#### About this task

It is possible to automatically assign a custom password policy for a set of users using a virtual attribute. The virtual attribute can be configured so that it can use a range of criteria for selecting the entries for which the virtual attribute should appear.

### Steps

1. Create an LDIF file, which may be used to add a group to the server.

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Engineering Managers,ou=groups,dc=example,dc=com
objectClass: groupOfUniqueNames
objectClass: top
cn: Engineering Managers
uniqueMember: uid=user.0,ou=People,dc=example,dc=com ou: groups
```

2. Use `ldapmodify` to add the entries to the server.

```
$ bin/ldapmodify --defaultAdd --filename groups.ldif
```

3. Use `dsconfig` to create a virtual attribute that will add the `ds-pwp-password-policy-dn` attribute with a value of `cn=Demo Password Policy,cn=Password Policies,cn=config` to the entries for all users that are members of the `cn=Engineering Managers,ou=Groups,dc=example,dc=com` group.

```
$ bin/dsconfig create-virtual-attribute \
--name "Eng Mgrs Password Policy" \
--type user-defined \
--set "description:Eng Mgrs Grp PWPolicy" \
--set enabled:true \
--set attribute-type:ds-pwp-password-policy-dn \
--set "value:cn=Demo Password Policy,cn=Password Policies,cn=config" \
--set "group-dn:cn=Engineering Managers,ou=Groups,dc=example,dc=com
```

4. Use `ldapsearch` to verify that a user in the group contains the assigned password policy DN.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
```

```
ds-pwp-password-policy-dn
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Demo Password Policy,cn=Password
Policies,cn=config
```

## Deleting a Password Policy

You can delete a password policy using either the `dsconfig` tool (in interactive or non-interactive mode) or the Administrative Console.

### To Delete a Password Policy

About this task

Custom password policies may be removed using either the `dsconfig` tool (in interactive or non-interactive mode) or the Administrative Console).

Steps

- Run the `dsconfig` command with the `delete-password-policy` subcommand to remove a password policy.

```
$ bin/dsconfig delete-password-policy \
 --policy-name "Demo Password Policy"
```

## Modifying a User's Password

There are two primary ways to change user passwords in the Directory Server:

- Perform a modify operation which replaces the value of the password attribute (often `userPassword`). Note that in some configurations, when a user attempts to change his or her own password it may be necessary to perform the modification by removing the password value and adding the desired new value to demonstrate that the user knows the current password value.
- Use the password modify extended operation to change the password. Note that if a user is changing his or her own password, it may be necessary to provide the current password value. The server will allow a new password to be provided (assuming that the new password is acceptable to all configured password validators), or it may automatically generate a new password for the user.

Note that regardless of the mechanism used to change the password, all password values should be provided in clear text rather than pre-encoded, and the user will be required to have sufficient access control rights to update the password attribute in the target user's entry. Further, when one user attempts to change the password for another user, then the requester will be required to have the `password-reset` privilege.

### Validating a Password

The requirements that the server will impose for a password change can be displayed to users. The `get password quality requirements extended` operation can be used to retrieve information about the requirements, which can then be sent to an end user before an attempted password change. These requirements can also be used to enable client-side validation, so that any password problems can be identified before it is sent to the server. The `password validation details request control` can be included in an `add` or `modify` request, or a `password modify extended` request, to identify which validation requirements were not met by the password provided in the request.

Password validators can be configured with user-friendly messages that describe the password requirements, and the messages that should be returned if a proposed password does not satisfy those requirements. The server will generate these messages if they are not provided in the configuration.

Password validator properties include **validator-requirement-description** and **validator-failure** message. The following is a simple password validator configuration that requires passwords to contain a minimum of five characters, and lists custom validator messages:

```
$ dsconfig create-password-validator \
 --validator-name "Minimum 5 Characters Password Validator" \
 --type length-based --set enabled:true \
 --set "validator-requirement-description:The password must contain
 at least 5 characters." \
 --set "validator-failure-message:The password did not contain
 at least 5 characters." \
 --set min-password-length:5
```

After the password validator is created, it should be assigned to a Password Policy to take affect:

```
$ dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Minimum 5 Characters Password Validator"
```

### Retiring a Password

An account password can be retired and rotated out of service, instead of immediately invalidated. This enables a new password to be assigned to an account while keeping the original password valid for a period of time to enable a transition. This is useful for application service accounts that require uninterrupted authentication with the server.

This behavior is disabled by default, but can be enabled in the password policy configuration by setting the **password-retirement-behavior** and **maximum-retired-password-age** properties.

To manually retire an account password or purge a password that has been retired, use the **ldapmodify** and **ldappasswordmodify** commands with options **--retireCurrentPassword** and **--purgeCurrentPassword**. To use these commands on an account, the password policy that governs the account must have the **password-retirement-behavior** enabled.

### To Change a User's Password using the Modify Operation

#### Steps

- Use **ldapmodify** to change a user's password by replacing the `userPassword` attribute.

```
$ bin/ldapmodify
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
replace: userPassword
userPassword: newpw
```

### To Change a User's Password using the Password Modify Extended Operation

#### Steps

- Use **ldappasswordmodify** to request that the Password Modify extended operation be used to modify a user's password.

```
$ bin/ldappasswordmodify --authzID dn:uid=jdoe,ou=People,dc=example,dc=com \
 --newPassword newpw
```

## To Use an Automatically-Generated Password

### Steps

- Use `ldappasswordmodify` to automatically generate a new password for a user.

```
$ bin/ldappasswordmodify --authzID "u:user.1"
```

```
The LDAP password modify operation was successful
Generated Password: fbi27oqy
```

## Enabling YubiKey Authentication

Users can be enabled to authenticate with YubiKey devices (available from Yubico), which generate secure one-time passwords, with the UNBOUNDID-YUBIKEY-OTP SASL mechanism. A YubiKey device generates a different password for every authentication attempt, and that one-time password is sent to a validation service to ensure that it is genuine and has not been used in an earlier authentication attempt. Although it is possible to use this one-time password as the only proof of identity, it is typically combined with a static password as a form of two-factor authentication.

YubiKey authentication requires server configuration and the addition of this capability to a user entry. Configuration of a client ID and API key to use when communicating with the validation service is also required. The API key is a shared secret between the YubiKey validation service and the client that is interacting with it, and is used when generating digital signatures so that both the server and the YubiKey validation service can ensure that the peer server is genuine.

All server and user entry configuration details are available in the *Security Guide*.

## Enabling Social Login

Authentication involving credentials that do not reside in, or cannot be forwarded to or validated by the Directory Server (such as social login through Facebook, Google, or Twitter) can be enabled with the the UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL mechanism. The bind request will not include any credentials, and authentication with this mechanism will not actually change the state of the underlying client connection. The server will behave as if the bind request included the retain identity request control, regardless of whether or not that control was included.

Bind requests using this mechanism can include any request controls that are permitted with other bind requests. If the externally-processed authentication is successful, the client can include the get password policy state issues request control in the bind request to obtain information about any password policy state issues that can cause the Directory Server authentication attempt to fail. The password policy request control can also be included to obtain certain password policy state warnings and errors, or to look for the password expired/password expiring controls in the bind response.

All server and user entry configuration details are available in the *PingDirectory Server Security Guide*.

## Managing User Accounts

The Directory Server provides a user management utility, the `manage-account` tool, that provides a means to quickly view and manipulate a number of password and account policy properties for a user or group of users.

**Note:** A disabled account status (for example, `account-is-disabled: true`) is different from an *account lockout* due to password policy. Unlocking a user account can be done with the `manage-account` tool. A disabled account requires the administrator to enable the account; password resets are not involved.

PingDirectory Server also hosts the Self Service Account Manager project at <https://github.com/pingidentity/ssam>, which is a customizable web application allowing users to perform their own account

registration, profile updates, and password changes. The project is for testing and development purposes, and is not a supported PingDirectory Server application.

### To Return the Password Policy State Information

#### Steps

- Use **manage-account** to get information about the account's password policy.

```
$ bin/manage-account get-all \
 --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Password Policy DN: cn=Demo Password Policy,cn>Password Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration: 1209600
Seconds Until Password Expiration Warning: 0
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count: 3
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

### To Determine Whether an Account is Disabled

#### Steps

- Use **manage-account** to determine whether a user's account has been disabled.

```
$ bin/manage-account get-account-is-disabled \
 --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: true
```

### To Disable an Account

#### Steps

- Use **manage-account** to disable a user's account.

```
$ bin/manage-account set-account-is-disabled \
 --operationValue true --targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: true
```

## To Enable a Disabled Account

### Steps

- Use `manage-account` to enable a user's account.

```
$ bin/manage-account clear-account-is-disabled \
--targetDN uid=user.1,ou=People,dc=example,dc=com
```

```
Account Is Disabled: false
```

## To Assign the Manage-Account Access Privileges to Non-Root Users

### About this task

Non-root users (e.g., `uid=admin`) with admin right privileges require access control permission to interact with certain password policy operational attributes when using the `manage-account` tool.

For example, the presence of the `ds-pwp-account-disabled` operational attribute in an entry determines that the entry is disabled. If the non-root admin user does not have the access privilege to read or interact with the `ds-pwp-account-disabled` operational attribute, the `manage-account` tool may report that the account is active. An account is considered active if the `ds-pwp-account-disabled` operational attribute does not exist in the entry or if the admin user does not have permission to see it.

Use the following procedure to give access rights to the non-root admin user.

### Steps

1. Create a non-root user admin account, such as `uid=admin,dc=example,dc=com`. Grant the `password-reset` privilege to the account. See step 1 and 6 in the Configuring Administrators section for more information.
2. Run the `manage-account` tool to view the account status for an account.

```
$ bin/manage-account get-all \
--targetDN uid=user.0,ou=People,dc=example,dc=com
```

```
Password Policy DN: cn=Default Password Policy,cn=Password
Policies,cn=config
Account Is Disabled: false
Account Expiration Time:
Seconds Until Account Expiration:
Password Changed Time: 19700101000000.000Z
Password Expiration Warned Time:
Seconds Until Password Expiration:
Seconds Until Password Expiration Warning:
Authentication Failure Times:
Seconds Until Authentication Failure Unlock:
Remaining Authentication Failure Count:
Last Login Time:
Seconds Until Idle Account Lockout:
Password Is Reset: false
Seconds Until Password Reset Lockout:
Grace Login Use Times:
Remaining Grace Login Count: 0
Password Changed by Required Time:
Seconds Until Required Change Time:
Password History:
```

3. Grant access control privileges to an account. The following allows access to manage accounts to a helpdesk user. Depending on the configuration requirements, this user may also need the `permit-get-password-policy-state-issues` and `password-reset` privileges.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword||ds-pwp-last-login-time||ds-pwp-password-
changed-by-required-time||ds-pwp-reset-time||ds-pwp-warned-time||
ds-pwp-account-disabled||ds-pwp-account-expiration-time||ds-pwp-password-
policy-dn||ds-pwp-auth-failure||ds-pwp-last-login-ip-address||
ds-pwp-retired-password||ds-pwp-account-activation-time||pwdReset||
pwdChangedTime||pwdAccountLockedTime")
(version 3.0; acl "Grant full access to PWP related attributes to
helpdesk"; allow (all) userdn="ldap:///uid=helpdesk,dc=example,dc=com";)
```

4. Run the `manage-account` tool to disable an account. The following command sets the `account-is-disabled` property to true for the `uid=user.0,dc=example,dc=com`.

```
$ bin/manage-account set-account-is-disabled \
--targetDN uid=user.0,ou=People,dc=example,dc=com \
--operationValue true
```

```
Account Is Disabled: true
```

5. Run the `ldapsearch` tool to view the presence of the `ds-pwp-account-disabled` operational attribute in the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" "+"
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-account-disabled: true
```

## Disabling Password Policy Evaluation

The Directory Server provides a global configuration property (`disable-password-policy-evaluation`) that can be used to disable most password policy evaluation processing. This provides a convenience for those production environments that do not require password policy support. If the `disable-password-policy` property is set to true, passwords will still be encoded and evaluated, but only account expiration and account disabling will be in effect. All other password policy properties, such as password expiration, lockout, and force change on add or reset, are ignored.

The server also supports the use of a `bypass-pw-policy` privilege, which can be used to skip password policy evaluation for operations on a per-user basis. If a user has this privilege, then they will be allowed to perform operations on user entries that would normally be rejected by the password policy associated with the target entry. Note that this privilege will not have any effect for bind operations.

### To Globally Disable Password Policy Evaluation

#### Steps

- Use `dsconfig` to set the `disable-password-policy-evaluation` property globally for the Directory Server.

```
$ bin/dsconfig --no-prompt set-global-configuration-prop \
--set "disable-password-policy-evaluation:false"
```

## To Exempt a User from Password Policy Evaluation

### Steps

- Use `ldapmodify` to add the `bypass-pw-policy` privilege to a user entry.

```
$ bin/ldapmodify
dn: uid=user.1,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: bypass-pw-policy
```

## Managing Password Validators

A password validator is a password policy component that is used to determine if a new password is acceptable. A password policy can be configured with any number of password validators. If a password policy is configured with multiple password validators, then all of them must consider a proposed new password acceptable before it will be allowed.

### Password Validators

The PingDirectory Server offers a number of types of password validators, including those listed in the following table. It is also possible to use the Server SDK to create custom password validators with whatever constraints are necessary for your environment.

### Password Validators

| Password Validators                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attribute Value                    | Ensures that the proposed password does not match the value of another attribute in the user's entry. The validator can be configured to look in all attributes or in a subset of attributes. It can perform forward and reverse mapping, and it can also reject values which are substrings of another attribute.                                                                                                                                |
| Character Set                      | Ensures that the proposed password contains a sufficient number of characters from one or more user-defined character sets. For example, the validator can ensure that passwords must have at least one lowercase letter, one uppercase letter, one digit, and one symbol.                                                                                                                                                                        |
| Commonly-Used Passwords Dictionary | Ensures that the proposed password is not one of 10,000 commonly used passwords. These are words that are common for attackers to use when trying to access user accounts. The Commonly-Used Passwords validator is invoked by the Secure Password Policy by default. The word list is located in <code>&lt;server-root&gt;/config/commonly-used-passwords.txt</code> , and can be used to create a custom validator, but should not be modified. |
| Dictionary                         | Ensures that the proposed password is not present in a specified dictionary file, optionally also testing the password with all characters in reverse order. A large dictionary file is provided with the server, but the administrator can supply an alternate dictionary. In this case, then the dictionary must be a plain-text file with one word per line.                                                                                   |
| Haystack Password Validator        | Ensures that the proposed password is secure based on a combination of its length and the types of characters that it contains. For example, a longer password containing only lowercase letters may be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols. This is based on the Gibson Research Corporation Password Haystacks concept.                                                  |

| Password Validators                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Length-Based Password Validator     | Ensures that the number of characters in the proposed new password is within an acceptable range. Both a maximum and minimum number of characters may be specified.                                                                                                                                                                                                                                                                                                                                                                                                          |
| Regular Expression Validator        | Ensures that a proposed password either matches or does not match a given regular expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Repeated Characters                 | Ensures that a proposed password does not contain a substring in which the same character is repeated more than a specified number of times (for example, "aaaaa" or "aaabbb"). The validator can be configured to operate in a case-sensitive or case-insensitive manner, and you can also define custom sets of equivalent characters (for example, you could define all digits as equivalent, so the proposed password could not contain more than a specified number of consecutive digits).                                                                             |
| Similarity-Based Password Validator | Ensures that the proposed new password is not too similar to the current password, using the Levenstein Distance algorithm, which calculates the number of characters that need to be inserted, removed, or replaced to transform one string into another. Note that for this password validator to be effective, it is necessary to have access to the user's current password. Therefore, if this password validator is to be enabled, the <code>password-change-requires-current-password</code> attribute in the password policy configuration must also be set to true. |
| Unique Characters                   | Ensures that the proposed password contains at least a specified minimum number of unique characters, optionally using case-insensitive validation.                                                                                                                                                                                                                                                                                                                                                                                                                          |

### Configuring Password Validators

You can use the `dsconfig` configuration tool or the Administrative Console to configure or modify any password validators. Once you have defined your password validators, you can add them to an existing password policy. The following example procedures show the `dsconfig` non-interactive commands necessary to carry out such tasks. If you use `dsconfig` in interactive command-line mode, you can access the Password Validator menu in the Basic Objects menu. For more details on the password validator properties, see the *PingDirectory Server Configuration Reference*.

#### To View the List of Defined Password Validators

##### Steps

- Use `dsconfig` to view the set of password validators defined in the Directory Server.

```
$ bin/dsconfig --no-prompt list-password-validators
```

#### To Configure the Attribute Value Password Validator

##### Steps

- Use `dsconfig` to edit the existing default configuration for the Attribute Value Password Validator. For example, the following change configures the validator to only examine a specified set of attributes..

```
$ bin/dsconfig set-password-validator-prop \
--validator-name "Attribute Value" \
--set match-attribute:cn \
--set match-attribute:sn \
--set match-attribute:telephonenumber \
--set match-attribute:uid
```

2. Update an existing password policy to use the Attribute Value Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Attribute Value"
```

3. Test the Attribute Value Password Validator by submitting a password that is identical to one of the configured attributes (cn, sn, telephonenumber, uid).

```
$ bin/ldappasswordmodify --authzID "uid=user.0,ou=People,dc=example,dc=com" \
 --newPassword user.0
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in the
server: The provided password was found in another attribute in the user
entry
```

## To Configure the Character Set Password Validator

### Steps

1. Use **dsconfig** to edit the existing default configuration. In this example, we change the requirement for special characters making them optional in a password, and add a requirement that at least two digits must be included in the password. Thus, in this example, all newly created passwords must have at least one lowercase letter, one uppercase letter, two digits, and optionally any special characters listed.

```
$ bin/dsconfig set-password-validator-prop \
 --validator-name "Character Set" \
 --remove character-set:1:0123456789 \
 --remove "character-set:1:~\!@#\$\%^&*()-_+=[]{}|;:,.<>/?" \
 --add character-set:2:0123456789 \
 --add "character-set:0:~\!@#\$\%^&*()-_+=[]{}|;:,.<>/?" \
 --set allow-unclassified-characters:false
```

2. Update an existing password policy to use the Character Set Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Character Set"
```

3. Test the Character Set Password Validator by submitting a password that meets the requirements (one lowercase letter, one uppercase letter, two digits). The following example should reject the given password because it does not pass the Character Set Password Validator.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abab1
```

## To Configure the Length-Based Password Validator

### Steps

1. Use **dsconfig** to edit the existing default configuration. In this example, we set the required minimum number of characters in a password to five.

```
$ bin/dsconfig create-password-validator \
 --validator-name "Length-Based Password Validator" \
 --set max-password-length:5 --set min-password-length:5
```

2. Update an existing password policy to use the Length-Based Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
```

```
--set "password-validator:Length-Based Password Policy"
```

3. Test the Length-Based Password Validator by submitting a password that has fewer than the minimum number of required characters.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword abcd
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined in
the server: The provided password is shorter than the minimum required
length of
5 characters
```

## To Configure the Regular Expression Password Validator

### Steps

1. Use `dsconfig` to create a Regular Expression password validator. The following password validator checks that the password contains at least one number, one lowercase letter, and one uppercase letter with no restrictions on password length. If the password matches the regular expression, then it will be accepted. When using the following command, remember to include the LDAP/LDAPS connection parameters (host name and port), bind DN, and bind password.

```
$ bin/dsconfig create-password-validator \
 --validator-name "Regular Expression" \
 --type regular-expression --set enabled:true \
 --set "match-pattern:^\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-Z])\w*$" \
 --set match-behavior:require-match
```

2. Update an existing password policy to use the Regular Expression validator.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Regular Expression"
```

3. Test the Regular Expression Validator by submitting a password that meets the requirements (contains one number, one lowercase letter, and one uppercase letter), then run it again with a password that does not meet these requirements.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaA1
```

```
The LDAP password modify operation was successful
```

4. Try another password. The following password should fail, because no uppercase letter is present.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" --newPassword baaa1
```

```
Error Message: The provided new password failed the validation checks
defined in the server: The provided password is not acceptable because it
does
not match regular expression pattern '^\w*(?=\w*\d)(?=\w*[a-z])(?=\w*[A-
Z])\w*$'
```

## To Configure the Repeated Character Password Validator

### Steps

1. Use `dsconfig` to edit the existing default configuration.

- In this example, we set the maximum consecutive length of any character to 3. For example, the following validator rejects any passwords, such as "baaaa1" or "4eeeb", etc.

```
$ bin/dsconfig set-password-validator-prop \
 --validator-name "Repeated Characters" \
 --set max-consecutive-length:3
```

- Or, you can configure the validator to reject any character from a pre-defined character set that appears more than the specified number of times in a row (2). You can also specify more than one character set. For example, the following validator defines two character sets: [abc] and [123]. It rejects any passwords with more than two consecutive characters from a character set. Thus, "aaa", "bbb", "ccc", "abc", or "123" and so on fails, but "12a3" is okay.

```
$ bin/dsconfig set-password-validator-prop \
 --validator-name "Repeated Characters" \
 --set character-set:123 --set character-set:abc
```

2. Update an existing password policy to use the Repeated Character Password Validator.

```
$ bin/dsconfig --no-prompt set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Repeated Characters"
```

3. Test the Repeated Character Validator by submitting a password that has more than the maximum allowable length of consecutive characters.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" \
 --newPassword baaa1
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined
in the server: The provided password contained too many instances of the
same
character appearing consecutively. The maximum number of times the same
character may appear consecutively in a password is 2
```

## To Configure the Similarity-Based Password Validator

### Steps

1. Use `dsconfig` to edit the existing default configuration. In this example, we set the minimum number of differences to 2.

```
$ bin/dsconfig set-password-validator-prop \
 --validator-name "Similarity-Based Password Validator" \
 --set min-password-difference:2
```

2. Update an existing password policy to use the Similarity-Based Password Validator. The `password-change-requires-current-password` property must be set to TRUE, so that the password policy will ensure that the user's current password is available when that user is choosing a new password.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Similarity-Based Password Validator" \
 --set password-change-requires-current-password:true
```

3. Test the Similarity-Based Password Validator by submitting a password that has fewer than the minimum number of changes (e.g., 2). The `ldappasswordmodify` command requires the `--currentPassword` option when testing the Similarity-Based Password Validator.

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" \
 --currentPassword abcde --newPassword abcdd
```

```
The LDAP password modify operation failed with result code 49
```

### To Configure the Unique Characters Password Validator

#### Steps

1. Use `dsconfig` to edit the existing default configuration. In this example, we set the minimum number of unique characters that a password is allowed to contain to 3.

```
$ bin/dsconfig set-password-validator-prop \
 --validator-name "Similarity-Based" --set min-unique-characters:3
```

2. Update an existing password policy to use the Unique Characters Password Validator.

```
$ bin/dsconfig set-password-policy-prop \
 --policy-name "Default Password Policy" \
 --set "password-validator:Unique Characters"
```

3. Test the Unique Characters Password Validator by submitting a password that has fewer than the minimum number of unique characters (e.g., 3).

```
$ bin/ldappasswordmodify \
 --authzID "uid=user.0,ou=People,dc=example,dc=com" \
 --newPassword aaaaa
```

```
The LDAP password modify operation failed with result code 53
Error Message: The provided new password failed the validation checks
defined
in the server: The provided password does not contain enough unique
characters.
The minimum number of unique characters that may appear in a user password
is 3
```

## Managing Replication

---

The PingDirectory Server provides a robust replication system to ensure high availability and fast failover in production environments. Write requests can be handled by every server in the topology with the replication component performing immediate synchronization with other members. The replicated server environment ensures that LDAP clients can seamlessly fail over to another server instance.

This chapter presents the architectural overview of replication, detailed configuration steps, ways to monitor replication as well as troubleshooting steps:

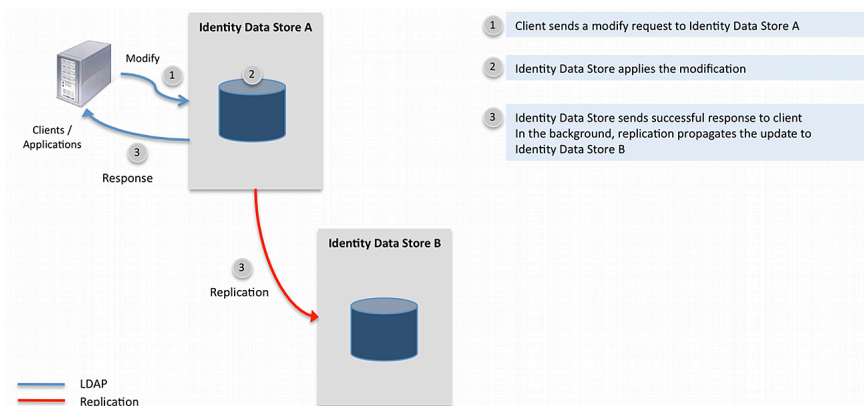

### Overview of Replication

Replication is a data synchronization mechanism that ensures that updates made to a database are automatically replayed to other servers. Replication improves data availability when unforeseen or planned outages occur, and improves search performance by allowing client requests to be distributed across multiple servers.

By default, all Directory Servers participating in replication are writable, so that LDAP clients can perform updates at any of these Directory Server instances. These updates will be propagated to the other servers automatically in the background and applied in the same order as the updates were entered. The

replication process flow is designed to immediately propagate changes to the other replicas in the topology with little or no latency.

The following figure demonstrates the basic flow of replication.

### MY TITLE Replication Process Flow

The benefits of replication can be summarized as follows:

- **High-Availability.** Because the data is fully replicated on all other servers in the topology, replication allows participating servers to process all types of client requests. This mitigates any availability issues when a particular server is down due to a planned maintenance or unplanned outage. For those servers that are temporarily unavailable, they will receive updates when they become available again.
- **Improved Search Performance.** Search requests may be directed to any Directory Server participating in replication, which improves search performance over systems that only access single servers. Note, however, that replication does not improve write throughput since updates need to be applied at all servers.
- **WAN Friendly Data Synchronization.** The built-in compression feature in the replication protocol allows efficient propagation of updates over WAN links.

### Replication Versus Synchronization

Replication is not a general purpose synchronization facility as it creates replicas with exact copies of the replicated data. Synchronization, on the other hand, can transform data between two different Directory Information Tree (DIT) structures, map attribute types, synchronize subsets of branches and specific object classes. The differences between replication and synchronization are illustrated as follows:

- **Replication cannot Synchronize between Different DIT Structures.** The DN of replicated entries must be the same on all servers. In some situations, it may be desirable to replicate entries with the help of DN mapping that are under different base DNs, but represent the same data, for example `uid=john.doe,ou=people,o=corp` on one server may represent the same user as `uid=john.doe,ou=people,dc=example,dc=com`. This is not supported by replication. Synchronization fully supports this feature.
- **Replication cannot Map Attribute Types or Transform Attribute Values.** In some situations, it may be necessary to map attribute types or transform attribute values when synchronizing data from one server to another. Replication does not support either attribute type mappings or attribute value transformations.
- **Replication does Not Support Fractional Replication.** Replication cannot be configured to replicate a subset of the attribute types from the replicated data set. Synchronization fully supports this feature.
- **Replication does Not Support Sparse Replication.** Replication cannot be configured to replicate entries with a particular object class only. Synchronization fully supports this feature.
- **Replication Requires Full Control of Replicated Data.** When two servers participate in replication, both servers implicitly trust each other using public key cryptography and apply all updates received via replication, which is considered an internal operation. While trust between servers is established

between two endpoint servers, synchronization does not require full control of the data. Disparate server system endpoints can be synchronized, such as a PingDirectory Server and a RDBMS database endpoint with each fully in control of its own data.

If replication does not meet your data synchronization requirements, consider using PingDataSync Server, which provides the versatility and robust performance required for most production environments.

## Replication Terminology

The following replication terms are used throughout this chapter.

### Replication Terminology

| Term                 | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Assured Replication  | For applications that require immediate access to replicated data or require data consistency over response time, administrators can configure <i>assured replication</i> , where data is guaranteed to replicate <i>before</i> the response is returned to the client.                                                                                                                                                  |
| Change Number        | A 64-bit number used to consistently order replication updates across the entire topology. It is composed of 3 fields: the timestamp of the update (measured in milliseconds since 00:00:00 UTC, January 1, 1970), the Replica ID, and the Sequence Number.                                                                                                                                                              |
| Conflict             | Client updates made at different replicas affecting the same entry may be found in conflict when the updates are replayed at another replica. The Change Number of each update allows most of these conflicts to be resolved automatically. Certain updates, such as adding an entry with different attribute values at two servers simultaneously, result in conflicts that are flagged for required manual resolution. |
| Eventual Consistency | When not using assured replication, recent updates from LDAP clients are not immediately present at all servers. Out-of-sync data will be eventually synchronized and will be consistent on all servers. The network latency typically controls how long a given update takes to replicate.                                                                                                                              |
| Global Administrator | The administrative user with full rights to manage the replication topology. The user is created at the time of replication enable between two non-replicating servers and thereafter copied to newly enabled servers. The replication command-line utility expects the user name of the Global Administrator (by default, admin). The user is stored in <code>cn=Topology Admin Users,cn=Topology,cn=config</code> .    |
| Historical Data      | Historical Data are records of attribute value changes as a result of an LDAP Modify Operation. Historical Data is stored in the <code>ds-sync-hist</code> attribute of the target entry. This information allows replication to resolve conflicts from simultaneous LDAP Modify operations automatically.                                                                                                               |
| Location             | The collection of servers that may have similar performance characteristics when accessed from this Directory Server or reside in the same data center or city. A separate location setting may be defined for each data center, such as Austin, London, Chicago, etc. Location settings are used in the selection of the WAN Gateway server.                                                                            |
| Modify Conflict      | A conflict between two LDAP Modify operations. Conflicts arising from LDAP Modify operations are automatically resolved.                                                                                                                                                                                                                                                                                                 |

| Term                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Naming Conflict          | Any conflict other than Modify Conflicts. Naming conflicts typically include an operation that changes the DN of the target entry, creates an entry, or deletes an entry at one Replica.                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Replica                  | The component in the Directory Server that handles interaction with a single replication domain, for example, the <code>dc=example,dc=com</code> replication domain within the <code>userRoot</code> backend.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Replica ID               | The unique identifier of a replica that is set automatically in the corresponding Replication Domain configuration entry at each participating server. The replica ID identifies the source of each update in the replication topology.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Replica State            | A list of the most recent change numbers of replication updates that have been applied to a replica. There can be at most one change number from each replica in the state. The replica state helps the Replication Server component to determine which updates the Replica has not received yet.                                                                                                                                                                                                                                                                                                                                                                   |
| Replication              | An automated background process that pushes directory server data changes to all other replicas.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Replication Changelog    | <p>A backend maintained by each replication server independently that records updates from each replica. This backend is distinct from the LDAP Changelog and the two should not be confused. The main distinction is as follows:</p> <ul style="list-style-type: none"> <li>▪ The LDAP Changelog (i.e., the external changelog that clients can access) physically resides at <code>&lt;server-root&gt;/db/changelog</code>.</li> <li>▪ The Replication Changelog Backend (i.e., the changelog that replication servers use) physically resides at <code>&lt;server-root&gt;/changelogDB</code> and is not accessible by clients and server extensions.</li> </ul> |
| Replication Domain       | The data configured for replication as defined by the base DN. Updates to entries at and below the base DN will be replicated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Replication Replay       | When a replica locally applies the update received via a replication server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Replication Server       | A component within the Directory Server process that is responsible for propagating directory server data changes to and from replicas. Each Directory Server instance participating in replication is also running a replication server.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Replication Server ID    | The unique identifier of a replication server set automatically in its configuration object at each server in the replication topology. This identifier is used in the connection management code of the replication servers.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Replication Server State | A list of the most recent change numbers of replication updates that have been processed by a replication server. There can be at most one change number from each replica in the topology. The Replication Server State is used to determine which updates need to be sent to other replication servers. Similarly, the replica can use the Replication Server State to identify the set of updates to send to the replication server.                                                                                                                                                                                                                             |
| Sequence Number          | A field in the change number that indicates the sequence of the client updates at a particular replica. For every update at the replica, the number is incremented. The initial value of the sequence number is 1. The number is stored as a 32-bit integer, but only positive values are used. The sequence number can roll over.                                                                                                                                                                                                                                                                                                                                  |

| Term                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WAN Gateway          | The designated replication server that assumes the WAN Gateway role within a collection of co-located replication servers (i.e., servers that are defined with identical location settings). Replication update messages between servers at different locations are routed through WAN gateways. The WAN Gateway role is assigned automatically by the protocol based on the server's WAN Gateway Priority setting. If the WAN Gateway server is down for any reason, the server with the next highest WAN Gateway Priority will dynamically assume the WAN Gateway role. |
| WAN Gateway Priority | The configuration setting that determines which replication server assumes the WAN Gateway role. The replication server with the lowest WAN Gateway Priority value in a location assumes the role of the WAN Gateway. The priority values can be set to 0 (never be a gateway), or any value from 1 (highest priority) to 10 (lowest priority).                                                                                                                                                                                                                           |

## Replication Architecture

The major elements of replication in the PingDirectory Server are introduced in this section.

### Eventual Consistency

Replication is based on an eventual-consistency model, where updates that are propagated through a connected network of servers will eventually be consistent on all servers over a very short period of time. In a typical update operation, a client application updates an entry or group of entries on the PingDirectory Server with an ADD, DELETE, MODIFY, or MODIFY DN operation. After processing the operation, the Directory Server returns an LDAP response, while concurrently propagating the update to the other servers in the replicated topology. This concurrent processing model allows the client to continue submitting update requests without waiting for a replication completion response from the server. Alternatively, assured replication can be configured for specific write requests that requires local or global consistency, across datacenter locations, before a response is returned to the client. For more information, see [Configuring Assured Replication](#) on page 799.

To support this processing model, replication never locks the targeted entries at the other Directory Server instances before an update can be made locally. This means that the replicated Directory Servers may have an inconsistent view of the targeted entry for a very short period of time but will catch up as the propagated changes are applied. The eventual-consistency model also allows clients to complete update operations faster, since clients do not have to wait for replication to propagate the change. The rate of update operations remains the same no matter how many Directory Servers participate in replication.

### Replicas and Replication Servers

Each Directory Server has an embedded replication server that is responsible for transmitting updates to other replication servers. There is a separate component, called a replica, for each replicating base DN, such as `cn=schema, dc=example, dc=com`. Each replica connects to the embedded replication server running within the Directory Server JVM process.

When a client application updates an entry on the Directory Server, the replica sends an update message to its embedded replication server. The replication server applies the change to the `replicationChangeLog` backend repository and then sends an update message to the connected replication server on another directory server. The replication server on other directory servers then passes the change to the appropriate replica, which in turn applies the change to its backend after performing conflict resolution. This standard setup is seen in the figure below.

## MY TITLE Replicas and Replication Servers

### Authentication and Authorization

The authentication in the Replication Protocol is based on public key cryptography using client certificate authentication via TLS. The certificate used for authentication is stored in the `ads-truststore` backend of the Directory Server. During replication setup, the command-line utility distributes public keys to all directory servers to establish trust between the Directory Servers and to enable client authentication via TLS.

The authorization model of replication is simple: once authenticated, the remote Directory Server is fully authorized to exchange replication messages with the local Directory Server. There is no other access control in place.

### Logging

The access log messages in the Directory Server indicate if the update was received via replication and includes the corresponding change number. This allows the administrator to track which Directory Server the update originated from.

## Replication Deployment Planning

The following should be considered before deploying in a production environment:

- **Minimizing Replication Conflicts.** Attention should be paid to the origin of client write requests to prevent a conflict. If two different clients attempt to create an entry with the same name, DN, at the same time against different servers, the possibility exists that both client requests will succeed. In this case, a conflict alert will be sent by the server. However, understand the client traffic pattern beforehand will minimize these occurrences. The Directory Server's Assured Replication feature and the PingDirectoryProxy Server can both assist in minimizing conflicts.
- **Replication Purge Delay.** Adjust the default one-day replication purge delay, consistently across all servers, to accommodate automatic catchup of changes when a server is offline for an extended period of time. The replication changes database, stored in `<server-root>/changelogDb`, grows larger as the replication purge delay is increased. A minimum value should be defined.

The rest of this section highlights other topics of consideration.

### Location

In multi-site deployments, it is strongly recommended to configure the directory servers with location information using the `dsconfig create-location` command and `dsconfig set-global-configuration-prop` command. The Directory Server cannot determine LAN boundaries automatically, so incorrect location settings can result in undesired WAN communication. By default, replication also compresses all traffic between directory servers in different locations.

We recommend setting up the locations prior to enabling replication. The `dsreplication enable` command prompts for location information if you have forgotten to define the property.

### User-Defined LDAP

Directory Servers participating in replication are required to have a uniform user-defined schema. The `dsreplication` command-line utility sets up replication for the schema backend the first time replication is enabled to ensure that future schema changes are propagated to all directory servers.

### Disk Space

Replication increases the disk space required for the Directory Server. The Replication Changelog backend keeps changes from all directory servers for 24 hours by default. After this time period, also known as the purge delay, the backend is trimmed automatically.

In addition, within the `userRoot` and other local DN backends, attribute-level changes are recorded for a short period of time in the `ds-sync-hist` attribute of the entry targeted by an LDAP Modify operation. This attribute is used to resolve all conflicts resulting from LDAP Modify operations automatically.

The disk space impact of replication is highly dependent on the rate and size of changes in the replication topology, and the Replication Changelog purge delay.

### Memory

Compared to a standalone directory server, replicated directory server instances require slightly more memory. All of the items discussed in the Disk Space section have an impact on the amount of memory the Directory Server is using. The additional replication overhead is typically less than 5%.

### Time Synchronization

Even though replication has a built-in mechanism to compensate for the potential clock skew between hosts, it is generally recommended to keep system clocks in sync within the deployment.

### Communication Ports

The replication server component in each directory server listens on a TCP/IP port for replication communication (the replication server port). This port, typically 8989, must be accessible from all directory servers participating in replication. The server-to-server communication channel is kept alive using a heartbeat, which occurs every 10 seconds. This traffic will prevent firewalls from closing connections prematurely.

The replication command-line utility (`dsreplication`) requires access to all directory servers participating in replication. This includes the LDAP or LDAPS port of the directory servers.

Keep these communication requirements in mind when configuring firewalls.

### Hardware Load Balancers

Replication allows writes to be directed to any directory server in the topology. Distributing write operations in a round-robin fashion, however, may introduce conflicts. In particular, distributing a series of LDAP Add, Delete and Modify DN operations targeting the same DN in quick succession can result in conflicts that require manual intervention. The Assured Replication feature can help prevent conflicts created by the same client application.

If possible, consider using server affinity with the load balancer that either associates a client IP address or a client connection with a single directory server instance at a time. Also, consider using the PingDirectoryProxy Server for load balancing LDAP traffic. The Server Affinity feature in the Directory Proxy Server enables replication-friendly load balancing.

### Directory Proxy Server

In addition, to facilitate replication-friendly load balancing, the PingDirectoryProxy Server should be considered in every replication deployment. The Directory Proxy Server can automatically adapt to

conditions in backend directory servers using health checks and route traffic accordingly. For example, traffic can be re-routed from directory servers with large backlog of replication updates.

### To Display the Server Information for a Replication Deployment

#### Steps

- Run the `dsreplication status` command with the `--displayServerTable` option.

```
$ bin/dsreplication status --displayServerTable
```

```

--- Replication Status for dc=example,dc=com: ---
Server : Location : Priority (1) : Status
-----:-----:-----:-----
austin-01.example.com:8989 : US : 1 (*) : Available
austin-02.example.com:8989 : US : 2 : Available
london-01.example.com:8989 : UK : 5 : Available
london-02.example.com:8989 : UK : 5 (*) : Available
sydney-01.example.com:8989 : AU : 5 (*) : Available
sydney-02.example.com:8989 : AU : 5 : Available

[1] WAN Gateway Priority. WAN gateways are marked with a *. To minimize
WAN utilization, the server with the WAN Gateway role is the only server
in a location that exchanges updates with remote locations.

--- Replication Status for dc=example,dc=com: Enabled ---

### To Display All Status Information for a Replication Deployment

#### Steps

- Run the `dsreplication status` command with the `--showAll` option. You can also use the `--showAll` option together with the `--displayServerTable` option to see the server table information for the replication topology.

## Enabling Replication

Enabling replication between multiple Directory Servers means that any change within the replicated base DN is automatically propagated to all other Directory Servers in the topology. Configuration changes are not replicated, but can be through the use of Server Groups. Therefore, each Directory Server should be configured according to the deployment design.

#### Overview

To interface with the replication topology, the Directory Server provides a command-line utility, `dsreplication`, that must be used to manage and monitor replication.

Replication setup involves the following basic steps:

- **Set up the servers.** This is the basic installation steps to set up a Directory Server instance.
- **Import or restore data to one server.** After setting up the servers, at least one server should have the target data loaded through `import-ldif` or `restore`.
- **Enable replication between the servers.** Using the `dsreplication` tool, enable replication for each server to be included in the replication topology. The `dsreplication enable` subcommand should be run  $N - 1$  times for a topology of  $N$  servers. See [Command Line Interface](#) for more information.
- **Initialize data from source server to every server in the topology.** Run the `dsreplication initialize` subcommand for every target server that needs a copy of the data from the source server.
- **Verifying the replication topology.** Administrators can check the replication status after configuring the topology using the `dsreplication status` tool.

### Command Line Interface

Replication topologies are configured and maintained using the `dsreplication` command-line utility, which supports interactive and non-interactive modes. If you are running the server for the first time, we recommend using the `dsreplication` tool in interactive mode.

The `dsreplication` tool has the following format including some important subcommands listed in the section [The dsreplication Command-Line Utility](#):

```
dsreplication {subcommand} {connection parameters}
```

The `dsreplication` tool keeps a history of invocations in the `logs/tools/dsreplication.history` file and keeps a log of up to 10 `dsreplication` sessions in the `logs/tools` directory.

### What Happens When You Enable Replication

The `dsreplication enable` subcommand is used to set up replication. The `enable` subcommand carries out the following functions:

- If it does not already exist, the global administrator user is created. The global administrator user has all the rights and privileges to update replication-related configuration objects. Most `dsreplication` subcommands require the global administrator.
- The server instances are registered in the `cn=topology, cn=config` tree. The registration includes basic host name, port information as well as the public key used during the replication authentication process.

In case both servers are already participating in replication, the `cn=topology, cn=config` is merged to retain the server information from existing topologies.

- The embedded replication server is enabled. Servers already in replication will see their replication server configuration updated with the information of the new replication server.
- A replication domain is created for the requested base DNs. In case the first base DN is enabled, the replication domains for two additional base DNs are also enabled: `cn=topology, cn=config` and `cn=schema`.
- Initialization for the `cn=topology, cn=config` base DN is executed. This will ensure that `cn=topology, cn=config` is uniform across the replication topology.
- Initialization for the `cn=schema` base DN is executed. This will ensure that a uniform schema is present in the replication topology.
- Initialization must be performed for the enabled base DNs.

### Initialization

Replica initialization transfers a copy of the backend containing the replication domain to a target server. This should be performed after replication is enabled with the `dsreplication initialize` subcommand. There is no impact on the source server during this process.

**Note:** When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying `host 1, port1`. When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

- **dsreplication initialize.** The recommended approach for replica initialization. The `dsreplication initialize` subcommand performs the most efficient copy of data needed to initialize one or more replicas on a target server. Any existing data on the target server replica will be lost and the backend containing the base DN will be taken offline on the target server during the initialization.
- **Binary Copy.** The database copy method involves copying database backup files from the source directory server to one or more target servers. The Directory Server provides tools necessary for backing up and restoring backends. Using `server-root/bin/backup`, create a backup of the backend containing the replicated base DN. The backup files then need to be transferred to the target server(s) and restored individually with `server-root/bin/restore`. There are additional considerations when using database copy as the means to initialize a target replica:
  - If encryption is enabled on the servers, then a database `bin/encryption-settings export` then `bin/encryption-settings import` must be performed on the `encryption-settings` backend.
  - When using database copy to initialize a server which has been offline longer than the replication purge delay, the database copy of the `replicationChanges`, `schema`, and `adminRoot` backends are required.

### Replica Generation ID

Each replica has a generation ID, which is an integer that summarizes the replica. It provides replication with a quick and simple means of determining if two replicas contain the same data. If they do contain the same data, they'll have the same generation ID.

When replication is operating correctly, all of the replicas for each replicated base DN will have the same generation ID. The generation ID is stored on each replica as the operational attribute `ds-sync-generation-id`. For example:

```
ldapsearch -b 'dc=example,dc=com' -s base '(&)' ds-sync-generation-id
dn: dc=example,dc=com
ds-sync-generation-id: 2058329333
```

When the server starts, or when replication is enabled, the generation ID is computed for each affected replica that does not already have a generation ID stored as `ds-sync-generation-id`. The following is used to calculate the generation ID:

- The total number of entries in the replica. This is referred to as "the count."
- The first 1000 entries in the replica are converted to normalized LDIF, which is referred to as "the LDIF." Normalized LDIF only includes attributes `objectclass`, `sn`, `cn` and `ds-entry-unique-id`, and uses OIDs in place of attribute names.
- The Adler-32 checksum is calculated with the string produced by concatenating the count and the LDIF as input. This Adler-32 checksum is the generation ID.
- The generation ID is stored on the base DN as `ds-sync-generation-id`. This is so that the ID does not need to be computed the next time the replica is loaded.

## Deploying a Basic Replication Topology

This section describes how to set up a two-server replication topology. The example uses the LDAP and replication server ports 1389 and 8989 respectively.

## Replica Ports

| Host Name           | LDAP Port | Replication Port |
|---------------------|-----------|------------------|
| server1.example.com | 1389      | 8989             |
| server2.example.com | 1389      | 8989             |

## To Deploy a Basic Replication Deployment

### Steps

1. Install the first directory server with 2000 sample entries.

```
$./setup --cli --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389
\ --rootUserPassword pass --sampleData 10000 --no-prompt
```

2. Install the second directory server either on a separate host or the same host as the first, but with a different LDAP port.

```
$./setup --cli --acceptLicense --baseDN "dc=example,dc=com" --ldapPort 1389
\ --rootUserPassword pass --no-prompt
```

3. From the first server, run the `bin/dsreplication` command in interactive mode to configure a replication topology:

```
$ bin/dsreplication
```

4. From the Replication Main menu, select the Manage the topology option.

```
>>>> Replication Main Menu
```

```
What do you want to do?
```

- ```

1) Display replication status
2) Manage the topology (add and remove servers)
3) Initialize replica data over the network
4) Initialize replica data manually
5) Replace existing data on all servers

q) quit
```

```
Enter choice: 2
```

5. From the Manage Replication Topology menu, choose the Enable Replication option.

```
>>>> Manage Replication Topology
```

```
Select an operation for more information.
```

- ```

1) Enable Replication -- add or re-attach a server to the topology
2) Disable Replication -- permanently remove a running replica from the
topology
3) Remove Defunct Server -- permanently remove an unavailable server
from the
topology
4) Cleanup Server -- remove replication artifacts from an offline,
local server
(allowing it to be re-added to a topology)

b) back
q) quit
```

```
Enter choice [b]: 1
```

6. On the Enable Replication menu, read the brief introduction on what will take place during the setup, and then, enter "c" to continue the enable process.
7. Next, enter the LDAP connection parameters for the first of the two replicas that you are configuring. First, enter the host name or IP address of the first server.
8. Next, enter the type of LDAP connection to the first server: 1) LDAP, 2) LDAP with SSL, or 3) LDAP with StartTLS.
9. Type the LDAP listener port for the first replica. If you are a root user, you will see port 389 as the default. Others will see port 1389.
10. Authenticate as a root DN, such as `cn=Directory Manager`. You will be prompted later in the process to set up a global administrator and password. The global administrator is the user ID that manages the replication topology group.
11. Repeat steps 7–10 for the second replica.
12. Next, the `dsreplication` tool checks for the base DN on both servers. In order to enable replication, data must be present on at least one of the servers. For this example, press Enter to select the default base DN, `dc=example,dc=com`.

```
Choose one or more available base DN's for which to enable replication:
```

- ```
1)  dc=example,dc=com
c)  cancel
```

```
Enter one or more choices separated by commas [1]:
```

 **Note:** If you see the following message:

```
There are no base DN's available to enable replication between the two
servers.
```

In most cases, a base DN was not set up on one of the directory servers or the backend is disabled.

13. Next, the prompt asks if you want to set up entry balancing using the Directory Proxy Server. Press Enter to accept the default (no), since we are not setting up replication in an entry-balanced environment in this scenario. For more information, see the *PingDirectoryProxy Server Administration Guide*.

```
Do you plan to configure entry balancing using the Directory Proxy Server?
(yes / no) [no]:
```

14. Next, enter the replication port for the first replica (default, 8989). The port must be free.
15. If the first server did not have a pre-defined location setting, `dsreplication` will prompt you to enter a location. Press Enter to accept the default (yes) to set up a Location for the first server. Enter the name of the server's location.

```
The first server has not been configured with a location.
Assigning a location to each server in the replication topology reduces
network traffic in multi-site deployments. Would you like to set the
location in the first server? (yes / no) [yes]
```

```
The location of the first server: Austin
```

16. Repeat the previous steps for the second directory server. Again, if you did not pre-define a location setting for the second server, you will be prompted to enter this information.
17. At this time, set up the Global Administrator user ID (default is "admin") and a password for this account. The Global Administrator user ID manages the directory servers used in the replication topology.

```
Specify the user ID of the global administrator account
```

```

that will be used to manage the Ping Identity
      Directory Server
instances to be replicated [admin]:

Password for the global administrator:
Confirm Password:

```

18. Return to the Replication Main Menu and enter the number corresponding to initializing data over the network.
19. On the Initialize Replica Data over the Network menu, select Initialize to initialize data on a single server, and then enter `c` to continue.
20. Next, specify a server in the replication topology. For this example, enter the host name or IP address, LDAP connection type, LDAP port, Global Admin user ID and password of the first server.
21. Next, select the source server that is hosting the data to which the target server will be initialized. For this example, select the first server, since the sample dataset has been loaded onto this server.
22. Next, select the base DN that will be initialized. In most cases, the base DN for the root suffix will be replicated. In this example, `dc=example,dc=com`.
23. Next, select the second server in this example that will have its data initialized, and then enter the Global Admin user ID and password for the target server. Any data present on the target server will be over-written.
24. Press Enter to confirm that you want to initialize data on the target server. When completed, you should see "Base DN initialized successfully."

```

Initializing the contents of a base DN removes all the existing contents of
that base DN. Do you want to remove the contents of the selected base DN's on
server
server2.example.com:1389 and replace them with the contents of server
server1.example.com:1389? (yes / no) [yes]:

```

25. On the Initialize Replica Data Over Network menu, enter `b` to back out one level to the main menu. Then, on the Replication Main menu, enter the number to view the replication status.

```

--- Replication Servers: dc=example,dc=com ---
Server          : Location : Conflict Entries : Backlog : Recent
Change Rate
-----
ds1 (example.com:1389) : austin  : 0                : 0       : 0
ds2 (example.com:1389) : austin  : 0                : 0       : 0

```

A Deployment with Non-Interactive dsreplication

This example will create a four-server topology spanning two data centers. The four servers are already installed and have locations Austin and Budepest defined.

Note: When enabling or initializing servers, the `--topologyFilePath` option can be used with `dsreplication` to specify a file with a series of hosts and ports available in the topology that can be used as source servers. This option is used in place of specifying host 1, port1. When the hosts file is used for an enable or initialize action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available for replication. This file is generated with the `manage-topology export` command.

To Deploy with Non-Interactive dsreplication

Steps

1. Generate the sample data using the `make-ldif` tool on the first server.

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10K.template \
  --ldifFile ldif/10K.ldif
```

2. Select a server from which to import data, and to be the source for future initialization to other servers. Stop this server, import the sample LDIF and start again, or perform a task-based `import-ldif` with the connection options.

```
$ bin/stop-server
$ bin/import-ldif --backendID userRoot --ldifFile ldif/10K.ldif
$ bin/start-server
```

3. Enable replication by choosing a specific server and running `dsreplication enable` three times. For the first invocation, create the replication topology administrator with the name `admin`.

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin02.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 budapest01.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

```
$ bin/dsreplication enable --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 budapest02.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

4. Initialize the other servers (the `dc=example,dc=com` replicas) from the server that had the data imported with `import-ldif`. To minimize the WAN transfers, initialize `budapest02` from `budapest01`.

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination austin02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt
```

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination budapest01.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt
```

```
$ bin/dsreplication initialize --hostSource budapest01.example.com --
portSource 1389 \
  --hostDestination budapest02.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com --no-
prompt
```

5. View the state of replication.

```
$ bin/dsreplication status --adminPassword password --no-prompt --
displayServerTable --showAll
```

To Use dsreplication with SASL GSSAPI (Kerberos)

Before you begin

This example procedure assumes that you have configured SASL GSSAPI on all servers in the replication topology and that they are working properly.

About this task

The Directory Server's utilities all support SASL GSSAPI options for systems using Kerberos as its main authentication mechanism. The following procedure shows how to use `dsreplication` with SASL GSSAPI to set up a new `replication.admin` identity, while enabling replication on a server. The following are important points about the configuration:

- A separate Kerberos identity is required to manage replication. Existing Kerberos credentials can be used to interact with the server when enabling replication and creating the new identity.
- The new identity, such as `replication.admin`, must not exist as the `cn` or `uid` value under any public base DN.

Steps

1. Set the LDAP Connection Handler to explicitly listen on the server's host name address.

```
$ bin/dsconfig set-connection-handler-prop \
--handler-name "LDAP Connection Handler" \
--remove listen-address:0.0.0.0 --add listen-address:host.example.com
```

2. Update the identity mapper to have `cn=topology,cn=config` included in the list of base DN's and to add the `cn` attribute to match attributes. This step is required to map the admin account to the Kerberos realm.

```
$ bin/dsconfig set-identity-mapper-prop \
--mapper-name "Regular Expression" \
--add match-attribute:cn \
--set "match-base-dn:cn=topology,cn=config" \
--set match-base-dn:dc=example,dc=com
```

3. Invoke replication enable, authenticating as the existing kerberos `authid`. Note that no bind DN's and passwords are required to authenticate because we are using SASL binding. However, the new replication admin user requires a password at creation time, so we recommend using a strong random password. Once SASL is working, you will no longer have to provide this random password. Also note that we are forcing the use of the ticket cache, so make sure you have properly authenticated as `ds.admin` from your local host and the ticket is not expired in the cache.

```
$ kinit -p ds.admin
$ bin/dsreplication enable \
--host1 server1.example.com --port1 1389 --replicationPort1 1989 \
--host2 server2.example.com --port2 2389 --replicationPort2 2989 \
--baseDN dc=example,dc=com \
--adminUID replication.admin --adminPassword strongPassword \
--saslOption1 mech=gssapi --saslOption1 authid=ds.admin@EXAMPLE.COM \
--saslOption1 useTicketCache=true --saslOption1 requireCache=true \
--saslOption2 mech=gssapi --saslOption2 authid=ds.admin@EXAMPLE.COM \
--saslOption2 useTicketCache=true --saslOption2 requireCache=true
```

4. Use `dsreplication initialize` to initialize data on remote server.

```
$ kinit -p replication.admin
```

```
$ bin/dsreplication initialize \
--hostSource server1.example.com --portSource 1389 \
--hostDestination server2.example.com --portDestination 2389 \
--baseDN dc=example,dc=com \
--saslOption mech=GSSAPI \
--saslOption authID=replication.admin@EXAMPLE.COM \
--no-prompt
```

5. The temporary `userPassword` can now be deleted from the `replication.admin` entry. Create a file called `remove-password.ldif` with these contents:

```
dn: cn=replication.admin,cn=Administrators,cn=topology,cn=config
changetype: modify
delete: userPassword
```

6. Apply the modifications using `ldapmodify`:

```
$ ./ldapmodify --filename remove-password.ldif -o mech=GSSAPI
-o authid=replication.admin@example.com \
--saslOption useTicketCache=true \
--hostname host.example.com --port 1389 \
--noPropertiesFile
```

7. Check the topology's status by running `dsreplication status`. The `--saslOption useTicketCache=true` and `--saslOption requireCache=true` properties, instead of providing a password, for all `dsreplication` commands after properly creating the admin accounts and mappers.

```
$ bin/dsreplication status \
--saslOption mech=gssapi \
--saslOption authid=replication.admin@EXAMPLE.COM \
--saslOption useTicketCache=true --saslOption requireCache=true \
--hostname host.example.com --port 1389 \
--no-prompt
```

Configuring Assured Replication

The PingDirectory Server's replication mechanism is based on the eventual-consistency model, which is a loosely-connected topology that propagates updates to other servers without waiting for their corresponding replication response messages. As a result, there is a small window of time where updates are not all present on the replicas as the changes are replicating through the system. There are, however, deployments that require *immediate* access to replicated data. In such cases, administrators can configure *Assured Replication*, which ensures that replication has completed *before* the update response is returned to the client.

From the LDAP client's perspective, assured replication has no bearing on the result code of the operation, just on the time in which it takes to receive the response for those requests in which replication assurance is applied. Detailed information regarding assurance processing is available to an LDAP client with awareness of the assured replication control.

The assured replication mechanism takes advantage of server location to distinguish between local and remote servers to allow different policies to apply. For example, a common assurance approach is to respond to a client update after all servers in the same location have applied the update, and one or more servers in remote locations have received the update. In addition, the level of assurance applied to each operation can be explicitly requested by the client and/or specified by the server configuration using the Replication Assurance Policy.

Assured replication is supported by client requests directly to PingDirectory Server and/or through a PingDirectoryProxy Server.

About the Replication Assurance Policy

Assured replication uses a *Replication Assurance Policy* to define the properties needed to ensure that replication has satisfactorily completed before the update response is returned to the client. Multiple policies can be defined but only one policy is matched with a client update request. Each policy contains an evaluation order index which, together with an optional request and connection criteria, provides flexibility in matching a policy to request.

The Replication Assurance Policy defines local and remote assurance *levels*. A *level* defines how rigorous the policy should be when waiting for propagation of updates, while *local* and *remote* distinguish servers in the same location versus servers in remote locations. Although optional, it is recommended that request or connection criteria be associated with a policy to apply replication assurance appropriately.

The Directory Server contains a Default Replication Assurance Policy that is enabled but has no assurance levels assigned. In addition to using the Default Replication Assurance Policy, any number of policies can be created and enabled. When a client request is received, the server iterates through the list of enabled policies according to each policy's *evaluation-order-index* property. A smaller *evaluation-order-index* value (e.g., 1) has precedence over policies with larger *evaluation-order-index* values (e.g., 2, 3, 4, etc.). The *evaluation-order-index* values do not need to be contiguous. The first policy that matches a request is associated with the operation.

The Replication Assurance Policy, which is defined on the PingDirectory Server and not on the PingDirectoryProxy Server, has the following properties:

- **evaluation-order-index.** Determines the evaluation order (the smaller value has precedence) among multiple Replication Assurance Policies that match against an operation.
- **local-level.** Specifies the assurance level used to replicate to local servers. A local server is defined as a server with the same `location` property value as set in the global configuration. The `local-level` property must be set to an assurance level as strict as the `remote-level` property. For example, if the `remote-level` is set to "processed-all-remote-locations," then the `local-level` property must be "processed-all-servers."
 - **None.** Replication to any local server is not assured.
 - **received-any-server.** At least one available local server must receive a replication update before a response is sent to the client.
 - **processed-all-servers.** All available local servers must complete replay of the replication update before the response is sent to the client. If a singular server is enabled, or only one server is available for a particular location, `processed-all-servers` will return a value of `false`.
- **remote-level.** Specifies the assurance level used to replicate to remote servers. A remote server is defined as a server that has a different `location` property value as set in the global configuration.
 - **None.** Replication to any remote server is not assured.
 - **received-any-remote-location.** At least one server at any available remote location must receive a replication update before a response is sent to the client.
 - **received-all-remote-locations.** All available remote servers must receive a replication update before the response is sent to the client.
 - **processed-all-remote-servers.** All available servers at all locations must complete replay of the replication update before the response is sent to the client. If a single server is enabled, or only one server is available for a particular location, `processed-all-remote-servers` will return a value of `false`.
- **timeout.** Specifies the maximum length of time to wait for the replication assurance requirements to be met before timeout and replying to the client.
- **connection-criteria.** Specifies connection criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and request criteria are specified for a policy, then both must match an operation for the policy to be assigned.
- **request-criteria.** Specifies request criteria used to indicate which operations from clients matching this criteria use this policy. If both connection criteria and a request criteria are specified for a policy, then both must match an operation for the policy to be assigned.

Servers in a replication topology are not required to share a homogeneous set of policies; you can configure the Replication Assurance Policies differently on the replicas in a topology. For example, if you configure server A to match add operations to a `processed-all-servers` assurance level, and server B to match add operations to a local `received-any-server` level, then add operations received on server A will have the assurance level of `processed-all-servers` and add operations received on server B will have the assurance level of `received-any-server`.

For more detailed information, see the *PingDirectory Server Configuration Reference Guide*.

Points about Assured Replication

The following are some points when implementing Assured Replication:

- **Client Controls.** The client may optionally include an assured replication request control with each operation. This control allows the client to specify bounds on assurance levels and/or override the timeout assigned by the matching replication assurance policy for the associated operation. The server always honors these request controls. See [About the Assured Replication Controls](#) for more information.
- **Directory Proxy Server.** Replication assurance policies are not supported on the PingDirectoryProxy Server. Replication client controls are passed through to the underlying Directory Server backend.
- **Schema backend Replication.** The schema backend is not supported by Assured Replication. Replication assurance policies that include criteria to match this backend will be rejected.
- **Backward Compatibility.** Server versions that support assured replication are backwards-compatible with prior versions that do not support assured replication.
- **WAN-Friendly Replication.** Assured replication functions independently from WAN-Friendly Replication and the notion of WAN Gateways.
- **Global Configuration Properties.** The Directory Server provides two configurable global configuration properties that determine the timing of the assurance source and maximum number of replication backup updates to be recognized as an available source.
 - **replication-assurance-source-timeout-suspend-duration.** Specifies the amount of time a replication assurance source will be suspended from assurance requirements if it experiences an assurance timeout. While suspended, the source will be excluded from assurance requirements for all operations originating on this Directory Server. This avoids the situation of repeated timeouts caused by degraded or offline servers. Default is 10 seconds.
 - **replication-assurance-source-backlog-fast-start-threshold.** Specifies the maximum number of replication backlog updates a replication assurance source can have and be immediately recognized as an available source. If a source connects to this server with more than the configured threshold backlog updates, it will be excluded from assurance requirements for all operations originating from this Directory Server until it completes at least one assurance successfully (i.e. this Directory Server receives an update acknowledgement message from it within the timeout window). Default is 1000.

To Configure Assured Replication

About this task

This example illustrates configuring a variety of assured replication policies. In practice it's common for all servers to have the same policy. The following example assumes that three servers are configured on localhost, on ports 1389, 2389 and 3389. Note that each server has a default Replication Assurance Policy with no assurance levels set.

Steps

1. On server 1, use `dsconfig` to create request criteria for add operations. This request criteria will be used to match any add operation with the Replication Assurance Policy that will be configured in the next step.

```
$ bin/dsconfig create-request-criteria \
```

```
--criteria-name Adds \
--type simple \
--set operation-type:add
```

2. On server 1, set up the Replication Assurance Policy to make all add operations assured with a level of processed-all-servers, which indicates that all local servers in the topology must complete replay of the replication update before the response is sent to the client. Specify the Adds request criteria configured in the previous step.

```
$ bin/dsconfig create-replication-assurance-policy \
--policy-name "Adds Processed All Locally" \
--set evaluation-order-index:1 \
--set local-level:processed-all-servers \
--set "timeout:500ms" \
--set request-criteria:Adds
```

3. On server 1, repeat the previous two steps for modify operations. The Replication Assurance Policy "Mods Received Any Locally" ensures that at least one available local server must receive a replication modify update before a response is sent to the client.

```
$ bin/dsconfig create-request-criteria \
--criteria-name Mods \
--type simple \
--set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
--policy-name "Mods Received Any Locally" \
--set evaluation-order-index:2 \
--set local-level:received-any-server \
--set "timeout:500ms" \
--set request-criteria:Mods
```

4. On server 2, repeat steps 1-3 to set up the Adds and Mods request criteria and its respective Replication Assurance Policy.

```
$ bin/dsconfig create-request-criteria \
--criteria-name Adds \
--type simple \
--set operation-type:add

$ bin/dsconfig create-request-criteria \
--criteria-name Mods \
--type simple \
--set operation-type:modify

$ bin/dsconfig create-replication-assurance-policy \
--policy-name "Adds Received Any Locally" \
--set evaluation-order-index:1 \
--set local-level:received-any-server \
--set "timeout:500ms" \
--set request-criteria:Adds

$ bin/dsconfig create-replication-assurance-policy \
--policy-name "Mods Processed All Locally" \
--set evaluation-order-index:2 \
--set local-level:processed-all-servers \
--set "timeout:500ms" \
--set request-criteria:Mods
```

5. Leave server 3 with the default Replication Assurance Policy configured with no assurance levels or criteria. In practice it is common for all servers to have the same assurance levels or criteria.

6. On server 1, list the policies on the server using the `dsconfig` command to confirm that they exist on the server.

```
$ bin/dsconfig list-replication-assurance-policies
```

Replication Assurance Policy	Type	enabled	evaluation-order-index	local-level	remote-level
Adds Processed All Locally	generic	true	1	processed-all-servers	none
Mods Received Any Locally	generic	true	2	received-any-server	none
Default Replication Assurance Policy	generic	true	9999	none	none

7. Repeat the previous step on server 2 and server 3. Server 3 should only show the Default Replication Assurance Policy.
8. Check the Replication Assurance counters on all servers before any add or modify operation using `ldapsearch`. They should be set to zero. These counters are on the replica server, which is where the policy is matched and assigned. On server 1, run the following command:

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance
```

```
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

9. Check the Replication Summary table on all of the servers. For example, on server 1, run the following command:

```
$ bin/ldapsearch --baseDN "cn=Replication Summary
dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance
```

```
replication-assurance-submitted-operations: 0
replication-assurance-local-completed-normally: 0
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
```

10. Add an entry to the server 1 Directory Server. Check that the counters matched the newly added entry to the "Adds Processed All Locally" Policy and that it completed assured.

```
$ bin/ldapmodify --filename add-user.ldif --defaultAdd
```

```
$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance
```

```
replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
```

```

replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy:
0
replication-assurance-policy-matches: Mods Received Any Locally: 0
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-remote-level-uses: none: 1

$ bin/ldapsearch --baseDN "cn=Replication Summary
dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 1
replication-assurance-local-completed-normally: 1
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0

```

- 11.** Perform a modify of an entry under `dc=example,dc=com` on server 1. Check that the counters matched the modify operation to the "Mods Processed All Locally" policy and that the operations completed assured.

```

$ bin/ldapsearch --baseDN "cn=Replica dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0
replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0
replication-assurance-policy-matches: Adds Processed All Locally: 1
replication-assurance-policy-matches: Default Replication Assurance Policy:
0
replication-assurance-policy-matches: Mods Received Any Locally: 1
replication-assurance-local-level-uses: processed-all-servers: 1
replication-assurance-local-level-uses: received-any-server: 1
replication-assurance-remote-level-uses: none: 2

$ bin/ldapsearch --baseDN "cn=Replication Summary
dc_example_dc_com,cn=monitor" \
  "(objectclass=*)" | grep replication-assurance

replication-assurance-submitted-operations: 2
replication-assurance-local-completed-normally: 2
replication-assurance-local-completed-abnormally: 0
replication-assurance-local-completed-with-timeout: 0
replication-assurance-local-completed-with-shutdown: 0
replication-assurance-local-completed-with-unavailable-server: 0
replication-assurance-remote-completed-normally: 0

```

```

replication-assurance-remote-completed-abnormally: 0
replication-assurance-remote-completed-with-timeout: 0
replication-assurance-remote-completed-with-shutdown: 0
replication-assurance-remote-completed-with-unavailable-server: 0

```

You have successfully configured Assured Replication.

About the Assured Replication Controls

The LDAP SDK for Java provides an implementation of an LDAP control that can be included in add, bind, modify, modify DN, and certain extended requests to indicate the level of replication assurance desired for the associated operation. The OID for this control is 1.3.6.1.4.1.30221.2.5.28, and may have a criticality of either TRUE or FALSE.

For specific details, see the LDAP SDK javadoc for the `AssuredReplicationRequestControl` class.

Managing the Topology

The following sections describe common topology management operations.

Note: When enabling or disabling replication within a topology that contains multiple product versions, the `dsreplication` tool must be run from the server root location of a member of the topology that has the oldest product version.

To Add a Server to the Topology

About this task

The following steps assume an existing directory server topology. The commands are identical for initial enable between two servers, where one server contains data for the replication domain stored in the `userRoot` backend. If database encryption is being used on the servers in the topology, it is important that the server being initialized has a copy of the `encryption-settings` backend from the source server.

Steps

1. A majority of servers (more than 50%) in the topology and the new server, should be online.
2. Enable replication for the base DN, or base DNs, using an existing server as `host1` and the new server as `host2`.

```

$ bin/dsreplication enable \
  --host1 austin01.example.com --port1 1389 \
  --bindDN1 "cn=Directory Manager" --bindPassword1 password \
  --replicationPort1 8989 --host2 austin03.example.com --port2 1389 \
  --bindDN2 "cn=Directory Manager" --bindPassword2 password \
  --replicationPort2 8989 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt

```

3. Optionally, compare the configurations between the two hosts used in the `dsreplication enable` command. Make sure settings are consistent across the topology and are also consistent with the new system:

```

$ bin/config-diff --sourceLocal \
  --targetHost austin03.example.com \
  --targetBindDN "cn=directory manager" \
  --targetBindPassword pass --targetPort 1389

```

Disabling Replication and Removing a Server from the Topology

When removing a server from the topology, the remaining servers need to be made aware of the change. If the server to remove is online, only one invocation of `dsreplication disable` is necessary. If the server to remove is offline, the following steps are required:

1. Run `remove-defunct-server` from another server in the topology.
2. Run `remove-defunct-server` on the offline server to removed.

Similar to the `enable` command, more that 50% of servers not being removed from the topology must be online during the process.

If additional servers are offline and cannot be online while removing the server, you must distinguish between offline servers that are offline permanently and those that are offline temporarily. If servers are offline permanently, use `remove-defunct-server` to remove them. If servers are offline temporarily, they update automatically after they are online. The following examples show the steps in more detail:

- **Removing a server that is still online.** The `dsreplication disable` command can be run from any server, but a majority of servers in the topology need to be online.

```
$ bin/dsreplication disable --hostname austin03.example.com --port 1389 \
  --baseDN dc=example,dc=com --adminUID admin --adminPassword password \
  --no-prompt
```

- **Removing a server that is offline.** The `remove-defunct-server` tool can be run against any server not being removed from the topology. More than 50% of servers in the topology must be online. The `remove-defunct-server` tool can be issued after setting the JVM property `"com.unboundid.connectionutils.LdapResponseTimeoutMillis"` to change the default ten-minute timeout for each server to take out of rotation. If multiple servers need to be removed, this approach speeds up the process.

```
$ bin/remove-defunct-server --serverInstanceName austin01 \
  --bindDN "cn=Directory Manager" --bindPassword password
```

To remove any topology references, run the `remove-defunct-server` tool on each server that is removed from the topology, as follows:

```
$ bin/remove-defunct-server --no-prompt
```

The option `--ignore-online` removes an online server cleanly from the topology.

Replacing the Data for a Replicating Domain

In the rare event that the data for the entire replication domain (such as the backend) needs to be replaced, perform the following steps:

To Replace the Data

Steps

1. With all servers online, the `dsreplication pre-external-initialization` command must be run once against any server in the topology. This stops replication for the domain. No writes are made by clients to any of the servers.

```
$ bin/dsreplication pre-external-initialization --hostname
austin01.example.com \
  --port 1389 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

2. Using `import-ldif`, replace the data for `dc=example,dc=com`. Make sure that the input LDIF is free of any replication attributes by using the `--excludeReplication` option. The `--overwriteExistingEntries` option is necessary to overwrite the existing data for the domain. For example, to perform the `import-ldif` with the server offline:

```
$ bin/import-ldif --ldifFile new-data.ldif --backendID userRoot --
excludeReplication --overwriteExistingEntries
```

3. Initialize the other servers in the topology with `dsreplication initialize`, using the server which has the new data as the source host. For example:

```
$ bin/dsreplication initialize --hostSource austin01.example.com --
portSource 1389 \
  --hostDestination budapest01.example.com --portDestination 1389 \
  --adminUID admin --adminPassword password --baseDN dc=example,dc=com \
  --no-prompt
```

4. Run `dsreplication post-external-initialization` once from any server in the topology. All servers in the topology must be online:

```
$ bin/dsreplication post-external-initialization --hostname
austin01.example.com \
  --port 1389 --baseDN dc=example,dc=com --adminUID admin \
  --adminPassword password --no-prompt
```

Advanced Configuration

The following sections are advanced configuration procedures that may be appropriate for your company's deployment.

Changing the replicationChanges DB Location

You can change the `replicationChanges` DB location if on-disk space issues arise. The replication changelog database can live outside `<server-root>` and be placed in another location on the file system. In that case, you must specify the absolute path of the replication changelog directory.

To Change the replicationChanges DB Location

Steps

1. Use `dsconfig` to change the database location for the replication changelog, which by default is at `<server-root>/changelogDb`. The following command sets the replication changelog backend to `<server-root>/data/directory/changelogDB`. Remember to include the LDAP connection parameters (host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-db-directory:/data/directory/changelogDb" \
  --bindDN "cn=Directory Manager" --bindPassword secret --no-prompt
```

2. Stop the server, move the DB files, and then restart the server.

```
$ bin/stop-server
$ mv changelogDb /data/directory
$ bin/start-server
```

Modifying the Replication Purge Delay

The replication purge delay specifies the period after which the directory server purges changes on the replication server database. Any change that is older than the purge delay is removed from the replication server database regardless of whether the change has been applied.

Currently, the PingDirectory Server sets the default purge delay to one day. Administrators can change the default purge delay using the `dsconfig` tool. To ensure proper replication processing, you must have the same purge delay value set for all replication servers in the topology.

To Modify the Replication Purge Delay

Steps

- Use **dsconfig** to change the purge delay. The property accepts time units of seconds (s), minutes (m), hours (h), days (d), or weeks (w). The following command is entered on the command line and changes the purge delay from the default one day to two days.

In **dsconfig** interactive mode, open the **Advanced objects** menu. Select **Replication Server**. Select the replication synchronization provider, and then select the option to change the replication purge delay.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set "replication-purge-delay:2 d"
```

Configuring a Single Listener-Address for the Replication Server

By default, the replication server binds the listening ports to all available interfaces of the machine. To bind the listener to a specific address, the address must be the host name provided when replication is enabled and the `listen-on-all-addresses` property must be set to `FALSE`.

The replication server's configuration entry already stores a host name for itself so that it can resolve the address and specify it during the socket bind. If the server information is missing from the system, an error message will be generated with instructions on specific address binding. You can use the **dsconfig** tool to change the value of the `listen-on-all-addresses` property from `TRUE` (default) to `FALSE`.

To Configure a Replication Server to Listen on a Single Address

Steps

- Create a new directory server instance with replication enabled on port 8989.
- Run **netstat** to see the ports bound for listening on port 8989. Notice that `*.8989` means that it is listening on all addresses.

```
$ netstat -an | grep LISTEN | grep 8989
```

- Run **dsconfig** to disable listening on all addresses for the replication server.

```
$ bin/dsconfig set-replication-server-prop \
  --provider-name "Multimaster Synchronization" \
  --set listen-on-all-addresses:false
```

- Run **netstat** again to see the ports bound for listening on port 8989. Notice that `<address>.8989` (for example, `10.8.1.211.8989`) means that it is listening on the one address.

Monitoring Replication

Replication in the PingDirectory Server can be monitored the following ways:

- The **dsreplication status** subcommand displays basic information about the replicated base DN, the number of entries replicated as well as the approximate size of replication backlogs at each Directory Server.
- The more detailed information about the state of replication can be obtained via the information exposed in its monitoring framework under `cn=monitor`. Administrators can monitor their replication topologies using several tools and protocols: the PingDataMetrics Server, SNMP, LDAP, JMX, or through the Administrative Console. See [Managing Logging and Monitoring](#).
- The Periodic Stats Logger plugin allows collecting replication statistics for profiling server performance. For more information, see [Profiling Server Performance Using the Periodic Stats Logger](#).

Monitoring Replication Using cn=monitor

The `cn=monitor` branch has a number of entries that store the replication state of a topology.

- **Direct LDAP Server <baseDN> <host name:port> <serverID>**. Defines an LDAP server that is directly connected to the replication server that you are querying. The information in this entry applies to the replication server local to the `cn=monitor` entry. For detailed information, see [Summary of the Direct LDAP Monitor Information](#).
- **Indirect LDAP Server <baseDN> <serverID>**. Defines an LDAP server that is connected to another replication server in the topology. While this server is connected to the same topology, it is not connected to the replication server being queried. For detailed information, see [Summary of the Indirect LDAP Server Monitor Information](#).
- **Remote Repl Server <baseDN> <host name:port> <serverID>**. Defines a remote replication server that is connected to the local replication server. Information in this entry is in respect to the Replication Server local to the `cn=monitor` branch. For detailed information, see [Summary of the Remote Replication Server Monitor Information](#).
- **Replica <baseDN>**. Stores information for an instance of the replicated naming context— also known as the replica—with respect to the Directory Server and its communication with a replication server. The Replica information is what is responsible for sending and receiving changes from the replication servers. For detailed information, see [Summary of the Replica Monitor Information](#).
- **Replication Server <replPort> <serverID>**. Shows the information specific to the Replication Server running, for example, on the replication port <replPort> with a server ID of <serverID>. This entry defines the replication server. For detailed information, see [Summary of the Replication Server Monitor Information](#).
- **Replication Server Database <baseDN> <serverID>**. Shows information for the changelog table of replica (suffix) in the replication server. As the Replication Server receives updates from the Directory Server, it records those changes in the changelog table. For detailed information, see [Summary of the Replication Server Database Monitor Information](#).
- **Replication Server Database Environment <baseDN>**. Shows the information for the database environment for the replication server backend plus the total number of records added to and deleted from the database. For detailed information, see [Summary of the Replication Server Database Environment Monitor Information](#).
- **Replication Summary <baseDN>**. Shows summary information on the replication topology and the state for a particular base DN. For detailed information, see [Summary of the Replication Summary Monitor Information](#).
- **Replication Changes Backend**. Shows the backend information for all replication changes. For detailed information, see [Summary of the Replication Changes Backend Monitor Information](#).
- **Replication Protocol Buffer**. Shows the state of the buffer (initially 4k) for protocol operations, which is stored in thread local storage. For detailed information, see [Summary of the Replication Protocol Buffer Monitor Information](#).

Replication Best Practices

The following are recommended best practices related to replication based on our observations in actual production environments.

About the dsreplication Command-Line Utility

The following points involve some security practices as applies to replication. For specific questions, please contact your authorized support provider.

- **Developing Scripts.** The `dsreplication` utility maintains the history of executed `dsreplication` commands with the full command-line arguments in the `logs/tools/dsreplication.history` file. The recorded commands may be used to develop scripts to set up and configure replication.

Scripts invoking the `dsreplication` utility in non-interactive mode should check the return code from the `dsreplication` process. A non-zero return code indicates some sort of failure.

If output messages from the `dsreplication` utility are not desired, use the `--quiet` option to suppress them.

The utility, by default, fails if one or more warnings are issued during the command execution. Warnings can be suppressed using the `--ignoreWarnings` option. For example, this option is required when using `dsreplication` with non-fully-qualified host names (for example, `localhost`), otherwise `dsreplication` will fail. In production environments, use of this flag is strongly discouraged.

The `dsreplication` utility also provides an `--ignoreLock` option that specifies that the tool should continue processing in non-interactive mode or in scripts even if the replication topology has been locked by another invocation of `dsreplication`. However, this option should be used with caution.

- **Concurrent Use.** With the exception of the `dsreplication status` subcommand, the `dsreplication` subcommands cannot be executed concurrently. The command-line utility locks the replication topology at one or more servers to prevent accidental configuration changes caused by multiple `dsreplication` subcommands running at the same time. It is best to avoid concurrent configuration changes in general.
- **Status.** The `dsreplication status` subcommand requires the Replication Servers to provide monitoring information. This can lead to a delay before the output of `dsreplication status` is displayed. By default, `dsreplication` will display the status for all replicated domains (with the exception of the special domains of the schema and the server registry).

It is recommended to select a particular base DN for `dsreplication status` if multiple base DNs are configured for replication.

It is also recommended to avoid invoking `dsreplication status` too often (more than once every 15 seconds) or from multiple locations at the same time. Some of the information displayed by `dsreplication status` is based on monitor information that is not refreshed every time the monitor is queried.

The `status` subcommand should not be used for collecting performance metrics. It is best to rely on replication-related information captured by the Periodic Stats Logger plugin.

- **Topology Tasks.** The `dsreplication` tool allows specifying more than one server in a topology to act as the host for other servers for the `enable` and `initialize` actions. The `--topologyFilePath` option can be used to specify a file with a series of hosts and ports in the topology. When the hosts file is used for an `enable` or `initialize` action, the servers in the file are tried sequentially until the new server is successfully enabled or added. The rest of the servers in the file are ignored. This ensures that a host server is always available. This file is generated with the `manage-topology export` command.

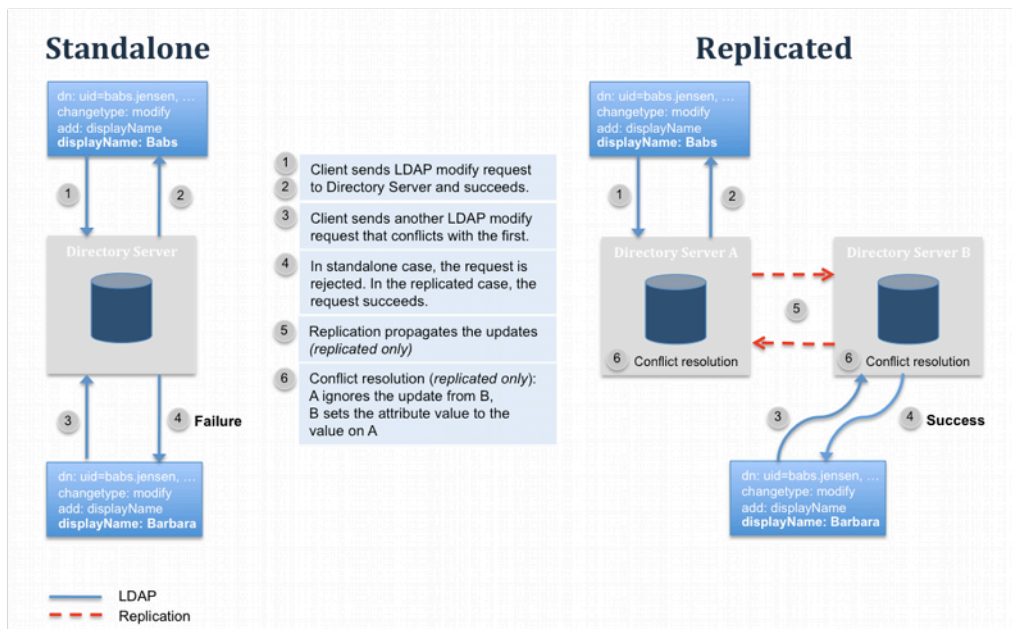

Replication Conflicts

This section provides more in-depth information on replication conflicts than presented in earlier sections, so that administrators can understand the mechanisms and possible scenarios behind these conflicts.

Updates to Directory Server entries in a replication topology may happen independently, since replication guarantees only eventual consistency, not strong consistency. The eventual consistency model also means that conflicting changes can be applied at different directory server instances. In most cases, the Directory Server is able to resolve these conflicts automatically and in a consistent manner (i.e., all directory server instances in a replication topology will resolve each and every conflict the same way). However, in some scenarios, as seen below, manual administrative action is required. For any of these unresolved conflicts, the administrator is notified via administrative alerts.

On a high-level, the conflict resolution algorithm tries to resolve conflicts as if the operations causing the conflict in a distributed environment has been applied to a single directory server instance. For example, if

the same entry is added to two different directory server instances at about the same time, then once these operations have been replicated, both directory servers will keep only the entry that was added first. The following figure highlights the differences between standalone versus replicated environments.

MY TITLE Conflicting Operations in Standalone versus Replicated Environments

Types of Replication Conflicts

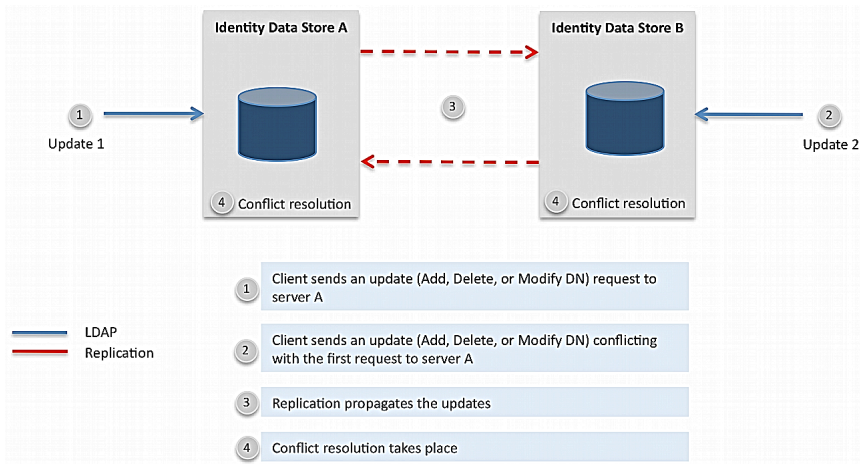

There are fundamentally two types of replication conflicts: naming and modification conflicts. Naming conflicts include operations that cause conflicts with the naming (DN) of the existing or new entries, while modification conflicts include operations that result in conflicts in the modification of attributes.

Naming Conflict Scenarios

For all of the naming conflict scenarios in the table below, assume the following:

- Update 1 was applied at Directory Server 1
- Update 2 was applied at Directory Server 2
- Update 1 occurred shortly before Update 2, so that Directory Server 2 received Update 1 after Update 2 was applied

The naming conflict scenario is illustrated in the following figure:

MY TITLE Naming Conflict Scenario

The following table shows the result of a modification conflict depending on the type of updates that occurs. The code does not compare change sequence numbers (CSNs) but applies operations in the order they were received. This may lead to inconsistent replays.

Naming Conflict Scenarios

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Modify	Delete	Yes	Modify is discarded.
Modify	Modify DN	Yes	New entry is located based on the entryUUID and Modify is applied to the renamed entry.
Delete	Delete	Yes	Delete operation is ignored.
Delete	Modify DN	Yes	Delete operation is applied to the renamed entry.
Delete of A	Add of B under A	Yes	Entry B is renamed and Entry A is deleted.
Modify DN	Delete of the same entry targeted by the Modify DN	Yes	Modify DN operation is ignored.
Modify DN with a new parent	Delete of parent	No	The entry targeted in the Modify DN operation is marked as a conflict entry.
Modify DN with a new parent	Modify DN of the parent	Yes	The entry will be moved under the new DN of the parent.
Modify DN of A with new DN B	Modify DN of C with new DN B	No	A and B will be conflict entries.
Add A	Modify DN of the parent of A	Yes	The entry is added under the new DN of the parent.
Add A	Delete of the parent of A	No	The added entry is marked as a conflict entry.

Update 1	Update 2	Automatic Resolution?	Result of Conflict Resolution at Directory Server 2 When Update 1 is received
Add A	Add A with same set of attributes	Yes	The entryUUID of the incoming Add operation applied to the existing entry.
Add A	Add A with different set of attributes (or values)	No	The existing entry is marked as a conflicting entry and the incoming Add is executed.

Modification Conflict Scenarios

Modification conflicts are always resolved automatically and no manual action is required. The LDAP Modify operation allows the following modification types:

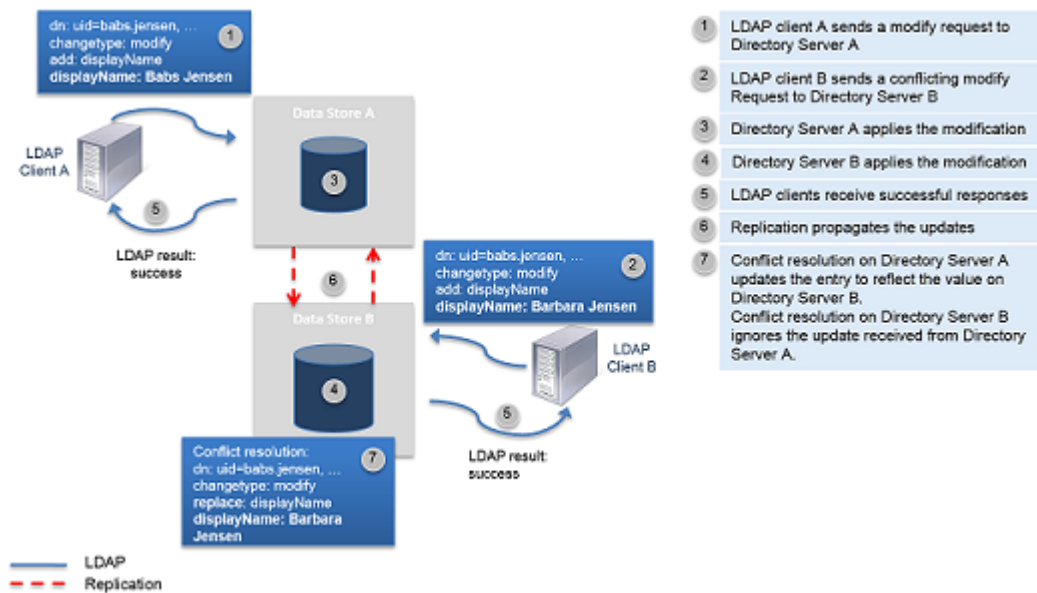

- Add of one or more values
- Delete of one or more values or the entire attribute
- Replacement of all values

Replication does not currently support the increment LDAP modification type.

For all of the operations in the table below, assume the following:

- LDAP Modify 1 was applied at Directory Server 1
- LDAP Modify 2 was applied at Directory Server 2
- LDAP Modify 1 occurred shortly before LDAP Modify 2, so that Directory Server 2 received LDAP Modify 1 after LDAP Modify 2 was applied.

The modification conflict scenario is illustrated in the figure below:

MY TITLE Modification Conflict Scenario

The following table shows the result of a modification conflict depending on the type of updates that occurs:

Modification Conflict Scenarios

Modify 1	Modify 2	Result of Conflict Resolution at Directory Server 2 When Modify 1 is received
Add of a single-value attribute	Add of the same attribute with a different value	Incoming Modify is ignored.
Delete of a single-valued attribute	Replacement of the value of the same attribute	Incoming Delete is ignored.
Replacement of a single-valued attribute	Delete of the same attribute	Incoming Replacement is ignored.
Delete some values from a multi-valued attribute	Delete some values from a multi-valued attribute	Incoming Delete is ignored.
Delete a multi-valued attribute	Delete of the same multi-valued attribute	Incoming Delete is ignored.
Delete a multi-valued attribute	Add the same multi-valued attribute	Incoming Delete is ignored.
Delete value X from a multi-valued attribute	Delete value X from the same multi-valued attribute	Incoming Delete is ignored.
Delete value X from a multi-valued attribute	Add value Y to the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Delete value Y from the same multi-valued attribute	Delete of value X is applied.
Delete value X from a multi-valued attribute	Replace all values of the same multi-valued attribute	Incoming Delete is ignored.
Add of values X and Y to a multi-valued attribute	Delete value X from the same multi-valued attribute	Only value Y is added.
Delete value X from a multi-valued attribute	Add of values X and Y to the same multi-valued attribute	Incoming Delete is ignored.

Troubleshooting Replication

The following sections provide information to troubleshoot your replication deployment.

Recovering a Replica with Missed Changes

If a server has been offline for a period of time longer than the replication purge delay, the `dsreplication initialize` command must be performed to bring the replica into sync with the topology.

Server startup is the only time missed changes are detected. A missed change is a change that the replica detects that it needs, but which cannot be found within any other replication server's replicationChanges backend (stored in the path server root `/changeLogDb`). If missed changes are detected, the server enters lockdown mode, where only privileged clients can make requests. Any other server that is not missing changes can be used as a source for `dsreplication initialize`.

If a manual backup and restore of the server is required, then the following steps are equivalent to `dsreplication initialize`.

Performing a manual initialization

About this task

In the event that an online initialization is not possible, the following steps can be used to initialize a server.

Steps

1. From another server in the replication topology, back up the `userRoot`, `schema`, and `replicationChanges` backends to the `<server-root>/bak` directory. If data encryption is enabled, the `encryption-settings` backend should also be exported, as one or more encryption settings IDs may need to be imported into the new replica.

```
$ source-server-root>/bin/backup --backendID userRoot --backupDirectory \
  bak/userRoot
$ <source-server-root>/bin/backup --backendID schema --backupDirectory \
  bak/schema
$ <source-server-root>/bin/backup --backendID replicationChanges \
  --backupDirectoryd bak/replicationChanges
$ <source-server-root>/bin/encryption-settings export --id <id> \
  --output-file bak/exported-key
```

2. Copy the `bak` directory to the new replica.

```
$ scp -r <source-server-root>/bak/* \
  <user>@<destination-server>:<destination-server-root>/bak
```

3. Stop the server and restore the `userRoot`, `schema`, `changelog`, and `replicationChanges` backends. If the `encryption-settings` backend was exported, it should be imported before restoring any of the backends.

```
$ <destination-server-root>bin/encryption-settings import --input-file \
  bak/exported-key --set-preferred
Enter the PIN used to encrypt the definition:
$ <destination-server-root>/bin/restore --backupDirectory bak/userRoot
$ <destination-server-root>/bin/restore --backupDirectory bak/schema
$ <destination-server-root>/bin/restore --backupDirectory \
  bak/replicationChanges
```

4. Start the server using `bin/start-server`.

Fixing Replication Conflicts

Replication conflicts can occur when an incompatible change to an entry is made on two replicas at the same time. The change is processed on one replica and then replicated to the other replica, which causes the conflict. While most conflicts are resolved automatically, some require manual action.

To fix replication conflicts, initialize the replica containing the conflicts with the data from another replica that does not have conflicts. If the database is large and the number of conflicts small, running `ldapmodify` against the server with the conflict will work if the command includes the Replication Repair Control specified by OID value 1.3.6.1.4.1.30221.1.5.2. The Replication Repair Control prevents the change from replicating. It also enables changing operational attribute values, which are not normally writable.

The following steps provide an example of using the Replication Repair Control to fix replication conflicts by applying change to only the server with the conflict. There are two examples: one for a modification conflict found by performing an `ldapdiff`, and the other for a naming conflict.

To Fix a Modify Conflict

Steps

1. The `bin/ldap-diff` tool can be used to isolate conflicting entries between two replicas. The following uses the tool to search across the entire base DN for any difference in user attributes, and reports the difference in `difference.ldif`. Replace the `sourceHost` value with the server that needs the adjustment.

```
$ bin/ldap-diff --sourceHost austin02.exmple.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --
sourceBindPassword pass \
--targetHost austin01.example.com --targetPort 1389
\
--targetBindDN "cn=Directory Manager" --
targetBindPassword
--baseDN "dc=example,dc=com" --outputLDIF
difference.ldif \
--searchFilter "(objectclass=*)" --numPasses 3 "*"
pass \
"^userPassword"
```

2. The `difference.ldif` file is in a format that can be used with `ldapmodify` to apply changes to the server that contains conflicts. The `ldap-diff` command must have been run with the `sourceHost` value as the server with conflicts. The following is an example of the contents of `difference.ldif`:

```
dn: uid=user.1,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 568 232 6789
-
delete: mobile
mobile: +1 568 591 7372
-
```

3. Run `bin/ldapmodify` to correct the entries on only the server with conflicts.

```
$ bin/ldapmodify --bindPassword password -J "1.3.6.1.4.1.30221.1.5.2" \
--filename difference.ldif
```

To Fix a Naming Conflict

Steps

1. In this example, a naming conflict was encountered when the replica attempted to replay an ADD of `uid=user.200,ou=people,dc=example,dc=com`. In other words, two clients added the entry at the same time as an entry of the same name was added on another replica.

```
[18/Feb/2010:14:53:12 -0600] category=EXTENSIONS severity=SEVERE_ERROR
msgID=1880359005 msg="Administrative alert type=replication-unresolved-
conflict
id=bbd2cbaf-90a4-42af-94a8-c1a42df32fc6
class=com.unboundid.directory.server.replication.plugin.ReplicationDomain
msg='An unresolved conflict was detected for DN
uid=user.200,ou=People,dc=example,dc=com.
The conflicting entry has been renamed to
entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com'"
```

2. The Directory Server prepends the entryUUID to the DN of the conflicting attribute and adds a `ds-sync-conflict-entry` auxiliary object class to the entry to aid in search. For example, the following

command searches for any entry that has the `ds-sync-conflict-entry` objectclass and returns only the DNs that match the filter. You should see the conflicting entry for `uid=user.200`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub \
  "(objectclass=ds-sync-conflict-entry)" "1.1"
```

```
dn: entryuuid=69807e3d-ab27-43a3-8759-
ec0d8d6b3107+uid=user.200,ou=People,dc=example,dc=com
```

```
dn: entryuuid=523c430e-
a870-4ebe-90f8-9cd811946420+uid=user.200,ou=People,dc=example,dc=com
```

Note: Conflict entries are not returned unless the `objectclass=ds-sync-conflict-entry` is present in the search filter.

- After comparing the conflict entry with the target entry, the difference can be applied in a manner similar to the previous example using `ldapmodify` with the Replication Repair Control. The conflict entry can also be deleted using this command. Run `bin/ldapmodify` with the Replication Repair Control to make the fix. When making changes using the Replication Repair Control, the updates will not be propagated via replication. You should examine each and every replica one by one, and apply the necessary modifications using the request control.

```
$ bin/ldapmodify -J "1.3.6.1.4.1.30221.1.5.2" \
  --filename difference.ldif
```

Fixing Mismatched Generation IDs

A warning that multiple generation IDs were detected for a specific suffix indicates that one or more replicas need to be re-initialized. If the warning is presented from a server after an initialization, it could be that `post-external-initialization` was not run as part of a global change in data. Running this command will fix the situation. The `dsreplication status` command will warn when any generation IDs are different across the topology.

Replication Reference

The following section shows general reference information related to replication.

Summary of the `dsreplication` Subcommands

A summary of the `dsreplication` subcommands and functions is presented in the table below.

dsreplication subcommands

Subcommand	Description
cleanup-local-server	<p>Removes replication-related artifacts from the configuration, schema as well as the server registry while the local server is offline. The subcommand does not remove references to this server from other replicas and replication servers in the topology. Therefore, it is recommended to remove this server first from the replication topology either by using the <code>disable</code> or <code>remove-defunct-server</code> subcommands. Since this subcommand can only be executed when the server is offline, replication attributes from suffixes other than the server registry or the schema will not be removed. The tool will produce an LDIF file, <code>logs/cleanup-backends.ldif</code> that may be used to the remove replica state from the base entry of these suffixes after the server is restarted.</p> <p>To remove the replication history from regular suffixes, export the formerly replicated suffixes using the <code>--excludeReplication</code> option of the <code>export-ldif</code> command. The resulting LDIF file can be re-imported using the <code>import-ldif</code> command. For example:</p> <pre>\$ bin/export-ldif --backendID userRoot -- excludeReplication \ --ldifFile cleansed.ldif \$ bin/import-ldif --backendID userRoot --ldifFile cleansed.ldif</pre> <p>Exporting using the <code>--excludeReplication</code> option of the <code>export-ldif</code> command will also remove the replica state from the output. The LDIF created by the <code>cleanup-local-server</code> subcommand does not need to be applied after the server is restarted.</p>
disable	Disables replication on the specified server for the provided base DN and removes references to this server in the other servers with which it is replicating data.
enable	Updates the configuration of the servers to replicate the data under the specified base DN. If one of the servers is already replicating the data under the base DN with other servers, executing this subcommand will update the configuration of all the servers (so it is sufficient to execute the command line once for each server you add to the replication topology).
initialize	Initializes the data under the specified base DN on the destination server with the contents on the source server.
initialize-all	Initializes the data under the specified base DN on all servers in the replication topology with the contents on the specified server.
post-external-initialization	Used with <code>pre-external-initialization</code> , the command resets the generation ID based on the newly-loaded data. This subcommand must be called after initializing the contents of all the replicated servers using the <code>import-ldif</code> tool or <code>dsreplication initialize</code> . Specify the list of base DN's that have been initialized and provide the credentials of any of the servers that are being replicated. See the usage of the <code>pre-external-initialization</code> subcommand for more information. This subcommand only needs to be run on one of the replicas once.

Subcommand	Description
pre-external-initialization	Clears the existing generation ID and removes all accumulated changes of the replicated suffix from the replication changelog database at each and every replication server. This subcommand should be used when globally restoring the replicas on all of the servers in a topology. You must specify the list of base DN's that will be initialized and provide the credentials of any of the servers that are being replicated. After calling this subcommand, initialize the contents of all the servers in the topology, then call the <code>post-external-initialization</code> subcommand. This subcommand only needs to be run on one of the replicas once.
remove-defunct-server	Removes an offline defunct server from the replication on all servers in the topology.
status	Displays the status of replication domains. If no base DN's are specified as parameters, the information for all base DN's is displayed. Available options with the status subcommand are: <code>--showAll</code> , <code>--displayServerTable</code> , <code>--location</code> .

Summary of the Direct LDAP Monitor Information

The following table provides a description of the attributes in the `cn=Direct LDAP Server` monitor entry. The DN for the monitor entry is as follows:

```
dn: cn=Direct LDAP Server <baseDN> <host name:ldapPort> <serverID>,cn=monitor
```

Direct LDAP Monitor Information

Monitor Attribute	Description
replica-id:<serverID>	Replica ID number.
replication-backlog	Number of changes that the replication server has not seen from the server.
missing-changes	Number of missing changes.
approximate-delay	Difference between the time of the last change that the replication server has seen from the LDAP server and the most current timestamp on the latest change on the server.
base-dn	Base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Displays the replication protocol version.
generation-id	Generation ID for the base DN on the Directory Server.
restricted	Boolean that indicates whether the replication domain is restricted in an Entry Balancing Configuration with the Directory Proxy Server.
ack-sent	Number of acknowledgement messages sent to this replica (not currently used).
ack-received	Number of acknowledgement messages received from this replica (not currently used).
add-sent	Number of protocol messages with an LDAP Add sent to this replica.
add-received	Number of protocol messages with an LDAP Add received from this replica.

Monitor Attribute	Description
delete-sent	Number of protocol messages with an LDAP Delete sent to this replica.
delete-received	Number of protocol messages with an LDAP Delete received from this replica.
done-sent	Number of done messages sent to this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has been initialized over the replication protocol.
done-received	Number of done messages received from this replica. A done message indicates an end of online initialization session. If the value is non-zero, then this replica has completed the initialization of other replicas over the replication protocol.
entry-sent	Number of entry messages sent to this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from this replica. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to this replica.
error-received	Number of error messages received from this replica.
heartbeat-sent	Number of heartbeat messages sent to this replica.
heartbeat-received	Number of heartbeat messages received from this replica (should always be 0, since the replica never sends a heartbeat message to the server).
initialize-request-sent	Number of initialize-request messages sent to this replica. This message is sent when another replica requested initialization of its data using the replication protocol.
initialize-request-received	Number of initialize-request messages received from this replica. This message is sent when this replica requested initialization of its data using the replication protocol from another replica.
initialize-target-sent	Number of initialize-target messages sent to this replica. This message is sent before another replica has started the initialization of this replica.
initialize-target-received	Number of initialize-target messages received from this replica. This message is sent before this replica starts the initialization of one or more replicas.
ldap-server: <hostname:ldapPort>	The hostname and port of the local replication server.
modify-sent	Number of protocol messages with an LDAP Modify sent to this replica.
modify-received	Number of protocol messages with an LDAP Modify received from this replica.
modify-dn-sent	Number of protocol messages with an LDAP Modify DN sent to this replica.
modify-dn-received	Number of protocol messages with an LDAP Modify DN received from this replica.

Monitor Attribute	Description
repl-server-start-sent	Number of replication-server-start messages sent to this replica (should never be more than 1). The Replication Server responds with this message to the start message received from the replica.
repl-server-start-received	Number of replication-server-start messages received from this replica (should always be 0).
reset-generation-id-sent	Number of reset generation ID messages received from this replica.
reset-generation-id-received	Number of reset generation ID messages sent to this replica (should always be 0).
server-start-sent	Number of server-start messages sent to this replica (should always be 0).
server-start-received	Number of server-start messages received from this replica (should never be more than 1). Server-start is the first message the replica sends after establishing a replication connection.
window-sent	Number of window messages sent to this replica. Window messages are used for cumulative acknowledgement in the replication protocol.
window-received	Number of window messages received from this replica. Window messages are used for cumulative acknowledgement in the replication protocol.
window-probe-sent	Number of window probe messages sent to this replica (should always be 0).
window-probe-received	Number of window probe messages received from this replica. The replica sends a window probe message to the server if the send window in the replica is closed and the replica is unable to publish updates to the server.
update-sent	Number of changes sent to this server.
update-received	Number of changes received from this server.
internal-connection	Indicates if the replica is in the same process as the replication server.
server-state	Displays the state of the replica. Displays the latest change number that the replica has seen from all the other replicas including itself.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last five seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a five second period since the replication server was started.
max-send-window	Maximum number of changes that can be sent to the LDAP server before requiring an ACK.

Monitor Attribute	Description
current-send-window	Current number of changes remaining to be sent to the LDAP server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received by the LDAP server before sending an ACK.
current-rcv-window	Number of changes remaining to be received by the LDAP server before sending an ACK Server.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the server. This is a temporary state, when loading data into the topology or the replica has not been initialized. Normally, it should be false.

Summary of the Indirect LDAP Server Monitor Information

The following table provides a description of the attributes in the `cn=Indirect LDAP Server` monitor entry. These attributes provide information about a Directory Server that is connected to a different replication server in the topology.

```
dn: cn=Indirect LDAP Server <baseDN> <serverID>,cn=monitor
```

Indirect LDAP Server Monitor Information

Monitor Attribute	Description
replica-id: <serverID>	ID number identifying the replica.
base-dn: <baseDN>	Base DN
connected-to: Remote Repl Server <baseDN> <host name:replPort> <replID>	Replication server to which the directory server is connected.
replication-backlog	Number of changes that the replication server has not seen from the server.
approximate-delay	Amount of time between the last change seen by this Directory Server and the most recent change seen by the remote replication server. This value is the amount of time between the time stamps, not the amount of time required to synchronize the two servers.
generation-id	Generation ID for this suffix on this remote replication server.
consumed-update-recent-rate	Rate that the connected Replication Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Replication Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.

Summary of the Remote Replication Server Monitor Information

The following table provides a description of the attributes in the `cn=Remote Repl Server` monitor entry. The DN for the monitor entry is as follows:

```
dn: cn=Remote Repl Server <baseDN> <host name:replPort> <serverID>,cn=monitor
```

Remote Replication Server Monitor Information

Monitor Attribute	Description
replication-server: <host name>:<repl port>	Host name and replication port number of the Replication Server.
replication-server-id:<serverID>	Server ID for the Replication Server.
available	Indicates if the remote replication server is available or not. Values: true or false.
sending-paused	Indicates if sending is paused. Values: true or false.
receiving-paused	Indicates if receiving is paused. Values: true or false.
wan-gateway-priority	Specifies the WAN Gateway priority of the remote replication server.
is-wan-gateway	Indicates if the remote replication server is a WAN Gateway. Values: true or false.
wan-gateway-desired	<p>Indicates if the remote replication server is a desired gateway. Values: true or false. This entry together with the <code>is-wan-gateway</code> property indicates the desired state.</p> <ul style="list-style-type: none"> ▪ is-wan-gateway=false, wan-gateway-desire=false: Indicates another server with a higher gateway priority exists or the gateway priority is set to disabled. ▪ is-wan-gateway=false, wan-gateway-desire=true: Indicates that the remote replication server wants to be a WAN gateway. ▪ is-wan-gateway=true, wan-gateway-desire=false: Indicates that the remote replication server wants to give up its role as a WAN gateway. ▪ is-wan-gateway=false, wan-gateway-desire=true: Indicates the remote replication server wants to remain as a gateway server.
base-dn	base DN
ssl-encryption	Flag to indicate if SSL encryption is in use.
protocol-version	Replication protocol version.
generation-id	Generation ID for this suffix on this remote replication server.
restricted	Indicates that remote replication server is in an entry-balancing deployment.
add-sent	Number of protocol messages with an LDAP Add sent to the remote replication server.
add-received	Number of protocol messages with an LDAP Add received from the remote replication server.
delete-sent	Number of protocol messages with an LDAP Delete sent to the remote replication server.
delete-received	Number of protocol messages with an LDAP Delete received from the remote replication server.
done-sent	Number of done messages sent to the remote replication server. A done message indicates an end of online initialization session.
done-received	Number of done messages received from the remote replication server. A done message indicates an end of online initialization session.

Monitor Attribute	Description
entry-sent	Number of entry messages sent to the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
entry-received	Number of entry messages received from the remote replication server. Entry messages carry replicated data to initialize replicas over the replication protocol.
error-sent	Number of error messages sent to the remote replication server.
error-received	Number of error messages received from the remote replication server.
heartbeat-sent	Number of heartbeat messages sent to the remote replication server.
heartbeat-received	Number of heartbeat messages received from the remote replication server.
initialize-request-sent	Number of initialize-request messages sent to the remote replication server. This message is used during online initialization from one replica to another.
initialize-request-received	Number of initialize-request messages received from the remote replication server. This message is used during online initialization from one replica to another.
initialize-target-sent	Number of initialize-target messages sent to the remote replication server. This message is used before online initialization from one replica to another.
initialize-target-received	Number of initialize-target messages received from the remote replication server. This message is used before online initialization from one replica to another.
modify-sent	Number of protocol messages with an LDAP Modify sent to the remote replication server.
modify-received	Number of protocol messages with an LDAP Modify received from the remote replication server.
modify-dn-sent	Number of protocol messages with an LDAP Modify DN sent to the remote replication server.
modify-dn-received	Number of protocol messages with an LDAP Modify DN received from the remote replication server.
monitor-sent	Number of monitor messages sent to the remote replication server. This message is primarily used when communicating with directory servers running a prior release.
monitor-received	Number of monitor messages received from the remote replication server. This message is primarily used when communicating with directory servers running a prior release.
monitor-request-sent	Number of monitor requests sent to the remote replication server. The receiving server will respond with a monitor message that includes server's information about the state of the topology.
monitor-request-received	Number of monitor requests received from the remote replication server. This server will respond with a monitor message that includes server's information about the state of the topology.

Monitor Attribute	Description
monitor-v2-sent	Number of monitor messages sent to the remote server. This monitor message is only used with Directory Server v3.5 or later.
monitor-v2-received	Number of monitor messages received from the remote server. This monitor message is only used with Directory Server v3.5 or later.
pause-sending-updates-sent	Number of pause-sending-updates messages sent to the remote server. The remote server must stop sending update messages to this server when receiving this message.
pause-sending-updates-received	Number of pause-sending-updates messages received from the remote server. This server will stop sending update messages to the remote server upon receiving this message.
repl-server-start-sent	Number of replication-server-start messages sent to the remote replication server (should never be more than 1). The Replication Server responds with this message to the replication-server-start message received from remote replication servers.
repl-server-start-received	Number of replication-server-start messages received from the remote replication server (should never be more than 1) window-sent: the number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
reset-generation-id-sent	Number of reset generation ID messages received from the remote replication server. This message is sent before and after the data is initialized in the topology.
reset-generation-id-received	Number of reset generation ID messages sent to the remote replication server. This message is sent before and after the data is initialized in the topology.
server-info-sent	Number of replication server information messages sent to the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
server-info-received	Number of replication server information messages received from the remote replication server. This message tells other replication servers about the replicas directly connected to the sending server. This message is also used to distribute information about the location of replicas.
set-source-location-sent	Number of set-source-locations messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
set-source-location-received	Number of set-source-locations messages sent to the remote replication server. This message is used by WAN gateway servers to request update messages from additional locations.
start-sending-updates-sent	Number of start-sending-updates messages sent to the remote replication server. The remote server may only start sending updates to this server after receiving this message.
start-sending-updates-received	Number of start-sending-updates messages received from the remote server. Sending update messages to the remote server may only start after receiving this message.

Monitor Attribute	Description
window-sent	Number of window messages sent to the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
window-received	Number of window messages received from the remote replication server. Window messages are used for cumulative acknowledgement in the replication protocol.
messages-sent	Total number of messages sent.
messages-received	Total number of messages received.
update-sent	Total number of updates sent.
update-received	Total number of updates received.
server-state	Displays the server state of the remote replication server. It displays the last change seen on the remote replication server.
consumed-update-recent-rate	Rate that the connected Directory Server is consuming updates sent by this replication server, expressed as the number of updates per second and measured over the last five seconds.
consumed-update-peak-rate	Highest rate that the connected Directory Server has consumed updates sent by this replication server, measured over a five second period since the replication server was started.
produced-update-recent-rate	Rate that the connected Directory Server has sent updates to this replication server, expressed as the number of updates per second and measured over the last five seconds.
produced-update-peak-rate	Highest rate that the connected Directory Server has sent updates to this replication server, measured over a five second period since the replication server was started.
max-send-window	Maximum number of changes that can be sent to the remote replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the remote replication server before requiring an ACK.
max-rcv-window	Maximum number of changes that can be received from the remote replication server before sending an ACK.
current-rcv-window	Number of changes remaining to be received from the remote replication server before sending an ACK.
degraded	Indicates that the generation ID of the replica does not match the generation ID of the remote replication server. This is a temporary state, when loading data into the topology or the replica has not been initialized. Normally, it should be false.

Summary of the Replica Monitor Information

The following table provides a description of the attributes in the `cn=Replica` monitor entry for a specific base DN.

```
dn: cn=Replica <baseDN>,cn=monitor
```

Indirect LDAP Server Monitor Information

Monitor Attribute	Description
base-DN: <baseDN>	Specified base DN. The monitor entries track your company's base DN (or <code>dc=example,dc=com</code>), <code>cn=schema</code> , and <code>cn=topology,cn=config</code> .
connected-to: Replication Server <replPort> <serverID>	Replication port number and server ID of the replication server to which this LDAP Server is connected. The first number is the replication server port number and the second number is the <code>server-id</code> of the replication server.
lost-connections	Number of times the Directory Server has lost connection to a replication server.
received-updates	Number of updates that the Directory Server Replica has received from the connected replication server.
sent-updates	Number of updates sent to the replication server.
pending-updates	Number of updates pending to send to the replication server.
replayed-updates	Total number of updates from the replication server that have been replayed for this replica.
replayed-updates-ok	Number of updates for this replica that have been successfully replayed with no conflicts.
replayed-update-failed	Number of updates for this replica that were successfully replayed after automatically resolving a modify conflict.
resolved-modify-conflicts	Number of updates for this replica that were successfully resolved after a modify conflict.
resolved-naming-conflicts	Number of updates for this replica that were successfully resolved after a naming conflict.
unresolved-naming-conflicts	Number of updates for this replica that could not be replayed due to an unresolvable naming conflict.
replica-id	Server ID for this replica.
max-rcv-window	Maximum number of changes that the Directory Server Replica can receive at a time before sending an acknowledgment back to the replication server.
current-rcv-window	Current received window size for this replica.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-rcv-window	Number of changes remaining to be received from the replication server before it must send an ACK.
max-send-window	Maximum number of changes that the Directory Server Replica can send at a time to the replication server before requiring an ACK.
current-send-window	Number of changes remaining to be sent to the replication server before requiring an ACK.
ssl-encryption	Flag to indicate if SSL encryption is in use.
generation-id	Generation ID for this suffix on the Directory Server.
replication-backlog	Number of changes that are from this replica.

Summary of the Replication Server Monitor Information

The following table provides a description of the attributes in the `cn=Replication Server` monitor entry.

```
dn: cn=Replication Server <baseDN> <replServerID>,cn=monitor
```

Replication Server Monitor Information

Monitor Attribute	Description
<code>replication-server-id</code>	Server ID for the Replication server ID.
<code>replication-server-port</code>	Port number on which the replication server listens for communication from other servers.
<code>base-dn: <baseDN></code>	Indicates the suffix to which this replication server database applies.
Generation IDs by Base DN	List of generation IDs for each base DN on the server.
<code>num-outgoing-replication-server-connections</code>	Number of outgoing connections from the replication server.
<code>num-incoming-replication-server-connections</code>	Number of incoming connections into the replication server.
<code>num-incoming-replica-connections</code>	Number of incoming connections to the replica.

Summary of the Replication Server Database Monitor Information

The following table provides a description of the attributes in the `cn=Replication Server database` monitor entry.

```
dn: cn=Replication Server database <baseDN> <replServerID>,cn=monitor
```

Replication Server Database Monitor Information

Monitor Attribute	Description
<code>database-replica-id: <replicaID></code>	Specifies the replication server ID.
<code>base-dn: <baseDN></code>	Indicates the suffix to which this replication server database applies.
<code>first-change</code>	<p>First change number that is in this replication database table for this suffix from this <code>server-id</code>. For example, an example entry looks like the following:</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
<code>last-change</code>	<p>Last change number that is in this replication database table for this suffix from this <code>server-id</code>. For example, an example entry looks like the following:</p> <pre>0000012209EA622C390D00000002 Mon Jun 22 16:41:11 CDT 2011</pre>
<code>queue-size</code>	Number of changes in the replication server queue waiting to be sent to this remote replication server database.
<code>queue-size-bytes</code>	Size in bytes of all the messages waiting in the queue.

Monitor Attribute	Description
records-added	Displays the number of records changed or added to the DIT.
records-removed	Displays the number of records removed from the DIT.

Summary of the Replication Server Database Environment Monitor Information

The following table provides a description of the attributes in the `cn=Replication Server Database Environment` monitor entry, which includes the environment variables associated with the Oracle Berkeley Database Java Edition backend.

```
dn: cn=Replication Server Database Environment,cn=monitor
```

Replication Server Database Environment Monitor Information

Monitor Attribute	Description
je-version	Current version of the Oracle Berkeley Java Edition.
current-db-cache-size	Current DB cache size.
max-db-cache-size	Maximum DB cache size.
db-cache-percent-full	Percentage of the cache used by the Directory Server.
db-directory	Directory that holds the changelogDb file.
db-on-disk-size	Size of the DB on disk.
cleaner-backlog	Number of log files that must be cleaned for the cleaner to meet its target utilization.
random-read-count	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
random-write-count	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
sequential-read-count	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
sequential-write-count	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
nodes-evicted	Accumulated number of nodes evicted.
active-transaction-count	Number of currently active transactions.
num-checkpoints	Number of checkpoints. A checkpoint is a process that writes to your log files all the internal BTree nodes and structures modified as a part of write operations to your log files to facilitate a quick recovery.
checkpoint-in-progress: false	Indicates if a checkpoint is in progress.
total-checkpoint-duration-millis	Total time in milliseconds for all checkpoints.
average-checkpoint-duration-millis	Average time in milliseconds for all checkpoints.
last-checkpoint-duration-millis	Duration in milliseconds of the last checkpoint run.
last-checkpoint-start-time	Start time of the last checkpoint.
last-checkpoint-stop-time	Stop time of the last checkpoint.
millis-since-last-checkpoint	Time in milliseconds since the last checkpoint.

Monitor Attribute	Description
read-locks-held	Total read locks currently held.
write-locks-held	Total write locks currently held.
transactions-waiting-on-locks	Total transactions waiting for locks
je-env-stat-AdminBytes	Number of bytes of JE cache used for log cleaning metadata and other administrative structure.
je-env-stat-BufferBytes	Total memory currently consumed by log buffers, in bytes.
je-env-stat-CacheDataBytes	Total memory of cache used for data.
je-env-stat-CacheTotalBytes	Total amount of JE cache in use, in bytes.
je-env-stat-CleanerBacklog	Number of files to be cleaned to reach the target utilization.
je-env-stat-CursorsBins	Number of bottom internal nodes (BINs) encountered by the INCompressor that had cursors referring to them when the compressor ran. The compressor thread cleans up the internal BTree as records are deleted to ensure unused nodes are not present.
je-env-stat-DataBytes	Amount of JE cache used for holding data, keys and internal Btree nodes, in bytes.
je-env-stat-DbClosedBins	Number of bins encountered by the INCompressor that had their database closed between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-EndOfLog	Location of the next entry to be written to the log.
je-env-stat-InCompQueueSize	Number of entries in the INCompressor queue when the getStats() call was made.
je-env-stat-LastCheckpointEnd	Location in the log of the last checkpoint end.
je-env-stat-LastCheckpointId	ID of the last checkpoint.
je-env-stat-lastCheckpointStart	Location in the log of the last checkpoint start.
je-env-stat-lockBytes	Number of bytes of JE cache used for holding locks and transactions.
je-env-stat-NBINsStripped	Number of BINS stripped by the evictor.
je-env-stat-NCacheMiss	Total number of requests for database objects which were not in memory.
je-env-stat-NCheckpoints	Total number of checkpoints run so far.
je-env-stat-NCleanerDeletions	Number of cleaner file deletions this session.
je-env-stat-NCleanerEntriesRead	Accumulated number of log entries read by the cleaner.
je-env-stat-NCleanerRuns	Number of cleaner runs this session.
je-env-stat-NClusterLNProcessed	Accumulated number of leaf nodes (LNs) processed because they qualify for clustering.
je-env-stat-NDeltaINFlush	Accumulated number of delta internal nodes (INs) flushed to the log.
je-env-stat-NEvictPasses	Number of passes made to the evictor.
je-env-stat-NFSyncRequests	Number of fsyncs requested through the group commit manager. Fsync() synchronizes the file system after a write or a transaction.
je-env-stat-NFSyncTimeouts	Number of fsync requests submitted to the group commit manager which timed out.

Monitor Attribute	Description
je-env-stat-NFSyncs	Number of fsyncs issued through the group commit manager.
je-env-stat-NFileOpens	Number of times a log file has been opened.
je-env-stat-NFullBINFlush	Accumulated number of full bottom internal nodes (BINS) flushed to the log.
je-env-stat-NFullINFlush	Accumulated number of full INs flushed to the log.
je-env-stat-NINsCleaned	Accumulated number of INs cleaned.
je-env-stat-NINsDead	Accumulated number of INs that were not found in the tree anymore (deleted).
je-env-stat-NINsMigrated	Accumulated number of INs migrated.
je-env-stat-NINsObsolete	Accumulated number of INs obsolete.
je-env-stat-NLNQueueHits	Accumulated number of LNs processed without a tree lookup.
je-env-stat-NLNscleaned	Accumulated number of LNs cleaned.
je-env-stat-NLNscleaned	Accumulated number of LNs cleaned.
je-env-stat-NLNscleaned	Accumulated number of LNs that were not found in the tree anymore (deleted).
je-env-stat-NLNscleaned	Accumulated number of LNs encountered that were locked.
je-env-stat-NLNscleaned	Accumulated number of LNs that were marked for migration during cleaning.
je-env-stat-NLNscleaned	Accumulated number of LNs migrated.
je-env-stat-NLNscleaned	Accumulated number of LNs obsolete.
je-env-stat-NLogBuffers	Number of log buffers currently instantiated.
je-env-stat-NMarkedLNscleaned	Accumulated number of LNs processed because they were previously marked for migration.
je-env-stat-NNodesExplicitlyEvicted	Accumulated number of nodes evicted.
je-env-stat-NNodesScanned	Accumulated number of nodes scanned to select the eviction set.
je-env-stat-NNodesSelected	Accumulated number of nodes selected to evict.
je-env-stat-NNotResident	Number of requests for database objects not contained within the in memory data structures.
je-env-stat-NOpenFiles	Number of files currently open in the file cache.
je-env-stat-NPendingLNscleaned	Accumulated number of pending LNs that could not be locked for migration because of a long duration application lock.
je-env-stat-NPendingLNscleaned	Accumulated number of LNs processed because they were previously locked.
je-env-stat-NRandomReadBytes	Number of bytes read which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomReads	Number of disk reads which required repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NRandomWriteBytes	Number of bytes written which required repositioning the disk head more than 1MB from the previous file position.

Monitor Attribute	Description
je-env-stat-NRandomWrites	Number of disk writes which required repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NRepeatFaultReads	Number of reads which had to be repeated when faulting in an object from disk because the read chunk size controlled by <code>je.log.faultReadSize</code> is too small.
je-env-stat-NRepeatIteratorReads	Number of times we try to read a log entry larger than the read buffer size and can't grow the log buffer to accommodate the large object.
je-env-stat-NRootNodesEvicted	Accumulated number of database root nodes evicted.
je-env-stat-NSequentialReadBytes	Number of bytes read which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialReads	Number of disk reads which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWriteBytes	Number of bytes written which did not require repositioning the disk head more than 1MB from the previous file position.
je-env-stat-NSequentialWrites	Number of disk writes which did not require repositioning the disk head by more than 1MB from the previous file position.
je-env-stat-NSharedCacheEnvironments	Number of environments using the shared cache.
je-env-stat-NTempBufferWrites	Number of writes which had to be completed using the temporary marshalling buffer because the fixed size log buffers specified by <code>je.log.totalBufferBytes</code> and <code>je.log.numBuffers</code> were not large enough.
je-env-stat-NToBeClearedLNsProcessed	Accumulated number of LNs processed because they are soon to be cleaned.
je-env-stat-NonEmptyBins	Number of non-empty bins.
je-env-stat-ProcessedBins	Number of bins that were successfully processed by the INCompressor.
je-env-stat-RequiredEvictBytes	Number of bytes that must be evicted to get within the memory budget.
je-env-stat-SharedCacheTotalBytes	Total amount of the shared JE cache in use, in bytes.
je-env-stat-SplitBins	Number of bins encountered by the INCompressor that were split between the time they were put on the compressor queue and when the compressor ran.
je-env-stat-TotalLogSize	Approximation of the current total log size in bytes.
je-env-stat-NOwners	Total lock owners in the lock table.
je-env-stat-NReadLocks	Total read locks currently held.
je-env-stat-NRequests	Total number of lock requests to date.
je-env-stat-NTotalLocks	Total locks currently in the lock table.
je-env-stat-NWaiters	Total transactions waiting for locks.
je-env-stat-NWaits	Total number of lock waits to date.
je-env-stat-NWriteLocks	Total write locks currently held.

Monitor Attribute	Description
je-env-stat-LastCheckpointTime	Time of the last checkpoint.
je-env-stat-LastTxnId	Last transaction ID allocated.
je-env-stat-NAborts	Number of transactions that have aborted.
je-env-stat-NActive	Number of transactions that are currently active.
je-env-stat-NBegins	Number of transactions that have begun.
je-env-stat-NCommits	Number of transactions that have committed.
je-env-stat-NXAAborts	Number of XA transactions that have aborted.
je-env-stat-NXACommits	Number of XA transactions that have committed.
je-env-stat-NXAPrepares	Number of XA transactions that have been prepared.

Summary of the Replication Summary Monitor Information

The following table provides a description of the attributes in the `cn=Replication Summary` monitor entry.

```
dn: cn=Replication Summary <baseDN>,cn=monitor
```

Replication Summary Monitor Information

Monitor Attribute	Description
base-dn:<baseDN>	Base DN summary.
replica: replica-id, ldap-server connected-to, generation-id, replication-backlog, recent-update-rate, peak-update-rate, age-of-oldest- backlog-change	Summary information for each replica in the topology. This entry appears for each replica in the topology with its own respective properties.
replication-server: server-id, server, generation-id, status, last-connected, last-failed, failed-attempts, attributes.	Summary information for each remote replication server only in the topology. This entry appears for each Replication Server in the topology with its own respective <code>serverID</code> and <code>server</code> properties.

Monitor Attribute	Description
update-queue: id, max-count, current-count, max-size, current-size, polling-source, polling-source-changed	<p>Summary information for each update queue on a server:</p> <ul style="list-style-type: none"> ▪ id. The ID of the receiving replica or replication server ▪ max-count. The maximum number of update messages that the sending replication server will keep in memory for the receiving replica or replication server. If the receiver cannot accept messages fast enough for any reason (high load, network latency, etc), then this queue will fill up. When that happens, the sending replication server will read update messages from the changelog backend. This slows down the update processing considerably. ▪ current-count. The number of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this counter is decremented. ▪ max-size. The maximum total size (in bytes) of update messages that may be in the queue. This queue is capped by both the maximum count (<code>max-count</code>) and the <code>max-size</code> setting, whichever is reached first. ▪ current-size. The total size of update messages currently on the queue that have not been sent to the receiving replica or replication server. Every time the sending replication server sends an update to the receiving replica or replication server, this value is decremented by the size of the published update message. ▪ polling-source. Either 'memory' or 'db'. If set to 'memory', the sending replication server relies only on the in-memory queue to push update messages to the receiving replica or replication server. If set to 'db', update messages are read and sorted from the changelog database, which is significantly slower than publishing updates from the in-memory queue. ▪ polling-source-changed. The total number of times the polling-source attribute has changed value (either from 'db' to 'memory' or from 'memory' to 'db'). If this value changes very frequently, then the queue size setting is probably too low.

Summary of the replicationChanges Backend Monitor Information

The following table provides a description of the attributes in the `cn=replicationChanges Backend` monitor entry.

```
dn: cn=replicationChanges Backend,cn=monitor
```

replicationChanges Backend Monitor Information

Monitor Attribute	Description
ds-backend-id	ID descriptor for the backend. Typically, this will be "replicationChanges".
ds-backend-base-dn	Base DN for the backend. Typically, this will be <code>cn=replicationChanges</code> .
ds-backend-is-private	Flag to indicate if the backend is private.
ds-backend-entry-count	Entry count for the backend.

Monitor Attribute	Description
ds-base-dn-entry-count	Entry count for the base DN and the specified base DN.
ds-backend-writability-mode	Flag to indicate if the backend is writable or not.

Summary of the Replication Protocol Buffer Monitor Information

The following table provides a description of the attributes in the `cn=Replication Protocol Buffer` monitor entry. The monitors provide information on the state of the buffer for protocol operations, which is kept in the local storage.

```
dn: cn=Replication Protocol Buffer,cn=monitor
```

Replication Protocol Buffer Monitor Information

Monitor Attribute	Description
saved-buffers	Number of protocol buffers. Initial buffer size is 4k.
reallocations	Number of times the buffers had to be reallocated due to insufficient size.
large-buffer-creates	Number of times a buffer larger than 512k was requested.
large-buffer-evictions	Number of times a buffer was removed from the thread local storage, because it has grown above 512k.

Advanced Topics Reference

This chapter presents background reference information covering advanced replication topics.

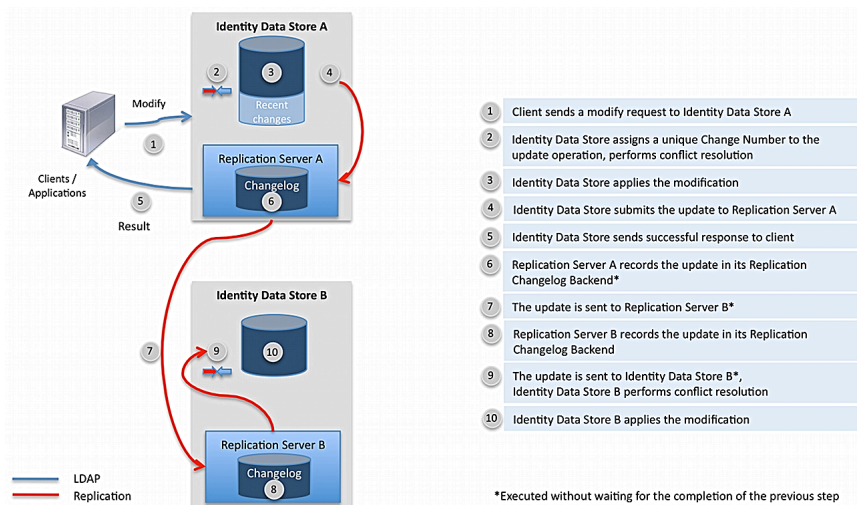

About the Replication Protocol

Replication communicates using a proprietary binary protocol that is implemented on top of the TCP/IP protocol using SSL encryption. Some protocol messages are used for administrative purposes (such as WAN Gateway server negotiation or flow control), some carry updates to replicated data, while others are directed to all servers for monitoring requests.

In a replicated topology, each participating Directory Server is connected to every other server via the replication server port in order to monitor health. Servers which share the same location setting are also connected to rapidly replicate changes and lastly the WAN Gateway servers are all interconnected to replicate changes across locations.

Directory Servers keep connections open as long as possible to reduce the communication latency when messages are exchanged. Heartbeat messages are transmitted on a regular basis to detect a network failure or an unresponsive directory server as early as possible. Heartbeat messages also prevent idle connections from being closed by firewalls.

The following detailed communication flow will be used to describe major components of replication. This illustration is the expanded view of figure shown in the Overview section.

MY TITLE Replication Communication Flow

Step 1. Client sends a Modify request to Directory Server A.

Step 2. Directory Server A assigns a unique change number to the operation. Conflict resolution is executed to see if the Modify request is in conflict with the existing attribute types or values in the existing entry. The change number is assigned before the Directory Server backend is updated so that the arrival order of client requests can be preserved. Historical data in the target entry is updated to reflect the change. Note that historical data is only updated for ADD and MODIFY operations.

Step 3. Directory Server applies the modifications in the corresponding backend.

Step 4. If the MODIFY operation successfully completes, then the Directory Server will submit the update to its embedded *Replication Server*. The Replication Server is a component within the Directory Server process responsible for propagating updates to and from the replication topology. The Directory Server itself only communicates with a single replication server, whereas the replication server component is connected to all other replication servers. If the Directory Server process exits unexpectedly and some updates have not been passed to the Replication Server, the backend has the ability to recover the last 50,000 recent changes that were processed at this server, guaranteeing that these changes can be replicated when the server starts up. The figure above also shows that replication protocol is used not just between replication servers but also between the Directory Server and the Replication Server.

Step 5. The response is sent to the client. In this example, a successful response is assumed.

Step 6. The Replication Server records the update in its own Changelog backend (i.e., backend ID of `replicationChanges`) and on disk with the path to `changelogDb` under the server root. The Replication Changelog backend keeps track of updates at each and every Directory Server in the replication topology. When a Directory Server joins the replication topology after being disconnected for some reason, updates from the Replication Changelog backend are re-sent to this Directory Server. Old records from the Replication Changelog backend are purged, which by default removes records older than 24 hours. If the backend does not contain all of the records that another Directory Server needed when rejoining the replication topology, then the replicated data set in the Directory Server must be re-initialized. In this case, the Directory Server enters lockdown mode and an administrative alert is sent.

Step 7. The Replication Server submits the update to the replication server component in Directory Server B. If there were more Directory Servers in this example, the Replication Server would submit the update to all the other replication servers in the same location.

Step 8. Just like in Step 6, the Replication Server component receiving an update inserts the change into its Replication Changelog backend.

Step 9. The update is forwarded to the Replica in Directory Server B. Conflict resolution is executed to see if the Modify request is in conflict with the existing attribute types or values in the existing entry.

Step 10. The Directory Server applies the modification in the corresponding backend. The Recent Changes database is not updated, because only updates that originated at this Directory Server are recorded in the Recent Changes database.

Change Number

As seen in the previous Figure, the Directory Server assigns a unique change number to each update operation (specifically, ADD, DELETE, MODIFY, or MODIFY DN operations) to track each request when received from a client. The change number not only identifies each and every update, but it also allows ordering updates to the replicated data the same way on each Directory Server. The change number is composed of the following multiple fields:

- **Timestamp** that identifies when the update was made. The timestamp is time-zone-independent and recorded with millisecond resolution.
- **Server ID** that uniquely identifies the Directory Server where the update was made.
- **Sequence number** that defines the order of the updates received from external clients at a particular directory server.

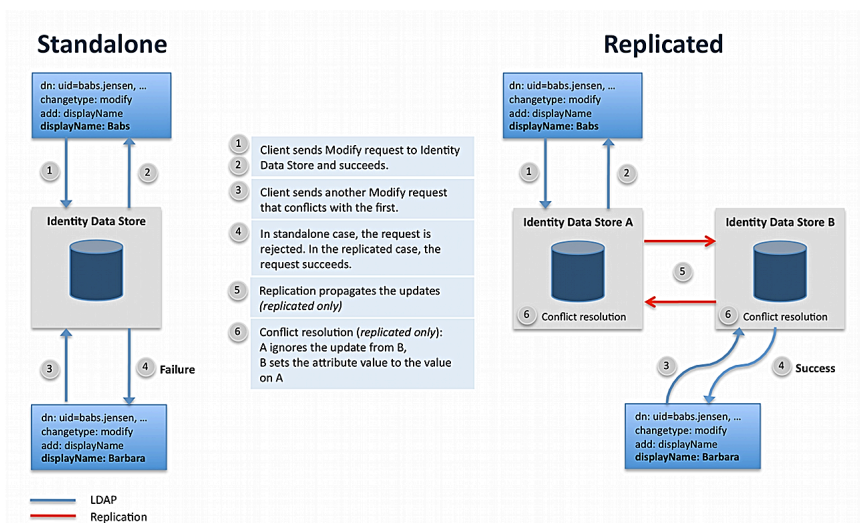

The replication protocol also sets a virtual clock that eliminates the need for synchronized time on servers. For troubleshooting purposes, however, it is still recommended to keep the system clocks synchronized.

Conflict Resolution

The eventual-consistency model employed in replication introduces a window where conflicting updates targeting the same entry may be applied at two different Directory Servers. In general, two updates to the same Directory Server are in conflict if the update that arrived later fails. Conflict resolution, when possible, corrects conflicts introduced by clients automatically. There are some exceptions, however, when manual administrative action is required. For example, adding an entry in one replica and deleting the parent of this entry on another replica simultaneously will introduce a conflict that requires manual action. In a carefully implemented deployment, the risk of introducing conflicts that require manual action can be significantly reduced or even eliminated.

The conflict resolution algorithm in the PingDirectory Server uses a mechanism that orders all updates in the replication topology. Each update in the Directory Server is assigned a unique change number. The change number is attached to each update propagated via replication and allows each Directory Server to order updates exactly the same way.

Consider the following example that results in a conflict: add a single-valued attribute with different values to an entry concurrently at two Directory Servers (shown in the figure below). It is easy to see that the second operation would fail if a client attempted to add the same attribute to the same entry at the same Directory Server. In a replicated environment, the conflict is not immediately seen if these updates are applied concurrently at two different Directory Servers. The conflict is handled only after replication propagates the updates. The Directory Servers resolve the conflict independently of the other server. On one Directory Server, the entry will be updated to reflect the correct value; on the other Directory Server, the value will stay the same. As result, each Directory Server will independently resolve the conflict the same way based on the ordering of the updates. This example is illustrated below:

MY TITLE Conflict Resolution Process Flow

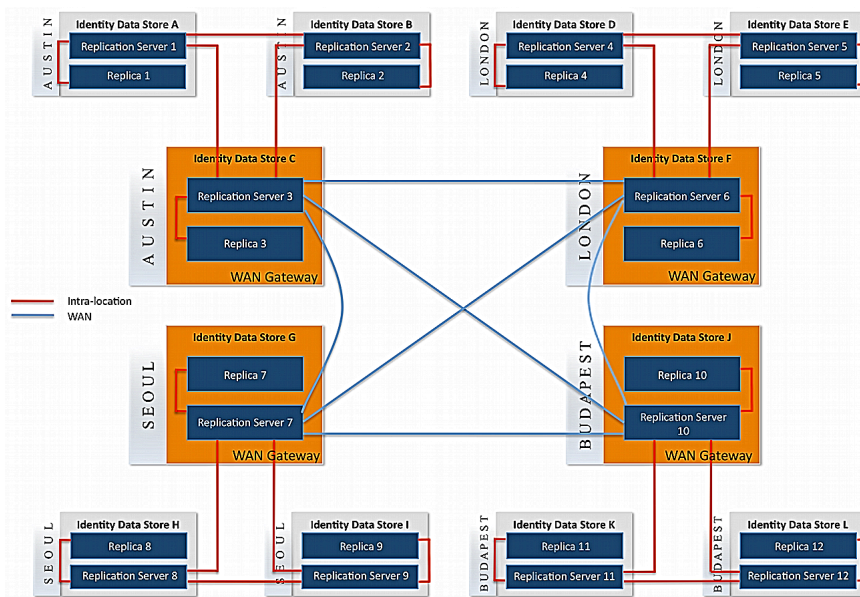

WAN-Friendly Replication

Many multi-national corporations that have data centers in different countries must minimize latency over WAN to ensure acceptable performance for their client applications. To minimize WAN latency, the Directory Server assigns one of two roles to the replication servers: the role of standard replication transmitting updates to the other co-located replication servers; the other role, a WAN-dedicated replication server designed to send updates to other WAN-designated replication servers in other locations. This two-role system minimizes WAN traffic by pushing all replication updates onto the connected replication servers that are designated as WAN Gateway Servers. Only the designated WAN Gateway Servers can transmit the update messages to other connected WAN Gateway servers at other locations.

WAN Gateway Server

The Directory Server's replication mechanism relies on the server's location information to reduce protocol traffic on WAN links. During protocol negotiation, the replication server with the highest WAN Gateway priority (priority 1 indicates the highest priority) automatically assumes the role as the WAN Gateway Server for that particular location. The Gateway Server's main function is to route update messages from other non-gateway servers at the same location to remote WAN Gateway servers at other locations. Similarly, at the destination point, the replication server with the WAN Gateway role will receive update messages from other WAN gateway servers at other locations and push them out to all replication servers at the current location. This setup ensures that all WAN communication flows through the WAN Gateway Servers.

The figure below shows a basic connection configuration for updates. Keep in mind that all of the replication servers are fully connected to each other for monitoring or server negotiation purposes.

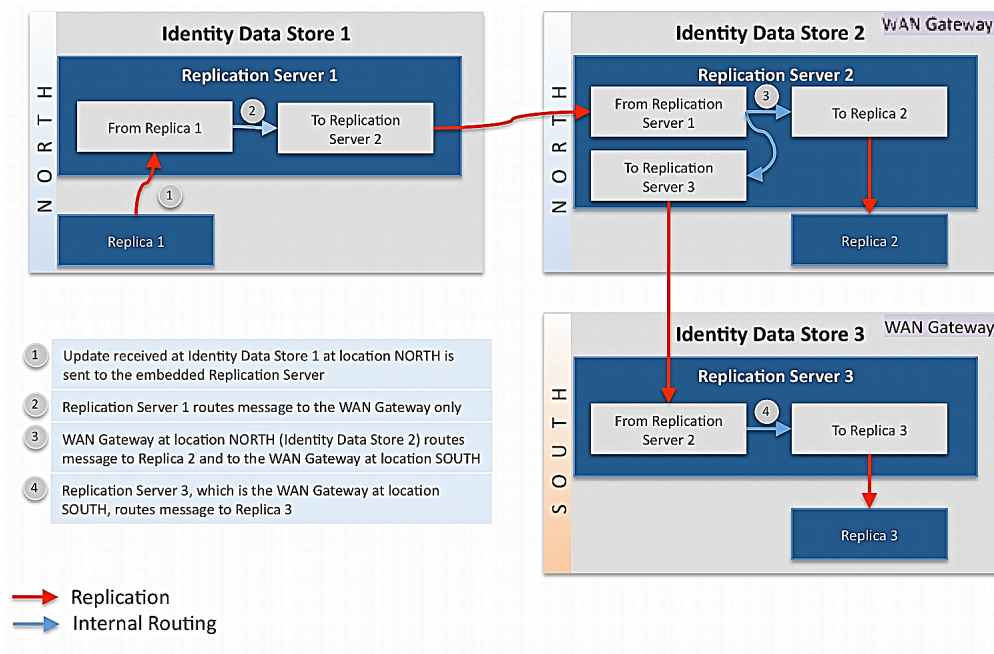

MY TITLE WAN Gateway Servers

If the WAN Gateway Server is temporarily unavailable due to a planned or unplanned downtime, the system will dynamically re-route updates to a newly designated WAN Gateway Server in the same location. The replication server with the next highest WAN Gateway priority number automatically assumes the WAN Gateway role. For deployments with entry-balancing Directory Proxy Servers, there will be one WAN Gateway Server per data set.

By default, all servers are enabled to serve as WAN Gateways and all are set to priority 5, which is simply a way to make them all equal. If necessary, the WAN Gateway priority can be changed using `dsconfig` after replication has been enabled.

WAN Message Routing

Non-gateway replication servers forward update messages from replicas to co-located replication servers only. It is the responsibility of the WAN gateway server to forward these messages to WAN gateway servers at other locations. The figure below illustrates how an update message is routed from a non-gateway server to a remote location.

MY TITLE WAN Message Routing

WAN Gateway Server Selection

The WAN Gateway role is dynamically assigned to the most suitable server in a particular location. In most cases, the replication server with the higher WAN Gateway priority (e.g., priority 1 indicates the highest priority) assumes this role.

A replication server will not attempt to become a WAN Gateway if any of the following conditions exists:

- The WAN Gateway priority is set to 0
- The replication server is backlogged at server startup
- The current WAN Gateway has higher priority
- The WAN Gateway has not been elected yet, but higher priority replication servers are present in the location

The currently active WAN Gateway server will give up the gateway role in the following cases:

- The server has started the shutdown process
- The server is preparing for a scheduled maintenance cycle
- The server learns about a higher priority replication server in its location

Replication servers send WAN Gateway information to other servers at regular intervals using the replication protocol. This allows the replication servers to take the appropriate action, for example, to become a WAN Gateway, if necessary without any manual administrative action.

WAN Replication in Mixed-Version Environments

WAN Gateway Role assignment is only available on PingDirectory Servers version 3.5 or later. Legacy servers (i.e., pre-3.5) will never be selected as WAN Gateways. Updates from legacy replication servers are forwarded to all replication servers and not funneled to a single WAN Gateway. Also, updates from remote WAN Gateways will be forwarded to the legacy replication servers. Both of these actions will effectively increase WAN traffic during replication.

Recovering a Replication Changelog

About this task

In the event that the replication changelog is compromised (<server-root>/changelogDb), possibly due to a disk or NAS failure, perform the following steps.

Steps

1. Stop the server.
2. Backup **replicationChanges** from a remote server with the following command:

```
$ bin/backup --backupDirectory /app/backups/replicationChanges \
  --backendID replicationChanges
```

3. Copy the **replicationChanges** backup from the remote server and restore it on the local host as follows:

```
$ bin/restore --backupDirectory /app/tmp/replicationChanges
```

4. Start the server.

Disaster Recovery

About this task

In the event that data is compromised across all systems and a restore is necessary, perform the following steps. These steps assume that no read or write operations are performed by any servers during this process.

- Note:** The following should be considered for disaster recovery:
- With the default configuration, the server automatically exports all data nightly using the **Export All Non-Administrative Backends** recurring task. Up to seven days of exports are maintained. It is recommended that these be archived on another system.
 - The Data Recovery Log logs all changes in a reversible format to `logs/data-recovery/data-recovery`.
 - The `bin/extract-data-recovery-log-changes` tool provides the ability to redo or undo any changes from the `logs/data-recovery/data-recovery` logs.
 - The combination of these allows you to either rebuild the data set to any point in time or to revert specific changes on a live data set (for example, if an errant application mistakenly wipes out some data).

- Note:** See [LDIF Export as a Recurring Task](#) on page 476 for information about LDIF exports.

Steps

1. Stop all servers.
2. Run the following command on all servers:

```
$ /bin/dsreplication cleanup-local-server
```

3. Locate the backup or exported LDIF file that represents the last working copy of the database.
4. Restore the backup or import the LDIF file on a single server. If importing an LDIF file, use the `--excludeReplication` option with the `import-ldif` command.

5. Start the restored server. The server can now receive client requests.
6. Start another server in lockdown mode with the following command:

```
$ start-server --skipPrime --lockdownMode
```

7. Enable replication from the first server to the second server.
8. Initialize the second server from the first with the following command:

```
$ bin/dsreplication initialize
```

9. Restart the second server or use the `bin/leave-lockdown-mode` command to leave the server in lockdown mode. The second server can now receive client requests.
10. Repeat steps 6 through 9 for any other servers.

Managing Logging

The PingDirectory Server supports a rich set of log publishers to monitor access, debug, and error messages that occur during normal server processing. Administrators can view the standard set of default log files as well as configure custom log publishers with pre-defined filtering with its own log rotation and retention policies.

This chapter presents the following information:

Default Directory Server Logs

The Directory Server provides a standard set of default log files to monitor the server activity. You can view this set of logs in the `PingDirectory/logs` directory. The following default log files are available on the Directory Server and are presented below.

Directory Server Logs

Log File	Description
access	File-based Access Log that records operations processed by the Directory Server. Access log records can be used to provide information about problems during operation processing (for example, unindexed searches, failed requests, etc.), and provide information about the time required to process each operation.
change-notifications.log	Records changes to data anywhere in the server, which match one or more configured change subscriptions.
config-audit.log	Records information about changes made to the Directory Server configuration in a format that can be replayed using the <code>dsconfig</code> tool
errors	File-based Error Log. Provides information about warnings, errors, and significant events that occur during server processing.
expensive-ops	Expensive Operations Log. Disabled by default. Provides only those operations that took longer than 1000 milliseconds to complete.
failed-ops	Failed Operations Log. Provides information on all operations that failed in single-line log format.
replication	Records any replication errors and publishes them to the file system.
searches-returning-no-entries	Searches Returning No Entries Log. Disabled by default. Provides information only on operations that did not return any entries.

Log File	Description
server.out	Records anything written to standard output or standard error, which includes startup messages. If garbage collection debugging is enabled, then the information will be written to server.out.
server.pid	Stores the server's process ID.
server.status	Stores the timestamp, a status code, and an optional message providing additional information on the server status.
setup.log	Records messages that occur during the initial configuration of a Directory Server with the <code>setup</code> tool.
tools	Directory that holds logs for long running utilities: <code>import-ldif</code> , <code>export-ldif</code> , <code>backup</code> , <code>restore</code> , <code>verify-index</code> . Current and previous copies of the log are present in the Directory Server.
update.log	Records messages that occur during a Directory Server update.

Types of Log Publishers

The PingDirectory Server provides several classes of log publishers for parsing, aggregating, and filtering information events that occur during normal processing in the server. There are three primary types of Log Publishers: access logs, debug logs, and error logs. Each type has multiple subtypes of log files based on the log server type:

Types of Log Publishers

Log Publisher Type	Description
Access	Provides the requests received and responses returned by the Directory Server. The information can be used to understand the operations performed by clients and to debug problems with the client applications. It can also be used for collecting usage information for performance and capacity planning purposes. There are tools described later that can analyze the access log to provide summaries of the LDAP activity and performance.
File-based Audit Log	Special type of access logger that provides detailed information about changes processed within the server. Disabled by default.
JDBC-based Access Log	Stores access log information using a JDBC database connection. Disabled by default.

Log Publisher Type	Description
	<p>File-based Access Logs</p> <p>Provides a character-based stream used by TextWriter Publishers as a target for outputting log records. There are six types of file-based loggers:</p> <ul style="list-style-type: none"> ▪ Admin Alert Access Log. Generates administrative alerts for any operations that match the criteria for this access logger. Disabled by default. ▪ File-based Access Log. Publishes access log messages to the file system. Enabled by default. ▪ Syslog-based Access Log. Publishes access log messages to a syslogd port. Disabled by default. ▪ Expensive-Operations Access Log. Publishes only those access log messages of operations that take longer than 1000 milliseconds. Disabled by default. ▪ Failed-Operations Access Log. Publishes only those access log messages of operations that failed for any reason. Enabled by default. ▪ Successful Searches with No Entries Returned Log. Publishes only those access log messages of search operations that failed to return any entries. Disabled by default.
Debug	<p>Provides information about warnings, errors, or significant events that occur within the server.</p> <p>Debug ACI Logger</p> <p>Stores debug information on ACI evaluation for any request operations against the server</p> <p>File-based Error Logs</p> <p>There are two types of File-based Error Logs:</p> <ul style="list-style-type: none"> ▪ Error log. Publishes error messages to the file system. Enabled by default. ▪ Replication log. Publishes replication error messages to the file system. Enabled by default. <p>JDBC-based Error Logs</p> <p>Stores error log information using a JDBC database connection. Disabled by default.</p> <p>Syslog-based Error Logs</p> <p>Publishes error messages to a syslogd port.</p>

Viewing the List of Log Publishers

You can quickly view the list of log publishers on the Directory Server using the `dsconfig` tool.

Note: Initially, the JDBC, syslog, and Admin Alert log publishers must specifically be configured using `dsconfig` before they appear in the list of log publishers. Procedures to configure these types of log publishers appear later in this chapter.

To View the List of Log Publishers

Steps

- Use `dsconfig` to view the log publishers.

```
$ bin/dsconfig list-log-publishers
```

Log Publisher	Type	enabled
Debug ACI Logger	debug-access	false
Expensive Operations Access Logger	file-based-access	false
Failed Operations Access Logger	file-based-access	true
File-Based Access Logger	file-based-access	true
File-Based Audit Logger	file-based-audit	false
File-Based Debug Logger	file-based-debug	false
File-Based Error Logger	file-based-error	true
Replication Repair Logger	file-based-error	true
Successful Searches with No Entries Returned	file-based-access	false

Enabling or Disabling a Default Log Publisher

You can enable or disable any log publisher available on the Directory Server using the `dsconfig` tool. By default, the following loggers are disabled and should be enabled only when troubleshooting an issue on the server:

- Expensive Operations Access Logger
- File-Based Audit Logger
- File-Based Debug Logger
- Successful Searches with No Entries Returned

To Enable a Default Access Log

Steps

- Use `dsconfig` to enable an Access Log Publisher. In this example, enable the Expensive-Ops log, which will record only those access log messages that take 1000 milliseconds or longer.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Expensive Operations Access Logger" --set enabled:true
```

Managing Access and Error Log Publishers

The Access Log records every request received and response returned by the Directory Server. The Access Log stores the IDs for the client connection, operation, the LDAP message involved with each client request, and the server response. The information can be used to debug any problems with a client application by correlating the numeric operation identifier to the client request or response.

The Directory Server supports multiple classes of access log publishers depending on your logging requirements. The following types of access log publishers are available on the system:

- File-Based Access Log Publishers.** Provides a character-based `TextWriter` stream for outputting log records. There are three subclasses of `TextWriter` access logs:
 - File-Based Access Logs.** Enabled by default. The File-based Access Log publishes access messages to the file system as `<server-root>/logs/access`. The Failed-Operations Log, Expensive-Operations Log, and the Searches with No Entries Returned Log are specialized types

of the File-Based Access Log and shows only specific information necessary for troubleshooting purposes.

- **Admin-Alert Access Logs.** Disabled by default. The Admin-Alert Access Log is specialized type of logger that automatically generates administrative alerts for any operations that match a criteria for this access log publisher.
- **Syslog-Based Access Logs.** Disabled by default. The Syslog Access Log publishes access messages to a syslogd port.
- **File-Based Audit Logs.** Disabled by default. The Audit Log provides detailed information about modifications (writes) processed within the Directory Server. The File-based Audit Log publishes access messages to the file system as `<server-root>/logs/audit`.
- **JDBC-Based Access Logs.** Disabled by default. The JDBC-based Access Log provides information using a JDBC database connection.
- **JDBC-Based Error Logs.** Disabled by default. The JDBC-based Error Log provides information using a JDBC database connection.

Managing File-Based Access Log Publishers

The PingDirectory Server supports a flexible and configurable Access Logging system that provides a full set of customized components to meet your system's logging requirements. The default Access Log can be configured to write information to a log file with two records per operation, one for the request received and one for the response returned. It can also be configured to write one message per operation or configured to record information about a subset of operations processed by the server. In addition to modifying existing default log files, you can create custom log publishers to monitor specific properties or connection criteria. For more information, see [Creating New Log Publishers](#).

The Directory Server can be configured to use multiple access log publishers writing logs to different files using different configurations. This approach makes it possible to have fine-grained logging for various purposes (for example, a log that contains only failed operations, a log that contains only operations requested by root users, or a log that contains only operations that took longer than 20ms to complete).

The Directory Server provides an additional mechanism to filter access logs to record only a subset of messages of one or more types. The access log filtering mechanism uses the operation criteria (connection, request, result, search-entry, search-reference) to determine whether a given message should be logged based on information associated with the client connection as well as information in the operation request/response messages. For more information, see [Configuring Filtered Logging](#).

Access Log Format

The Access Log has a standard format that lists various elements identifying the connection and operation occurring within the Directory Server. By default, each operation generates one access log message.

The Access Log displays the following common properties:

- **Timestamp.** Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Connection Type.** Displays the connection type requested by the client and the response by the server. Examples include the following:
 - CONNECT
 - BIND REQUEST/RESULT
 - UNBIND REQUEST
 - DISCONNECT
 - SEARCH REQUEST/RESULT
 - MODIFY REQUEST/RESPONSE
 - others include: ABANDON, ADD, COMPARE, DELETE, EXTENDED OPERATION, MODIFY, MODIFY DN
- **Connection ID.** Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation. The connection ID is unique for a span of time on a single server. Values

of the connection ID will be re-used when the server restarts or when it has had enough connections to cause the identifier to wrap back to zero.

- **Operation ID.** Numeric identifier, starting incrementally with 0, that identifies the operation. The operation ID is unique for a span of time on a single server. Values of the operation ID will be re-used when the server restarts or when it has serviced enough operations to cause the identifier to wrap back to zero.
- **Result Code.** LDAP result code that determines the success or failure of the operation result. Result messages include a result element that indicates whether the operation was successful or if failed, the general category for the failure, and an etime element that indicates the length of time in milliseconds that the server spent processing the operation.

The Directory Server provides a useful tool `<server-root>/bin/ldap-result-code` (UNIX, Linux) or `<server-root>\bat\ldap-result-code` (Windows), that displays all of the result codes used in the system. You can use the utility if you are not sure what a result code means. For example, use the following:

- `ldap-result-code --list` displays all of the defined result codes in the Directory Server.
- `ldap-result-code --int-value 16654` displays the name of the result code with a numeric value of 16654.
- `ldap-result-code --search operation` displays a list of all result codes whose name includes the substring "operation".
- **Elapsed Time.** Displays the elapsed time (milliseconds) during which the operation completed its processing.
- **Message ID.** Numeric identifier, starting incrementally with 1, which identifies the LDAP message used to request the operation.

Access Log Example

The following example shows output from the Access Log in `<server-root>/logs/access`:

```
[01/Jun/2011:14:48:17 -0500] CONNECT conn=0 from="10.8.1.243" to="10.8.1.243"
protocol="LDAP"
[01/Jun/2011:14:48:17 -0500] BIND REQUEST conn=0 op=0 msgID=1 version="3"
dn="cn=Directory Manager"
authType="SIMPLE"
[01/Jun/2011:14:48:17 -0500] BIND RESULT conn=0 op=0 msgID=1 resultCode=0
etime=26.357
authDN="cn=Directory Manager,cn=Root DNs,cn=config"
[01/Jun/2011:14:48:17 -0500] UNBIND REQUEST conn=0 op=1 msgID=2
[01/Jun/2011:14:48:17 -0500] DISCONNECT conn=0 reason="Client Unbind"
... (more output) ...
```

Modifying the Access Log Using dsconfig Interactive Mode

The File-Based Access Log can be modified to include or exclude all log messages of a given type using the `dsconfig` tool in interactive or non-interactive mode.

To Modify the Access Log Using dsconfig Interactive Mode

Steps

1. Use `dsconfig` in interactive mode to modify the access log properties.

```
$ bin/dsconfig
```

2. Follow the prompts to specify the LDAP connection parameters for host name or IP address, connection type (LDAP, SSL, or StartTLS), port number, bind DN and password.
3. On the Directory Server main menu, type the number corresponding to the Log Publisher.
4. On the **Log Publisher Management** menu, enter the option to view and edit an existing log publisher.
5. On the **Log Publisher** menu, type the number corresponding to File-based Access Logger.

6. On the **File-Based Access Log Publisher** menu, type the number corresponding to the property that you want to change, and then follow the prompts.
7. Type `f` to apply the changes.

Modifying the Access Log Using `dsconfig` Non-Interactive Mode

You can use the `dsconfig` tool in non-interactive mode to quickly modify a log publisher property on the command line or in a script. For information on each property, see the *Directory Server Configuration Reference Guide*, which is an HTML document listing the various properties for each Directory Server component.

To Modify the Access Log Using `dsconfig` Non-Interactive Mode

Steps

- Use `dsconfig` with the `--no-prompt` option with the properties that you want to modify or set for your access log. In this example, enable the properties to include the instance name and startup ID.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Access
  Logger" \
  --set include-instance-name:true --set include-startup-id:true
```

Modifying the Maximum Length of Log Message Strings

By default, the Directory Server sets the maximum length of log message strings to 2000 characters. This value is configurable for any access log publisher, except the Syslog publisher, which is set to 500 characters. You can change the maximum length of log message strings by setting the `max-string-length` configuration property. If any string has more than the configured number of characters, then that string will be truncated and a placeholder will be appended to indicate the number of remaining characters in the original string.

To Modify the Maximum Length of Log Message Strings

Steps

- Use `dsconfig` to set the `max-string-length` property for an access log. The following command configures the "File-based Access Logger" to include the instance name and the maximum length of the log message strings to 5000 characters.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set include-instance-name:true \
  --set max-string-length:5000
```

Generating Access Logs Summaries

The Directory Server provides a convenience tool, `summarize-access-log`, that generates a summary of one or more file-based access logs. The summary provides analytical metric information that could be useful for administrators. The following metrics are provided in each summary:

- Total time span covered by the log files.
- Number of connections established and the average rate of new connections per second.
- IP addresses of up to the top 20 of the clients that most frequently connect to the server, the number of connections by each address, and the percentage of connections of each.
- Total number of operations processed, the number of operations of each type, the percentage of each type out of the total number, and the average rate per second for each type of operation.
- Average processing time for all operations and for each type of operation.
- Histogram of the processing times for each type of operation.

- Up to the 20 most common result codes for each type of operation, the number of operations of that type with that result code, and the percentage of operations of that type with that result code.
- Number of unindexed searches processed by the server.
- Breakdown of the scopes used for search operations with the number of percentage of searches with each scope.
- Breakdown of the most common entry counts for search operations with the number and percentage of searches that returned that number of entries.
- Breakdown of the most commonly used filter types for searches with a scope other than "base" (that is, those searches for which the server will use es when processing the filter). These filters will be represented in a generic manner so that any distinct assertion values or substring assertion elements will be replaced with question marks and attribute names in all lowercase characters (for example, (givenName=John) would be represented as (givenName=?)).

To Generate an Access Log Summary

Steps

- Use the `bin/summarize-access-log` with path to one or more access log files.

```
$ bin/summarize-access-log /path/to/logs/access
```

```
Examining access log /path/to/logs/access Examined 500 lines in 1 file
covering a total duration of 1 day, 22 hours, 57 minutes, 31 seconds
```

```
Total connections established: 69 (0.000/second)
Total disconnects: 69 (0.000/second)
```

```
Most common client addresses:
```

```
127.0.0.1: 61 (88.406)
```

```
10.8.1.209: 8 (11.594)
```

```
Total operations examined: 181 ...
(metric for each operation examined) ...
```

```
Average operation processing duration: 22.727ms
Average add operation processing duration: 226.600ms
Average bind operation processing duration: 5.721ms
Average delete operation processing duration: 77.692ms
Average modify operation processing duration: 35.530ms
Average search operation processing duration: 4.017ms
```

```
Count of add operations by processing time:
... (histogram for add operations) ...
```

```
Count of bind operations by processing time:
... (histogram for bind operations) ...
```

```
Count of delete operations by processing time:
... (histogram for delete operations) ...
```

```
Count of modify operations by processing time:
... (histogram for modify operations) ...
```

```
Count of search operations by processing time:
... (histogram for search operations) ...
```

```
Most common add operation result codes:
```

```
success: 11 (84.615%)
```

```
entry already exists: 2 (15.385%)
```

```
Most common bind operation result codes:
```

```

success: 4 (50.000%)
invalid credentials: 4 (50.000%)

Most common delete operation result codes:
success: 1 (100.000%)

Most common modify operation result codes:
success: 9 (69.231%)
no such object: 4 (30.769%)

Most common search operation result codes:
success: 133 (91.724%)
no such object: 12 (8.276%)

Number of unindexed searches: 0

Most common search scopes:
BASE: 114 (78.621%)
SUB: 16 (11.034%)
ONE: 15 (10.345%)

Most common search entry counts:
1: 119 (82.069%)
0: 17 (11.724%)
2: 5 (3.448%)
10: 4 (2.759%)

Most common generic filters for searches with a non-base scope:
(objectclass=?): 19 (61.290%)
(ds-backend-id=?): 12 (38.710%)

```

About Log Compression

The Directory Server supports the ability to compress log files as they are written. This feature can significantly increase the amount of data that can be stored in a given amount of space, so that log information can be kept for a longer period of time.

Because of the inherent problems with mixing compressed and uncompressed data, compression can only be enabled at the time the logger is created. Compression cannot be turned on or off once the logger is configured. Further, because of problems in trying to append to an existing compressed file, if the server encounters an existing log file at startup, it will rotate that file and begin a new one rather than attempting to append to the previous file.

Compression is performed using the standard gzip algorithm, so compressed log files can be accessed using readily-available tools. The `summarize-access-log` tool can also work directly on compressed log files, rather than requiring them to be uncompressed first. However, because it can be useful to have a small amount of uncompressed log data available for troubleshooting purposes, administrators using compressed logging may wish to have a second logger defined that does not use compression and has rotation and retention policies that will minimize the amount of space consumed by those logs, while still making them useful for diagnostic purposes without the need to uncompress the files before examining them.

You can configure compression by setting the `compression-mechanism` property to have the value of "gzip" when creating a new logger.

About Log Signing

The Directory Server supports the ability to cryptographically sign a log to ensure that it has not been modified in any way. For example, financial institutions require audit logs for all transactions to check for correctness. Tamper-proof files are therefore needed to ensure that these transactions can be properly validated and ensure that they have not been modified by any third-party entity or internally by

unscrupulous employees. You can use the `dsconfig` tool to enable the `sign-log` property on a Log Publisher to turn on cryptographic signing.

When enabling signing for a logger that already exists and was enabled without signing, the first log file will not be completely verifiable because it still contains unsigned content from before signing was enabled. Only log files whose entire content was written with signing enabled will be considered completely valid. For the same reason, if a log file is still open for writing, then signature validation will not indicate that the log is completely valid because the log will not include the necessary "end signed content" indicator at the end of the file.

To validate log file signatures, use the `validate-file-signature` tool provided in the `bin` directory of the server (or the `bat` directory for Windows systems).

Once you have enabled this property, you must disable and then re-enable the Log Publisher for the changes to take effect.

About Encrypting Log Files

The Directory Server supports the ability to encrypt log files as they are written. The `encrypt-log` configuration property controls whether encryption will be enabled for the logger. Enabling encryption causes the log file to have an `.encrypted` extension (and if both encryption and compression are enabled, the extension will be `.gz.encrypted`). Any change that affects the name used for the log file could prevent older files from getting properly cleaned up.

Like compression, encryption can only be enabled when the logger is created. Encryption cannot be turned on or off once the logger is configured. For any log file that is encrypted, enabling compression is also recommended to reduce the amount of data that needs to be encrypted. This will also reduce the overall size of the log file. The `encrypt-file` tool (or custom code, using the LDAP SDK's `com.unboundid.util.PassphraseEncryptedInputStream`) is used to access the encrypted data.

To enable encryption, at least one encryption settings definition must be defined in the server. Use the one created during setup, or create a new one with the `encryption-settings create` command. By default, the encryption will be performed with the server's preferred encryption settings definition. To explicitly specify which definition should be used for the encryption, the `encryption-settings-definition-id` property can be set with the ID of that definition. It is recommended that the encryption settings definition is created from a passphrase so that the file can be decrypted by providing that passphrase, even if the original encryption settings definition is no longer available. A randomly generated encryption settings definition can also be created, but the log file can only be decrypted using a server instance that has that encryption settings definition.

When using encrypted logging, a small amount of data may remain in an in-memory buffer until the log file is closed. The encryption is performed using a block cipher, and it cannot write an incomplete block of data until the file is closed. This is not an issue for any log file that is not being actively written. To examine the contents of a log file that is being actively written, use the `rotate-log` tool to force the file to be rotated before attempting to examine it.

To Configure Log Signing

Steps

1. Use `dsconfig` to enable log signing for a Log Publisher. In this example, set the `sign-log` property on the File-based Audit Log Publisher.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
--set sign-log:true
```

2. Disable and then re-enable the Log Publisher for the change to take effect.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
Logger" \
```

```
--set enabled:false
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
--set enabled:true
```

To Validate a Signed File

About this task

The Directory Server provides a tool, **validate-file-signature**, that checks if a file has not been tampered with in any way.

Steps

- Run the **validate-file-signature** tool to check if a signed file has been tampered with. For this example, assume that the `sign-log` property was enabled for the File-Based Audit Log Publisher.

```
$ bin/validate-file-signature --file logs/audit
```

```
All signature information in file 'logs/audit' is valid
```

Note: If any validation errors occur, you will see a message similar to the one as follows:

```
One or more signature validation errors were encountered
while validating the contents of file 'logs/audit':
* The end of the input stream was encountered without
  encountering the end of an active signature block.
  The contents of this signed block cannot be trusted
  because the signature cannot be verified
```

To Configure Log File Encryption

Steps

- Use **dsconfig** to enable encryption for a Log Publisher. In this example, the File-based Access Log Publisher "Encrypted Access" is created, compression is set, and rotation and retention policies are set.

```
$ bin/dsconfig create-log-publisher-prop --publisher-name "Encrypted Access"
 \
  --type file-based-access \
  --set enabled:true \
  --set compression-mechanism:gzip \
  --set encryption-settings-definition-
id:332C846EF0DCD1D5187C1592E4C74CAD33FC1E5FC20B726CD301CDD2B3FFBC2B \
  --set encrypt-log:true \
  --set log-file:logs/encrypted-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

- To decrypt and decompress the file:

```
$ bin/encrypt-file --decrypt \
  --decompress-input \
  --input-file logs/encrypted-access.20180216040332Z.gz.encrypted \
  --output-file decrypted-access
Initializing the server's encryption framework...Done
Writing decrypted data to file '/ds/PingDirectory/decrypted-access' using a
```

```
key generated from encryption settings definition
'332c846ef0dcd1d5187c1592e4c74cad33fc1e5fc20b726cd301cdd2b3ffbc2b'
Successfully wrote 123,456,789 bytes of decrypted data
```

Creating New Log Publishers

The PingDirectory Server provides customization options to help you create your own log publishers with the `dsconfig` command.

When you create a new log publisher, you must also configure the log retention and rotation policies for each new publisher. For more information, see [Configuring Log Rotation](#) and [Configuring Log Retention](#).

To Create a New Log Publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create and configure the new log publisher. This example shows how to create a logger that only logs disconnect operations.

```
$ bin/dsconfig create-log-publisher \
--type file-based-access --publisher-name "Disconnect Logger" \
--set enabled:true \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set log-connects:false \
--set log-requests:false --set log-results:false \
--set log-file:logs/disconnect.log
```

Note: To configure compression on the logger, add the option to the previous command:

```
--set compression-mechanism: gzip
```

Compression cannot be disabled or turned off once configured for the logger. Therefore, careful planning is required to determine your logging requirements including log rotation and retention with regards to compressed logs.

2. If needed, view log publishers with the following command:

```
$ bin/dsconfig list-log-publishers
```

To Create a Log Publisher Using `dsconfig` Interactive Command-Line Mode

Steps

1. On the command line, type `bin/dsconfig`.
2. Authenticate to the server by following the prompts.
3. On the main menu, select the option to configure the log publisher.
4. On the **Log Publisher** menu, select the option to create a new log publisher.
5. Select the Log Publisher type. In this case, select **File-Based Access Log Publisher**.
6. Type a name for the log publisher.
7. Enable it.
8. Type the path to the log file, relative to the Directory Server root. For example, `logs/disconnect.log`.
9. Select the rotation policy to use for this log publisher.
10. Select the retention policy to use for this log publisher.

11. On the Log Publisher Properties menu, select the option for `log-connects:false`, `log-disconnects:true`, `log-requests:false`, and `log-results:false`.

12. Type `f` to apply the changes.

Configuring Log Rotation

The Directory Server allows you to configure the log rotation policy for the server. When any rotation limit is reached, the Directory Server rotates the current log and starts a new log. If you create a new log publisher, you must configure at least one log rotation policy.

You can select the following properties:

- **Time Limit Rotation Policy.** Rotates the log based on the length of time since the last rotation. Default implementations are provided for rotation every 24 hours and every 7 days.
- **Fixed Time Rotation Policy.** Rotates the logs every day at a specified time (based on 24-hour time). The default time is 2359.
- **Size Limit Rotation Policy.** Rotates the logs when the file reaches the maximum size for each log. The default size limit is 100 MB.
- **Never Rotate Policy.** Used in a rare event that does not require log rotation.

To Configure the Log Rotation Policy

Steps

- Use `dsconfig` to modify the log rotation policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --remove "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --add "rotation-policy:7 Days Time Limit Rotation Policy"
```

Configuring Log Rotation Listeners

The Directory Server provides two log file rotation listeners: the copy log file rotation listener and the summarize log file rotation listener, which can be enabled with a log publisher. Log file rotation listeners allow the server to perform a task on a log file as soon as it has been rotated out of service. Custom log file listeners can be created with the Server SDK.

The copy log file rotation listener can be used to compress and copy a recently-rotated log file to an alternate location for long-term storage. The original rotated log file will be subject to deletion by a log file retention policy, but the copy will not be automatically removed. Use the following command to create a new copy log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Copy on Rotate" \
  --type copy \
  --set enabled:true \
  --set copy-to-directory:/path/to/archive/directory \
  --set compress-on-copy:true
```

The path specified by the `copy-to-directory` property must exist, and the file system containing that directory must have enough space to hold all of the log files that will be written there. The server automatically monitors free disk space on the target file system and generates administrative alerts if the amount of free space gets too low.

The summarize log file rotation listener invokes the `summarize-access-log` tool on a recently-rotated log file and writes its output to a file in a specified location. This provides information about the number and types of operations processed by the server, processing rates and response times, and other useful metrics. Use this with access loggers that log in a format that is compatible with the `summarize-access-`

log tool, including the **file-based-access** and **operation-timing-access** logger types. Use the following command to create a new summarize log file rotation listener:

```
$ dsconfig create-log-file-rotation-listener \
  --listener-name "Summarize on Rotate" \
  --type summarize \
  --set enabled:true \
  --set output-directory:/path/to/summary/directory
```

The summary output files have the same name as the rotated log file, with an extension of **.summary**. If the **output-directory** property is specified, the summary files are written to that directory. If not specified, files are placed in the directory in which the log files are written.

As with the copy log file rotation listener, summary files are not automatically deleted. Although files are generally small in comparison to the log files themselves, make sure that enough space is available in the specified storage directory. The server automatically monitors free disk space on the file system to which the summary files are written.

Configuring Log Retention

The Directory Server allows you to configure the log retention policy for each log on the server. When any retention limit is reached, the Directory Server removes the oldest archived log prior to creating a new log. Log retention is only effective if you have a log rotation policy in place. If you create a new log publisher, you must configure at least one log retention policy.

- **File Count Retention Policy.** Sets the number of log files you want the Directory Server to retain. The default file count is 10 logs. If the file count is set to 1, then the log will continue to grow indefinitely without being rotated.
- **Free Disk Space Retention Policy.** Sets the minimum amount of free disk space. The default free disk space is 500 MBytes.
- **Size Limit Retention Policy.** Sets the maximum size of the combined archived logs. The default size limit is 500 MBytes.
- **Time Limit Retention Policy.** Sets the maximum length of time that rotated log files should be retained.
- **Custom Retention Policy.** Create a new retention policy that meets your Directory Server's requirements. This will require developing custom code to implement the desired log retention policy.
- **Never Delete Retention Policy.** Used in a rare event that does not require log deletion.

To Configure the Log Retention Policy

About this task

Steps

- Use **dsconfig** to modify the log retention policy for the access logger.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Access Logger" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

Configuring Filtered Logging

The PingDirectory Server provides a mechanism to filter access log messages based on specific criteria. The filtered log can then be used with a custom log publisher to create and to generate your own custom logs. Adding new filtered logs and associate publishers does not change the behavior of any existing logs. For example, adding a new log that only contains operations that were unsuccessful does not result in those operations being removed from the default access log.

The following example shows how to create a set of criteria that matches any operation that did not complete successfully. It then explains how to create a custom access log publisher that logs only operations matching that criteria. Note that this log does not include messages for connects or disconnects, and only a single message is logged per operation. This message contains both the request and result details.

To run log filtering based on any operation result (for example, result code, processing time, and response controls), turn off request logging and set the `include-request-details-in-result-messages` property to `TRUE`. Since filtering based on the results of an operation cannot be done until the operation completes, the server has no idea whether to log the request. Therefore, it might log request messages but not log any result messages. Instead, if you can only log result messages and include request details in the result messages, then only messages for operations that match the result criteria are logged. All pertinent information about the corresponding requests are included.

To Configure a Filtered Log Publisher

Steps

1. Use the `dsconfig` command in non-interactive mode to create a result criteria object set to `failure-result-codes`, a predefined set of result codes that indicate when an operation did not complete successfully.

```
$ bin/dsconfig create-result-criteria --type simple \
  --criteria-name "Failed Operations" --set result-code-criteria:failure-
  result-codes
```

2. Use `dsconfig` to create the corresponding log publisher that uses the result criteria. The log rotation and retention policies are also set with this command.

```
$ bin/dsconfig create-log-publisher \
  --type file-based-access \
  --publisher-name "Filtered Failed Operations" \
  --set enabled:true \
  --set log-connects:false \
  --set log-disconnects:false \
  --set log-requests:false \
  --set "result-criteria:Failed Operations" \
  --set log-file:logs/failed-ops.log \
  --set include-request-details-in-result-messages:true \
  --set "rotation-policy:7 Days Time Limit Rotation Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"
```

3. View the `failed-ops.log` in the `logs` directory. Verify that only information about failed operations is written to it.

Managing Admin Alert Access Logs

Admin Alert Access Logs are a specialized form of filtered log that automatically generates an administrative alert when criteria configured for the log publisher matches those messages in the access log.

About Access Log Criteria

Configuring an Admin Alert Access Log requires that you configure the criteria for the access log messages. Each criteria can be either a Simple or an Aggregate type. The Simple type uses the set of properties for the client connection, operation request, and the contents of any operation-specific requests or results. The Aggregate type provides criteria that contains Boolean combination of other operation-specific criteria objects. For more information, see the *Ping Identity Directory Server Configuration Reference*.

The criteria can be one or more of the following:

- **Connection Criteria.** Defines sets of criteria for grouping and describing client connections based on a number of properties, including protocol, client address, connection security, and authentication state.
- **Request Criteria.** Defines sets of criteria for grouping and describing operation requests based on a number of properties, including properties for the associated client connection, the type of operation, targeted entry, request controls, target attributes, and other operation-specific terms.
- **Result Criteria.** Defines sets of criteria for grouping and describing operation results based on a number of properties, including the associated client connection and operation request, the result code, response controls, privileges missing or used, and other operation-specific terms.
- **Search Entry Criteria.** Defines sets of criteria for grouping and describing search result entries based on a number of properties, including the associated client connection and operation request, the entry location and contents, and included controls.
- **Search Reference Criteria.** Defines sets of criteria for grouping and describing search result references based on a number of properties, including the associated client connection and operation request, reference contents, and included controls.

Configuring an Admin Alert Access Log Publisher

Prior to configuring an Admin Alert Access Log, you must establish an administrative alert handler in your system. For more information, see [Working with Administrative Alert Handlers](#).

To Configure an Admin Alert Access Log Publisher

Steps

1. Use `dsconfig` to create a criteria object for the Admin Alert Access Log. For this example, we want to log only write operations that target user entries. The following command matches any of the specified operations whose target entry matches the filter `"(objectClass=person)"`.

If you are using the `dsconfig` tool in interactive mode, the menu items for the criteria operations are located in the Standard objects menu.

```
$ bin/dsconfig create-request-criteria --type simple \
  --criteria-name "User Updates" \
  --set operation-type:add \
  --set operation-type:delete \
  --set operation-type:modify \
  --set operation-type:modify-dn \
  --set "any-included-target-entry-filter:(objectClass=person)"
```

2. Use `dsconfig` to create a log publisher of type `admin-alert-access`.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "User Updates Admin Alert Access Log" \
  --type admin-alert-access \
  --set "request-criteria:User Updates" \
  --set include-request-details-in-result-messages:true \
  --set enabled:true
```

Managing Syslog-Based Access Log Publishers

The Directory Server supports access logging using the syslog protocol that has been part of the Berkeley Software Distribution (BSD) operating systems for many years. Syslog provides a flexible, albeit simple, means to generate, store and transfer log messages that is supported on most UNIX and Linux operating systems.

The quasi-standard syslog message format cannot exceed 1 kbytes and has three important parts:

- **PRI.** Specifies the message priority based on its facility and severity. The message facility is a numeric identifier that specifies the type of log messages, such as kernel messages, mail system messages, etc. The severity is a numeric identifier that specifies the severity level of the operation that is being reported. Together, the facility and the severity determine the priority of the log message indicated

by angled brackets and 1-3 digit priority number. For example, "<0>", "<13>", "<103>" are valid representations of the PRI.

- **Timestamp and Host Name.** The timestamp displays the current date and time of the log. The host name or IP address displays the source of the log.
- **Message.** Displays the actual log message.

Administrators can configure syslog to handle log messages using log priorities that are based on the message's facility and severity. This feature allows users to configure the logging system in such a way that messages with high severities can be sent to a centralized repository, while lower severity messages can be stored locally on a server.

 **Note:** Since the numeric values of the severity and facility are operating system-dependent, the central repository must only include syslog messages from compatible OS types, otherwise the meanings of the PRI field is ambiguous.

Before You Begin

You will need to identify the host name and port to which you want to connect. Because the Syslog Protocol uses User Datagram Protocol (UDP) packets, we highly recommend that you use `localhost` and utilize some additional logging tools, such as `syslog-ng`. UDP is unreliable and unsecure means to transfer data packets between hosts.

Default Access Log Severity Level

All messages are logged at the syslog severity level of 6, which is `Informational: informational` messages. Note that this value is not standard across different types of UNIX or Linux systems. Please consult your particular operating system.

Syslog Facility Properties

When using syslog, specify a facility for the access log messages. As an advanced property, you can select a number that corresponds to the facility you wish to use. The default value for the `syslog-facility` property is 1 (one) for user-level messages. Note that these values are not standard across different types of UNIX or Linux systems. Please consult your particular operating system documentation for properties specific to that system.

Syslog Facility Properties

Facility	Description
0	kernel messages
1	user-level messages (default)
2	mail system
3	system daemons
4	security/authorization messages
5	messages generated internally by syslogd
6	line printer subsystem
7	network news subsystem
8	UUCP subsystem
9	clock daemon
10	security/authorization messages
11	FTP daemon

Facility	Description
12	NTP subsystem
13	log audit
14	log alert
15	clock daemon
16	local use 0
17	local use 1
18	local use 2
19	local use 3
20	local use 4
21	local use 5
22	local use 6
23	local use 7

Queue-Size Property

The maximum number of log records that can be stored in the asynchronous queue is determined by the `queue-size` property. The default queue size set is 10000, which means that the server will continuously flush messages from the queue to the log. The server does not wait for the queue to fill up before flushing to the log. Therefore, lowering this value can impact performance.

Configuring a Syslog-Based Access Log Publisher

You can configure a Syslog-based Access Log Publisher using the `dsconfig` tool. We recommend that you use syslog locally on localhost and use `syslog-ng` to send the syslog messages to remote syslog servers.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

To Configure a Syslog-Based Access Log Publisher

Steps

- Use `dsconfig` to create a log publisher of type `syslog-based-access`.

If you are using the `dsconfig` tool in interactive mode, the menu item for Syslog Facility is an advanced property, which can be exposed by typing `a` (for "show advanced properties") on the Syslog-Based Access Log Publisher menu.

```
$ bin/dsconfig create-log-publisher \
--publisher-name "syslog-access" \
--type syslog-based-access \
--set syslog-facility:4 \
--set enabled:true
```

Managing the File-Based Audit Log Publishers

The Directory Server provides an audit log, a specialized version of the access log, for troubleshooting problems that may occur in the course of processing. The log records all changes to the data in LDIF format so that administrators can quickly diagnose the changes an application made to the data or replay the changes to another server for testing purposes.

The audit log does not record authentication attempts but can be used in conjunction with the access log to troubleshoot security-related issues. The audit log is disabled by default because it does adversely impact the server's write performance.

Audit Log Format

The audit log uses standard LDIF format, so that administrators can quickly analyze what changes occurred to the data. The audit log begins logging when enabled and should be used to debug any issues that may have occurred. Some common properties are the following:

- **Timestamp.** Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Connection ID.** Numeric identifier, starting incrementally with 0, that identifies the client connection that is requesting the operation.
- **Operation ID.** Numeric identifier, starting incrementally with 0, that identifies the operation.
- **Modifiers Name.** Displays the DN of the user who made the change.
- **Update Time.** Records the `modifyTimestamp` operational attribute.

Audit Log Example

The following example shows output from the Audit Log in the `<server-root>/ logs/audit`. The first entry shows when the audit log was enabled. The second entry show changes made to a user entry.

```
# 05/Jun/2011:10:29:04 -0500; conn=0; op=55
dn: cn=File-Based Audit Logger,cn=Loggers,cn=config
changetype: modify
replace: ds-cfg-enabled
ds-cfg-enabled: true
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z

# 05/Jun/2011:10:31:20 -0500; conn=2; op=1
dn: uid=user.996,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 115 426 4748
-
replace: homePhone
homePhone: +1 407 383 4949
-
replace: modifiersName
modifiersName: cn=Directory Manager,cn=Root DNs,cn=config
-
replace: modifyTimestamp
modifyTimestamp: 20131010020345.546Z
```

Enabling the File-Based Audit Log Publisher

You can enable the File-Based Audit Log Publisher using the `dsconfig` tool. The audit log can impact the Directory Server's write performance, so enable it only when troubleshooting any issues.

To Enable the File-Based Audit Log Publisher

Steps

- Use `dsconfig` to enable the File-Based Audit Log Publisher. For this example, the instance name and startup ID is also enabled in the audit log.

```
$ bin/dsconfig set-log-publisher-prop \
--publisher-name "File-Based Audit Logger" \
--set enabled:true \
--set include-instance-name:true \
--set include-startup-id:true
```

Obscuring Values in the Audit Log

You can obscure the values of specific attributes in the audit log using the `obscure-attribute` property. Each value of an obscured attribute is replaced in the audit log with a string of the form "***** OBSCURED VALUE *****". By default, attributes are not obscured, because the values of password attributes appear in hashed form rather than in the clear.

Managing the JDBC Access Log Publishers

The Directory Server supports the Java Database Connectivity (JDBCTM) API, which allows access to SQL datastores by means of its JDBC drivers. The JDBC 4.0 API, part of the Java SDK, provides a seamless method to interface with various database types in heterogeneous environments.

By easily connecting to a database, the Directory Server can be configured to implement a centralized logging system with different databases. Centralized logging simplifies log correlation and analysis tasks and provides security by storing data in a single repository. Some disadvantages of centralized logging are that data flow asymmetries may complicate synchronization or network provisioning and may unduly burden the central repository with possibly heavy loads.

Before You Begin

Before configuring the JDBC Access Log Publisher, you need to carry out two essential steps to set up the database.

- Install the database drivers in the Directory Server `lib` directory.
- Define the log mapping tables needed to map access log elements to the database column data. Only those elements in the log mapping table gets logged by the JDBC Log Publisher.

The following sections provide more information about these tasks.

Configuring the JDBC Drivers

The Directory Server supports a number of JDBC drivers available in the market. We highly recommend using the JDBC 4 drivers supported in the Java platform. For example, for Oracle databases, you need to use the `ojdbc.jar` driver for Java and any associated JAR files (National Language Support jars, and others) required to connect with the particular database. The following databases are supported:

- DB2
- MySQL
- Oracle Call Interface (OCI)
- Oracle Thin
- PostgreSQL
- SQL Server

To Configure the JDBC Driver

Steps

- Obtain the JAR file(s) for your particular database, and copy it into the `<server-root>/lib` directory.

Configuring the Log Field Mapping Tables

The log field mapping table associates access log fields to the database column names. You can configure the log field mapping table using the `dsconfig` tool, which then generates a DDL file that you can import into your database. The DDL file is generated when you create the JDBC Log Publisher.

To uniquely identify a log record, we recommend always mapping the following fields: `timestamp`, `startupid`, `message-type`, `connection-id`, `operation-type`, `instance-name`.

The table name is not part of this mapping.

The Directory Server also provides three options that you can quickly select for creating a log field mapping table:

- Complete JDBC Access Log Field Mappings.** Maps all 52 object properties.
- Complete JDBC Error Log Field Mappings.** Maps all 8 object properties.
- Simple JDBC Access Log Field Mappings.** Maps a common set of object properties.
- Custom JDBC Access Log Field Mappings.** Create a custom set of JDBC log field mappings.
- Custom JDBC Error Log Field Mappings.** Create a custom set of JDBC error log field mappings.

To Configure the Log Field Mapping Tables

Steps

- Use `dsconfig` to create a log field mapping table. On the main menu, type `o` to change to the Standard Object menu, and type the number corresponding to Log Field Mapping.
- On the **Log Field Mapping management** menu, enter the option to create a new Log Field Mapping.
- On the **Log Field Mapping template** menu, enter the option to select a complete JDBC Access Log Field mapping to use as a template for your new field mapping.
- Next, enter a name for the new field mapping. In this example, type `my-jdbc-test`.
- On the **Access Log Field Mapping Properties** menu, select a property for which you want to change the value. Any property that is undefined will not be logged by the JDBC Access Log Publisher. When complete, type `f` to save and apply the changes.
- On the **Log Field Mapping Management** menu, type `q` to exit the menu.
- View the existing Log Mappings on the system.

```
$ bin/dsconfig list-log-field-mappings
```

```
Log Field Mapping                : Type
-----
Complete JDBC Access Log Field Mappings : access
Complete JDBC Error Log Field Mappings  : error
my-jdbc-test                       : access
Simple JDBC Access Log Field Mappings   : access
```

Configuring the JDBC Access Log Publisher using dsconfig Interactive Mode

After setting up the drivers and the log mapping table, use the `dsconfig` utility to configure the JDBC Access Log Publisher on the Directory Server. The following example uses `dsconfig` interactive mode to illustrate the steps required to configure the log publisher and the external database server.

To Configure the JDBC Access Log Publisher

Steps

1. Copy the database JAR files to the `<server-root>/lib` directory, and then restart the Directory Server.
2. Launch the `dsconfig` tool in interactive command-line mode.

```
$ bin/dsconfig
```

3. Next, type the connection parameters to bind to the Directory Server. Enter the host name or IP address, type of LDAP connection (LDAP, SSL, or StartTLS) that you are using on the Directory Server, the LDAP listener port number, the user bind DN, and the bind DN password.
4. On the main menu, type the number corresponding to Log Publisher.
5. On the **Log Publisher management** menu, enter the option to create a new Log Publisher.
6. On the **Log Publisher template** menu, type `n` to create a new Log Publisher.
7. On the **Log Publisher Type** menu, enter the option to create a new JDBC-Based Access Log Publisher.
8. Type a name for the JDBC Access Log Publisher.
9. On the **Enabled Property** menu, enter the option to enable the log publisher.
10. On the **Server Property** menu, enter the option to create a new JDBC External Server.
11. Next, type the name for the JDBC External Server. This is a symbolic name used to represent the DBMS.
12. On the **JDBC Driver Type Property** menu, type the number corresponding to the type of JDBC database driver type.
13. Next, type a name for the `database-name` property. This is the DBMS database name. The database name must contain the table referred to in the generated DDL.
14. Next, type the host name or IP address (`server-host-name`) of the external server.
15. Type the server listener port. In this example, type `1541`.
16. Review the properties for the external server, and the type `f` to apply the changes.
17. If you need to supply your own JDBC URL, type `a` for advanced properties to open the `jdbc-driver-url` property and supply the appropriate URL. The example below shows how to access an Oracle Thin Client connection using a SID instead of a Service.

```
>>>> Configure the properties of the JDBC External Server
```

```
Property Value(s)
```

```
-----
1) description -
2) jdbc-driver-type oraclethin
3) jdbc-driver-url jdbc:oracle:thin@myhost:1541:my_SID
4) database-name jdbc-test
5) server-host-name localhost
6) server-port 1541
7) user-name -
8) password -

?) help
f) finish - create the new JDBC External Server
a) hide advanced properties of the JDBC External Server
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit
```

```
Enter choice [b]: f
```

```
JDBC External Server was created successfully
```

18. When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file. Import the DDL file to your database.

Configuring the JDBC Access Log Publisher Using dsconfig Non-Interactive Mode

The following example uses `dsconfig` non-interactive mode to illustrate the steps to configure the log publisher and the external database server presented in the previous section.

To Configure the JDBC Access Log Publisher in Non-Interactive Mode

Steps

1. Use `dsconfig` with the `--no-prompt` option to create the JDBC external server.

```
$ bin/dsconfig --no-prompt create-external-server \
  --server-name jdbc-external \ --type jdbc \
  --set jdbc-driver-type:oraclethin \
  --set database-name:ubid_access_log \
  --set server-host-name:localhost --set server-port:1541
```

2. Use `dsconfig` to create the log publisher.

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-test \
  --type jdbc-based-access \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

3. When the JDBC Log Publisher is created, the Directory Server automatically generates a DDL file of the Log Field Mappings in the `<server-root>/logs/ddls/<name-of-logger>.sql` file. Import the DDL file to your database.

The procedure to configure the JDBC-Based Error Log Publisher is similar to creating a JDBC-Based Access Log Publisher. You can run the previous `dsconfig` command with the `--type jdbc-based-error` as follows:

```
$ bin/dsconfig --no-prompt create-log-publisher \
  --publisher-name jdbc-error-test \
  --type jdbc-based-error \
  --set enabled:true \
  --set server:jdbc-external \
  --set "log-field-mapping:Simple JDBC Access Log Field Mappings"
```

Managing the File-Based Error Log Publisher

The Error Log reports errors, warnings, and informational messages about events that occur during the course of the Directory Server's operation. Each entry in the error log records the following properties (some are disabled by default and must be enabled):

- **Timestamp.** Displays the date and time of the operation. Format: DD/Month/ YYYY:HH:MM:SS <offset from UTC time>
- **Category.** Specifies the message category that is loosely based on the server components.
- **Severity.** Specifies the message severity of the event, which defines the importance of the message in terms of major errors that need to be quickly addressed. The default severity levels are: `fatal-error`, `notice`, `severe-error`, `severe-warning`.
- **Message ID.** Specifies the numeric identifier of the message.
- **Message.** Stores the error, warning, or informational message.

Error Log Example

The following example displays the error log for the PingDataMetrics Server. The log is enabled by default and is accessible in the `<server-root>/logs/errors` file.

```
[21/Oct/2012:05:15:23.048 -0500] category=RUNTIME_INFORMATION severity=NOTICE

```

To Modify the File-Based Error Logs

Steps

- Use `dsconfig` to modify the default File-Based Error Log.

```
$ bin/dsconfig set-log-publisher-prop \
--publisher-name "File-Based Error Logger" \
--set include-product-name:true --set include-instance-name:true \
--set include-startup-id:true
```

Managing the Syslog-Based Error Log Publisher

The Directory Server supports a Syslog-Based Error Log Publisher using the same mechanism as the Syslog-Based Access Log Publisher. You can easily configure the error logger using the `dsconfig` tool.

Syslog Error Mapping

The Directory Server automatically maps error log severities to the syslog severities. The following mappings are used:

Error to Syslog Severities Mappings to Syslog

Error Log Facility	Syslog Severity
FATAL_ERROR,0	Syslog Emergency
SEVERE_ERROR,1	Syslog Alert

Error Log Facility	Syslog Severity
SEVERE_WARNING,2	Syslog Critical
MILD_ERROR,3	Syslog Error
MILD_WARNING,4	Syslog Warn
NOTICE,5	Syslog Notice
INFORMATION,6	Syslog Info
DEBUG,7	Syslog Debug

Configuring a Syslog-Based Error Log Publisher

You can configure a Syslog-based Error Log Publisher using the `dsconfig` tool. Again, we recommend that you use syslog locally on `localhost` and use `syslog-ng` to send the data packets over the UDP protocol.

Because syslog implementations differ by vendor, please review your particular vendor's syslog configuration.

To Configure a Syslog-Based Error Log Publisher

Steps

- Use `dsconfig` to create a log publisher of type `syslog-based-error`. In this example, set the syslog facility to 4 for security/authorization messages.

```
$ bin/dsconfig create-log-publisher --publisher-name "syslog-error" \
  --type syslog-based-error --set syslog-facility:4 --set enabled:true
```

Creating File-Based Debug Log Publishers

The Directory Server provides a File-Based Debug Log Publisher that can be configured when troubleshooting a problem that might occur during server processing. Because the debug data may be too large to maintain during normal operations, the Debug Log Publisher must be specifically configured and enabled. The Debug Log reports the following types of information:

- Exception data thrown by the server.
- Data read or written to network clients.
- Data read or written to the database.
- Access control or password policy data made within the server.

You can use the `dsconfig` tool to create a debug log publisher. You should only create a debug logger when troubleshooting a problem due to the voluminous output the Directory Server generates.

To Create a File-Based Debug Log Publisher

Steps

- Use `dsconfig` to create the debug log publisher. The `log-file` property (required) sets the debug log path. You must also specify the rotation and retention policy for the debug log.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "File-Based Debug Logger" \
  --type file-based-debug \
  --set enabled:true \
  --set log-file:/logs/debug \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy"
```

To Delete a File-Based Debug Log Publisher

Steps

- Use `dsconfig` to create the debug log publisher.

```
$ bin/dsconfig delete-log-publisher \
  --publisher-name "File-Based Debug Logger"
```

Managing Monitoring

The PingDirectory Server also provides a flexible monitoring framework that exposes its monitoring information under the `cn=monitor` entry and provides interfaces through the PingDataMetrics Server, the Administrative Console, SNMP, JMX, and over LDAP. The Directory Server also provides a tool, the Periodic Stats Logger, to profile server performance.

This chapter presents the following information:

The Monitor Backend

The Directory Server exposes its monitoring information under the `cn=monitor` entry. Administrators can use various means to monitor the servers, including the PingDataMetrics Server, through SNMP, the Administrative Console, JConsole, LDAP command-line tools, and the Periodic Stats Logger. Use the `bin/status` tool to display server component activity and state.

The list of all monitor entries can be seen using `ldapsearch` as follows:

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --baseDN "cn=monitor" "(objectclass=*)" cn
```

The following table describes a subset of the monitor entries:

Directory Server Monitoring Components

Component	Description
Active Operations	Provides information about the operations currently being processed by the Directory Server. Shows the number of operations, information on each operation, and the number of active persistent searches.
Backends	Provides general information about the state of an a Directory Server backend, including the entry count. If the backend is a local database, there is a corresponding database environment monitor entry with information on cache usage and on-disk size.
Client Connections	Provides information about all client connections to the Directory Server. The client connection information contains a name followed by an equal sign and a quoted value (e.g., <code>connID="15"</code> , <code>connectTime="20100308223038Z"</code> , etc.)
Connection Handlers	Provides information about the available connection handlers on the Directory Server, which includes the LDAP and LDIF connection handlers. These handlers are used to accept client connections and to read requests and send responses to those clients.
Disk Space Usage	Provides information about the disk space available to various components of the Directory Server.
General	Provides general information about the state of the Directory Server, including product name, vendor name, server version, etc.

Component	Description
Index	Provides on each index. The monitor captures the number of keys preloaded, and counters for read/write/remove/open-cursor/read-for-search. These counters provide insight into how useful an index is for a given workload.
HTTP/HTTPS Connection Handler Statistics	Provides statistics about the interaction that the associated HTTP connection handler has had with its clients, including the number of connections accepted, average requests per connection, average connection duration, total bytes returned, and average processing time by status code.
JVM Stack Trace	Provides a stack trace of all threads processing within the JVM.
LDAP Connection Handler Statistics	Provides statistics about the interaction that the associated LDAP connection handler has had with its clients, including the number of connections established and closed, bytes read and written, LDAP messages read and written, operations initiated, completed, and abandoned, etc.
Processing Time Histogram	Categorizes operation processing times into a number of user-defined buckets of information, including the total number of operations processed, overall average response time (ms), number of processing times between 0ms and 1ms, etc.
System Information	Provides general information about the system and the JVM on which the Directory Server is running, including system host name, operation system, JVM architecture, Java home, Java version, etc.
Version	Provides information about the Directory Server version, including build ID, version, revision number, etc.
Work Queue	<p>Provides information about the state of the Directory Server work queue, which holds requests until they can be processed by a worker thread, including the requests rejected, current work queue size, number of worker threads, and number of busy worker threads. The work queue configuration has a <code>monitor-queue-time</code> property set to <code>true</code> by default. This logs messages for new operations with a <code>qtime</code> attribute included in the log messages. Its value is expressed in milliseconds and represents the length of time that operations are held in the work queue.</p> <p>A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the <code>ldapsearch</code> command for example, use the <code>--useAdministrativeSession</code> option. The requester must have the <code>use-admin-session</code> privilege (included for root users). By default, eight threads are available for this purpose. This can be changed with the <code>num-administrative-session-worker-threads</code> property in the work queue configuration.</p>

Monitoring Disk Space Usage

The disk space usage monitor provides information about the amount of usable disk space available for Directory Server components. The disk space usage monitor evaluates the free space at locations registered through the `DiskSpaceConsumer` interface by various components of the server. Disk space monitoring excludes disk locations that do not have server components registered. However, other disk locations may still impact server performance, such as the operating system disk, if it becomes full. When relevant to the server, these locations include the server root, the location of the `/config` directory, the

location of every log file, all JE backend directories, the location of the changelog, the location of the replication environment database, and the location of any server extension that registers itself with the DiskSpaceConsumer interface.

The disk space usage monitor provides the ability to generate administrative alerts, as well as take additional action if the amount of usable space drops below the defined thresholds.

Three thresholds can be configured for this monitor:

- **Low space warning threshold.** This threshold is defined as either a percentage or absolute amount of usable space. If the amount of usable space drops below this threshold, then the Directory Server will generate an administrative alert but will remain fully functional. It will generate alerts at regular intervals that you configure (such as once a day) unless action is taken to increase the amount of usable space. The Directory Server will also generate additional alerts as the amount of usable space is further reduced (e.g., each time the amount of usable space drops below a value 10% closer to the low space error threshold). If an administrator frees up disk space or adds additional capacity, then the server should automatically recognize this and stop generating alerts.
- **Low space error threshold.** This threshold is also defined as either a percentage or absolute size. Once the amount of usable space drops below this threshold, then the server will generate an alert notification and will begin rejecting all operations requested by non-root users with "UNAVAILABLE" results. The server should continue to generate alerts during this time. Once the server enters this mode, then an administrator will have to take some kind of action (e.g., running a command to invoke a task or removing a signal file) before the server will resume normal operation. This threshold must be less than or equal to the low space warning threshold. If they are equal, the server will begin rejecting requests from non-root users immediately upon detecting low usable disk space.
- **Out of space error threshold.** This threshold may also be defined as a percentage or absolute size. Once the amount of usable space drops below this threshold, then the PingDirectory Server will generate a final administrative alert and will shut itself down. This threshold must be less than or equal to the low space error threshold. If they are equal, the server will shut itself down rather than rejecting requests from non-root users.
- **Disk space monitoring for tools.** The server monitors disk space consumption during processing for the `export-ldif`, `rebuild-index`, and `backup` tools. Space is monitored every 10 seconds if usable space for all monitored paths is greater than 15 percent of the capacity of those volumes. If usable space for any path drops below 15 percent, or below 10GB free, the space check frequency is increased to every second. Warning messages are generated if available space falls below 10 percent, or below 5GB free. If usable space for any path drops below two percent, or 1GB free, the tool processing is aborted and files may be removed to free up space.

The default configuration uses the same values for the low space error threshold and out of space error threshold. This is to prevent having the server online but rejecting requests, which will cause problems with applications trying to interact with the server. The low space warning threshold generates an alert before the problem becomes serious, well in advance of available disk space dropping to a point that it is critical.

The default values may not be suitable for all disk sizes, and should be adjusted to fit the deployment. Determining the best values should factor in the size of the disk, how big the database may become, how much space log files may consume, and how many backups will be stored.

The threshold values may be specified either as absolute sizes or as percentages of the total available disk space. All values must be specified as absolute values or as percentages. A mix of absolute values and percentages cannot be used. The low space warning threshold must be greater than or equal to the low space error threshold, the low space error threshold must be greater than or equal to the out of space error threshold, and the out of space error threshold must be greater than or equal to zero.

If the out of space error threshold is set to zero, then the server will not attempt to automatically shut itself down if it detects that usable disk space has become critically low. If the amount of usable space reaches zero, then the database will preserve its integrity but may enter a state in which it rejects all operations with an error and requires the server (or at least the affected backends) to be restarted. If the low space error threshold is also set to zero, then the server will generate periodic warnings about low available disk space

but will remain fully functional for as long as possible. If all three threshold values are set to zero, then the server will not attempt to warn about or otherwise react to a lack of usable disk space.

Monitoring with the PingDataMetrics Server

The PingDataMetrics Server is an invaluable tool for collecting, aggregating and exposing historical and instantaneous data from the various Ping Identity servers in a deployment. The PingDataMetrics Server relies on a captive PostgreSQL datastore for the metrics, which it collects from internal instrumentation across the instances, replicas, and data centers in your environment. The data is available via a Monitoring API that can be used to build custom dashboards and monitoring applications to monitor the overall health of your PingData Platform system. For more information, refer to the *PingDataMetrics Server Administration Guide*.

About the Collection of System Monitoring Data

All PingDirectory Servers have the capability to monitor the health of the server and host system they run on for diagnostic review and troubleshooting. Initially, the servers do not collect any performance data until they are prepared for monitoring by a Metrics Server using the `monitored-servers add-servers` tool or an administrator enables system health data collection for real-time inspection and querying. At a high level, all of the important server and machine metrics which can be monitored are available in the `cn=monitor` backend.

The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local JE databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (cpu, disk, network) and what kind of data aggregation occurs for LDAP application statistics. The Stats Collector plugin ensures that a PingDataMetrics Server is able to gather all of the detailed data required for a comprehensive diagnostic review.

The Stats Collector plugin relies exclusively on entries in the `cn=monitor` backend to sample data using LDAP queries. The Stats Collector plugin is the primary driver of performance data collection for LDAP, server response, replication, local JE databases, and host system machine metrics. Stats Collector configuration determines the sample and collection intervals, granularity of data (basic, extended, verbose), types of host system collection (cpu, disk, network) and the type of data aggregation that occurs for LDAP application statistics. The Stats Collector plugin is configured with the `dsconfig` tool and collects data using LDAP queries. For example, the `--server-info:extended` option includes collection for the following:

- CPU
- JVM memory
- Memory
- Disk information
- Network information

Utilization metrics are gathered via externally invoked OS commands, such as `iostat` and `netstat`, using platform-specific arguments and version-specific output parsing.

Enabling the Host System monitor provider automatically gathers CPU and memory utilization but only optionally gathers disk and network information. Disk and network interfaces are enumerated in the configuration by device names (e.g., `eth0` or `lo`), and by disk device names (e.g., `sd1`, `sdab`, `sda2`, `scsi0`).

Monitoring Key Performance Indicators by Application

The PingDirectory Server can be configured to track many key performance metrics (for example, throughput and response-time) by the client applications requesting them. This feature is invaluable for measuring whether the Ping Identity infrastructure meets all of your service-level agreements (SLA) that have been defined for client applications.

When enabled, the per-application monitoring data can be accessed in the `cn=monitor` backend, the Periodic Stats Logger, and made available for collection by the Metrics Server. See the “Profiling Server Performance Using the Periodic Stats Logger” for more information on using that component. Also, see the Directory Server Configuration section of the *PingDataMetrics Server Administration Guide* for details on configuring the server to expose metrics that interest you. Tracked application information is exposed in the PingDataMetrics Server by metrics having the 'application-name' dimension. See the documentation under `docs/metrics` of the PingDataMetrics Server for information on which metrics are available with the 'application-name' dimension.

Configuring the External Servers

Before you install the PingDataMetrics Server, you need to configure the servers you will be monitoring: PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. The PingDataMetrics Server requires all servers to be version 3.5.0 or later. See the administration guides for each product for installation instructions.

Once you have installed the Directory Server, you can use the `dsconfig` tool to make configuration changes for the PingDataMetrics Server. When using the `dsconfig` tool interactively, set the complexity level to Advanced, so that you can make all the necessary configuration changes.

Preparing the Servers Monitored by the PingDataMetrics Server

The Metrics Backend manages the storage of metrics and provides access to the stored blocks of metrics via LDAP. The Metrics Backend is configured to keep a maximum amount of metric history based on log retention policies. The default retention policy uses the Default Size Limit Retention Policy, Free Disk Space Retention Policy, and the File Growth Limit Policy, limiting the total disk space used to 500 MB. This amount of disk typically contains more than 24 hours of metric history, which is ample. The Directory Server keeps a metric history so that the PingDataMetrics Server can be down for a period and then catch up when it comes back online.

The following two commands create a Retention Policy that limits the number of files to 2000, and sets the Metrics Backend to flush data to a new file every 30 seconds.

```
$ bin/dsconfig create-log-retention-policy \
  --policy-name StatsCollectorRetentionPolicy \
  --type file-count --set number-of-files:2000

$ bin/dsconfig set-backend-prop \
  --backend-name metrics --set sample-flush-interval:30s \
  --set retention-policy:StatsCollectorRetentionPolicy
```

These commands configure the Metrics Backend to keep 16 hours of metric history, which consumes about 250 MB of disk, ensuring that captured metrics are available to the PingDataMetrics Server within 30 seconds of when the metric was captured. The value of the `sample-flush-interval` attribute determines the maximum delay between when a metric is captured and when it can be picked up by the PingDataMetrics Server.

The flush interval can be set between 15 seconds and 60 seconds, with longer values resulting in less processing load on the PingDataMetrics Server. However, this flush interval increases the latency between when the metric was captured and when it becomes visible in the Dashboard Application. If you change the `sample-flush-interval` attribute to 60 seconds in the example above, then the Directory Server keeps 2000 minutes of history. Because the number of metrics produced per unit of time can vary depending on the configuration, no exact formula can be used to compute how much storage is required for each hour of history. However, 20 MB per hour is a good estimate.

Configuring the Processing Time Histogram Plugin

The Processing Time Histogram plugin is configured on each Directory Server and Directory Proxy Server as a set of histogram bucket ranges. When the bucket ranges for a histogram change, the PingDataMetrics Server notices the change and marks samples differently. This process allows for histograms with the

same set of bucket definitions to be properly aggregated and understood when returned in a query. If different servers have different bucket definitions, then a single metric query cannot return histogram data from the servers.

You should try to keep the Processing Time Histogram bucket definitions the same on all servers. Having different definitions restricts the ability of the PingDataMetrics Server API to aggregate histogram data across servers and makes the results of a query asking "What percentage of the search requests took less than 12 milliseconds?" harder to understand.

For each server in your topology, you must set the `separate-monitor-entry-per-tracked-application` property of the processing time histogram plugin to true. This property must be set to expose per-application monitoring information under `cn=monitor`. When the `separate-monitor-entry-per-tracked-application` property is set to true, then the `per-application-ldap-stats` property must be set to `per-application-only` on the Stats Collector Plugin and vice versa.

For example, the following `dsconfig` command line sets the required properties of the Processing Time Histogram plugin:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Processing Time Histogram" \
  --set separate-monitor-entry-per-tracked-application:true
```

The following `dsconfig` command line sets the `per-application-ldap-stats` property of the Stats Collector plugin to `per-application-only`:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Stats Collector" \
  --set per-application-ldap-stats:per-application-only
```

Setting the Connection Criteria to Collect SLA Statistics by Application

If you want to collect data about your SLAs, you need to configure connection criteria for each Service Level Agreement that you want to track. The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used when the server needs to perform matching based on connection-level properties, such as filtered logging. For assistance using connection criteria, contact your authorized support provider.

For example, imagine that we are interested in collecting statistics on data that is accessed by clients authenticating as the Directory Manager. We need to create connection criteria on the Directory Server that identifies any user authenticating as the Directory Manager. The connection criteria name corresponds to the `application-name` dimension value that clients will specify when accessing the data via the API. When you define the Connection Criteria, change the `included-user-base-dn` property to include the Directory Manager's full LDIF entry.

The following `dsconfig` command line creates connection criteria for the Directory Manager:

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Directory Manager" \
  --type simple \
  --set "included-user-base-dn:cn=Directory Manager,cn=Root DNs,cn=config"
```

Updating the Global Configuration

You also need to create Global Configuration-tracked applications for each app (connection criteria) you intend to track. The `tracked-application` property allows individual applications to be identified in the server by connection criteria. The name of the tracked application is the same as the name you defined for the connection criteria.

For example, the following `dsconfig` command line adds the connection criteria we created in the previous step to the list of tracked applications:

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set "tracked-application:Directory Manager"
```

The value of the `tracked-application` field corresponds to the value of the `application-name` dimension value that clients will specify when accessing the data via the API.

Proxy Considerations for Tracked Applications

In a proxy environment, the criteria should be defined in the Directory Proxy Server since the Directory Proxy Server passes the application name through to the Directory Server in the intermediate client control. If a client of the Directory Proxy Server or Directory Server happens to use the intermediate client control, then the client name specified in the control will be used as the application name regardless of the criteria listed in the `tracked-application` property.

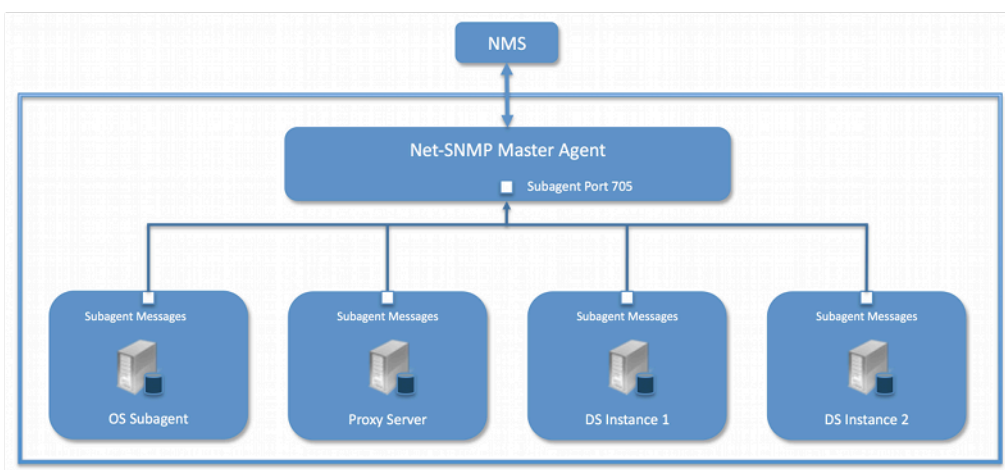

Monitoring Using SNMP

The PingDirectory Server supports real-time monitoring using the Simple Network Management Protocol (SNMP). The Directory Server provides an embedded SNMPv3 subagent plugin that, when enabled, sets up the server as a managed device and exchanges monitoring information with a master agent based on the AgentX protocol.

SNMP Implementation

In a typical SNMP deployment, many production environments use a network management system (NMS) for a unified monitoring and administrative view of all SNMP-enabled devices. The NMS communicates with a master agent, whose main responsibility is to translate the SNMP protocol messages and multiplex any request messages to the subagent on each managed device (for example, Directory Server instance, Directory Proxy Server, Data Sync Server, or OS Subagent). The master agent also processes responses or traps from the agents. Many vendors provide commercial NMS systems. Consult with your NMS system for specific information.

The PingDirectory Server contains an SNMP subagent plugin that connects to a Net-SNMP master agent over TCP. The main configuration properties of the plugin are the address and port of the master agent, which default to localhost and port 705, respectively. When the plugin is initialized, it creates an AgentX subagent and a managed object server, and then registers as a MIB server with the Directory Server instance. Once the plugin's startup method is called, it starts a session thread with the master agent. Whenever the connection is lost, the subagent automatically attempts to reconnect with the master agent. The Directory Server's SNMP subagent plugin transmits only read-only values for polling or trap purposes. (Set and inform operations are not supported). SNMP management applications cannot perform actions on the server on their own or by means of an NMS system.

MY TITLE Example SNMP Deployment

One important note is that the PingDirectory Server was designed to interface with a Net-SNMP (version 5.3.2.2 or later) master agent implementation with AgentX over TCP. Many operating systems provide their own Net-SNMP module. However, SMA disables some features present in the Net-SNMP package and only enables AgentX over UNIX Domain Sockets, which cannot be supported by Java. If your operating system has a native Net-SNMP master agent that only enables UNIX Domain Sockets, you must download and install a separate Net-SNMP binary from its web site.

Configuring SNMP

Because all server instances provide information for a common set of MIBs, each server instance provides its information under a unique SNMPv3 context name, equal to the server instance name. The server instance name is defined in the Global Configuration, and is constructed from the host name and the server LDAP port by default. Consequently, information must be requested using SNMPv3, specifying the context name that pertains to the desired server instance. This context name is limited to 30 characters or less. Any context name longer than 30 characters will result in an error message. Since the default context name is limited to 30 characters or less, and defaults to the server instance name and the LDAP port number, pay special attention to the length of the fully-qualified (DNS) host name.

Note: The Directory Server supports SNMPv3, and only SNMPv3 can access the MIBs. For systems that implement SNMP v1 and v2c, Net-SNMP provides a proxy function to route requests in one version of SNMP to an agent using a different SNMP version.

To Configure SNMP

Steps

1. Enable the Directory Server's SNMP plugin by using the `dsconfig` tool. Make sure to specify the address and port of the SNMP master agent. On each Directory Server instance, enable the SNMP subagent. Note that the SNMPv3 context name is limited to 30 bytes maximum. If the default dynamically-constructed instance name is greater than 30 bytes, there will be an error when attempting to enable the plugin. Enable the SNMP Subagent Alert Handler so that the sub-agent will send traps for administrative alerts generated by the server.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" --set enabled:true
```

2. View the error log. You will see a message that the master agent is not connected, because it is not yet online.

```
The SNMP sub-agent was unable to connect to the master
agent at localhost/705: Timeout
```

3. Edit the SNMP agent configuration file, `snmpd.conf`, which is often located in `/etc/snmp/snmpd.conf`. Add the directive to run the agent as an AgentX master agent:

```
master agentx agentXSocket tcp:localhost:705
```

Note that the use of `localhost` means that only sub-agents running on the same host can connect to the master agent. This requirement is necessary since there are no security mechanisms in the AgentX protocol.

4. Add the trap directive to send SNMPv2 traps to `localhost` with the community name, `public` (or whatever SNMP community has been configured for your environment) and the port.

```
trap2sink localhost public 162
```

5. To create a SNMPv3 user, add the following lines to the `/etc/snmp/snmpd.conf` file.

```
rwuser initial
createUser initial MD5 setup_passphrase DES
```

6. Run the following command to create the SNMPv3 user.

```
snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost create snmpuser initial
```

7. Start the `snmpd` daemon and after a few seconds you should see the following message in the Directory Server error log:

```
The SNMP subagent connected successfully to the master agent
at localhost:705. The SNMP context name is host.example.com:389
```

8. Set up a trap client to see the alerts that are generated by the Directory Server. Create a config file in `/tmp/snmptrapd.conf` and add the directive below to it. The directive specifies that the trap client can process traps using the public community string, and can log and trigger executable actions.

```
authcommunity log, execute public
```

9. Install the MIB definitions for the Net-SNMP client tools, usually located in the `/usr/share/snmp/mibs` directory.

```
$ cp resource/mib/* /usr/share/snmp/mibs
```

10. Then, run the trap client using the `snmptrapd` command. The following example specifies that the command should not create a new process using `fork()` from the calling shell (`-f`), do not read any configuration files (`-C`) except the one specified with the `-c` option, print to standard output (`-Lo`), and then specify that debugging output should be turned on for the User-based Security Module (`-Dusm`). The path after the `-M` option is a directory that contains the MIBs shipped with our product (i.e., `server-root/resource/mib`).

```
$ snmptrapd -f -C -c /tmp/snmptrapd.conf -Lf /root/trap.log -Dusm \
-m all -M +/usr/share/snmp/mibs
```

11. Run the Net-SNMP client tools to test the feature. The following options are required: `-v` <SNMP version>, `-u` <user name>, `-A` <user password>, `-l` <security level>, `-n` <context name (instance name)>. The `-m all` option loads all MIBs in the default MIB directory in `/usr/share/snmp/mibs` so that MIB names can be used in place of numeric OIDs.

```
$ snmpget -v 3 -u snmpuser -A password -l authNoPriv -n host.example.com:389 \
-m all localhost localDBBackendCount.0

$ snmpwalk -v 3 -u snmpuser -A password -l authNoPriv -n
host.example.com:389 \
-m all localhost systemStatus
```

MIBS

The Directory Server provides SMIPv2-compliant MIB definitions (RFC 2578, 2579, 2580) for distinct monitoring statistics. These MIB definitions are to be found in text files under `resource/mib` directory under the server root directory.

Each MIB provides managed object tables for each specific SNMP management information as follows:

- **LDAP Remote Server MIB.** Provides information related to the health and status of the LDAP servers that the Directory Proxy Server connects to, and statistics about the operations invoked by the Directory Proxy Server on those LDAP servers.
- **LDAP Statistics MIB.** Provides a collection of connection-oriented performance data that is based on a connection handler in the Directory Server. A server typically contain only one connection handler and therefore supplies only one table entry.
- **Local DB Backend MIB.** Provides key metrics related to the state of the local database backends contained in the server.

- **Processing Time MIB.** Provides a collection of key performance data related to the processing time of operations broken down by several criteria but reported as a single aggregated data set.
- **Replication MIB.** Provides key metrics related to the current state of replication, which can help diagnose how much outstanding work replication may have to do.
- **System Status MIB.** Provides a set of critical metrics for determining the status and health of the system in relation to its work load.

For information on the available monitoring statistics for each MIB available on the Directory Server and the Directory Proxy Server, see the text files provided in the `resource/mib` directory below the server installation.

The Directory Server generates an extensive set of SNMP traps for event monitoring. The traps display the severity, description, name, OID, and summary. For information about the available alert types for event monitoring, see the `resource/mib/UNBOUNDDID-ALERT-MIB.txt` file.

Monitoring with the Administrative Console

Ping Identity has an Administrative Console for administrators to configure the directory server. The console also provides a status option that accesses the server's monitor content.

To View the Monitor Dashboard

Steps

1. Ensure that the Directory Server is running.
2. Open a browser to `http://server-name:8443/console`.
3. Type the root user DN and password, and then click **Login**.
4. Use the top level navigation dropdown and select 'Status.'
5. On the Administrative Console's Status page, select the Monitors tab.

Accessing the Processing Time Histogram

The PingDirectory Server provides a processing time histogram that classifies operation response time into user-defined buckets. The histogram tracks the processing on a per operation basis and as a percentage of the overall processing time for all operations. It also provides statistics for each operation type (add, bind, compare, delete, modify, modify DN, search).

To Access the Processing Time Histogram

Steps

1. On the Administrative Console, click **Configuration > Status > Monitors tab**.
2. Select **Processing Time Histogram**. Other monitor entries can be accessed in similar ways.

Monitoring with JMX

The PingDirectory Server supports monitoring the JVM™ through a Java Management Extensions (JMX™) management agent, which can be accessed using JConsole or any other kind of JMX client. The JMX interface provides JVM performance and resource utilization information for applications running Java. You can monitor generic metrics exposed by the JVM itself, including memory pools, threads, loaded classes, and MBeans, as well as all the monitor information that the Directory Server provides. You can also subscribe to receive JMX notifications for any administrative alerts that are generated within the server.

Running JConsole

Before you can access JConsole, you must configure and enable the JMX Connection Handler for the Directory Server using the `dsconfig` tool. See [Configuring the JMX Connection Handler and Alert Handler](#).

To invoke the JConsole executable, type `jconsole` on the command line. If `JDK_HOME` is not set in your path, you can access JConsole in the `bin` directory of the `JDK_HOME` path.

To Run JConsole

Steps

1. Use `JConsole` to open the Java Monitoring and Management Console. You can also run JConsole to monitor a specific process ID for your application: `jconsole PID`. Or you can run JConsole remotely using: `jconsole hostname:port`.

```
$ jconsole
```

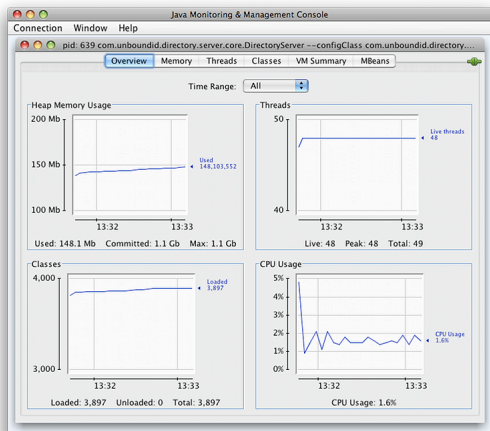

Note: If SSL is configured on the JMX Connection Handler, you must specify the Directory Server jar file in the class path when running `jconsole` over SSL. For example, run the following `jconsole` command:

```
$ jconsole \
  -J-Djavax.net.ssl.trustStore=/path/to/certStores/truststore \
  -J-Djavax.net.ssl.trustStorePassword=secret \
  -J-Djava.class.path=$SERVER_ROOT/lib/PingDirectory.jar:/Library/Java/
  JavaVirtualMachines/jdk-version.jdk/Contents/Home/lib/jconsole.jar
```

2. On the **Java Monitoring & Administrative Console**, click **Local Process**, and then click the **PID** corresponding to the directory server.

3. Review the resource monitoring information.

Monitoring the Directory Server Using JConsole

You can set up JConsole to monitor the Directory Server using a remote process. Make sure to enable the JMX Connection Handler and to assign at least the `jmx-read` privilege to a regular user account (the `jmx-notify` privilege is required to subscribe to receive JMX notifications). Do not use a root user account, as this would pose a security risk.

To Monitor the Directory Server using JConsole

Steps

1. Start the Directory Server.

```
$ bin/start-server
```

2. Enable the JMX Connection handler using the `dsconfig` tool. The handler is disabled by default. Remember to include the LDAP connection parameters (host name, port, bindDN, bindPassword).

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" --set enabled:true
```

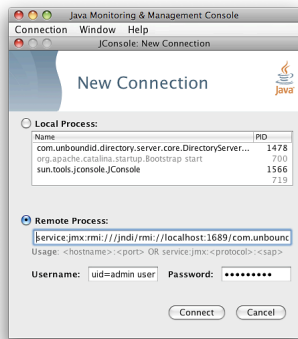

3. Assign `jmx-read`, `jmx-write`, and `jmx-notify` (if the user receives notifications) to the user.

```
$ bin/ldapmodify --hostname server1.example.com --port 1389 \
  --bindDN "cn=Directory Manager" --bindPassword secret
dn: uid=admin,dc=example,dc=com
changetype: modify
replace: ds-privilege-name
ds-privilege-name: jmx-read
ds-privilege-name: jmx-write
ds-privilege-name: jmx-notify
```

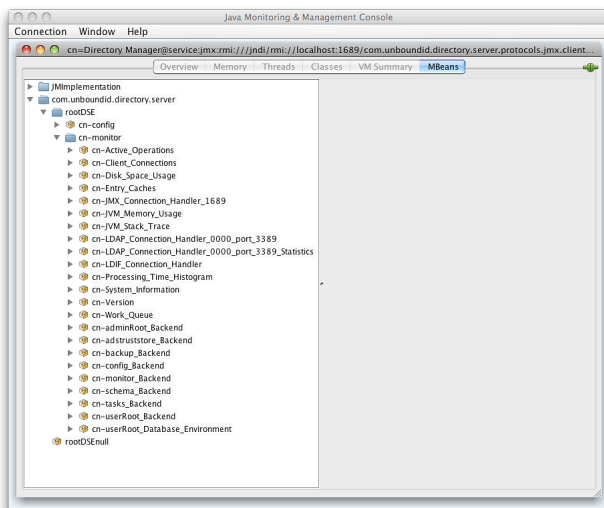

4. On the **Java Monitoring & Administrative Console**, click **Remote Process**, and enter the following JMX URL using the host and port of your Directory Server.

```
service:jmx:rmi:///jndi/rmi://<host>:<port>/
com.unboundid.directory.server.protocols.jmx.client-unknown
```

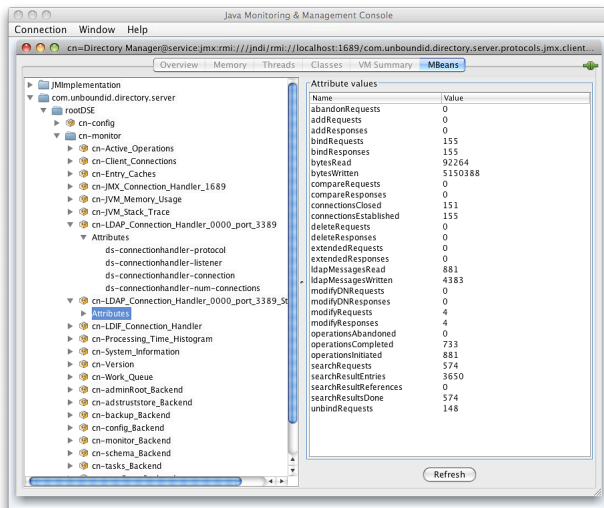

5. In the **Username** and **Password** fields, type the bind DN and password for a user that has at least the `jmx-read` privilege. Click **Connect**.

6. Click **com.unboundid.directory.server**, and expand the `rootDSE` node and the `cn-monitor` subnode.

7. Click a monitoring entry. In this example, click the **LDAP Connection Handler** entry.

Monitoring Using the LDAP SDK

You can use the monitoring API to retrieve monitor entries from the Directory Proxy Server as well as to retrieve specific types of monitor entries.

For example, you can retrieve all monitor entries published by the Directory Server and print the information contained in each using the generic API for accessing monitor entry data as follows:

```
for (MonitorEntry e : MonitorManager.getMonitorEntries(connection))
{
    System.out.println("Monitor Name: " + e.getMonitorName());
    System.out.println("Monitor Type: " + e.getMonitorDisplayName());
    System.out.println("Monitor Data:");
    for (MonitorAttribute a : e.getMonitorAttributes().values())
    {
        for (Object value : a.getValues())
        {
            System.out.println(" " + a.getDisplayName() + ": " +
String.valueOf(value));
        }
    }
    System.out.println();
}
}
```

For more information about the LDAP SDK and the methods in this example, see the *LDAP SDK* documentation.

Monitoring over LDAP

The PingDirectory Server exposes a majority of its information under the `cn=monitor` entry. You can access these entries over LDAP using the `ldapsearch` tool.

```
$ bin/ldapsearch --hostname server1.example.com --port 1389 \
--bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
--baseDN "cn=monitor" "(objectclass=*)"
```

Profiling Server Performance Using the Stats Logger

The Directory Server ships with a built-in Stats Logger that is useful for profiling server performance for a given configuration. At a specified interval, the Stats Logger can write server statistics to a JSON file or to a log file in a comma-separated format (.csv), which can be read by spreadsheet applications. The logger has a negligible impact on server performance unless the `log-interval` property is set to a very small value (less than 1 second). The statistics logged and their verbosity can be customized.

The Stats Logger can also be used to view historical information about server statistics including replication, LDAP operations, host information, and gauges. Either update the configuration of the existing Stats Logger Plugin to set the advanced `gauge-info` property to `basic/extended` to include this information, or create a dedicated Periodic Stats Logger for information about statistics of interest.

For information about how to enable this logging and where to find the log file, see [To Enable the Stats Logger](#) on page 880.

To Enable the Stats Logger

About this task

By default, the Directory Server ships with the built-in 'Stats Logger' disabled. To enable it using the `dsconfig` tool or the Administrative Console, go to **Plugins** menu (available on the Advanced object menu), and then, select .

Steps

1. Run `dsconfig` in interactive mode. Enter the LDAP or LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. Enter `o` to change to the Advanced Objects menu.

3. On the main menu, enter the number for Plugins.
4. On the **Plugin** menu, enter the number corresponding to view and edit an existing plugin.
5. On the **Plugin selection** list, enter the number corresponding to the Stats Logger.
6. On the **Stats Logger Plugin** menu, enter the number to set the `enabled` property to `TRUE`. When done, enter `f` to save and apply the configuration. The default logger will log information about the server every second to `<server-root>/logs/dsstats.csv`. If the server is idle, nothing will be logged, but this can be changed by setting the `suppress-if-idle` property to `FALSE` (`suppress-if-idle=false`).

```
>>>> Configure the properties of the Stats Logger Plugin
```

Property	Value(s)
1) description	Logs performance stats to a log file periodically.
2) enabled	false
3) local-db-backend-info	basic
4) replication-info	basic
5) entry-cache-info	-
6) host-info	-
7) included-ldap-application	If per-application LDAP stats is enabled, then stats will be included for all applications.
8) log-interval	1 s
9) collection-interval	200 ms
10) suppress-if-idle	true
11) header-prefix-per-column	false
12) empty-instead-of-zero	true
13) lines-between-header	50
14) included-ldap-stat	active-operations, num-connections, op-count-and-latency, work-queue
15) included-resource-stat	memory-utilization
16) histogram-format	count
17) histogram-op-type	all
18) per-application-ldap-stats	aggregate-only
19) ldap-changelog-info	-
20) gauge-info	none
21) log-file	logs/dsstats.csv
22) log-file-permissions	640
23) append	true
24) rotation-policy	Fixed Time Rotation Policy, Size Limit Rotation Policy
25) retention-policy	File Count Retention Policy
?) help	
f) finish	- apply any changes to the Periodic Stats Logger Plugin
a) hide advanced properties	of the Periodic Stats Logger Plugin
d) display the equivalent dsconfig command lines	to either re-create this object or only to apply pending changes
b) back	
q) quit	

```
Enter choice [b]:
```

7. Run the Directory Server. For example, if you are running in a test environment, you can run the **search-and-mod-rate** tool to apply some searches and modifications to the server. You can run **search-and-mod-rate --help** to see an example command.
8. View the Stats log output at `<server-root>/logs/dsstats.csv`. You can open the file in a spreadsheet.

To Configure Multiple Periodic Stats Loggers

About this task

Multiple Periodic Stats Loggers can be created to log different statistics, view historical information about gauges, or to create a log at different intervals (such as logging cumulative operations statistics every hour). To create a new log, use the existing Stats Logger as a template to get reasonable settings, including rotation and retention policy.

Steps

1. Run `dsconfig` by repeating steps 1–3 in [To Enable the Stats Logger](#).
2. From the **Plugin management** menu, enter the number to create a new plugin.
3. From the **Create a New Periodic Stats Logger Plugin** menu, enter `t` to use an existing plugin as a template.
4. Enter the number corresponding to the existing stats logger as a template.
5. Next, enter a descriptive name for the new stats logger. For this example, type `Stats Logger-10s`.
6. Enter the log file path to the file. For this example, type `logs/dsstats2.csv`.
7. On the menu, make any other change to the logger. For this example, change the `log-interval` to `10s`, and the `suppress-if-idle` to `false`. When finished, enter `f` to save and apply the configuration.
8. You should now see two loggers `dsstats.csv` and `dsstats2.csv` in the `logs` directory.

StatsD monitoring endpoint

The Monitoring Endpoint configuration type provides the StatsD Endpoint type that you can use to transfer metrics data in the StatsD format.

Examples of metrics you can send are:

- Busy worker thread count
- Garbage collection statistics
- Host system metrics such as CPU and memory

For a list of available metrics, use the interactive `dsconfig` menu for the Stats Collector Plugin or in the Administrative Console, edit the **Stats Collector** plugin as explained in the second example.

You configure the Monitoring Endpoint using the `dsconfig` command. When you configure Monitoring Endpoint, you include:

- The endpoint's hostname
- The endpoint's port
- A toggle to use TCP or UDP
- A toggle to use SSL if you use TCP

For example, to configure a new StatsD Monitoring Endpoint to send UDP data to localhost port 8125 using `dsconfig`:

```
dsconfig create-monitoring-endpoint \
  --type statsd \
  --endpoint-name StatsDEndpoint \
  --set enabled:true \
  --set hostname:localhost \
  --set server-port:8125 \
  --set connection-type:unencrypted-udp
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.

2. In the **Logging, Monitoring, and Notifications** section, click **Monitoring Endpoints**.
3. Click **New Monitoring Endpoint**.

You can send data to any number of monitoring endpoints.

The Stats Collector Plugin controls the metrics used by the StatsD monitoring endpoint. To send metrics with the StatsD monitoring endpoint, you must enable the Stats Collector Plugin. Also, you must configure the Stats Collector Plugin to indicate the metrics to send.

To enable the Stats Collector Plugin or to configure the type of data sent, use the `dsconfig` command or the Administrative Console. For example, to enable the Stats Collector Plugin to send host CPU metric, memory metrics, and server status metrics using `dsconfig`:

```
dsconfig set-plugin-prop \
  --plugin-name "Stats Collector" \
  --set enabled:true \
  --set host-info:cpu \
  --set host-info:disk \
  --set status-summary-info:basic
```

If you are using the Administrative Console:

1. Click **Show Advanced Configuration**.
2. In the **LDAP (Administration and Monitoring)** section, click **Plugin Root**
3. Edit the **Stats Collector** plugin.

After you enable the Stats Collector and create the StatsD monitoring endpoint, you can:

- Use the data with Splunk as explained in [Sending Metrics to Splunk with StatsD](#) on page 883.
- Configure other tools that support StatsD, such as CloudWatch or a Prometheus StatsD exporter, to use the data. For more information about this configuration, see your tool's StatsD documentation. Configure the StatsD monitoring endpoint to use the correct host and port. The `dsconfig create-monitoring-endpoint` example above uses a host of localhost and a port of 8125. You can also set these values in the Administrative Console.

Sending Metrics to Splunk with StatsD

About this task

With the StatsD Endpoint type, you can send metric data to a Splunk installation.

In Splunk, you can use SSL to secure ports that are open for StatsD.

Note:

StatsD metrics are typically sent over UDP. By using UDP, the client sending metrics does not have to block as it would if using TCP. However, using TCP guarantees order and ensures no metrics are lost.

You can configure open UDP (or TCP) ports in Splunk to accept only connections from a certain hostname or IP address.

To securely send UDP (or TCP) data to Splunk, you can:

Steps

1. Send the data to a Splunk Universal Forwarder.
2. Have the forwarder communicate with the Splunk Indexer over SSL.

Adding Custom Logged Statistics to a Periodic Stats Logger

Add custom statistics based on any attribute in any entry under `cn=monitor` using the Custom Logged Stats object. This configuration object provides powerful controls for how monitor attributes are written to the log. For example, you can extract a value from a monitor attribute using a regular expression. Newly created Custom Logged Stats will automatically be included in the Periodic Stats Logger output.

Besides allowing a straight pass-through of the values using the 'raw' statistic-type, you can configure attributes to be treated as a counter (where the interval includes the difference in the value since the last interval), an average, a minimum, or a maximum value held by the attribute during the specified interval. The value of an attribute can also be scaled by a fixed value or by the value of another monitor attribute.

Note: Custom third-party server extensions that were written using the Server SDK can also expose interval statistics using a Periodic Stats Logger. The extension must first implement the SDK's `MonitorProvider` interface and register with the server. The monitor attributes produced by this custom `MonitorProvider` are then available to be referenced by a Custom Logged Stats object.

To illustrate how to configure a Custom Logged Statistics Logger, the following procedure reproduces the built-in "Consumer Total GB" column that shows up in the output when the `included-resource-stat` property is set to `memory-utilization` on the Periodic Stats Logger. The column is derived from the `total-bytes-used-by-memory-consumers` attribute of the `cn=JVM Memory Usage, cn=monitor` entry as follows:

```
dn: cn=JVM Memory Usage,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-memory-usage-monitor-entry
objectClass: extensibleObject
cn: JVM Memory Usage
...
total-bytes-used-by-memory-consumers: 3250017037
```

To Configure a Custom Logged Statistic Using `dsconfig` Interactive

Steps

1. Run `dsconfig` and enter the LDAP/LDAPS connection parameters when prompted.

```
$ bin/dsconfig
```

2. On the Directory Server configuration main menu (Advanced Objects menu), enter the number corresponding to Custom Logged Stats.
3. On the Custom Logged Stats menu, enter the number corresponding to Create a new Custom Logged Stats.
4. Select the Stats Logger Plugin from the list if more than one is present on the system. If you only have one stats logger, press **Enter** to confirm that you want to use the existing plugin.
5. Enter a descriptive name for the Custom Logged Stats. For this example, enter `Memory Usage`.
6. From the `monitor-objectclass` property menu, enter the objectclass attribute to monitor. For this example, enter `ds-memory-usage-monitor-entry`. You can run `ldapsearch` using the base DN "`cn=JVM Memory Usage,cn=monitor`" entry to view the entry.
7. Next, specify the attributes of the monitor entry that you want to log in the stats logger. In this example, enter `total-bytes-used-by-memory-consumers`, and then press **Enter** again to continue.
8. Next, specify the type of statistics for the monitored attribute that will appear in the log file. In this example, enter the option for raw statistics as recorded by the logger.
9. In the Custom Logged Stats menu, review the configuration. At this point, we want to set up a column name that lists the Memory Usage. Enter the option to change the `column-name` property.

10. Next, we want to add a specific label for the column name. Enter the option to add a value, and then enter **Memory Consumer Total (GB)**, and press **Enter** again to continue.
11. Confirm that you want to use the `column-name` value that you entered in the previous step, and then press `Enter` to use the value.
12. Next, we want to scale the Memory Consumer Totals by one gigabyte. On the **Custom Logged Stats** menu, enter the option to change the `divide-value-by` property.
13. On the `divide-value-by` property menu, enter the option to change the value, and then enter 1073741824 (i.e., 1073741824 bytes = 1 gigabytes).
14. On the **Custom Logged Stats** menu, review your configuration. When finished, enter `f` to save and apply the settings.

```
>>>> Configure the properties of the Custom Logged Stats
>>>> via creating 'Memory Usage' Custom Logged Stats

Property                                     Value(s)
-----
1) description                               -
2) enabled                                   true
3) monitor-objectclass                       ds-memory-usage-monitor-entry
4) include-filter                            -
5) attribute-to-log                          total-bytes-used-by-memory-consumers
6) column-name                               Memory Consumer Total (GB)
7) statistic-type                            raw
8) header-prefix                             -
9) header-prefix-attribute                   -
10) regex-pattern                            -
11) regex-replacement                        -
12) divide-value-by                           1073741824
13) divide-value-by-attribute                 -
14) decimal-format                           #.##
15) non-zero-implies-not-idle                false

?) help
f) finish - create the new Custom Logged Stats
a) hide advanced properties of the Custom Logged Stats
d) display the equivalent dsconfig arguments to create this object
b) back
q) quit
```

Enter choice [b]:

The Custom Logged Stats was created successfully

When the Custom Logged Stats configuration change is completed, the new stats value should immediately show up in the Stats Logger output file.

To Configure a Custom Stats Logger Using `dsconfig` Non-Interactive

Steps

- Use the `dsconfig` non-interactive command-line equivalent to create your custom stats logger. The following one-line command replicates the procedure in the previous section. This command produces a column named "Memory Consumer Total (GB)" that contains the value of the `total-bytes-used-by-memory-consumers` attribute pulled from the entry with the `ds-memory-usage-monitor-entry` objectclass. This value is scaled by 1073741824 to get to a value represented in GBs.

```
$ bin/dsconfig create-custom-logged-stats --plugin-name "Stats Logger" \
--stats-name "Memory Usage" --type custom \
--set monitor-objectclass:ds-memory-usage-monitor-entry \
```

```
--set attribute-to-log:total-bytes-used-by-memory-consumers \
--set "column-name:Memory Consumer Total (GB)" --set statistic-type:raw \
--set divide-value-by:1073741824
```

Managing Notifications and Alerts

The PingDirectory Server provides delivery mechanisms for account status notifications and administrative alerts using SMTP, JMX, or SNMP in addition to standard error logging. Alerts and events reflect state changes within the server that may be of interest to a user or monitoring service. Notifications are typically the delivery of an alert or event to a user or monitoring service. Account status notifications are only delivered to the account owner notifying a change in state in the account.

This chapter presents the following topics:

Working with Account Status Notifications

The PingDirectory Server supports notification handlers that can be used to notify users and/or administrators of significant changes related to password policy state for user entries. The following two notification handlers are available:

- **Error Log Account Status Notification Handler.** Enabled by default. The handlers send alerts to the error log when an account event occurs.
- **SMTP Account Status Notification Handler.** Disabled by default. You can enable the SMTP Handler with the `dsconfig` command to send notifications to designated email addresses.

Account Status Notification Types

The handlers send alerts when one of the account status events described in the following table occurs during password policy processing.

Account Status Notification Types

Account Status Notification Types	Description
account-disabled	Generates a notification whenever a user account is disabled by an administrator.
account-enabled	Generates a notification whenever a user account is enabled by an administrator.
account-expired	Generates a notification whenever a user authentication attempt fails because the account has expired.
account-idle-locked	Generates a notification whenever a user authentication attempt fails because the account has been locked after idling for too long.
account-permanently-locked	Generates a notification whenever a user account is permanently locked (requiring administrative action to unlock the account) after too many failed attempts.
account-reset-locked	Generates a notification whenever an authentication attempt fails because the user account is locked because the user failed to change a password within the required interval that was reset by an administrator.
account-temporarily-locked	Generates a notification whenever a user account is temporarily locked after too many failed attempts.
account-unlocked	Generates a notification whenever a user account is unlocked by an administrator.

Account Status Notification Types	Description
password-changed	Generates a notification whenever a user changes his or her own password.
password-expired	Generates a notification whenever a user authentication fails because the password has expired.
password-expiring	Generates a notification the first time that a password expiration warning is encountered for a user password.
password-reset	Generates a notification whenever a user's password is reset by an administrator.

Working with the Error Log Account Status Notification Handler

The Error Log Account Status Notification Handler is enabled by default and sends alerts when one of the account status events occur.

To Disable the Error Log Account Status Notification Handler

Steps

- Use the `dsconfig` tool to disable the Error Log Handler. You can view the log at `logs/error`.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  ---handler-name "Error Log Handler" --set enabled:false
```

To Remove a Notification Type from the Error Log Handler

Steps

- While not recommended, if you want to remove an account status notification type, use the `dsconfig` tool with the `--remove` option.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "Error Log Handler" \
  --remove account-status-notification-type: password-reset
```

Working with the SMTP Account Status Notification Handler

You can enable account status notifications to be sent to designated email addresses of end users, administrators, or both through an outgoing SMTP server. The email message is automatically generated from template files that contain the text to use in the message body. For example, the message subject for the account-disabled event is:

```
account-disabled: Your directory account has been disabled.
```

The message templates are located in the `config/messages` directory. The typical message body template is as follows:

```
Your directory account has been disabled.
```

```
For further assistance, please contact a server administrator.
```

By default, the sender address is `notifications@example.com`, but you can configure your own address.

Before you enable the SMTP Account Status Notification Handler, you must configure the Directory Server to use at least one mail server as shown below. You can configure an SMTP server using `dsconfig` and the `set-global-configuration-prop` option.

To Configure the SMTP Server

Steps

1. Use `dsconfig` to configure a simple mail server.

```
$ bin/dsconfig create-external-server --server-name smtp1 \
  --type smtp --set server-host-name:smtp.example.com
```

2. Use `dsconfig` to configure an SMTP server. This command adds the server to the global list of mail servers that the Directory Server can use.

```
$ bin/dsconfig set-global-configuration-prop \
  --set smtp-server:smtp1
```

To Configure a StartTLS Connection to the SMTP Server

Steps

1. Use `dsconfig` to configure a StartTLS connection to the server.

```
$ bin/dsconfig create-external-server \
  --server-name myTLSServer --type smtp \
  --set server-host-name:tls.smtp.example.com \
  --set server-port:587 \
  --set smtp-security:starttls \
  --set user-name:MyAccountName \
  --set password:AAD5yZ+DjvwiYkBSMer6GQ6B3szQ6gSSBjA=
```

2. Use `dsconfig` to configure a newly-created SMTP server. This command adds the server to the global list of mail servers that the Directory Server can use.

```
$ bin/dsconfig set-global-configuration-prop \
  -set smtp-server:myTLSServer
```

To Configure an SSL Connection to the SMTP Server

Steps

1. Use `dsconfig` to create an external SMTP server using SSL.

```
$ bin/dsconfig create-external-server \
  --server-name ssl.smtp.example.com \
  --type smtp --set server-host-name:smtp.gmail.com \
  --set server-port:465 \
  --set smtp-security:ssl \
  --set "user-name:my.name@example.com" \
  --set password:xxxxxx --set "smtp-timeout:10s"
```

2. Use `dsconfig` to configure an SMTP server. This command adds the server to the global list of mail servers that the Directory Server can use.

```
$ bin/dsconfig set-global-configuration-prop \
  --set smtp-server:ssl.smtp.example.com
```

To Enable the SMTP Account Status Notification Handler

Steps

- Use `dsconfig` to enable the SMTP account status notification handler.

```
$ bin/dsconfig set-account-status-notification-handler-prop \
  --handler-name "SMTP Handler" --set enabled:true \
  --set "recipient-address:admin@example.com" \
```

```
--set "sender-address:acct-status-notifications@example.com"
```

To View the Account Status Notification Handlers

Steps

- After you have enabled the SMTP server, view the list of account status notification handlers using **dsconfig**.

```
$ bin/dsconfig list-account-status-notification-handlers
```

```
Account Status Notification Handler : Type      : enabled
-----:-----:-----
Error Log Handler                   : error-log : true
SMTP Handler                         : smtp     : true
```

Associating Account Status Notification Handlers with Password Policies

To generate notifications whenever appropriate password policy state changes occur in the server, the password policy that governs the entry being updated must be configured to use one or more account status notification handlers. By default, password policies are not configured with any such handlers, and therefore, no account status notifications will be generated.

The set of account status notification handlers that should be in use for a password policy is controlled by the `account-status-notification-handler` property for that password policy. It can be configured using **dsconfig** or the Administrative Console. For example, the following change updates the default password policy, so that the error log account status notification handler will be invoked for any appropriate password policy state changes for entries governed by the default password policy:

```
$ bin/dsconfig set-password-policy-prop \
  --policy-name "Default Password Policy" \
  --set "account-status-notification-handler:Error Log Handler"
```

Working with Administrative Alert Handlers

The PingDirectory Server provides mechanisms to send alert notifications to administrators when significant problems or events occur during processing, such as problems during server startup or shutdown. The Directory Server provides a number of alert handler implementations, including:

- Error Log Alert Handler.** Sends administrative alerts to the configured server error logger(s).
- Exec Alert Handler.** Executes a specified command on the local system if an administrative alert matching the criteria for this alert handler is generated by the Directory Server. Information about the administrative alert will be made available to the executed application as arguments provided by the command.
- Groovy Scripted Alert Handler.** Provides alert handler implementations defined in a dynamically-loaded Groovy script that implements the `ScriptedAlertHandler` class defined in the Server SDK.
- JMX Alert Handler.** Sends administrative alerts to clients using the Java Management Extensions (JMX) protocol. Ping Identity uses JMX for monitoring entries and requires that the JMX connection handler be enabled.
- SMTP Alert Handler.** Sends administrative alerts to clients via email using the Simple Mail Transfer Protocol (SMTP). The server requires that one or more SMTP servers be defined in the global configuration.
- SNMP Alert Handler.** Sends administrative alerts to clients using the Simple Network Monitoring Protocol (SNMP). The server must have an SNMP agent capable of communicating via SNMP 2c.
- SNMP Subagent Alert Handler.** Sends SNMP traps to a master agent in response to administrative alerts generated within the server.
- Third Party Alert Handler.** Provides alert handler implementations created in third-party code using the Server SDK.

Administrative Alert Types

If enabled, the Directory Server can generate administrative alerts when the events occur. A full listing of system alerts and their severity is available in `<server-root>/docs/admin-alerts-list.csv`

Configuring the JMX Connection Handler and Alert Handler

You can configure the JMX connection handler and alert handler respectively using the `dsconfig` tool. Any user allowed to receive JMX notifications must have the `jmx-read` and `jmx-notify` privileges. By default, these privileges are not granted to any users (including root users or global administrators). For security reasons, we recommend that you create a separate user account that does not have any other privileges but these. Although not shown in this section, you can configure the JMX connection handler and alert handler using `dsconfig` in interactive command-line mode, which is visible on the "Standard" object menu.

To Configure the JMX Connection Handler

Steps

1. Use `dsconfig` to enable the JMX Connection Handler.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "JMX Connection Handler" \
  --set enabled:true \
  --set listen-port:1689
```

2. Add a new non-root user account with the `jmx-read` and `jmx-notify` privileges. This account can be added using the `ldapmodify` tool using an LDIF representation like:

```
dn: cn=JMX User,cn=Root DNs,cn=config
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-cfg-root-dn-user
givenName: JMX
sn: User
cn: JMX User
userPassword: password
ds-cfg-inherit-default-root-privileges: false
ds-cfg-alternate-bind-dn: cn=JMX User
ds-privilege-name: jmx-read
ds-privilege-name: jmx-notify
```

To Configure the JMX Alert Handler

Steps

- Use `dsconfig` to configure the JMX Alert Handler.

```
$ bin/dsconfig set-alert-handler-prop --handler-name "JMX Alert Handler" \
  --set enabled:true
```

Configuring the SMTP Alert Handler

By default, there is no configuration entry for an SMTP alert handler. To create a new instance of an SMTP alert handler, use the `dsconfig` tool.

Configuring the SMTP Alert Handler

Steps

- Use the `dsconfig` tool to configure the SMTP Alert Handler.

```
$ bin/dsconfig create-alert-handler \
  --handler-name "SMTP Alert Handler" \
  --type smtp \
  --set enabled:true \
  --set "sender-address:alerts@example.com" \
  --set "recipient-address:administrators@example.com" \
  --set "message-subject:Directory Admin Alert \%%alert-type\%%" \
  --set "message-body:Administrative alert:\n\%%alert-message\%%"
```

Configuring the SNMP Subagent Alert Handler

You can configure the SNMP Subagent alert handler using the `dsconfig` tool, which is visible at the "Standard" object menu. Before you begin, you need an SNMP Subagent capable of communicating via SNMP2c. For more information on SNMP, see [Monitoring Using SNMP](#).

To Configure the SNMP Subagent Alert Handler

Steps

- Use `dsconfig` to configure the SNMP subagent alert handler. The `server-host-name` is the address of the system running the SNMP subagent. The `server-port` is the port number on which the subagent is running. The `community-name` is the name of the SNMP community that is used for the traps.

The Directory Server also supports a SNMP Alert Handler, which is used in deployments that do not enable an SNMP subagent.

```
$ bin/dsconfig set-alert-handler-prop \
  --handler-name "SNMP Subagent Alert Handler" \
  --set enabled:true \
  --set server-host-name:host2 \
  --set server-port:162 \
  --set community-name:public
```

E-mail Account Status Notification Handler

The e-mail account status notification handler enables the sending of messages that can contain either a plain-text body, an HTML-formatted body, or both (in which case the recipient's email client determines which version to display). Messages can optionally include a set of attachments.

The `config/account-status-notification-email-templates` directory contains a set of template files that can be used to generate multi-part email messages to send to end users and server administrators when certain events occur that affect the state of a user account. A separate template is used for each type of event so that the message contents, recipients, and other details can be customized for specific events.

Account Status Notification Types

The following account status notification types are available.

- `account-temporarily-locked` -- A user's account has been temporarily locked due to too many failed authentication attempts. The account will remain locked until a configured length of time elapses, or until the password is reset by an administrator.
- `account-permanently-locked` -- A user's account has been permanently locked due to too many failed authentication attempts. The account will remain locked until the password is reset by an administrator.

- `account-idle-locked` -- An authentication attempt failed because it has been too long (longer than the `idle-lockout-interval` configured in the associated password policy) since the user last successfully authenticated to the server. The account will remain locked until the password is reset by an administrator.
- `account-reset-locked` -- An authentication attempt failed because the user's account was in a "must change password" state following an administrative password reset, but the user did not choose a new password in a timely manner (within the `max-password-reset-age` duration configured in the associated password policy). The account will remain locked until the password is reset again by an administrator.
- `account-unlocked` -- A locked user account has been unlocked (for example, by an administrative password reset).
- `account-disabled` -- A user's account has been administratively disabled (by setting the `ds-pwp-account-disabled` operational attribute to `true` in the user entry). The user will not be allowed to authenticate until this attribute is removed or its value is set to `false`.
- `account-enabled` -- A user's account has been administratively enabled (by setting the `ds-pwp-account-disabled` operational attribute to `false` in the user entry, or by removing this attribute from the entry).
- `account-not-yet-active` -- An authentication attempt failed because the user account is configured with an activation time (via the `ds-pwp-account-activation-time` operational attribute in the user's entry) that is in the future. The user will not be allowed to authenticate until this time arrives, until the activation time is removed, or until the activation time is set to a time in the past.
- `account-expired` -- An authentication attempt failed because the user account is configured with an expiration time (via the `ds-pwp-account-expiration-time` operational attribute in the user's entry) that is in the past. The user will not be allowed to authenticate until the expiration time is removed or set to a time in the future.
- `password-expired` -- An authentication attempt failed because the user's password has expired. The user will not be allowed to authenticate until their password is reset by an administrator (or until they change their own password if `allow-expired-password-changes` is set to `true` in the associated password policy).
- `password-expiring` -- The user successfully authenticated, but their password will expire in the near future (as determined by the `password-expiration-warning-interval` setting in the associated password policy). This notification type will only be generated the first time that a user authenticated within a given warning interval.
- `password-reset` -- A user's password has been reset by an administrator.
- `password-changed` -- A user changed their own password.
- `account-created` -- A new account was created in an add request that matches the criteria specified in the `account-creation-notification-request-criteria` property of the account status notification handler configuration.
- `account-updated` -- An existing account was updated in a modify or modify DN request that matches the criteria specified in the `account-update-notification-request-criteria` property of the account status notification handler configuration.

Message Template File Format

A message template file can contain the following sections:

- A required header section describing the sender, recipients, subject, and other header elements. This section must appear exactly once, and it must be the first section of the template file.
- An optional section providing a plain-text version of the message body. This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.
- An optional section providing an HTML-formatted version of the message body. This section may appear at most once, and at least one of the plain-text and HTML-formatted body sections must be present.

- An optional section providing information about an attachment to include in the message. This section can be included zero, one, or multiple times, and all attachment sections must appear after all other sections.

A message template file must start with a header section that specifies the recipient and sender addresses, the message subject, and the values of any custom headers that should appear in the message. It also indicates whether the template should be enabled and used to send email messages.

The header section must begin with the line `----- BEGIN HEADERS -----`, and may contain a number of name-value pairs that provide information about the message. Each name-value pair should appear on a separate line, and the name and value must be separated by a colon and optional spaces. The header section can include the following:

- **ENABLED** -- Specifies whether this template is enabled and should be used to generate an email message. This element must be present and must have a value of either `true` or `false`. This is primarily intended for cases in which a message should only be generated under certain circumstances. If you do not ever want a message sent for a particular notification type, you should not specify a template file for that notification type in the configuration for the multi-part email account status notification handler.
- **TO** -- Specifies a primary recipient for the email message. This recipient will be visible to all recipients. The value can be either an email address (for example, `jd@example.com`) or a name followed by the email address in angle brackets (for example, `John Doe <jd@example.com>`). To specify multiple TO recipients, this element can be specified multiple times. It can be omitted if the message should have only CC or BCC recipients, but the message must have at least one TO, CC, or BCC recipient.
- **CC** -- Specifies a carbon-copied recipient for the email message. This recipient will be visible to all recipients. The value can be either an email address (for example, `jd@example.com`) or a name followed by the email address in angle brackets (for example, `John Doe <jd@example.com>`). This element can be specified multiple times to specify multiple CC recipients. It can be omitted if the message should have only TO or BCC recipients, but the message must have at least one TO, CC, or BCC recipient.
- **BCC** -- Specifies a blind carbon-copied recipient for the email message. This recipient will not be visible to other recipients. The value can be either an email address (for example, `jd@example.com`) or a name followed by the email address in angle brackets (for example, `John Doe <jd@example.com>`). This element can be specified multiple times to specify multiple BCC recipients. It can be omitted if the message should have only TO or CC recipients, but the message must have at least one TO, CC, or BCC recipient.
- **FROM** -- Specifies the address from which the email message should appear to be sent. This value can be either an email address (for example, `jd@example.com`) or a name followed by the email address in angle brackets (for example, `John Doe <jd@example.com>`). This element must be specified exactly once.
- **REPLY-TO** -- Specifies the default address to which replies should be sent. The value can be either an email address (for example, `jd@example.com`) or a name followed by the email address in angle brackets (for example, `John Doe <jd@example.com>`). This element is optional and can only be specified once.
- **SUBJECT** -- Specifies the subject for the email message. This element must be specified exactly once.
- **HEADER** -- Defines a custom header that should be included in the email message. The header value itself should be a name-value pair with the name and value separated by a colon and optional spaces (for example, `X-Custom-Header-Name: Custom Header Value`). This is an optional element and can be specified multiple times to specify multiple headers with the same or different names.

The header section must be followed by plain-text and HTML-formatted body sections. Each of these sections consists of free-form text that can span multiple lines and continues until the beginning of the next section or the end of the template file is reached.

If a plain-text body is included, it must begin with the line `----- BEGIN PLAIN-TEXT BODY -----`. If an HTML-formatted body is included, it must begin with the line `----- BEGIN HTML BODY -----`. At least one of these sections must be included. If an HTML-formatted body section is included, it is

recommended that a plain-text body also be included for the benefit of clients that prefer plain text or cannot handle HTML content. Any blank lines at the beginning or end of the body text will be removed, but blank lines in the middle of the body are preserved.

The template can also contain any number of optional attachment sections that describe any attachments that should be included in the message. Each attachment must be specified in its own section at the end of the template, after the header, plain-text, and HTML-formatted body sections. Each attachment section must begin with the line `----- BEGIN ATTACHMENT -----` and can include the following elements (using the same colon-delimited syntax used in the header section):

- `FILENAME` -- The name (without any path information) of the file to be attached. This must be specified, and the file must exist in the same directory as the template file.
- `CONTENT-TYPE` -- The MIME type for the attachment. This is an optional element. If it is not specified, a default content-type of `application/octet-stream` is used.
- `INLINE` -- If `true` is specified, indicates that the attachment should be an inline attachment (for example, an image that should be referenced within the HTML body, in which case the image source path should be specified as `cid:` followed by the filename (for example, ``cid:company-logo.png``). If present, this value must be either `true` or `false`. If it is omitted, a default value of `false` is assumed.

Customizing the Message Content

Before the server parses the template file to generate a message, it pre-processes the file with the Apache Velocity templating engine (<https://velocity.apache.org>). This enables you to customize the message content with information from the account status notification, details from the associated user entry, and other information. The following variables are defined for use with custom directives:

- `$account_entry` -- The entry for the user associated with the account status notification.
- `$notification_type` -- The name of the notification type for the account status notification.
- `$notification_message` -- A human-readable message that provides a basic description of the account status notification.
- `$before_entry` -- A version of the associated entry as it appeared before the operation was processed. This is only available for notifications generated as a result of `modify` or `modify DN` operations.
- `$after_entry` -- A version of the associated entry as it appeared after the operation was processed. This is only available for notifications generated as a result of `modify` or `modify DN` operations.

In addition to the built-in directives provided by Velocity, the following custom directives are also available:

- `#getEntryDN(entry, variableName)` -- Retrieves a string representation of the provided entry's DN and stores it in the specified Velocity context variable.
- `#getHasAttribute(entry, attributeName, variableName)` -- Determines if the provided entry includes the specified attribute. If it contains the specified attribute, a value of `true` is stored in the specified Velocity context variable. If not, a value of `false` is stored.
- `#getUserAttributeNames(entry, variableName)` -- Retrieves a list of the names of the user attributes contained in the provided entry and stores this list in the specified Velocity context variable.
- `#getOperationalAttributeNames(entry, variableName)` -- Retrieves a list of the names of the operational attributes contained in the provided entry and stores this list in the specified Velocity context variable.
- `#getAttributeValue(entry, attributeName, variableName)` -- Retrieves the first value for the indicated attribute from the provided entry and stores it in the specified Velocity context variable. If the attribute is not present in the entry, the variable is removed from the context.
- `#getAttributeValues(entry, attributeName, variableName)` -- Retrieves the list of values for the indicated attribute from the provided entry and stores this list in the specified Velocity context variable. If the attribute is not present in the entry, an empty list is stored.
- `#getEntryMatchesLDAPFilter(entry, filterString, variableName)` -- Determines if the provided entry matches the LDAP filter with the given string representation. If the entry matches, a value of `true` is stored in the Velocity context variable. Otherwise, a value of `false` is stored.
- `#getJSONObjectValue(entry, attributeName, variableName)` -- Retrieves the first value that can be parsed as a JSON object for the indicated attribute and stores this object in the specified variable in

the Velocity context. If the attribute does not exist in the provided entry, or if none of its values can be parsed as a JSON object, the variable is removed from the context.

- `#getJSONObjectValues(entry, attributeName, variableName)` -- Retrieves a list of all values that can be parsed as JSON objects for the indicated attribute and stores this list in the specified variable in the Velocity context. If the attribute does not exist in the provided entry, or if none of its values can be parsed as JSON objects, an empty list is stored.
- `#getJSONFieldValue(jsonObject, fieldName, variableName)` -- Retrieves the first value for the indicated field from the provided JSON object and stores its string representation in the specified Velocity context variable. Nested fields can be targeted by using the period as a delimiter between field names (for example, `name.first` targets the `first` field inside a JSON object that is a value for the outer `name` field). If the field does not exist in the provided object, the variable is removed from the context.
- `#getJSONFieldValues(jsonObject, fieldName, variableName)` -- Retrieves all values for the indicated field from the provided JSON object and stores a list of their string representations in the specified Velocity context variable. Nested fields can be targeted by using the period as a delimiter between field names (for example, `name.first` targets the `first` field inside a JSON object that is a value for the outer `name` field). If the field does not exist in the provided object (or if its value is an empty array), an empty list is stored.
- `#getJSONObjectMatchesFilter(jsonObject, jsonObjectFilterString, variableName)` -- Determines if the provided JSON object matches the JSON object filter with the given string representation. If the JSON object matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
- `#getEntry(entryDN, variableName)` -- Retrieves the entry with the provided DN from the server and stores it in the specified Velocity context variable. If the entry does not exist, the variable is removed from the context.
- `#searchForEntries(baseDN, scopeString, filterString, variableName)` -- Performs an internal search with the provided base DN, scope (which must be one of `base`, `one`, `sub`, or `subordinates`), and filter, and stores the list of matching entries in the specified variable in the context. If the search does not match any entries, if it matches more than 20 entries, or if the search criteria is not indexed, then an empty list is stored.
- `#getParentDN(entryDN, variableName)` -- Determines the parent DN for the provided entry DN and stores it in the specified Velocity context variable. If the provided DN contains only a single component, an empty string is stored. If the provided DN is the null DN (and therefore does not have a parent), the variable is removed from the context.
- `#getIsAttributeModified(beforeEntry, afterEntry, attributeName, variableName)` -- Determines if the indicated attribute has been modified between the provided before and after representations of the entry. If the attribute has been modified, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
- `#getIsAnyAttributeModified(beforeEntry, afterEntry, attributeName1, attributeName2, ..., variableName)` -- Determines if at least one of the listed attributes has been modified between the provided before and after representations of the entry. If at least one of the listed attributes has been modified, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored. The first two arguments to this directive must be the before and after representations of the target entry, and the last argument must be the name of the variable in which to store the result. All arguments in between these are treated as the names or OIDs of the attributes for which to make the determination. At least one attribute name or OID must be provided.
- `#getModifiedAttributeNames(beforeEntry, afterEntry, variableName)` -- Determines which attributes have been modified between the provided before and after representations of the entry and stores a list of their names in the specified Velocity context variable. If the provided entries are identical, an empty list is stored.
- `#getModifiedAttributeAddedValues(beforeEntry, afterEntry, attributeName, variableName)` -- Retrieves a list of the values that have been added between the provided before and after representations of an entry for the indicated attribute and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only removed from the attribute, an empty list is stored.
- `#getModifiedAttributeRemovedValues(beforeEntry, afterEntry, attributeName, variableName)` -- Retrieves a list of the values that have been removed between the provided before and after

representations of an entry for the indicated attribute and stores this list in the specified Velocity context variable. If the attribute was not altered, or if values were only added to the attribute, an empty list is stored.

- `#getOperationMatchesConnectionCriteria(criteriaDN, variableName)` -- Determines if the operation that triggered the notification matches the connection criteria defined in the entry with the specified DN. If it matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
- `#getOperationMatchesRequestCriteria(criteriaDN, variableName)` -- Determines if the operation that triggered the notification matches the request criteria defined in the entry with the specified DN. If it matches, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.
- `#getNotificationPropertyNames(variableName)` -- Retrieves a list of the names of the account status notification properties that are defined for the notification and stores this list in the specified Velocity context variable.
- `#getNotificationPropertyValue(propertyName, variableName)` -- Retrieves the first value for the given account status notification property and stores it in the specified Velocity context variable. If the property is not defined, the variable is removed from the context.
- `#getNotificationPropertyValues(propertyName, variableName)` -- Retrieves the list of values for the given account status notification property and stores this list in the specified Velocity context variable. If the property is not defined, an empty list is stored.
- `#getFormattedTimestamp(timestamp, formatString, variableName)` -- Retrieves a representation of the provided timestamp (which must be in generalized time form) formatted with the given format string (which must be compatible with the `java.text.SimpleDateFormat` class) and stores it in the specified Velocity context variable. The default time zone of the JVM is used.
- `#getFormattedTimestamp(timestamp, formatString, timeZone, variableName)` -- Retrieves a representation of the provided timestamp (which must be in generalized time form) formatted with the given format string (which must be compatible with the `java.text.SimpleDateFormat` class) in the indicated time zone (which must be compatible with the `java.time.ZoneId` class) and stores it in the specified Velocity context variable.
- `#getFileExistsInTemplateDirectory(fileName, variableName)` -- Determines if a file with the given name (which must not contain path information) exists in the same directory as the template. If the file exists, a value of `true` is stored in the specified Velocity context variable. Otherwise, a value of `false` is stored.

The following account status notification properties are available for use in conjunction with the `#getNotificationPropertyValue` and `#getNotificationPropertyValues` directives:

- `notification-type` -- The name of the account status notification type.
- `notification-time` -- A generalized time representation of the time that the notification was generated.
- `account-dn` -- The DN of the entry for the associated user account.
- `password-policy-dn` -- The DN of the password policy that governs the associated user account.
- `password-changed-time` -- A generalized time representation of the time the user's password was last changed.
- `seconds-since-password-change` -- The number of seconds since the account's password was last changed.
- `time-since-password-change` -- A human-readable duration indicating the length of time since the user's password was last changed.
- `account-is-usable` -- A value of `true` if the account is considered usable, or `false` if it is not usable (for example, if the account is locked/expired/not yet active, if the password is expired, if the user must choose a new password, etc.).
- `account-usability-errors` -- A list of human-readable strings providing information about any errors that currently affect the account's usability.
- `account-usability-warnings` -- A list of human-readable strings providing information about any warning conditions that have the potential to affect the account's usability in the near future.

- `account-usability-notice` -- A list of human-readable strings providing information about any notable account state conditions that are not expected to affect the account's usability in the near future.
- `account-is-disabled` -- The value `true` if the account has been administratively disabled, or `false` if it has not been administratively disabled.
- `account-is-not-yet-active` -- The value `true` if the account has an activation time in the future, or `false` if not.
- `account-activation-time` -- A generalized time representation of the account activation time, if defined.
- `seconds-until-account-activation` -- The number of seconds until the account becomes active if it has an activation time that is in the future.
- `time-until-account-activation` -- A human-readable duration indicating the length of time until the account becomes active if it has an activation time that is in the future.
- `seconds-since-account-activation` -- The number of seconds since the account became active if it has an activation time that is in the past.
- `time-since-account-activation` -- A human-readable duration indicating the length of time since the account became active if it has an activation time that is in the past.
- `account-is-expired` -- The value `true` if the account has an expiration time in the past, or `false` if not.
- `account-expiration-time` -- A generalized time representation of the account expiration time, if defined.
- `seconds-until-account-expiration` -- The number of seconds until the account expires if it has an expiration time in the future.
- `time-until-account-expiration` -- A human-readable duration indicating the length of time until the account expires if it has an expiration time in the future.
- `seconds-since-account-expiration` -- The number of seconds since the account expired if it has an expiration time in the past.
- `time-since-account-expiration` -- A human-readable duration indicating the length of time since the account expired if it has an expiration time in the past.
- `account-is-failure-locked` -- The value `true` if the account has been temporarily or permanently locked due to too many failed authentication attempts, or `false` if not.
- `failure-locked-time` -- A generalized time representation of the time that the account became failure-locked, if applicable.
- `account-unlock-time` -- A generalized time representation of the time that the account will be automatically unlocked, if it is temporarily locked due to too many failed authentication attempts.
- `seconds-until-unlock` -- The number of seconds until the account unlock time, if applicable.
- `time-until-unlock` -- A human-readable duration indicating the length of time until the account unlock time, if applicable.
- `failure-lockout-count` -- The number of failed authentication attempts required to lock an account, if configured.
- `failure-lockout-duration-seconds` -- The number of seconds that a failure-locked account will be prevented from authenticating, if defined.
- `failure-lockout-duration` -- A human-readable duration that indicates how long a failure-locked account will be prevented from authenticating, if defined.
- `account-is-idle-locked` -- The value `true` if the account is locked because it has been too long since the user last authenticated, or `false` if not.
- `idle-lockout-interval-seconds` -- The maximum number of seconds that may pass between successful authentications before an account becomes idle-locked, if configured.
- `idle-lockout-interval` -- A human-readable duration that indicates how much time may pass between successful authentications before an account becomes idle-locked, if configured.
- `last-login-time` -- A generalized time representation of the time that the user last successfully authenticated, if available.
- `seconds-since-last-login` -- The number of seconds that have passed since the user last successfully authenticated, if available.
- `time-since-last-login` -- A human-readable duration indicating the length of time that has passed since the user last successfully authenticated, if available.
- `last-login-ip-address` -- The IP address of the client from which the user last authenticated, if available.

- `account-is-reset-locked` -- The value `true` if the account is locked because the user failed to choose a new password in a timely manner after an administrative password reset, or `false` if not.
- `maximum-password-reset-age-seconds` -- The maximum number of seconds that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
- `maximum-password-reset-age` -- A human-readable duration indicating the maximum length of time that a user has to choose a new password after an administrative password reset before the account becomes reset-locked, if defined.
- `must-change-password` -- The value `true` if the user will be required to choose a new password before they are allowed to perform any other operations on the server, or `false` if not.
- `account-was-unlocked` -- The value `true` if the account had been locked but was just unlocked by the associated operation, or `false` if not.
- `password-is-expired` -- The value `true` if the account has an expired password, or `false` if not.
- `password-is-expiring` -- The value `true` if the account has a password that will expire in the near future (as determined by the `password-expiration-warning-interval` property in the associated password policy), or `false` if not.
- `maximum-password-age-seconds` -- The maximum number of seconds that an account is permitted to keep the same password before it expires, if defined.
- `maximum-password-age` -- A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
- `maximum-password-age` -- A human-readable duration indicating the maximum length of time that an account is permitted to keep the same password before it expires, if defined.
- `password-expiration-time` -- A generalized time representation of the time that the account's password did or will expire, if applicable.
- `seconds-until-password-expiration` -- The number of seconds until the account's password will expire, if it has an expiration time that is in the future.
- `time-until-password-expiration` -- A human-readable duration indicating the length of time until the account's password will expire, if it has an expiration time that is in the future.
- `seconds-since-password-expiration` -- The number of seconds since the account's password expired, if it has an expiration time that is in the past.
- `time-since-password-expiration` -- A human-readable duration indicating the length of time since the account's password expired, if it has an expiration time that is in the past.
- `old-password` -- The clear-text password that the account had before the associated operation was processed, if available.
- `new-password` -- The clear-text password that the account has after the associated operation was processed, if available.
- `new-generated-password` -- The clear-text password that was generated for the account by the associated operation, if applicable.
- `requester-ip-address` -- The IP address of the client that requested the associated operation, if available.
- `requester-dn` -- The DN of the account that requested the associated operation.
- `operation-type` -- The name of the operation type for the associated operation.
- `operation-id` -- A string representation of the operation ID for the associated operation.
- `connection-id` -- A string representation of the connection ID for the associated operation.
- `server-uuid` -- A string representation of the unique identifier generated for the server instance that processed the associated operation.
- `instance-name` -- The instance name for the server instance that processed the associated operation.

Working with the Alerts Backend

The Directory Server stores recently generated admin alerts in an Alerts Backend under the `cn=alerts` branch. The backend makes it possible to obtain admin alert information over LDAP for use with remote

monitoring. The backend's primary job is to process search operations for alerts. It does not support add, modify, or modify DN operations of entries in the `cn=alerts` backend.

The alerts persist on disk in the `config/alerts.ldif` file so that they can survive server restarts. By default, the alerts remain on disk for seven days before being removed. However, administrators can configure the number of days for alert retention using the `dsconfig` tool. The administrative alerts of Warning level or worse that have occurred in the last 48 hours are viewable from the output of the status command-line tool and in the Administrative Console.

To View Information in the Alerts Backend

Steps

- The following uses `ldapsearch` to view the admin alerts.

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
  --bindPassword secret --baseDN cn=alerts "(objectclass=ds-admin-alert)"
```

```
dn: ds-alert-id=3d1857a2-e8cf-4e80-ac0e-ba933be59eca,cn=alerts
objectClass: top
objectClass: ds-admin-alert
ds-alert-id: 3d1857a2-e8cf-4e80-ac0e-ba933be59eca
ds-alert-type: server-started
ds-alert-severity: info
ds-alert-type-oid: 1.3.6.1.4.1.32473.2.11.33
ds-alert-time: 20110126041442.622Z
ds-alert-generator: com.unboundid.directory.server.core.directory.server
ds-alert-message: The Directory Server has started successfully
```

To Modify the Alert Retention Time

Steps

1. Use `dsconfig` to change the maximum time information about generated admin alerts is retained in the Alerts backend. After this time, the information gets purged from the Directory Server. The minimum retention time is 0 milliseconds, which immediately purges the alert information.

```
$ bin/dsconfig set-backend-prop --backend-name "alerts" \
  --set "alert-retention-time: 2 weeks"
```

2. View the property using `dsconfig`.

```
$ bin/dsconfig get-backend-prop --backend-name "alerts" \
  --property alert-retention-time
```

```
Property : Value(s)
-----:-----
alert-retention-time : 2 w
```

To Configure Duplicate Alert Suppression

Steps

- Use `dsconfig` to configure the maximum number of times an alert is generated within a particular timeframe for the same condition. The `duplicate-alert-time-limit` property specifies the length of time that must pass before duplicate messages are sent over the administrative alert framework. The `duplicate-alert-limit` property specifies the maximum number of duplicate alert messages should be sent over the administrative alert framework in the time limit specified in the `duplicate-alert-time-limit` property.

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set duplicate-alert-limit:2 \
--set "duplicate-alert-time-limit:3 minutes"
```

Working with Alarms, Alerts, and Gauges

An alarm represents a stateful condition of the server or a resource that may indicate a problem, such as low disk space or external server unavailability. A gauge defines a set of threshold values with a specified severity that, when crossed, cause the server to enter or exit an alarm state. Gauges are used for monitoring continuous values like CPU load or free disk space (Numeric Gauge), or an enumerated set of values such as 'server unavailable' or 'server unavailable' (Indicator Gauge). Gauges generate alarms, when the gauge's severity changes due to changes in the monitored value. Like alerts, alarms have severity (NORMAL, WARNING, MINOR, MAJOR, CRITICAL), name, and message. Alarms will always have a Condition property, and may have a Specific Problem or Resource property. If surfaced through SNMP, a Probable Cause property and Alarm Type property are also listed. Alarms can be configured to generate alerts when the alarm's severity changes. The Alarm Manager, which governs the actions performed when an alarm state is entered, is configurable through the `dsconfig` tool and Administrative Console. A complete listing of system alerts, alarms, and their severity is available in `<server-root>/docs/admin-alerts-list.csv`.

There are two alert types supported by the server - standard and alarm-specific. The server constantly monitors for conditions that may need attention by administrators, such as low disk space. For this condition, the standard alert is `low-disk-space-warning`, and the alarm-specific alert is `alarm-warning`. The server can be configured to generate alarm-specific alerts instead of, or in addition to, standard alerts. By default, standard alerts are generated for conditions internally monitored by the server. However, gauges can only generate alarm-alerts.

The Directory Server installs a set of gauges that are specific to the product and that can be cloned or configured through the `dsconfig` tool. Existing gauges can be tailored to fit each environment by adjusting the update interval and threshold values. Configuration of system gauges determines the criteria by which alarms are triggered. The Stats Logger can be used to view historical information about the value and severity of all system gauges.

The Directory Server is compliant with the International Telecommunication Union CCITT Recommendation X.733 (1992) standard for generating and clearing alarms. If configured, entering or exiting an alarm state can result in one or more alerts. An alarm state is exited when the condition no longer applies. An `alarm_cleared` alert type is generated by the system when an alarm's severity changes from a non-normal severity to any other severity. An `alarm_cleared` alert will correlate to a previous alarm when the Condition and Resource properties are the same. The Condition corresponds to the Summary column in the `admin-alerts-list.csv` file.

Like the Alerts Backend, which stores information in `cn=alerts`, the Alarm Backend stores information within the `cn=alarms` backend. Unlike alerts, alarm thresholds have a state over time that can change in severity and be cleared when a monitored value returns to normal. Alarms can be viewed with the `status` tool. As with other alert types, alert handlers can be configured to manage the alerts generated by alarms.

To View Information in the Alarms Backend

Steps

- The following uses `ldapsearch` to view alarms. The following displays the listing for the CPU usage alarm.

```
$ bin/ldapsearch --port 1389 --bindDN "cn=Directory Manager" \
--bindPassword secret --baseDN cn=alarms "(objectclass=ds-admin-alarm)"
```

```
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
dn: ds-alarm-id=CPU Usage (Percent)-Host System,cn=alarms
objectClass: top
objectClass: ds-admin-alarm
ds-alarm-id: CPU Usage (Percent)-Host System
```

```

ds-alarm-condition: CPU Usage (Percent)
ds-alarm-specific-resource: Host System
ds-alarm-severity: CRITICAL
ds-alarm-previous-severity: CRITICAL
ds-alarm-details: Gauge CPU Usage (Percent) for Host System
                   has value 99, having had a value of 83.13 in the
                   previous interval. The severity is critical, having
                   assumed this severity Thu Sep 25 10:24:20 CDT 2014
                   when the value crossed threshold 80
ds-alarm-additional-text: If CPU use is high, check the server's current
                          workload
                          and other processes on this system and make any needed adjustments.
                          Reducing
                          the load on the system will lead to better response times
ds-alarm-start-time: 20140925152420.004Z
ds-alarm-critical-last-time: 20140925152420.004Z

```

Testing Alerts and Alarms

After alarms and alert handlers are configured, verify that the server takes the appropriate action when an alarm state changes by manually increasing the severity of a gauge. Alarms and alerts can be verified with the **status** tool.

To Test Alarms and Alerts

Steps

1. Configure a gauge with **dsconfig** and set the **override-severity** property to critical. The following example uses the CPU Usage (Percent) gauge.

```

$ dsconfig set-gauge-prop \
  --gauge-name "CPU Usage (Percent)" \
  --set override-severity:critical

```

2. Run the **status** tool to verify that an alarm was generated with corresponding alerts. The **status** tool provides a summary of the server's current state with key metrics and a list of recent alerts and alarms. The sample output has been shortened to show just the alarms and alerts information.

```

$ bin/status

```

```

Indeterminate Alarms

Indeterminate alarms are raised for a server condition for which a severity cannot be determined. In most cases these alarms are benign and do not issue alerts nor appear in the output of the `status` tool or Administrative Console by default. These alarms are usually caused by an enabled gauge that is intended to measure an aspect of the server that is not currently enabled. For example, gauges intended to monitor metrics related to replication may produce indeterminate alarms if a Directory Server is not currently replicating data. The gauge can be disabled if needed.

For more information about indeterminate alarms, view the gauge's associated monitor entry. There may be messages that can help determine the issue. The following is sample output from the `status` tool run with the `-alarmSeverity=indeterminate` option:

```

--- Alarms ---
Severity      : Severity Start : Condition      : Resource      : Details
              : Time           :                :               :
-----
Normal       : 26/Aug/2014    : Startup Begun : cn=config     : The Directory
Server       : 14:16:29 -0500 :                :               : is starting.
Indeterminate: 26/Aug/2014    : Replication   : not           : The value of

Managing SCIM Servlet Extensions

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. The SCIM 1.1 implementation is provided by the servlet extension named SCIM. The SCIM 2 implementation is provided by the servlet extension named SIMC2.

Managing the SCIM 1.1 Servlet Extension

The PingDirectory Server provides two System for Cross-domain Identity Management (SCIM) servlet extensions to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure, fast, and simple way. SCIM is an alternative to LDAP, allowing identity data provisioning between cloud-based applications over HTTPS. One servlet implements SCIM 1.1 and the other servlet implements SCIM 2.

This section describes fundamental SCIM concepts and provides information on configuring SCIM on your server.

Overview of SCIM 1.1 Fundamentals

Understanding the basic concepts of SCIM can help you use the SCIM extension to meet your deployment needs. SCIM allows you to:

- **Provision identities.** Through the API, you have access to the basic create, read, update, and delete functions, as well as other special functions.
- **Provision groups.** SCIM also allows you to manage groups.
- **Interoperate using a common schema.** SCIM provides a well-defined, platform-neutral user and group schema, as well as a simple mechanism to extend it.

The SCIM extension implements the 1.1 version of the SCIM specification. Familiarize yourself with this specification to help you understand and make efficient use of the SCIM extension and the SCIM SDK. The SCIM specifications are located on the Simplecloud website.

 **Note:** SCIM 1.1 will be deprecated in a future release.

Summary of SCIM 1.1 Protocol Support

PingDirectory Server supports all required features of the SCIM 1.1 protocol and most optional features. The following table describes SCIM features and whether they are supported.

SCIM Protocol Support

SCIM Feature	Supported
Etags	Yes
JSON	Yes
XML*	Yes
Authentication/Authorization	Yes, via HTTP basic authentication or OAuth 2.0 bearer tokens
Service Provider Configuration	Yes
Schema	Yes
User resources	Yes
Group resources	Yes
User-defined resources	Yes
Resource retrieval via GET	Yes
List/query resources	Yes
Query filtering*	Yes
Query result sorting*	Yes
Query result pagination*	Yes (Directory Server, not Directory Proxy Server)
Resource updates via PUT	Yes
Partial resource updates via PATCH*	Yes
Resource deletes via DELETE	Yes
Resource versioning*	Yes (requires configuration for updated servers)
Bulk*	Yes
HTTP method overloading	Yes
Raw LDAP Endpoints**	Yes

* denotes an optional feature of the SCIM protocol.

** denotes a PingDirectory Server extension to the basic SCIM functionality.

About the Identity Access API

The PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server support an extension to the SCIM 1.1 standard called the Identity Access API. The Identity Access API provides an alternative to LDAP by supporting CRUD (create, read, update, and delete) operations to access directory server data over an HTTP connection.

SCIM 1.1 and the Identity Access API are provided as a unified service through the SCIM HTTP Servlet Extension. The SCIM HTTP Servlet Extension can be configured to only enable core SCIM resources (e.g., 'Users' and 'Groups'), only LDAP object classes (e.g., `top`, `domain`, `inetOrgPerson`, or `groupOfUniqueNames`), or both. Because SCIM and the Identity Access API have different schemas, if both are enabled, there may be two representations with different schemas for any resources defined in the `scim-resources.xml` file: the SCIM representation and the raw LDAP representation. Likewise, because resources are exposed by an LDAP object class, and because these are hierarchical (e.g., `top` --> `person` --> `organizationalPerson` --> `inetOrgPerson`, etc.), a client application can access an entry in multiple ways due to the different paths/URIs to a given resource.

This chapter provides information on configuring the SCIM and the Identity Access API services on the PingDirectory Server.

Configuring SCIM 1.1

This section discusses details about the PingDirectory Server implementation of the SCIM protocol. Before reading this chapter, familiarize yourself with the SCIM Protocol specification, available on the Simplecloud website.

Creating Your Own SCIM 1.1 Application

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 1.1 SDK is available for download at <https://github.com/pingidentity/scim>.

Note: The value of a read-only SCIM attribute can be set by a POST operation if the SCIM attribute is a custom attribute in the `scim-resource.xml` config file, but not if the SCIM attribute is a core SCIM attribute.

Configuring the SCIM 1.1 Servlet Extension

The Directory Server provides a default SCIM HTTP Servlet Extension that can be enabled and configured using a `dsconfig` batch script located in the `config` directory. The script runs a series of commands that enables an HTTPS Connection Handler, increases the level of detail logged by the HTTP Detailed Access log publisher, and adds access controls to allow access to LDAP controls used by the SCIM Servlet Extension. There are additional optional configurations (e.g., changing the log format, enable `entryDN` virtual attribute and using VLV indexes) that you can make by altering the `dsconfig` batch script.

The SCIM resource mappings are defined by the `scim-resources.xml` file located in the `config` directory. This file defines the SCIM schema and maps it to the LDAP schema. This file can be customized to define and expose deployment specific resources. See [Managing the SCIM Schema](#) for more information.

The following procedures show how to configure SCIM on the server. The first example procedure shows the steps to manually configure SCIM without using the script. The second example procedure uses the `dsconfig` batch script to configure SCIM.

To Configure SCIM Manually

About this task

The following example procedure assumes that you have configured the Directory Server using the default settings, which means that SSL and the HTTPS Connection Handler have not been configured. The example also shows the `dsconfig` non-interactive commands. You can easily use the `dsconfig` interactive commands, which uses a menu-driven interface. If you use the `dsconfig` interactive, you must change to the Standard or Advanced object menu to access many of these configuration settings.

Steps

1. Set up your certificates. Follow the examples shown in the section *Managing Certificates*. You should have a keystore and truststore set up in the `config` directory. Make sure that the `keystore.pin` and `truststore.pin` are set.
2. Enable the key manager provider. The key manager provider accesses the certificate during the SSL handshaking process. If running `dsconfig` interactive, open the main menu, select "Key Manager Provider" -> "View and edit an existing Key Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

```
$ bin/dsconfig create-key-manager-provider \
```

```
--provider-name JKS \  
--type file-based --set enabled:true \  
--set key-store-file:config/keystore \  
--set key-store-type:JKS \  
--set key-store-pin-file:config/keystore.pin
```

3. Enable the trust manager provider. The trust manager provider determines if a presented certificate can be trusted. If running **dsconfig** interactive, open the main menu, select "Trust Manager Provider" -> "View and edit an existing Trust Manager Provider" -> "JKS" (or the type of certificate you are working with) -> "enabled" and then set the value to "true". Click "finish" to save the setting.

```
$ bin/dsconfig create-trust-manager-provider \  
--provider-name JKS \  
--type file-based --set enabled:true \  
--set trust-store-file:config/truststore \  
--set trust-store-type:JKS \  
--set trust-store-pin-file:config/truststore.pin
```

4. Configure the HTTPS Connection Handler. If not already created, this command creates and enables the connection handler, specifies the SCIM HTTP servlet extension and sets the listen port to a port of your choice, in this example, use 8443. The command also specifies the type of key manager and trust manager providers and sets the log publisher to "HTTP Detailed Access." If running **dsconfig** interactive, open the main menu, select "Connection Handler" -> "View and edit an existing Connection Handler" -> "HTTPS Connection Handler". Change the parameters to match your setup, and then, click "finish" to save the setting.

```
$ bin/dsconfig create-connection-handler \  
--handler-name "HTTPS Connection Handler" \  
--type http --set enabled:true \  
--set listen-port:8443 \  
--set use-ssl:true \  
--set http-servlet-extension:SCIM \  
--set "http-operation-log-publisher:HTTP Detailed Access" \  
--set key-manager-provider:JKS --set trust-manager-provider:JKS
```

If the HTTPS Connection Handler already exists, use the following:

```
$ bin/dsconfig set-connection-handler-prop \  
--handler-name "HTTPS Connection Handler" \  
--add http-servlet-extension:SCIM
```

5. Turn on the connection handler.

```
$ bin/dsconfig set-connection-handler-prop \  
--handler-name "HTTPS Connection Handler" \  
--add http-servlet-extension:SCIM
```

6. Add access controls to allow access to LDAP controls used by the SCIM Servlet Extension. These controls are the Post-Read Request Control (1.3.6.1.1.13.2), Server-Side Sort Request Control (1.2.840.113556.1.4.473), Simple Paged Results Control (1.2.840.113556.1.4.319), and Virtual List View Request Control (2.16.840.1.113730.3.4.9). We recommend using the following command to add access control instructions, rather than its **dsconfig** interactive equivalent.

```
$ bin/dsconfig set-access-control-handler-prop \  
--add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 || 1.2.840.113556.1.4.473  
|| 1.2.840.113556.1.4.319 || 2.16.840.1.113730.3.4.9")  
(version 3.0;acl "Authenticated access to controls used by the SCIM  
servlet  
extension"; allow (all) userdn="ldap:///all");'
```

7. Add access controls to allow read access to operational attributes used by the SCIM Servlet Extension. We recommend using the following non-interactive command to add access control instructions, rather than its `dsconfig` interactive equivalent.

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id
  ||
  createTimestamp || modifyTimestamp")
  (version 3.0;acl "Authenticated read access to operational attributes \
  used by the SCIM servlet extension"; allow (read,search,compare)
  userdn="ldap:///all";)'
```

8. Optional. The SCIM HTTP Connection Handler automatically uses a detailed HTTP log publisher, which is implemented in a proprietary format. If you need a standard W3C common log format publisher, enter the following command. If running `dsconfig` interactive, open the main menu, select "Log Publisher" -> "Create a new Log Publisher" -> "new Log Publisher created from scratch" -> "File Based Access Log Publisher", enter the parameters to match your setup, and then, click "finish" to save the setting. Go back to the main menu, select "Connection Handler" -> "HTTPS Connection Handler", and then add "HTTP Common Access" to the `http-operation-log-publisher` property. Click "finish" to save the setting.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access" \
  --type common-log-file-http-operation --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add "http-operation-log-publisher:HTTP Common Access"
```

9. Optional. To support searching or filtering by DN using the Identity Access API, you can enable the `entryDN` virtual attribute. If running `dsconfig` interactive, open the main menu, select "Virtual Attribute" -> "View and edit an existing Virtual Attribute" -> "Entry DN", and then change the enabled property to "true". Click "finish" to save the setting.

```
$ bin/dsconfig set-virtual-attribute-prop --name entryDN --set enabled:true
```

10. Optional. To support pagination, create some Virtual List View indexes. If running `dsconfig` interactive, open the main menu, select "Local DB VLV Index" -> "Create a new Local DB VLV Index" and then enter the properties needed for your setup. Click "finish" to save the setting. Repeat again for the "ascending-sn" index. Then, run the `rebuild-index` command to let the VLV Indexes take effect.

```
$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-uid --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+uid"

$ bin/dsconfig create-local-db-ylv-index --backend-name userRoot \
  --index-name ascending-sn \
  --set base-dn:dc=example,dc=com \
  --set scope:whole-subtree \
  --set "filter:(objectclass=inetorgperson)" \
  --set "sort-order:+sn"

$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index vlv.ascending-uid \
  --index vlv.ascending-sn
```

To Enable Resource Versioning

About this task

Resource versioning is enabled by default in new installations. Upgraded servers that had SCIM enabled need additional configuration to enable resource versioning.

Steps

1. Enable the **ds-entry-checksum** virtual attribute.

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name ds-entry-checksum \
  --set enabled:true
```

2. Remove any existing access controls required by SCIM for read access to operational attributes:

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-time || modifyTimestamp || ds-update-time")(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
```

3. Add new access controls required by SCIM for read access to operational attributes with the addition of the **ds-entry-checksum**:

```
$ bin/dsconfig set-access-control-handler-prop \
  --add 'global-aci:(targetattr="entryUUID || entryDN || ds-entry-unique-id || createTimestamp || ds-create-time || modifyTimestamp || ds-update-time || ds-entry-checksum")(version 3.0;acl "Authenticated read access to operational attributes used by the SCIM servlet extension"; allow (read,search,compare) userdn="ldap:///all"'
```

4. Enable SCIM resource versioning using the entry checksum virtual attribute:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set entity-tag-ldap-attribute:ds-entry-checksum
```

If enabled, the value of the **ds-entry-checksum** attribute is returned as the **ETag** header value when accessing the resource through SCIM, and is checked against the **If-Match** header when updating the resource. When accessing the resource through LDAP, use the **ds-entry-checksum** attribute instead.

To Configure the SCIM Servlet Extension using the Batch Script

About this task

The following example procedure assumes that you have set up your certificates, keystore, and truststore

Steps

1. Open the `<server-root>/config/scim-config-ds.dsconfig` script in a text editor.
2. For the optional elements (W3C common log, filtering by DN, and VLV Indexes, remove the comment (#) symbol on the **dsconfig** commands. Save the file when finished editing.
3. To enable the SCIM servlet extension, run the **dsconfig** batch file. Remember to include the bind parameters.

```
$ bin/dsconfig --batch-file config/scim-config-ds.dsconfig
```

SCIM 1.1 Servlet Extension Authentication

The SCIM 1.1 servlet supports authentication using either the HTTP Basic authentication scheme, or OAuth 2.0 bearer tokens. When authenticating using HTTP Basic authentication, the SCIM 1.1 servlet attempts to correlate the user name component of the Authorization header to a DN in the Directory Server. If the user name value cannot be parsed directly as a DN, it is correlated to a DN using an Identity Mapper. The DN is then used in a simple bind request to verify the password.

In deployments that use an OAuth authorization server, the SCIM 1.1 extension can be configured to authenticate requests using OAuth bearer tokens. The SCIM 1.1 extension supports authentication with OAuth 2.0 bearer tokens (per RFC 6750) using an OAuth Token Handler Server SDK Extension. Because the OAuth 2.0 specification does not specify how contents of a bearer token are formatted, PingDirectory Server provides the token handler API to decode incoming bearer tokens and extract or correlate associated authorization DNs.

Neither HTTP Basic authentication nor OAuth 2.0 bearer token authentication are secure unless SSL is used to encrypt the HTTP traffic.

To Configure Basic Authentication Using an Identity Mapper

About this task

By default, the SCIM servlet is configured to use the Exact Match Identity Mapper, which matches against the `uid` attribute. In this example, an alternate Identity Mapper is created so that clients can authenticate using `cn` values.

Steps

1. Create a new Identity Mapper that uses a match attribute of `cn`.

```
$ bin/dsconfig create-identity-mapper \
  --mapper-name "CN Identity Mapper" \
  --type exact-match \
  --set enabled:true \
  --set match-attribute:cn
```

2. Configure the SCIM servlet to use the new Identity Mapper.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM \
  --set "identity-mapper:CN Identity Mapper"
```

To Enable OAuth Authentication

About this task

To enable OAuth authentication, you need to create an implementation of the `OAuthTokenHandler` using the API provided in the Server SDK. For details on creating an `OAuthTokenHandler` extension, see the Server SDK documentation.

Steps

1. Install your OAuth token handler on the server using `dsconfig`.

```
$ bin/dsconfig create-oauth-token-handler \
  --handler-name ExampleOAuthTokenHandler \
  --type third-party \
  --set extension-
class:com.unboundid.directory.sdk.examples.ExampleOAuthTokenHandler
```

2. Configure the SCIM servlet extension to use it as follows:

```
$ bin/dsconfig set-http-servlet-extension-prop \
```

```
--extension-name SCIM \
--set oauth-token-handler:ExampleOAuthTokenHandler
```

Verifying the SCIM 1.1 Servlet Extension Configuration

You can verify the configuration of the SCIM 1.1 extension by navigating to a SCIM resource URL via the command line or through a browser window.

To Verify the SCIM Servlet Extension Configuration

About this task

You can verify the configuration of the SCIM extension by navigating to a SCIM resource URL via the command line or through a browser window.

Steps

- Run `curl` to verify that the SCIM extension is running. The `-k` (or `--insecure`) option is used to turn off `curl`'s verification of the server certificate, since the example Directory Server is using a self-signed certificate.

```
$ curl -u "cn=Directory Manager:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"

{"schemas":["urn:scim:schemas:core:1.0"],"id":"urn:scim:schemas:core:1.0",
"patch":{"supported":true},"bulk":{"supported":true,"maxOperations":10000,
"maxPayloadSize":10485760},"filter":{"supported":true,"maxResults":100},
"changePassword":{"supported":true},"sort":{"supported":true},
"etag":{"supported":false},"authenticationSchemes":[{"name":"HttpBasic",
"description":"The HTTP Basic Access Authentication scheme. This scheme is
not considered to be a secure method of user authentication (unless used in
conjunction with some external secure system such as SSL), as the user
name and password are passed over the network as cleartext.", "specUrl":
"http://www.ietf.org/rfc/rfc2617","documentationUrl":
"http://en.wikipedia.org/wiki/Basic_access_authentication"}]}
```

- If the user ID is a valid DN (such as `cn=Directory Manager`), the SCIM extension authenticates by binding to the Directory Server as that user. If the user ID is not a valid DN, the SCIM extension searches for an entry with that `uid` value, and binds to the server as that user. To verify authentication to the server as the user with the `uid` of `user.0`, run the following command:

```
$ curl -u "user.0:password" \
-k "https://localhost:8443/scim/ServiceProviderConfigs"
```

Configuring the Identity Access API

Once you have run the `<server-root>/config/scim-config-ds.dsconfig` script, the resources defined in the `scim-resources.xml` will be available as well as the Identity Access API. However, to allow SCIM access to the raw LDAP data, you must set a combination of configuration properties on the SCIM Servlet Extension using the `dsconfig` tool.

- include-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will be exposed. The object class used here will be the one that clients need to use when referencing Identity Access API resources. This property allows the special value `*` to allow all object classes. If `*` is used, then the SCIM servlet uses the same case used in the Directory Server LDAP Schema.
- exclude-ldap-objectclass.** Specifies a multi-valued property that lists the object classes for entries that will not be exposed. When this property is specified, all object classes will be exposed except those in this list.
- include-ldap-base-dn.** Specifies a multi-valued property that lists the base DNs that will be exposed. If specified, only entries under these base DNs will be accessible. No parent-child relationships in the DNs are allowed here.

- **exclude-ldap-base-dn.** Specifies a multi-valued property that lists the base DN's that will not be exposed. If specified, entries under these base DN's will not be accessible. No parent-child relationships in the DN's are allowed here.

Using a combination of these properties, SCIM endpoints will be available for all included object classes, just as if they were SCIM Resources defined in the `scim-resources.xml` file.

To Configure the Identity Access API

Steps

1. Ensure that you have run the `scim-config-ds.dsconfig` script to configure the SCIM interface. Be sure to enable the entryDN virtual attribute. See the [Configure SCIM](#) section for more information.
2. Set a combination of properties to allow the SCIM clients access to the raw LDAP data: `include-ldap-objectclass`, `exclude-ldap-objectclass`, `include-ldap-base-dn`, or `exclude-ldap-base-dn`.

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM --set 'include-ldap-objectclass:*' \
  --set include-ldap-base-dn:ou=People,dc=example,dc=com
```

The SCIM clients now have access to the raw LDAP data via LDAP object class-based resources as well as core SCIM resources as defined in the `scim.resource.xml` file.

To Disable Core SCIM Resources

Steps

1. Open the `config/scim-resources.xml` file, and comment out or remove the `<resource>` elements that you would like to disable.
2. Disable and re-enable the HTTP Connection Handler, or restart the server to make the changes take effect. In general, changing the `scim-resources.xml` file requires a HTTP Connection Handler restart or server restart.

 **Note:** When making other changes to the SCIM configuration by modifying the SCIM HTTP Servlet Extension using `dsconfig`, the changes take effect immediately without any restart required.

To Verify the Identity Access API Configuration

Steps

- Perform a curl request to verify the Identity Access API configuration.

```
$ curl -k -u "cn=directory manager:password" \
  -H "Accept: application/json" \
  "https://example.com/top/56c9fd6b-f870-35ef-9959-691c783b7318?
  attributes=entryDN,uid,givenName,sn,entryUUID"
  {"schemas":
  ["urn:scim:schemas:core:1.0","urn:unboundid:schemas:scim:ldap:1.0"],
   "id":"56c9fd6b-f870-35ef-9959-691c783b7318",
   "meta":{"lastModified":"2013-01-11T23:38:26.489Z",
   "location":"https://example.com:443/v1/top/56c9fd6b-
f870-35ef-9959-691c783b7318"},
   "urn:unboundid:schemas:scim:ldap:1.0":{"givenName":["Rufus"],"uid":
["user.1"],
   "sn":["Firefly"],"entryUUID":["56c9fd6b-f870-35ef-9959-691c783b7318"],
   "entrydn":"uid=user.1,ou=people,dc=example,dc=com"}}
```

Monitoring the SCIM Servlet Extension

The SCIM SDK provides a command-line tool, `scim-query-rate`, that measures the SCIM query performance for your extension. The SCIM extension also exposes monitoring information for each SCIM resource, such as the number of successful operations per request, the number of failed operations per request, the number of operations with XML or JSON to and from the client. Finally, the Directory Server automatically logs SCIM-initiated LDAP operations to the default File-based Access Logger. These operations will have an `origin='scim'` attribute to distinguish them from operations initiated by LDAP clients. You can also create custom logger or request criteria objects that can track incoming HTTP requests, which the SCIM extension rewrites as internal LDAP operations.

Testing SCIM Query Performance

You can use the `scim-query-rate` tool, provided in the SCIM SDK, to test query performance, by performing repeated resource queries against the SCIM server.

The `scim-query-rate` tool performs searches using a query filter or can request resources by ID. For example, you can test performance by using a filter to query randomly across a set of one million users with eight concurrent threads. The user resources returned to the client in this example is in XML format and includes the `userName` and `name` attributes.

```
scim-query-rate --hostname server.example.com --port 80 \
--authID admin --authPassword password --xml \
--filter 'userName eq "user.[1-1000000]"' --attribute userName \
--attribute name --numThreads 8
```

You can request resources by specifying a resource ID pattern using the `--resourceID` argument as follows:

```
scim-query-rate --hostname server.example.com --port 443 \
--authID admin --authPassword password --useSSL --trustAll \
--resourceName User \
--resourceID 'uid=user.[1-150000],ou=people,dc=example,dc=com'
```

The `scim-query-rate` tool reports the error `"java.net.SocketException: Too many open files"` if the open file limit is too low. You can increase the open file limit to increase the number of file descriptors.

Monitoring Resources Using the SCIM Extension

The monitor provider exposes the following information for each resource:

- Number of successful operations per request type (such as GET, PUT, and POST).
- Number of failed operations and their error codes per request type.
- Number of operations with XML or JSON from client.
- Number of operations that sent XML or JSON to client.

In addition to the information about the user-defined resources, monitoring information is also generated for the schema, service provider configuration, and monitor resources. The attributes of the monitor entry are formatted as follows:

```
{resource name}-resource-{request type}-{successful or error status code}
```

You can search for one of these monitor providers using an `ldapsearch` such as the following:

```
$ bin/ldapsearch --port 1389 bindDN uid=admin,dc=example,dc=com \
--bindPassword password --baseDN cn=monitor \
--searchScope sub "(objectclass=scim-servlet-monitor-entry)"
```

For example, the following monitor output was produced by a test environment with three distinct SCIM servlet instances, Aleph, Beth, and Gimel. Note that the first instance has a custom resource type called `host`.

```

$ bin/ldapsearch --baseDN cn=monitor \
  '(objectClass=scim-servlet-monitor-entry)'
dn: cn=SCIM Servlet (SCIM HTTP Connection Handler),cn=monitor

About the HTTP Log Publishers

HTTP operations may be logged using either a Common Log File HTTP Operation Log Publisher or a Detailed HTTP Operation Log Publisher. The Common Log File HTTP Operation Log Publisher is a built-in log publisher that records HTTP operation information to a file using the W3C common log format. Because the W3C common log format is used, logs produced by this log publisher can be parsed by many existing web analysis tools.

Log messages are formatted as follows:

- IP address of the client.
- RFC 1413 identification protocol. The Ident Protocol is used to format information about the client.
- The user ID provided by the client in an Authorization header, which is typically available server-side in the REMOTE_USER environment variable. A dash appears in this field if this information is not available.
- A timestamp, formatted as "[dd/MM/yyyy:HH:mm:ss Z]"
- Request information, with the HTTP method followed by the request path and HTTP protocol version.
- The HTTP status code value.
- The content size of the response body in bytes. This number does not include the size of the response headers.

The HTTP Detailed Access Log Publisher provides more information than the common log format in a format that is familiar to administrators who use the File-Based Access Log Publisher.

The HTTP Detailed Access Log Publisher generates log messages such as the following. The lines have been wrapped for readability.

```
[15/Feb/2012:21:17:04 -0600] RESULT requestID=10834128
from="10.2.1.114:57555" method="PUT"
url="https://10.2.1.129:443/Aleph/Users/6272c691-
38c6-012f-d227-0dfae261c79e" authorizationType="Basic"
requestContentType="application/json" statusCode=200
etime=3.544 responseContentLength=1063
redirectURI="https://server1.example.com:443/Aleph/Users/6272c691-38c6-012f-
d227-0dfae261c79e"
responseContentType="application/json"
```

In this example, only default log publisher properties are used. Though this message is for a RESULT, it contains information about the request, such as the client address, the request method, the request URL, the authentication method used, and the Content-Type requested. For the response, it includes the response length, the redirect URI, the Content-Type, and the HTTP status code.

You can modify the information logged, including adding request parameters, cookies, and specific request and response headers. For more information, refer to the `dsconfig` command-line tool help.

Configuring Advanced SCIM 1.1 Extension Features

The following sections show how to configure advanced SCIM 1.1 servlet extension features, such as bulk operation implementation, mapping SCIM resource IDs, and transformations.

Managing the SCIM 1.1 Schema

This section describes the SCIM schema and provides information on how to map LDAP schema to the SCIM resource schema.

About SCIM Schema

SCIM provides a common user schema and extension model, making it easier to interoperate with multiple Service Providers. The core SCIM schema defines a concrete schema for user and group resources that encompasses common attributes found in many existing schemas.

Each attribute is defined as either a single attribute, allowing only one instance per resource, or a multi-valued attribute, in which case several instances may be present for each resource. Attributes may be defined as simple, name-value pairs or as complex structures that define sub-attributes.

While the SCIM schema follows an object extension model similar to object classes in LDAP, it does not have an inheritance model. Instead, all extensions are additive, similar to LDAP Auxiliary Object Classes.

Mapping LDAP Schema to SCIM Resource Schema

The resources configuration file is an XML file that is used to define the SCIM resource schema and its mapping to LDAP schema. The default configuration of the `scim-resources.xml` file provides definitions for the standard SCIM Users and Groups resources, and mappings to the standard LDAP `inetOrgPerson` and `groupOfUniqueNames` object classes.

The default configuration may be customized by adding extension attributes to the Users and Groups resources, or by adding new extension resources. The resources file is composed of a single `<resources>` element, containing one or more `<resource>` elements.

For any given SCIM resource endpoint, only one `<LDAPAdd>` template can be defined, and only one `<LDAPSearch>` element can be referenced. If entries of the same object class can be located under different subtrees or base DN's of the Directory Server, then a distinct SCIM resource must be defined for each unique entry location in the Directory Information Tree. This can be implemented in many ways. For example:

- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, and each running under a unique HTTP connection handler.
- Create multiple SCIM servlets, each with a unique `scim-resources.xml` configuration, each running under a single, shared HTTP connection handler, but each with a unique context path.

Note that LDAP attributes are allowed to contain characters that are invalid in XML (because not all valid UTF-8 characters are valid XML characters). The easiest and most-correct way to handle this is to make sure that any attributes that may contain binary data are declared using `dataType=binary` in the `scim-resources.xml` file. Likewise, when using the Identity Access API make sure that the underlying LDAP schema uses the Binary or Octet String attribute syntax for attributes which may contain binary data. This will cause the server to automatically base64-encode the data before returning it to clients and will also make it predictable for clients because they can assume the data will always be base64-encoded.

However, it is still possible that attributes that are not declared as binary in the schema may contain binary data (or just data that is invalid in XML), and the server will always check for this before returning them to the client. If the client has set the content-type to XML, then the server may choose to base64-encode any values which are found to include invalid XML characters. When this is done, a special attribute is added to the XML element to alert the client that the value is base64-encoded. For example:

```
<scim:value base64Encoded="true">AAABPB0EBZc=</scim:value>
```

The remainder of this section describes the mapping elements available in the `scim-resources.xml` file.

About the <resource> Element

A `resource` element has the following XML attributes:

- `schema`: a required attribute specifying the SCIM schema URN for the resource. Standard SCIM resources already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom resources using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the resource used to access it through the SCIM REST API.
- `mapping`: a custom Java class that provides the logic for the resource mapper. This class must extend the `com.unboundid.scim.ldap.ResourceMapper` class.

A resource element contains the following XML elements in sequence:

- `description`: a required element describing the resource.
- `endpoint`: a required element specifying the endpoint to access the resource using the SCIM REST API.
- `LDAPSearchRef`: a mandatory element that points to an `LDAPSearch` element. The `LDAPSearch` element allows a SCIM query for the resource to be handled by an LDAP service and also specifies how the SCIM resource ID is mapped to the LDAP server.
- `LDAPAdd`: an optional element specifying information to allow a new SCIM resource to be added through an LDAP service. If the element is not provided then new resources cannot be created through the SCIM service.
- `attribute`: one or more elements specifying the SCIM attributes for the resource.

About the <attribute> Element

An `attribute` element has the following XML attributes:

- `schema`: a required attribute specifying the schema URN for the SCIM attribute. If omitted, the schema URN is assumed to be the same as that of the enclosing resource, so this only needs to be provided for SCIM extension attributes. Standard SCIM attributes already have URNs assigned for them, such as `urn:scim:schemas:core:1.0`. A new URN must be obtained for custom SCIM attributes using any of the standard URN assignment methods.
- `name`: a required attribute specifying the name of the SCIM attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is `false`.
- `required`: an optional attribute indicating whether the SCIM attribute is required to be present in the resource. The default value is `false`.

An attribute element contains the following XML elements in sequence:

- `description`: a required element describing the attribute. Then just one of the following elements:
 - `simple`: specifies a simple, singular SCIM attribute.
 - `complex`: specifies a complex, singular SCIM attribute.
 - `simpleMultiValued`: specifies a simple, multi-valued SCIM attribute.
 - `complexMultiValued`: specifies a complex, multi-valued SCIM attribute.

About the `<simple>` Element

A `simple` element has the following XML attributes:

- `dataType`: a required attribute specifying the simple data type for the SCIM attribute. The following values are permitted: `binary`, `boolean`, `dateTime`, `decimal`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simple` element contains the following XML element:

- `mapping`: an optional element specifying a mapping between the SCIM attribute and an LDAP attribute. If this element is omitted, then the SCIM attribute has no mapping and the SCIM service ignores any values provided for the SCIM attribute.

About the `<complex>` Element

The `complex` element does not have any XML attributes. It contains the following XML element:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute, and an optional mapping to LDAP. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

About the `<simpleMultiValued>` Element

A `simpleMultiValued` element has the following XML attributes:

- `childName`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard emails SCIM attribute is `email`.
- `dataType`: a required attribute specifying the simple data type for the plural SCIM attribute (i.e. the data type for the value sub-attribute). The following values are permitted: `binary`, `boolean`, `dateTime`, `integer`, `string`.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is `false`.

A `simpleMultiValued` element contains the following XML elements in sequence:

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.
- `mapping`: an optional element specifying a default mapping between the SCIM attribute and an LDAP attribute.

About the `<complexMultiValued>` Element

A `complexMultiValued` element has the following XML attribute:

- `tag`: a required attribute specifying the name of the tag that is used to encode values of the SCIM attribute in XML in the REST API protocol. For example, the tag for the standard addresses SCIM attribute is `address`.

A `complexMultiValued` element contains the following XML elements in sequence:

- `subAttribute`: one or more elements specifying the sub-attributes of the complex SCIM attribute. The standard `type`, `primary`, and `display` sub-attributes do not need to be specified.

- `canonicalValue`: specifies the values of the type sub-attribute that is used to label each individual value, and an optional mapping to LDAP.

About the <subAttribute> Element

A `subAttribute` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute.
- `readOnly`: an optional attribute indicating whether the SCIM sub-attribute is not allowed to be updated by the SCIM service consumer. The default value is false.
- `required`: an optional attribute indicating whether the SCIM sub-attribute is required to be present in the SCIM attribute. The default value is false.
- `dataType`: a required attribute specifying the simple data type for the SCIM sub-attribute. The following values are permitted: binary, boolean, dateTime, integer, string.
- `caseExact`: an optional attribute that is only applicable for string data types. It indicates whether comparisons between two string values use a case-exact match or a case-ignore match. The default value is false.

A `subAttribute` element contains the following XML elements in sequence:

- `description`: a required element describing the sub-attribute.
- `mapping`: an optional element specifying a mapping between the SCIM sub-attribute and an LDAP attribute. This element is not applicable within the `complexMultiValued` element.

About the <canonicalValue> Element

A `canonicalValue` element has the following XML attribute:

- `name`: specifies the value of the type sub-attribute. For example, work is the value for emails, phone numbers and addresses intended for business purposes.

A `canonicalValue` element contains the following XML element:

- `subMapping`: an optional element specifying mappings for one or more of the sub-attributes. Any sub-attributes that have no mappings will be ignored by the mapping service.

About the <mapping> Element

A `mapping` element has the following XML attributes:

- `ldapAttribute`: A required element specifying the name of the LDAP attribute to which the SCIM attribute or sub-attribute map.
- `transform`: An optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described in the [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#) section.

About the <subMapping> Element

A `subMapping` element has the following XML attributes:

- `name`: a required element specifying the name of the sub-attribute that is mapped.
- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM sub-attribute maps.
- `transform`: an optional element specifying a transformation to apply when mapping an attribute value from SCIM to LDAP and vice-versa. The available transformations are described later. The available transformations are described in [Mapping LDAP Entries to SCIM Using the SCIM-LDAP API](#).

About the <LDAPSearch> Element

An `LDAPSearch` element contains the following XML elements in sequence:

- `baseDN`: a required element specifying one or more LDAP search base DN's to be used when querying for the SCIM resource.

- `filter`: a required element specifying an LDAP filter that matches entries representing the SCIM resource. This filter is typically an equality filter on the LDAP object class.
- `resourceIDMapping`: an optional element specifying a mapping from the SCIM resource ID to an LDAP attribute. When the element is omitted, the resource ID maps to the LDAP entry DN. Note The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

Note: The `LDAPSearch` element can be added as a top-level element outside of any `<Resource>` elements, and then referenced within them via an ID attribute.

About the `<resourceIDMapping>` Element

The `resourceIDMapping` element has the following XML attributes:

- `ldapAttribute`: a required element specifying the name of the LDAP attribute to which the SCIM resource ID maps.
- `createdBy`: a required element specifying the source of the resource ID value when a new resource is created by the SCIM consumer using a POST operation. Allowable values for this element include `scim-consumer`, meaning that a value must be present in the initial resource content provided by the SCIM consumer, or `directory`, meaning that a value is automatically provided by the Directory Server (as would be the case if the mapped LDAP attribute is `entryUUID`).

The following example illustrates an `LDAPSearch` element that contains a `resourceIDMapping` element:

```
<LDAPSearch id="userSearchParams">
  <baseDN>ou=people,dc=example,dc=com</baseDN>
  <filter>(objectClass=inetOrgPerson)</filter>
  <resourceIDMapping ldapAttribute="entryUUID" createdBy="directory"/>
</LDAPSearch>
```

About the `<LDAPAdd>` Element

An `LDAPAdd` element contains the following XML elements in sequence:

- `DNTemplate`: a required element specifying a template that is used to construct the DN of an entry representing a SCIM resource when it is created. The template may reference values of the entry after it has been mapped using `{ldapAttr}`, where `ldapAttr` is the name of an LDAP attribute.
- `fixedAttribute`: zero or more elements specifying fixed LDAP values to be inserted into the entry after it has been mapped from the SCIM resource.

About the `<fixedAttribute>` Element

A `fixedAttribute` element has the following XML attributes:

- `ldapAttribute`: a required attribute specifying the name of the LDAP attribute for the fixed values.
- `onConflict`: an optional attribute specifying the behavior when the LDAP entry already contains the specified LDAP attribute. The value `merge` indicates that the fixed values should be merged with the existing values. The value `overwrite` indicates that the existing values are to be overwritten by the fixed values. The value `preserve` indicates that no changes should be made. The default value is `merge`.

A `fixedAttribute` element contains one or more `fixedValue` XML element, which specify the fixed LDAP values.

Validating Updated SCIM Schema

The PingDirectory Server SCIM extension is bundled with an XML Schema document, `resources.xsd`, which describes the structure of a `scim-resources.xml` resource configuration file. After updating the resource configuration file, you should confirm that its contents are well-formed and valid using a tool such as `xmllint`.

For example, you could validate your updated file as follows:

```
$ xmllint --noout --schema resources.xsd scim-resources.xml
scim-resources.xml validates
```

Mapping SCIM Resource IDs

The default `scim-resources.xml` configuration maps the SCIM resource ID to the LDAP `entryUUID` attribute. The `entryUUID` attribute, whose read-only value is assigned by the Directory Server, meets the requirements of the SCIM specification regarding resource ID immutability. However, configuring a mapping to the attribute may result in inefficient group processing, since LDAP groups use the entry DN as the basis of group membership. The resource configuration allows the SCIM resource ID to be mapped to the LDAP entry DN. However, the entry DN does not meet the requirements of the SCIM specification regarding resource ID immutability. LDAP permits entries to be renamed or moved, thus modifying the DN. Likewise, you can use the Identity Access API to change the value of an entry's RDN attribute, thereby triggering a MODDN operation.

A resource may also be configured such that its SCIM resource ID is provided by an arbitrary attribute in the request body during POST operations. This SCIM attribute must be mapped to an LDAP attribute so that the SCIM resource ID may be stored in the Directory Server. By default, it is the responsibility of the SCIM client to guarantee ID uniqueness. However, the UID Unique Attribute Plugin may be used by the Directory Server to enforce attribute value uniqueness. For information about the UID Unique Attribute Plugin, see "Working with the UID Unique Attribute plugin" in the *PingDirectory Server Administration Guide*.

Note: Resource IDs may not be mapped to virtual attributes. For more information about configuring SCIM Resource IDs, see "About the `<resourceIDMapping>` Element".

Using Pre-defined Transformations

Transformations are required to change SCIM data types to LDAP syntax values. The following pre-defined transformations may be referenced by the transform XML attribute:

- `com.unboundid.scim.ldap.BooleanTransformation`. Transforms SCIM boolean data type values to LDAP Boolean syntax values and vice-versa.
- `com.unboundid.scim.ldap.GeneralizedTimeTransformation`. Transforms SCIM `dateTime` data type values to LDAP Generalized Time syntax values and vice-versa.
- `com.unboundid.scim.ldap.PostalAddressTransformation`. Transforms SCIM formatted address values to LDAP Postal Address syntax values and vice-versa. SCIM formatted physical mailing addresses are represented as strings with embedded new lines, whereas LDAP uses the `$` character to separate address lines. This transformation interprets new lines in SCIM values as address line separators.
- `com.unboundid.scim.ldap.TelephoneNumberTransformation`. Transforms LDAP Telephone Number syntax (E.123) to RFC3966 format and vice-versa.

You can also write your own transformations using the SCIM API described in the following section.

Mapping LDAP Entries to SCIM Using the SCIM-LDAP API

In addition to the SCIM SDK, PingDirectory Server provides a library called SCIM-LDAP, which provides facilities for writing custom transformations and more advanced mapping.

You can add the SCIM-LDAP library to your project using the following dependency:

```
<dependency>
  <groupId>com.unboundid.product.scim</groupId>
  <artifactId>scim-ldap</artifactId>
  <version>1.5.0</version>
</dependency>
```

Create your custom transformation by extending the `com.unboundid.scim.ldap.Transformation` class. Place your custom transformation class in a jar file in the server's `lib` directory.

Note: The Identity Access API automatically maps LDAP attribute syntaxes to the appropriate SCIM attribute types. For example, an LDAP DirectoryString is automatically mapped to a SCIM string.

SCIM Authentication

SCIM requests to the LDAP endpoints will support HTTP Basic Authentication and OAuth2 Authentication using a bearer token. There is existing support for this feature in the Directory Server and the Directory Proxy Server using the OAuthTokenHandler API (i.e., via a Server SDK extension, which requires some technical work to implement).

Note that our implementation only supports the HTTP Authorization header for this purpose; we do not support the form-encoded body parameter or URI query parameter mechanisms for specifying the credentials or bearer token.

SCIM Logging

The Directory Server already provides a detailed HTTP log publisher to capture the SCIM and HTTP request details. To be able to correlate this data to the internal LDAP operations that are invoked behind the scenes, the Access Log Publisher will use `origin=scim` in access log messages that are generated by the SCIM servlet.

For example, you will see a message for operations invoked by replication:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="replication" dn="uid=user.3,ou=people,dc=example,dc=com"
```

Likewise for SCIM messages, you will see a message like this:

```
[30/Oct/2012:18:45:10.490 -0500] MODIFY REQUEST conn=-3 op=190 msgID=191
origin="scim" dn="uid=user.3,ou=people,dc=example,dc=com"
```

SCIM Monitoring

There are two facilities that can be used to monitor the SCIM activity in the server.

- **HTTPConnectionHandlerStatisticsMonitorProvider** -- Provides statistics straight about total and average active connections, requests per connection, connection duration, processing time, invocation count, etc.
- **SCMServletMonitorProvider** -- Provides high level statistics about request methods (POST, PUT, GET, etc.), content types (JSON, XML), and response codes, for example, `user-patch-404:26`.

The LDAP object class endpoints are treated as their own resource types, so that for requests using the Identity Access API, there will be statistics, such as `person-get-200` and `inetorgperson-post-401`.

Managing the SCIM 2.0 Servlet Extension

The PingDirectory Server provides a servlet extension that implements version 2.0 of the System for Cross-domain Identity Management (SCIM) specification. The SCIM 2.0 extension does not replace the existing SCIM 1.1 extension, and there are significant differences in how they are configured..

Supported SCIM 2.0 Endpoints

PingDirectory Server supports the following SCIM 2.0 endpoints:

Endpoint	Description	Supported HTTP methods
/ServiceProviderConfig	<p>Provides metadata that indicates the PingDirectory Server's authentication scheme (which is always OAuth 2.0) and its support for features that are optional in the SCIM standard.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas	<p>Lists the SCIM schemas that are configured for use on PingDirectory Server, and defines the various attributes available to resource types.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/Schemas/<schema>	<p>Retrieves a specific SCIM schema, as specified by the schema ID.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/ResourceTypes	<p>Lists all of the SCIM resource types that are configured for use on PingDirectory Server. Clients can use this information to determine the endpoint, core schema, and extension schemas of any resource types that the server supports.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/ResourceTypes/<resourceType>	<p>Retrieves a specific SCIM resource type, as specified by its ID.</p> <p>This endpoint is a metadata endpoint and is not subject to ACI restrictions.</p>	GET
/<resourceType>	<p>Creates a new resource (POST), or lists and filters resources (GET).</p>	GET, POST

Endpoint	Description	Supported HTTP methods
/<resourceType>/search	Lists and filters resources. This is used if passing query parameters in the URL is undesirable.	POST
/<resourceType>/<resourceId>	Retrieves a single resource (GET), modifies a single resource (PUT, PATCH), or deletes a single resource (DELETE).	GET, PUT, PATCH, DELETE

Configuring SCIM 2.0 on Your Server

Creating Your Own SCIM 2 Application

The System for Cross-domain Identity Management (SCIM) is an open initiative designed to make moving identity data to, from, and between clouds standard, secure, fast, and easy. The SCIM SDK is a pre-packaged collection of libraries and extensible classes that provides developers with a simple, concrete API to interact with a SCIM service provider.

The SCIM 2 SDK is available for download at <https://github.com/pingidentity/scim>.

Authentication Requirements for SCIM 2.0 Requests

All SCIM requests on a PingDirectory Server must use OAuth 2.0 bearer token authentication. Bearer tokens are evaluated using the SCIM 2 servlet extension's configured Access Token Validators. Basic authentication is not supported.

In addition to requiring bearer tokens, the server will not process any SCIM requests unless it has at least one encryption-settings definition in its encryption-settings database. You can create the necessary definition(s) with the encryption-settings command-line tool.

Note:

Note: Encryption settings need to be defined on the Proxy and all backend PD servers, and the encryption settings should match.

Defining Permissions for SCIM 2.0 Requests

Whether or not a SCIM request is executed on a server depends primarily on both the configured Access Control Instructions (ACIs) in the server and the scopes which are present in the provided OAuth bearer token used to authenticate the request.

Note: ACIs need to be defined on the backend PD servers instead of on the Proxy server.

Internally, all SCIM 2.0 requests are processed using the `cn=SCIM2 Servlet,cn=Root DNs,cn=config` service account. Whether a requested operation is allowed depends on the ACIs that apply to the operation. The `oauthscope bind` rule is particularly useful for this, since it allows the administrator to use the supplied OAuth scopes in ACI logic.

Due to implementation details, access to the `objectclass operational` LDAP attribute is necessary for SCIM requests to properly execute. However, it is not advisable to give the service account access to `objectclass` on a global level. Instead, add the ACI granting `objectclass` access to the LDAP subtree you wish to expose to clients. See [Configuring Permissions for SCIM 2.0 Operations](#) on page 927 for an example of this.

Note: ACIs that do not use the `oauthscope bind` rule can still apply to requested operations. For example, an ACI that grants unconditional read access to any authenticated LDAP user will also grant

unconditional read access to SCIM requests regardless of the provided OAuth scopes, since the requests are processed through the service account.

SCIM 2.0 Components

Unlike the SCIM 1.1 servlet extension, the SCIM 2.0 system is configured through the Administrative Console or with the `dsconfig` command-line tool. The SCIM 2.0 system consists of the following components:

- SCIM resource types
- SCIM schemas
 - SCIM attributes
 - SCIM sub-attributes
- SCIM attribute mappings (mapping resource types only)

A SCIM resource type defines a class of resources, such as users or devices. Every SCIM resource type features at least one SCIM schema, which defines the attributes that are available to each resource. If enabled for use, a SCIM resource type must also have a designated LDAP structural objectclass as well as an associated base DN.

The two types of SCIM resource types, mapping and passthrough, differ based on the definitions of the SCIM schema the resource types use.

- An LDAP mapping SCIM resource type requires an explicitly defined SCIM schema with explicitly defined mappings of SCIM attributes to LDAP attributes. Use a mapping SCIM resource type to exercise detailed control over the SCIM schema and its attributes and mappings.
- An LDAP passthrough SCIM resource type, by contrast, does not use an explicitly defined SCIM schema. Instead, an implicit schema is generated dynamically, based on the underlying LDAP schema. Use a passthrough SCIM resource type when you need to get started quickly.

A SCIM schema defines a collection of SCIM attributes, grouped under an identifier called a schema URN. Each SCIM resource type possesses a single core schema and can feature schema extensions, which act as secondary attribute groupings that the schema URN namespaces. SCIM Schemas are defined independently of SCIM resource types, and multiple SCIM resource types can use a single SCIM schema as a core schema or schema extension.

A SCIM attribute defines an attribute that is available under a SCIM schema. The configuration for a SCIM attribute defines its data type, regardless of whether it is required, single-valued, or multi-valued. When a SCIM attribute consists of SCIM sub-attributes, it is defined as a complex attribute.

A SCIM attribute mapping defines the manner in which a SCIM resource type maps the attributes in its SCIM schemas to native LDAP attributes of the PingDirectory Server.

Configuring an LDAP Mapping SCIM 2.0 resource type

About this task

This example shows how to add a simple mapping SCIM 2.0 resource type to a PingDirectory Server, backed by the device LDAP objectclass. This example assumes that you have already created an encryption-settings definition for the current server using the encryption-settings command-line tool.

Steps

1. Configure the SCIM2 HTTP Servlet Extension to use a Mock Access Token Validator. Remember that Mock Access Token Validators should never be used in production environments or with sensitive data.

```
dsconfig create-access-token-validator \
  --validator-name "SCIM2 Mock Validator" \
  --type mock \
  --set enabled:true
dsconfig set-http-servlet-extension-prop \
```

```
--extension-name SCIM2 \
--set "access-token-validator:SCIM2 Mock Validator"
```

2. Add the LDAP entries that will be mapped to the SCIM resource type to the PingDirectory Server. Create a file named `devices.ldif` with the following contents.

```
dn: ou=Devices,dc=example,dc=com
objectClass: top
objectClass: organizationalUnit
ou: Devices

dn: cn=device.0,ou=Devices,dc=example,dc=com
objectClass: top
objectClass: device
cn: device.0
description: Description for device.0

dn: cn=device.1,ou=Devices,dc=example,dc=com
objectClass: top
objectClass: device
cn: device.1
description: Description for device.1
```

3. Use the `ldapmodify` tool to load the `devices.ldif` file.

```
ldapmodify --defaultAdd --filename devices.ldif
```

4. Before creating the SCIM resource type, create the SCIM schema that the resource type will use.

```
dsconfig create-scim-schema \
--schema-name urn:pingidentity:schemas:Device:1.0 \
--set display-name:Device
```

5. Under this schema, add the string attribute's name and description.

```
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:Device:1.0 \
--attribute-name name \
--set required:true
dsconfig create-scim-attribute \
--schema-name urn:pingidentity:schemas:Device:1.0 \
--attribute-name description
```

6. Create the LDAP mapping SCIM resource type on the PingDirectory Server.

```
dsconfig create-scim-resource-type \
--type-name Devices \
--type ldap-mapping \
--set enabled:true \
--set endpoint:Devices \
--set structural-ldap-objectclass:device \
--set include-base-dn: ou=Devices,dc=example,dc=com \
--set lookthrough-limit:500 \
--set core-schema:urn:pingidentity:schemas:Device:1.0
```

7. Map the two SCIM attributes to the corresponding LDAP attributes. The following commands map the SCIM name attribute to the LDAP `cn` attribute, and map the SCIM description attribute to the LDAP description attribute.

```
dsconfig create-scim-attribute-mapping \
--type-name Devices \
--mapping-name name \
--set scim-resource-type-attribute:name \
```

```

--set ldap-attribute:cn \
--set searchable:true
dsconfig create-scim-attribute-mapping \
--type-name Devices \
--mapping-name description \
--set scim-resource-type-attribute:description \
--set ldap-attribute:description

```

8. Send the following request to the SCIM /ResourceTypes endpoint to confirm that the new resource type has been added..

```

curl -k -X GET \
https://localhost:8443/scim/v2/ResourceTypes \
-H 'Authorization: Bearer {"active":true}' \

```

9. The following JSON object should appear in the response in the “Resources” array:

```

...
"Resources": [{
  "schemas":["urn:ietf:params:scim:schemas:core:2.0:ResourceType"],
  "id":"Devices",
  "name":"Devices",
  "endpoint":"Devices",
  "schema":"urn:pingidentity:schemas:Device:1.0",
  "meta":{
    "resourceType":"ResourceType",
    "location":"https://localhost:8443/scim/v2/ResourceTypes/Devices"
  }
}]
...
}

```

Configuring Permissions for SCIM 2.0 Operations

About this task

This example assumes that you have set up an LDAP mapping SCIM 2.0 Resource Type for the device objectclass (see [Configuring an LDAP Mapping SCIM 2.0 resource type](#) on page 925).

Steps

1. Send the following request to the SCIM /Devices endpoint.

```

curl -k -X GET \
https://localhost:8443/scim/v2/Devices \
-H 'Authorization: Bearer {"active":true}' \

```

The response from the server should contain no search results:

```

{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"],
  "totalResults":0
}

```

}

Note: If any results are returned, it is likely that another ACI is allowing the SCIM request to succeed. Enabling the Debug ACI Log Publisher will help determine which ACI is responsible.

In regard to the empty search response, running `ldapsearch` on the `ou=Devices,dc=example,dc=com` subtree should confirm that entries exist. These do not appear in the response since SCIM requests do not have the permissions needed to view these.

2. Use the following `ldapmodify` command to place an ACI on the `ou=Devices,dc=example,dc=com` subtree. This gives read, search, and compare access to the `objectclass` attribute for all entries under the `ou=Devices,dc=example,dc=com` subtree, as long as the SCIM request includes the device scope.

```
$ ldapmodify
dn:ou=Devices,dc=example,dc=com
changetype:modify
add:aci
aci:(targetattr="objectclass")(version 3.0; acl "ACI for device scope";
  allow (read,search,compare) oauthscope="device");
```

3. Send the following request to the SCIM `/Devices` endpoint, this time including the device scope in the bearer token:

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Devices \
  -H 'Authorization: Bearer {"active":true, "scope":"device"}'
```

The response from the server should now contain the entries under the `ou=Devices,dc=example,dc=com` subtree. However, these are missing values for the name and description attributes since the ACI that was created earlier does not give access to the `cn` and description LDAP attributes to which they are mapped.

4. Use the following `ldapmodify` command to place another ACI on the `ou=Devices,dc=example,dc=com` subtree, which will give read, search, and compare access to both the `cn` and description LDAP attributes:

```
$ ldapmodify
dn:ou=Devices,dc=example,dc=com
changetype:modify
add:aci
aci:(targetattr="cn || description")(version 3.0; acl "ACI
  for device_extended scope"; allow (read,search,compare)
  oauthscope="device_extended");
```

5. Send the following request to the SCIM `/Devices` endpoint, this time including the `device_extended` scope along with the device scope in the bearer token.

```
curl -k -X GET \
  https://localhost:8443/scim/v2/Devices \
  -H 'Authorization: Bearer {"active":true, "scope":["device",
  "device_extended"]}'
```

The response from the server should now contain values for the name and description attributes.

SCIM 2.0 Searches

To prevent exhausting server resources, we recommend capping the total number of resources that are matched by a search. The configuration for each SCIM 2.0 resource type contains a `lookthrough-limit` property that defines this limit (the default `lookthrough-limit` value is 500).

If a search request exceeds the lookthrough limit, the client receives a 400 response with an error message similar to the following:

```
{
  "detail": "The search request matched too many results",
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:Error"],
  "scimType": "tooMany",
  "status": "400"
}
```

To prevent this error, the client should refine its search filter to return fewer matches.

SCIM 2.0 PATCH Operations

When using a `PATCH` request to modify a SCIM 2.0 resource that has one or more required SCIM 2.0 attributes, the requester must also have permissions to read the values of these required attributes, even if the `PATCH` request does not alter them.

For example, assume we want to modify an LDAP Mapping SCIM 2.0 resource type using the following schema definition, where `uid` and `cn` are mapped to their LDAP equivalents:

```
{
  "schemas": ["urn:ietf:params:scim:schemas:core:2.0:Schema"],
  "id": "urn:test:schema:person",
  "attributes": [
    {
      "name": "uid",
      "type": "string",
      "multiValued": false,
      "required": true,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    },
    {
      "name": "cn",
      "type": "string",
      "multiValued": false,
      "required": false,
      "caseExact": false,
      "mutability": "readWrite",
      "returned": "default",
      "uniqueness": "none"
    }
  ],
  ...
}
```

The following `PATCH` operation will fail if the SCIM 2 service account does not have access to both `uid` and `cn`:

```
{
  "schemas": ["urn:ietf:params:scim:api:messages:2.0:PatchOp"],
  "Operations": [{
    "op": "add",
    "path": "cn",
    "value": "new cn value"
  }]
}
```

Troubleshoot the SCIM 2.0 Servlet Extension

For security reasons, error messages specifically regarding LDAP systems are suppressed and do not appear in the HTTP responses from the server. Instead, you will see something similar to the following:

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": "400",
  "detail": "Request failed:
  correlationID='073eb1a8-8c51-48b3-83a0-380e1d4b4ab9'"
}
```

To view these messages, the Debug Trace Logger needs to be enabled. You can do this through the Administrative Console or with the following `dsconfig` command:

```
dsconfig set-log-publisher-prop --publisher-name "Debug Trace Logger" \
  --set enabled:true --add scim-message-type:error
```

The correlationID can then be used to determine which LDAP error messages in the Debug Trace Log correspond to the HTTP response.

Disable the SCIM 2.0 Servlet Extension

If you do not need to expose data through the SCIM 2 servlet, you can disable the SCIM 2.0 servlet extension by removing the SCIM2 HTTP servlet extension from the HTTPS connection handler, or from any other HTTP connection handler, and restart the handler:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --remove http-servlet-extension:SCIM2 \
  --set enabled:false

dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true
```

Managing Server SDK Extensions

The PingDirectory Server provides support for any custom extensions that you create using the Server SDK. This chapter summarizes the various features and extensions that can be developed using the Server SDK.

About the Server SDK

You can create extensions that use the Server SDK to extend the functionality of your Directory Server. Extension bundles are installed from a .zip archive or a file system directory. You can use the `manage-extension` tool to install or update any extension that is packaged using the extension bundle format. It opens and loads the extension bundle, confirms the correct extension to install, stops the server if necessary, copies the bundle to the server install root, and then restarts the server.

Note: The `manage-extension` tool may only be used with Java extensions packaged using the extension bundle format. Groovy extensions do not use the extension bundle format. For more information, see the "Building and Deploying Java-Based Extensions" section of the Server SDK documentation, which describes the extension bundle format and how to build an extension.

Available Types of Extensions

The Server SDK provides support for creating a number of different types of extensions for Ping Identity Server Products, including the PingDirectory Server, PingDirectoryProxy Server, and PingDataSync Server. Some of those extensions include:

Cross-Product Extensions

- Access Loggers
- Alert Handlers
- Error Loggers
- Key Manager Providers
- Monitor Providers
- Trust Manager Providers
- OAuth Token Handlers
- Manage Extension Plugins

PingDirectory Server Extensions

- Certificate Mappers
- Change Subscription Handlers
- Extended Operation Handlers
- Identity Mappers
- Password Generators
- Password Storage Schemes
- Password Validators
- Plugins
- Tasks
- Virtual Attribute Providers

PingDirectoryProxy Server Extensions

- LDAP Health Checks
- Placement Algorithms
- Proxy Transformations

PingDataSync Server Extensions

- JDBC Sync Sources
- JDBC Sync Destinations
- LDAP Sync Source Plugins
- LDAP Sync Destination Plugins
- Sync SourcesSync Destinations
- Sync Pipe Plugins

For more information on the Server SDK, see the documentation available in the SDK build.

DevOps and infrastructure as code

Derived from the words *development* and *operations*, the term *DevOps* refers to the practices that a company follows to ensure the production of high-quality products, while also minimizing the amount of time between the commitment of a system change and the implementation of that change in a production environment.

Most companies practice one of the following service models:

- **Pets** — With the *pets service model*, servers are built and managed manually, and are treated as unique and indispensable. Examples include mainframes, database systems, and load balancers.

- **Cattle** — With the *cattle service model*, arrays of multiple replaceable servers are built with automated tools. During a failure event, an array automatically restarts failed services and replicates data. Examples include web server arrays, search clusters, and multi-master datastores.

Historically, servers have been treated like pets. The failure of one or multiple servers was often viewed as an emergency, and extensive resources were usually required to repair the damage. In the new DevOps paradigm, servers are recognized as dispensable and treated like cattle. When a server fails, the infrastructure replaces it immediately, configuring the replacement server identically to the failed one. Because no human intervention is required to fix them, the servers are considered self-healing.

To help treat your servers more like cattle than pets, PingDirectory Server supports server profiles and features like topology-management tools. For example, the `manage-profile setup` represents a single command that performs all the steps from the pet service model on a `server-profile` directory, a well-defined directory structure with all the necessary server configuration bits. Similarly, the `manage-profile replace-profile` command performs similar steps with a single command invocation after a server is updated to a new version.

The scripts in the `server-profile` directory are declarative of the environment. Consequently, what you define in the `server-profile` directory is what you get on the servers. No one needs to identify a server's current configuration and compute the differences that must be applied to attain the appropriate end state. Prior to server profiles, this problem was difficult to address, especially where no history was available. In such scenarios, an administrator might have needed to obtain the current configuration from the servers, to manually compute the difference between the current and desired configuration, and to apply the configuration changes, hoping all the while that nobody had changed the configuration during the process. Server profiles eliminate this procedural approach to applying configuration changes, and they simplify the steps associated with determining what is deployed in an environment. For more information on server profiles, see [Server profiles](#) on page 933.

While server profiles provide a powerful mechanism for setting up a standalone server, they must work in tandem with topology-management tools to manage a topology of PingDirectory Servers. For example, the `dsreplication` and `remove-defunct-server` tools are used to manage the replication topology. In the past, customers experienced problems with these tools when servers were added and removed concurrently, as is typical in automated environments. This approach frequently generated errors and left the environment in a state from which it was difficult, or even impossible, to recover without manual intervention. Islands of replication could be created but not merged back together into a single topology, or online servers could not be removed from the topology. For more information about how PingDirectory Server addresses these limitations, see [Topology-management tools](#) on page 938.

Another principle that relates closely to DevOps is infrastructure as code (IaC), the concept of managing your operations in the same manner as your application and other code for general release with proper versioning, continuous integration, quality control, and release cycles. Customers who deploy PingDirectory Servers as pets today can take advantage of current DevOps and IaC principles to turn them into cattle.

Limitations when automating PingDirectory Server deployments

PingDirectory Server is a stateful application. User data is associated with it, and servers in a topology must be able to communicate bidirectionally with each other. The deployment of stateful applications is generally more challenging to automate than the deployment of stateless applications. However, by following certain industry-wide best practices, the deployment of stateful applications becomes easier to manage.

For stateful applications, we recommend maintaining a well-known network identifier for a server that does not change over its lifetime. Without this guarantee, the deployment automation workflows for the PingDirectory Server software does not work as expected. On infrastructure platforms like AWS, servers are generally assigned cattle-like internal host names. This strategy is acceptable if a well-defined external name is registered in a service discovery or lookup service, such as DNS.

Another important recommendation for stateful applications is the use of external, redundant persistent storage that is always available, and that functions independently of the server itself. Servers might come

and go, but they are always guaranteed to be attached to the same persistent storage when they are resurrected. Although the PingDirectory Server software does not require this guarantee, we recommend it for simpler, less error-prone deployment automation and for easier disaster recovery. For more information, see [Deployment automation](#) on page 939.

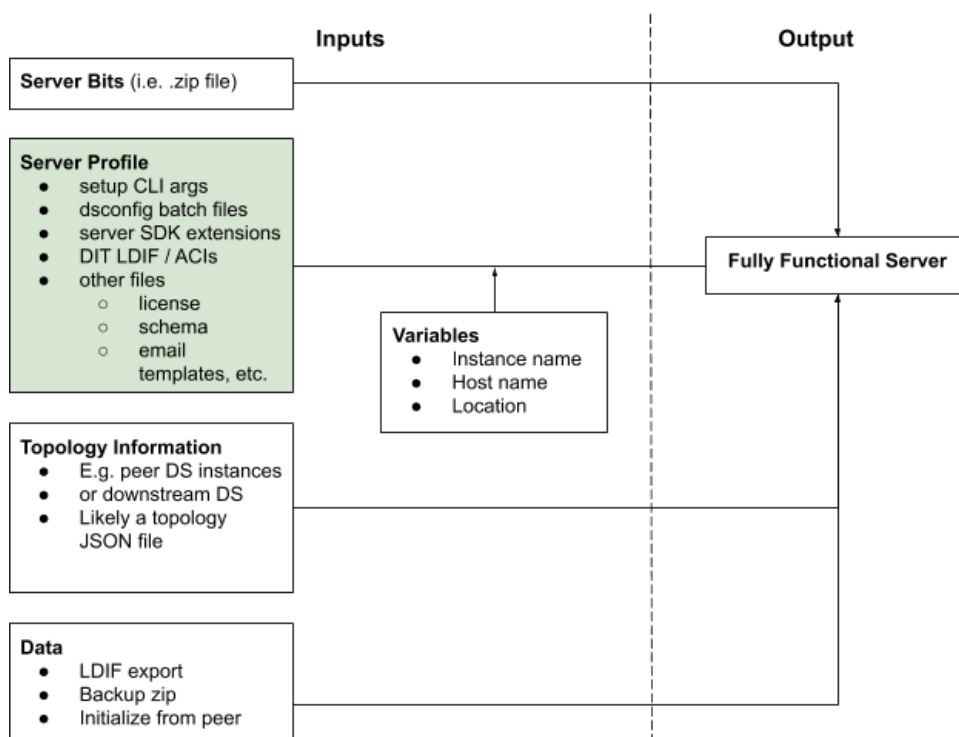

Server profiles

Regardless of the service model that your company follows, *server profiles* help you achieve your goals. At a basic level, a server profile defines a format for the configuration of a server by combining the following files into a single concrete structure:

- **dsconfig**
- Initial DIT
- Setup arguments
- Server SDK extensions
- Additional miscellaneous files

The primary goal of a server profile is to simplify the deployment of PingDirectory Server and related products by using deployment automation frameworks. When products support this capability, the amount of scripting that is required across automation frameworks – like Docker, Kubernetes, and Ansible – is reduced considerably.

The following image shows the role that a server profile plays in building a fully functional running server.

As a declarative form of a full server configuration, a server profile provides the following advantages:

- Provides a more complete and easily comparable way to define an individual server's configuration. Changes between different servers are easier to understand, and incremental changes to a server's configuration are easier to track.
- Ensures that each server instance is configured identically to its peers.
- Can be applied directly to new as well as previously installed instances.
- Shares a common configuration across a deployment pipeline of development, test, and production environments without unnecessary duplication. For information about substituting variables that differ by environment, see [Variable substitution](#) on page 934.

- Facilitates deployment automation by representing configuration as code.
- Reduces the number of additional configuration steps that are required to place a server into production.
- Makes the execution of various configuration changes more consistent and repeatable. The strategy of using a server profile to represent the final state of a server is less error-prone than recording a step-by-step process to attain that state.
- Can be managed easily in a version-control system.
- Simplifies the management of servers outside deployment automation frameworks.

A continuous deployment workflow can work with server profiles to make certain that changes to a server profile are moved automatically into production. In a stateful environment, the **manage-profile replace-profile** subcommand can be used to update existing servers. In a stateless environment, in which servers are considered immutable, **manage-profile setup** can be used to deploy new servers whenever a profile changes. With multiple environments, this deployment can be performed in a test environment before moving to production.

When working with zipped server SDK extensions and other files that might not be stored in a version-control system, the server profile can be modified to include these files prior to its use. For example, if the code for an extension is stored in a separate repository, it can be built and dropped into the server profile immediately before the **manage-profile** tool is run. This process is part of the deployment automation logic that uses the server profile, and it can be followed for any files that are needed by the server profile but whose versions are not controlled.

For more information about the **manage-profile** tool, see [About the manage-profile tool](#) on page 936.

Variable substitution

The **manage-profile** tool uses the format `${VARIABLE}` to support the substitution of variables in profiles. This format can be escaped by using another `$`. For example, after substitution, `$$${VARIABLE}` becomes `${VARIABLE}`.

Variable values can be read from a profile variables file or from environment variable values. If both options are used, the values that are specified in the file overwrite any environment variables.

The following code provides an example profile variables file.

```
MY_VARIABLE=value
MY_OTHER_VARIABLE=anothervalue
```

In this example, the tool provides the `PING_SERVER_ROOT` and `PING_PROFILE_ROOT` variables. The following table describes the built-in variables.

Built-in variable	Description
<code>PING_SERVER_ROOT</code>	Evaluates to the absolute path of the server's root directory.
<code>PING_PROFILE_ROOT</code>	Evaluates to the individual profile's root directory.

For more information about the tool's usage, run the command **bin/manage-profile --help**.

Profile structure

Use either of the following methods to create a server profile:

- Use the template named `server-profile-template.zip`, which is located in the `resource/` directory.
- Run the **manage-profile generate-profile** subcommand. The **manage-profile** tool references a file system directory structure rather than a ZIP file.

Files can be added to each directory as needed.

The following hierarchy represents the file structure of a basic server profile:

```
-server-profile/
  |-- dsconfig/
  |-- ldif/
  |   |-- userRoot/
  |-- misc-files/
  |-- server-root/
  |   |-- post-setup/
  |   |-- pre-setup/
  |-- server-sdk-extensions/
  |-- setup-arguments.txt
```

setup-arguments.txt

When creating a profile, the first step is to add arguments to the file `setup-arguments.txt`. When **manage-profile** setup is run, these arguments are passed to the server's setup tool. To view the arguments that are available in this file, run the server's `setup --help` command.

To provide the equivalent, non-interactive CLI arguments after any prompts have been completed, run **setup** interactively. The `setup-arguments.txt` file in the profile template contains an example set of arguments that can be changed.

`setup-arguments.txt` is the only required file in the profile.

dsconfig/

dsconfig batch files can be added to the `dsconfig` directory. These files, each of which must include a `.dsconfig` extension, contain **dsconfig** commands to apply to server.

Because the **dsconfig** batch files are ordered lexicographically, `00-base.dsconfig` runs before `01-second.dsconfig`, and so on.

To produce a `dsconfig` batch file that reproduces the current configuration, run `bin/config-diff`.

server-root/

Any server root files can be added to the `server-root` directory, including schema files, email template files, custom password dictionaries, and other files that must be present on the final server root. Add these files to the `server-root/pre-setup` or `server-root/post-setup` directory, depending on when they need to be copied to the server root. Most server root files are added to the `server-root/pre-setup` directory.

ldif/

Use LDIF files in the server profile to supply a base DIT, but not to import user data. Add LDIF files under the `ldif` directory. Place each LDIF file in a subdirectory that indicates the backend to which it is imported, such as `ldif/userRoot/` for the `userRoot` backend.

LDIF files require an `.ldif` extension and are ordered lexicographically.

server-sdk-extensions/

Add server SDK extension ZIP files to the `server-sdk-extensions` directory. Use the **manage-extension** tool to install them, and include any configuration that is necessary for the extensions in the profile's `dsconfig` batch files.

variables-ignore.txt

The `variables-ignore.txt` file is an optional component of the server profile. It is useful when adding bash scripts to the server root because such files often contain expressions that the **manage-profile** tool normally interprets as variables.

Add `variables-ignore.txt` to a profile's root directory to indicate the relative paths of any files that are not to have their variables substituted.

The following example shows the contents of a typical `variables-ignore.txt` file:

```
server-root/pre-setup/script-to-ignore.sh
server-root/post-setup/another-file-to-ignore.txt
```

server-root/permissions.properties

The `permissions.properties` file, located in the `server-root` directory, is an optional file that specifies the permissions to apply to files that are copied to the server root. These permissions are represented in octal notation. By default, server root files maintain their permissions when copied.

The following example shows the contents of a typical `permissions.properties` file:

```
default=700
file-with-special-permissions.txt=600
new-subdirectory/file-with-special-permissions.txt=644
bin/example-script.sh=760
```

misc-files/

Additional documentation and other files can be added to the `misc-files` directory, which the **manage-profile** tool does not use. Use the variable `PING_PROFILE_ROOT` to refer to files in this directory from other locations, such as `setup-arguments.txt`.

For example, a password file named `password.txt` in the `misc-files` directory could be referenced with `${PING_PROFILE_ROOT}/misc-files/password.txt` in `setup-arguments.txt`. Use a reference like this example to supply the file for the `--rootUserPasswordFile` argument in `setup-arguments.txt`.

About the manage-profile tool

The **manage-profile** tool is provided with the server to work with server profiles. It includes subcommands for creating, applying, and replacing server profiles, all of which significantly reduce the effort required by an administrator to configure a server appropriately.

The following sections describe these subcommands in more detail. For more information about the **manage-profile** tool, run `manage-profile --help`. For more information about each individual subcommand and its options, run `manage-profile <subcommand> --help`.

manage-profile generate-profile

To create a server profile from a configured server, use the **generate-profile** subcommand. The generated profile contains the following information, which provides a base for completing a profile:

- Command-line arguments that were used to set up the server
- `dsconfig` commands necessary to configure the server
- Installed server SDK extensions
- Files that are added to the server root

To produce a complete profile, some parts of the generated profile might require modifications, such as adding password files that `setup-arguments.txt` uses. The `--instanceName` and `--localHostName` arguments in `setup-arguments.txt` are made variables by **generate-profile**, and must be provided values when other **manage-profile** subcommands use the generated profile.

LDIF files must also be added manually to the generated profile.

manage-profile setup

To apply a server profile to a fresh, unconfigured server, use the `setup` subcommand, which replaces the normal setup tool when using a server profile. Run `manage-profile setup` to complete the following tasks:

- Copies the server root files
- Runs the setup tool
- Runs the `dsconfig` batch files
- Imports the LDIF files
- Installs the server SDK extensions
- Sets the server's cluster name to a unique value

Note: Cluster-wide configuration is automatically mirrored across all servers in the topology with the same cluster name. In a DevOps deployment with immutable servers, configuration mirroring introduces risk. Therefore, in most cases, cluster names should be unique for each server to avoid configuration mirroring.

While `manage-profile setup` is running, a copy of the profile is created in a temporary directory that can be specified by using the `--tempProfileDirectory` argument. The command leaves the server in a complete and running state when finished, unless the `--doNotStart` argument is specified.

manage-profile replace-profile

Run the `replace-profile` subcommand on a server that was originally set up with a server profile to replace its configuration with a new profile. The tool applies a specified server profile to an existing server while preserving its data, topology configuration, and replication configuration. New LDIF files from the replacement server profile are not imported.

While `manage-profile replace-profile` is running, the existing server is stopped and moved to a temporary directory that the `--tempServerDirectory` argument can specify. A fresh, new server is subsequently installed and set up with the new profile. The final server is left running if it was running before the command was started, and remains stopped if it was stopped.

Run `manage-profile replace-profile` from a second unzipped server install package on the same host as the existing server, similar to the `update` tool. Use the `--serverRoot` argument to specify the root of the existing server that will have its profile replaced.

If files have been added or modified in the server root since the most recent `manage-profile setup` or `manage-profile replace-profile` was run, they are included in the final server with the replaced profile. Otherwise, files specifically added from the `server-root` directory of the previous server profile are absent from the final server with the replaced profile. If errors occur during the subcommand, such as the new profile having an invalid `setup-arguments.txt` file, the existing server returns to its original state from before `manage-profile replace-profile` was run.

Note: The `manage-profile replace-profile` tool can update the server version when needed.

Note: The `manage-profile replace-profile` tool can directly apply configuration changes when there are no other changes in the new profile. This is a shorter process when making small changes to `dsconfig`.

Server profiles in a Pets service model

Server profiles and other DevOps concepts are also invaluable in a pets service model. For example, the step of using the `manage-profile generate-profile` subcommand to generate a server profile from a production server creates an easily consumable representation of the server's configuration. In nearly every scenario, the generation of a profile from an existing server is simpler than the piecing together manually of schemas, extensions, and other configuration information to create an image of that server.

Additionally, generated profiles can be backed up or checked in to source control to maintain a consistent picture of an active server's configuration.

Another valuable use of server profiles involves setting up servers in a test environment that is separate from production. For example, a profile that matches the profile of a production server can be generated and used to install a fresh test server that matches the production server. Further, variable substitution allows environmental changes, such as local host name or instance name, without requiring a separate profile. Because the server's original configuration matches the running production server, adjustments can be tested easily. This approach provides more consistency when you validate changes before moving them to production.

If a new test server has been set up with a server profile, `manage-profile replace-profile` can be used to apply changes to the profile. Rather than using scripts or a manual process to apply individual changes, `replace-profile` provides a consistent, repeatable method of moving to a new server profile. This strategy automates more easily and is less prone to human error.

For more information about the `manage-profile` tool, see [About the manage-profile tool](#) on page 936.

Topology-management tools

Because PingDirectory Server topology-management tools like `dsreplication` and `remove-defunct-server` feature internal retries, external deployment automation scripts are not required to incorporate retries. This approach mitigates transient failures and makes servers more robust in automated environments.

To support this approach, `dsreplication` and `remove-defunct-server` include a `--retryTimeoutSeconds` option, which specifies a timeout value for the entire command. If the command fails, it is retried until the timeout value is reached. The command is not aborted if the timeout expires mid-execution, so it is guaranteed to be executed at least once. The default value of zero indicates the command does not have a timeout and is not retried upon initial failure.

The `remove-defunct-server` tool can also be used to complete the following tasks:

- Remove an online server.

Because a server runs as a container's main process, and because shutting down a server re-spins the container, this task was impossible to complete in deployment automation environments that use containers. Automation scripts often resorted to hacks like impersonating an offline server by taking down the LDAP connection handler. In environments where security concerns prevented the use of LDAP, removing an online server was never an option.

- Remove servers without forcing a topology master when you do not have a quorum majority of online servers.

The topology registry uses a master-slave architecture in which all write requests are chained through a single write-master. When a master could not be nominated, the topology becomes read-only. To work around this issue, a single server had to be forced as a master to apply changes.

- Remove servers concurrently.

The `--ignoreOnline` option can be used to remove an online server, and the `--retryTimeoutSeconds` option can be used to increase robustness in concurrent environments.

Finally, `dsreplication enable` provides internal support for a seed server before the replication topology exists. To prevent the creation of separate islands of replicating servers when simultaneously enabling replication on multiple hosts with a topology JSON file, the server that appears first in lexicographical order in the topology JSON file is designated as the seed server. When enabling replication on the seed server itself with the topology JSON file, it stops and returns a `ERROR_SEED_AND_TARGET_SERVER_ARE_THE_SAME` code. This precaution avoids deadlocking a `dsreplication` process when replication is invoked concurrently. On the seed server itself, deployment automation scripts can treat this code as being successful.

Deployment automation

Automated workflows help shift the deployment process from a pets service model to a cattle service model. The primary tools that are required to manage the replication topology are **dsreplication** and **remove-defunct-server**.

Another key to every topology-management workflow is the `topology.json` file, which represents the intended state of the topology at any time. An administrator should create this file manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the **manage-topology export** subcommand.

The following code shows an example `topology.json` file:

```
{
  "serverInstances" : [
    {
      "instanceName" : "ds-0",
      "hostname" : "ds-0.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-1",
      "hostname" : "ds-1.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-2",
      "hostname" : "ds-2.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    {
      "instanceName" : "ds-3",
      "hostname" : "ds-3.ds-topology.production.svc.cluster.local",
      "location" : "Austin",
      "ldapPort" : 389,
      "ldapsPort" : 636,
      "replicationPort" : 989,
      "startTLSEnabled" : true,
      "preferredSecurity" : "SSL",
      "product" : "DIRECTORY"
    },
    ...
  ]
}
```

The remaining sections in this chapter describe the deployment automation that is necessary to satisfy the following workflows:

- Setting up the initial topology
- Initializing data on all servers
- Replacing crashed instances and scaling up
- Scaling down
- Rolling updates

Consistent network identifiers are required for each server instance. Additionally, we strongly recommend persistent storage for all server bits. The required level of automation changes slightly when this recommendation is not followed, as noted in each section.

Setting up the initial topology

About this task

The presence of the file `server.uuid` in the server's `config` directory indicates whether the server is being set up initially or being updated.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the **manage-topology export** subcommand.
2. The server instance is installed and configured with a server profile, as follows:

```
manage-profile setup \
  --profile /path/to/server-profile \
  --profileVariablesFile /path/to/instance-specific-variables.properties
```

3. If you are not using persistent storage, remove the previous self from the topology:

```
remove-defunct-server \
  --serverInstanceName \
  --bindDN dn \
  --bindPassword password \
  --retryTimeoutSeconds 120
```

If you are using persistent storage, proceed directly to the next step.

4. Use the following command to enable replication within the topology:

```
dsreplication enable \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

For the sake of simplicity, other **dsreplication** options are not shown.

5. Initialize the replication data, as follows:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json
```

Next steps

For more information about server profiles, see [Server profiles](#) on page 933.

Initializing data on all servers

About this task

Skip this step if you are using one of the following methods to load data during the initial setup:

- Each server instance imports the same user data from one or more LDIF backup files
- Data is synchronized from another source, such as an Active Directory server, to all servers
- No data is imported initially

Data must be imported and available on a single server only. Servers that do not feature user data must be initialized reliably and quickly.

Note: The absence of user data during the initial setup does not prevent the the environment from being set up correctly.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Import data into one of the server instances, as follows:

```
import-ldif --backendID userRoot \
  --ldifFile userData0.ldif \
  --ldifFile userData1.ldif
```

3. Initialize data on each server by using this server as the initial source:

```
dsreplication initialize \
  --topologyFilePath /path/to/topology.json \
  --retryTimeoutSeconds 120
```

For the sake of simplicity, other `dsreplication` options are not shown.

Replacing crashed instances and scaling up

About this task

The automation for this scenario is identical to the automation for [Setting up the initial topology](#) on page 940.

Scaling down

About this task

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. If the server is not present in the topology JSON file, remove it from the topology, as follows:

```
remove-defunct-server --topologyFilePath /path/to/topology.json \
  --ignore-online \
  --serverInstanceName instance-name
```

```
--retryTimeoutSeconds 120
```

For the sake of simplicity, LDAP bind options are omitted.

Rolling updates

About this task

The presence of the file `server.uuid` in the server's `config` directory indicates whether the server is being set up initially or being updated.

Steps

1. Create or obtain the `topology.json` file either manually or by using external automation. When promoting from a dev/test environment to a stage/prod environment, you can obtain a `topology.json` file using the `manage-topology export` subcommand.
2. Unzip the new server bits to a directory.
3. From the same directory, run the `update` tool to update the server instance, as follows:

```
update --serverRoot /path/to/server-root \  
--bindDN bind-dn \  
--bindPassword bind-password
```

4. From the same directory, replace the new server profile, as follows:

```
manage-profile replace-profile \  
--profile /path/to/server-profile \  
--profileVariablesFile /path/to/instance-specific-variables.properties
```

Troubleshooting the Server

The PingDirectory Server provides a highly-reliable service that satisfies your company's objectives. However, if problems do arise (whether from issues in the Directory Server itself or a supporting component, like the JVM, operating system, or hardware), then it is essential to be able to diagnose the problem quickly to determine the underlying cause and the best course of action to take towards resolving it.

This chapter provides information about how to perform this analysis to help ensure that the problem is resolved as quickly as possible. This chapter presents the following information:

Working with the Collect Support Data Tool

The Directory Server provides a significant amount of information about its current state including any problems that it has encountered during processing. If a problem occurs, the first step is to run the `collect-support-data` tool in the `bin` directory. The tool aggregates all relevant support files into a zip file that administrators can send to your authorized support provider for analysis. The tool also runs data collector utilities, such as `jps`, `jstack`, and `jstat` plus other diagnostic tools, and bundles the results in the zip file.

The tool may only archive portions of certain log files to conserve space, so that the resulting support archive does not exceed the typical size limits associated with e-mail attachments.

The data collected by the `collect-support-data` tool varies between systems. However, the tool always tries to get the same information across all systems for the target Directory Server. The data collected includes the configuration directory, summaries and snippets from the `logs` directory, an LDIF of the monitor and RootDSE entries, and a list of all files in the server root.

Server Commands Used in the Collect Support Data Tool

The following presents a summary of the data collectors that the `collect-support-data` tool archives in zip format. If an error occurs during processing, you can re-run the specific data collector command and send the results to your authorized support provider.

Directory Server Commands Used in the Collect-Support-Data Tool

Data Collector	Description
status	Runs <code>status -F</code> to show the full version information of the Directory Server (Unix, Windows).
server-state	Runs <code>server-state</code> to show the current state of the Directory Server process (Unix, Windows).

JDK Commands Used in the Collect-Support-Data Tool

JDK Commands Used in the Collect-Support-Data Tool

Data Collector	Description
jps	Java Virtual Machine Process status tool. Reports information on the JVM (Linux, Windows, Mac OS).
jstack	Java Virtual Machine Stack Trace. Prints the stack traces of threads for the Java process (Linux, Windows, Mac OS).
jstat	Java Virtual Machine Statistics Monitoring Tool. Displays performance statistics for the JVM (Linux, Windows, Mac OS).
jinfo	Displays the Java configuration information for the Java process (Linux, Windows, Mac OS).

Linux Commands Used in the collect-support-data Tool

Linux Commands Used in the Collect-Support-Data Tool

Data Collector	Description
tail	Displays the last few lines of a file. Tails the <code>/var/logs/messages</code> directory.
uname	Prints system, machine, and operating system information.
ps	Prints a snapshot of the current active processes.
df	Prints the amount of available disk space for file systems in 1024-byte units.
cat	Concatenates the following files and prints to standard output: <ul style="list-style-type: none"> ▪ <code>/proc/cpuinfo</code> ▪ <code>/proc/meminfo</code> ▪ <code>/etc/hosts</code> ▪ <code>/etc/nsswitch.conf</code> ▪ <code>/etc/resolv.conf</code>
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
uptime	Prints the time the server has been up and active.
dmesg	Prints the message buffer of the kernel.

Data Collector	Description
vmstat	Prints information about virtual memory statistics.
iostat	Prints disk I/O and CPU utilization information.
mpstat	Prints performance statistics for all logical processors.
pstack	Prints an execution stack trace on an active process specified by the pid.
top	Prints a list of active processes and how much CPU and memory each process is using.

MacOS Commands Used in the Collect Support Data Tool

MacOS Commands Used in the Collect-Support-Data Tool

Data Collector	Description
uname	Prints system, machine, and operating system information.
uptime	Prints the time the server has been up and active.
ps	Prints a snapshot of the current active processes.
system_profiler	Prints system hardware and software configuration.
vm_stat	Prints machine virtual memory statistics.
tail	Displays the last few lines of a file. Tails the <code>/var/log/system.log</code> directory.
netstat	Prints the state of network interfaces, protocols, and the kernel routing table.
ifconfig	Prints information on all interfaces.
df	Prints the amount of available disk space for file systems in 1024-byte units.
sample	Profiles a process during an interval.

Available Tool Options

The `collect-support-data` tool has some important options that you should be aware of:

- **--noLdap**. Specifies that no effort should be made to collect any information over LDAP. This option should only be used if the server is completely unresponsive or will not start and only as a last resort.
- **--pid {pid}**. Specifies the ID of an additional process from which information is to be collected. This option is useful for troubleshooting external server tools and can be specified multiple times for each external server, respectively.
- **--sequential**. Use this option to diagnose “Out of Memory” errors. The tool collects data in parallel to minimize the collection time necessary for some analysis utilities. This option specifies that data collection should be run sequentially as opposed to in parallel. This action has the effect of reducing the initial memory footprint of this tool at a cost of taking longer to complete.
- **--reportCount {count}**. Specifies the number of reports generated for commands that supports sampling (for example, `vmstat`, `iostat`, or `mpstat`). A value of 0 (zero) indicates that no reports will be generated for these commands. If this option is not specified, it defaults to 10.
- **--reportInterval {interval}**. Specifies the number of seconds between reports for commands that support sampling (for example, `mpstat`). This option must have a value greater than 0 (zero). If this option is not specified, it defaults to 1.
- **--maxJstacks {number}**. Specifies the number of jstack samples to collect. If not specified, the default number of samples collected is 10.

- **--collectExpensiveData**. Specifies that data on expensive or long running processes be collected. These processes are not collected by default, because they will impact the performance of a running server.
- **--comment {comment}**. Provides the ability to submit any additional information about the collected data set. The comment will be added to the generated archive as a README file.
- **--includeBinaryFiles**. Specifies that binary files be included in the archive collection. By default, all binary files are automatically excluded in data collection.
- **--adminPassword {adminPassword}**. Specifies the global administrator password used to obtain `dsreplication status` information.
- **--adminPasswordFile {adminPasswordFile}**. Specifies the file containing the password of the global administrator used to obtain `dsreplication status` information.

To Run the Collect Support Data Tool

Steps

1. Go to the server root directory.
2. Use the `collect-support-data` tool. Make sure to include the host, port number, bind DN, and bind password.

```
$ bin/collect-support-data --hostname 127.0.0.1 --port 389 \
  --bindDN "cn=Directory Manager" --bindPassword secret \
  --serverRoot /opt/PingDirectory --pid 1234
```

3. Email the zip file to your Authorized Support Provider.

Directory Server Troubleshooting Information

The Directory Server has a comprehensive default set of log files and monitor entries that are useful when troubleshooting a particular server problem.

Error Log

By default, this log file is available at `logs/errors` below the server install root and it provides information about warnings, errors, and other significant events that occur within the server. A number of messages are written to this file on startup and shutdown, but while the server is running there is normally little information written to it. In the event that a problem does occur, however, the server writes information about that problem to this file.

The following is an example of a message that might be written to the error log:

```
[11/Apr/2011:10:31:53.783 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The category field provides information about the area of the server from which the message was generated. Available categories include:

ACCESS_CONTROL, ADMIN, ADMIN_TOOL, BACKEND, CONFIG, CORE, DSCONFIG, EXTENSIONS, PROTOCOL, SCHEMA, JEB, SYNC, LOG, PLUGIN, PROXY, QUICKSETUP, REPLICATION, RUNTIME_INFORMATION, TASK, THIRD_PARTY, TOOLS, USER_DEFINED, UTIL, VERSION.

The severity field provides information about how severe the server considers the problem to be. Available severities include:

- **DEBUG** – Used for messages that provide verbose debugging information and do not indicate any kind of problem. Note that this severity level is rarely used for error logging, as the Directory Server provides a separate debug logging facility as described below.
- **INFORMATION** – Used for informational messages that can be useful from time to time but are not normally something that administrators need to see.

- **MILD_WARNING** – Used for problems that the server detects, which can indicate something unusual occurred, but the warning does not prevent the server from completing the task it was working on. These warnings are not normally something that should be of concern to administrators.
- **MILD_ERROR** – Used for problems detected by the server that prevented it from completing some processing normally but that are not considered to be a significant problem requiring administrative action.
- **NOTICE** – Used for information messages about significant events that occur within the server and are considered important enough to warrant making available to administrators under normal conditions.
- **SEVERE_WARNING** – Used for problems that the server detects that might lead to bigger problems in the future and should be addressed by administrators.
- **SEVERE_ERROR** – Used for significant problems that have prevented the server from successfully completing processing and are considered important.
- **FATAL_ERROR** – Used for critical problems that arise which might leave the server unable to continue processing operations normally.

The messages written to the error log may be filtered based on their severities in two ways. First, the error log publisher has a `default-severity` property, which may be used to specify the severity of messages logged regardless of their category. By default, this includes the `NOTICE`, `SEVERE_WARNING`, `SEVERE_ERROR`, and `FATAL_ERROR` severities.

You can override these severities on a per-category basis using the `override-severity` property. If this property is used, then each value should consist of a category name followed by an equal sign and a comma-delimited set of severities that should be logged for messages in that category. For example, the following override severity would enable logging at all severity levels in the `PROTOCOL` category:

```
protocol=debug,information,mild-warning,mild-error,notice,severe-
warning,severe-error,fatal-error
```

Note that for the purposes of this configuration property, any underscores in category or severity names should be replaced with dashes. Also, severities are not inherently hierarchical, so enabling the `DEBUG` severity for a category will not automatically enable logging at the `INFORMATION`, `MILD_WARNING`, or `MILD_ERROR` severities.

The error log configuration may be altered on the fly using tools like `dsconfig`, the Administrative Console, or the LDIF connection handler, and changes will take effect immediately. You can configure multiple error logs that are active in the server at the same time, writing to different log files with different configurations. For example, a new error logger may be activated with a different set of default severities to debug a short-term problem, and then that logger may be removed once the problem is resolved, so that the normal error log does not contain any of the more verbose information.

server.out Log

The `server.out` file holds any information written to standard output or standard error while the server is running. Normally, it includes a number of messages written at startup and shutdown, as well as information about any administrative alerts generated while the server is running. In most cases, this information is also written to the error log. The `server.out` file can also contain output generated by the JVM. For example, if garbage collection debugging is enabled, or if a stack trace is requested via "kill - QUIT" as described in a later section, then output is written to this file.

Debug Log

The debug log provides a means of obtaining information that can be used for troubleshooting problems but is not necessary or desirable to have available while the server is functioning normally. As a result, the debug log is disabled by default, but it can be enabled and configured at any time.

Some of the most notable configuration properties for the debug log publisher include:

- **enabled** – Indicates whether debug logging is enabled. By default, it is disabled.
- **log-file** – Specifies the path to the file to be written. By default, debug messages are written to the `logs/debug` file.

- **default-debug-level** – Specifies the minimum log level for debug messages that should be written. The default value is “error,” which only provides information about errors that occur during processing (for example, exception stack traces). Other supported debug levels include warning, info, and verbose. Note that unlike error log severities, the debug log levels are hierarchical. Configuring a specified debug level enables any debugging at any higher levels. For example, configuring the info debug level automatically enables the warning and error levels.
- **default-debug-category** – Specifies the categories for debug messages that should be written. Some of the most useful categories include caught (provides information and stack traces for any exceptions caught during processing), database-access (provides information about operations performed in the underlying database), protocol (provides information about ASN.1 and LDAP communication performed by the server), and data (provides information about raw data read from or written to clients).

As with the error and access logs, multiple debug loggers can be active in the server at any time with different configurations and log files to help isolate information that might be relevant to a particular problem.

Note: Enabling one or more debug loggers can have a significant impact on server performance. We recommend that debug loggers be enabled only when necessary, and then be scoped so that only pertinent debug information is recorded.

Debug targets can be used to further pare down the set of messages generated. For example, you can specify that the debug logs be generated only within a specific class or package. If you need to enable the debug logger, you should work with your authorized support provider to best configure the debug target and interpret the output.

Replication Repair Log

The replication repair log is written to `logs/replication` by default and records information about processing performed by the replication repair service. This log is used to resolve replication conflicts that can arise. For example, if the same entry is modified at the same time on two different systems, or if an attempt is made to create entries with the same DN at the same time on two different systems, the Directory Server records these events.

Config Audit Log and the Configuration Archive

The configuration audit log provides a record of any changes made to the server configuration while the server is online. This information is written to the `logs/config-audit.log` file and provides information about the configuration change in the form that may be used to perform the operation in a non-interactive manner with the `dsconfig` command. Other information written for each change includes:

- Time that the configuration change was made.
- Connection ID and operation ID for the corresponding change, which can be used to correlate it with information in the access log.
- DN of the user requesting the configuration change and the method by which that user authenticated to the server.
- Source and destination addresses of the client connection.
- Command that can be used to undo the change and revert to the previous configuration for the associated configuration object.

In addition to information about the individual changes that are made to the configuration, the Directory Server maintains complete copies of all previous configurations. These configurations are provided in the `config/archived-configs` directory and are gzip-compressed copies of the `config/config.ldif` file in use before the configuration change was made. The file names contain timestamps that indicate when that configuration was first used.

Access and Audit Log

The access log provides information about operations processed within the server. The default access log file is written to `logs/access`, but multiple access loggers can be active at the same time, each writing to different log files and using different configurations.

By default, a single access log message is generated, which combines the elements of request, forward, and result messages. If an error is encountered while attempting to process the request, then one or more forward-failed messages may also be generated.

```
[01/Jun/2011:11:10:19.692 -0500] CONNECT conn=49 from="127.0.0.1"
to="127.0.0.1"
  protocol="LDAP+TLS" clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.764 -0500] BIND RESULT conn=49 op=0 msgID=1 version="3"
  dn="cn=Directory Manager" authType="SIMPLE" resultCode=0 etime=0.401
  authDN="cn=Directory Manager,cn=Root DNs,cn=config"
  clientConnectionPolicy="default"
[01/Jun/2011:11:10:19.769 -0500] SEARCH RESULT conn=49 op=1 msgID=2
  base="ou=People,dc=example,dc=com" scope=2 filter="(uid=1)" attrs="ALL"
  resultCode=0 etime=0.549 entriesReturned=1
[01/Jun/2011:11:10:19.788 -0500] DISCONNECT conn=49 reason="Client Unbind"
```

Each log message includes a timestamp indicating when it was written, followed by the operation type, the connection ID (which is used for all operations processed on the same client connection), the operation ID (which can be used to correlate the request and response log messages for the operation), and the message ID used in LDAP messages for this operation.

The remaining content for access log messages varies based on the type of operation being processed, and whether it is a request or a result message. Request messages generally include the most pertinent information from the request, but generally omit information that is sensitive or not useful.

Result messages include a `resultCode` element that indicates whether the operation was successful or if failed and an `etime` element that indicates the length of time in milliseconds that the server spent processing the operation. Other elements that might be present include the following:

- **origin=replication** – Operation that was processed as a result of data synchronization (for example, replication) rather than a request received directly from a client.
- **message** – Text that was included in the `diagnosticMessage` field of the response sent to the client.
- **additionalInfo** – Additional information about the operation that was not included in the response sent back to the client.
- **authDN** – DN of the user that authenticated to the server (typically only included in bind result messages).
- **authzDN** – DN of an alternate authorization identify used when processing the operation (for example, if the proxied authorization control was included in the request).
- **authFailureID** – Unique identifier associated with the authentication failure reason (only included in non-successful bind result messages).
- **authFailureReason** – Information about the reason that a bind operation failed that might be useful to administrators but was not included in the response to the client for security reasons.
- **responseOID** – OID included in an extended response returned to the client.
- **entriesReturned** – Number of matching entries returned to the client for a search operation.
- **unindexed=true** – Indicates that the associated search operation could not be sufficiently processed using server indexes and a significant traversal through the database was required.

Note that this is not an exhaustive list, and elements that are not listed here may also be present in access log messages. The LDAP SDK for Java provides an API for parsing access log messages and provides access to all elements that they may contain.

The Directory Server provides a second access log implementation called the *audit log*, which is used to provide detailed information about write operations (add, delete, modify, and modify DN) processed within

the server. If the audit log is enabled, the entire content of the change is written to the audit log file (which defaults to `logs/audit`) in LDIF form.

The PingDirectory Server also provides a very rich classification system that can be used to filter the content for access log files. This can be helpful when debugging problems with client applications, because it can restrict log information to operations processed only by a particular application (for example, based on IP address and/or authentication DN), only failed operations, or only operations taking a long time to complete, etc.

Setup Log

The `setup` tool writes a log file providing information about the processing that it performs. By default, this log file is written to `logs/setup.log` although a different name may be used if a file with that name already exists, because the `setup` tool has already been run. The full path to the setup log file is provided when the `setup` tool has completed.

Tool Log

Many of the administrative tools provided with the Directory Server (for example, `import-ldif`, `export-ldif`, `backup`, `restore`, etc.) can take a significant length of time to complete write information to standard output or standard error or both while the tool is running. They also write additional output to files in the `logs/tools` directory (for example, `logs/tools/import-ldif.log`). The information written to these log files can be useful for diagnosing problems encountered while they were running. When running via the server tasks interface, log messages generated while the task is running may alternately be written to the server error log file.

je.info and je.config Files

The primary datastore used by the Directory Server is the Oracle Berkeley DB Java Edition (JE). The Directory Server provides two primary sources of information about processing within the database.

The first is logging performed by the JE code itself, and is written into the `je.info.0` file in the server containing the database files (for example, `db/userRoot/je.info.0`). In the event of a problem within JE itself, useful information about the nature of the problem may be written to this log. The level of information written to this log file is controlled by the `db-logging-level` property in the backend configuration object. It uses the standard Java logging framework for logging messages, so the standard SEVERE, WARNING, INFO, CONFIG, FINE, FINER, and FINEST levels are available.

The second is configuration information used when opening the database environment. When the backend database environment is opened, then the Directory Server will also write a file named `je.config` in the server containing the database files (for example, `db/userRoot/je.config`) with information about the configuration used.

LDAP SDK Debug Log

This log can be used to help examine the communication between the Directory Server and the Directory Proxy Server. It contains information about exceptions that occur during processing, problems establishing and terminating network connections, and problems that occur during the reading and writing of LDAP messages and LDIF entries. You can configure the types of debugging that should be enabled, the debug level that should be used, and whether debug messages should include stack traces. As for other file-based loggers, you can also specify the rotation and retention policies.

About the Monitor Entries

While the Directory Server is running, it generates a significant amount of information available through monitor entries. Monitor entries are available over LDAP in the `cn=monitor` subtree. The types of monitor entries that are available include:

- **General Monitor Entry (cn=monitor)** – Provides a basic set of general information about the server.
- **Active Operations Monitor Entry (cn=Active Operations,cn=monitor)** – Provides information about all operations currently in progress in the server.

- **Backend Monitor Entries (cn={id} Backend,cn=monitor)** – Provides information about the backend, including the number of entries, the base DN(s), and whether it is private.
- **Client Connections Monitor Entry (cn=Client Connections,cn=monitor)** – Provides information about all connections currently established to the server.
- **Connection Handler Monitor Entry (cn={name},cn=monitor)** – Provides information about the configuration of each connection handler and the client connections established to it.
- **Database Environment Monitor Entries (cn={id} Database Environment,cn=monitor)** – Provides statistics and other data from the Oracle Berkeley DB Java Edition database environment used by the associated backend.
- **Disk Space Usage Monitor Entry (cn=Disk Space Usage,cn=monitor)** – Provides information about the amount of usable disk space available to server components.
- **JVM Memory Usage Monitor Entry (cn=JVM Memory Usage,cn=monitor)** – Provides information about garbage collection activity, the amount of memory available to the server, and the amount of memory consumed by various server components.
- **JVM Stack Trace Monitor Entry (cn=JVM Stack Trace,cn=monitor)** – Provides a stack trace of all threads in the JVM.
- **LDAP Statistics Monitor Entries (cn={name} Statistics,cn=monitor)** – Provides information about the number of each type of operation requested and bytes transferred over the connection handler.
- **Processing Time Histogram Monitor Entry (cn=Processing Time Histogram,cn=monitor)** – Provides information about the number of percent of operations that completed in various response time categories.
- **SSL Context Monitor Entry (cn=SSL Context,cn=monitor)** – Provides information about the available and supported SSL Cipher Suites and Protocols on the server.
- **System Information Monitor Entry (cn=System Information,cn=monitor)** – Provides information about the underlying JVM and system.
- **Version Monitor Entry (cn=Version,cn=monitor)** – Provides information about the Directory Server version.
- **Work Queue Monitor Entry (cn=Work Queue,cn=monitor)** – Provides information about the state of the Directory Server work queue, including the number of operations waiting on worker threads and the number of operations that have been rejected because the queue became full.

Directory Server Troubleshooting Tools

The PingDirectory Server provides a set of tools that can also be used to obtain information for diagnosing and solving problems.

Server Version Information

If it becomes necessary to contact your authorized support provider, then it will be important to provide precise information about the version of the Directory Server software that is in use. If the server is running, then this information can be obtained from the "cn=Version,cn=monitor" entry. It can also be obtained using the command:

```
$ bin/status --fullVersion
```

This command outputs a number of important pieces of information, including:

- Major, minor, point and patch version numbers for the server.
- Source revision number from which the server was built.
- Build information including build ID with timestamp, OS, user, Java and JVM version for the build.
- Auxiliary software versions: Jetty, JZlib, SNMP4j (SNMP4J, Agent, Agentx), Groovy, LDAP SDK for Java, and the Server SDK.

LDIF Connection Handler

The Directory Server provides an LDIF connection handler that provides a way to request operations that do not require any network communication with the server. This can be particularly helpful if a configuration

problem or bug in the server has left a connection handler unusable, or if all worker threads are busy processing operations.

The LDIF connection handler is enabled by default and looks for LDIF files to be placed in the `config/auto-process-ldif` directory. This Directory Server does not exist by default, but if it is created and an LDIF file is placed in it that contains one or more changes to be processed, then those changes will be applied.

Any changes that can be made over LDAP can be applied through the LDIF connection handler. It is primarily intended for administrative operations like updating the server configuration or scheduling tasks, although other types of changes (including changes to data contained in the server) can be processed. As the LDIF file is processed, a new file is written with comments for each change providing information about the result of processing that change.

dbtest Tool

The `dbtest` tool provides a utility that can be used to obtain general information about the data in a backend database. The tool dumps information about entries or keys, and raw data from the database. It can also find keys that have exceeded the entry limit.

For example, the following command can be used to dump a list of all keys in the `objectClass.equality` that have exceeded the entry threshold:

```
$ bin/dbtest dump-database-container \
  --backendID userRoot \
  --baseDN "dc=example,dc=com" \
  --databaseName objectClass.equality \
  --onlyExceedingLimit
```

On a large database, many `dbtest` operations may take a long time to complete, since every record in the associated database is examined. Use the database name option to list a specific database. The following command displays information about the `uid.equality` database in the `dc=example,dc=com` entry container in the `userRoot` backend.

```
$ bin/dbtest list-database-containers -n userRoot -b "dc=example,dc=com" -d
uid.equality
```

Index Key Entry Limit

Indexes have keys that maintain a list of matching entries, up to the index entry limit. When that limit is reached, the key will not contain or maintain that list, and will just maintain a count of matching entries. To determine if index keys are approaching their limit, use either the `dbtest` tool or the `verify-index` tool.

While the `dbtest` tool can be used to gather general information, the `verify-index` tool provides statistical data about the percent of entries covered by the keys.

For example, the following command can be used to retrieve a list of keys that have exceeded the entry threshold:

```
$ bin/verify-index \
  --baseDN dc=example,dc=com \
  --listKeysExceedingIndexEntryLimit
```

The following is a sample of the data returned:

```
[12:06:05] Checked 6003 entries and found 0 error(s) in 2 seconds (average
rate 2453.2/sec)
[12:06:05] Statistics for records that have exceeded the entry limit:
[12:06:05] The st.equality index has 48 such record(s) limit=100 min=103
max=152 median=118
[12:06:05] 1. or (152 entries / 2.53% of all entries)
[12:06:05] 2. ma (132 entries / 2.20% of all entries)
.....
```

```
[12:06:05] The id2subtree index has 2 such record(s) limit=4000 min=6000
max=6002 median=6001
[12:06:05] 1. 1 => dc=example,dc=com (6002 entries / 99.98% of all entries)
.....
[12:06:05] The id2children index has 1 such record(s) limit=4000 min=6000
max=6000 median=6000
[12:06:05] 1. 2 => ou=People,dc=example,dc=com (6000 entries / 99.95% of all
entries)
[12:06:05] The objectClass.equality index has 4 such record(s) limit=4000
min=6001 max=6003 median=6001
[12:06:05] 1. top (6003 entries / 100.00% of all entries)
.....
```

Embedded Profiler

If the Directory Server appears to be running slowly, then it is helpful to know what operations are being processed in the server. The JVM Stack Trace monitor entry can be used to obtain a point-in-time snapshot of what the server is doing, but in many cases, it might be useful to have information collected over a period of time.

The embedded profiler is configured so that it is always available but is not active by default so that it has no impact on the performance of the running server. Even when it is running, it has a relatively small impact on performance, but it is recommended that it remain inactive when it is not needed. It can be controlled using the `dsconfig` tool or the Administrative Console by managing the "Profiler" configuration object in the "Plugin" object type, available at the standard object level. The `profile-action` property for this configuration object can have one of the following values:

- **start** – Indicates that the embedded profiler should start capturing data in the background.
- **stop** – Indicates that the embedded profiler should stop capturing data and write the information that it has collected to a `logs/profile{timestamp}` file.
- **cancel** – Indicates that the embedded profiler should stop capturing data and discard any information that it has collected.

Any profiling data that has been captured can be examined using the `profiler-viewer` tool. This tool can operate in either a text-based mode, in which case it dumps a formatted text representation of the profile data to standard output, or it can be used in a graphical mode that allows the information to be more easily understood.

To Invoke the Profile Viewer in Text-based Mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option.

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z
```

To Invoke the Profile Viewer in GUI Mode

Steps

- Run the `profile-viewer` command and specify the captured log file using the `--fileName` option. To invoke GUI mode, add the option `--useGUI`.

```
$ bin/profile-viewer --fileName logs/profile.20110101000000Z --useGUI
```

Oracle Berkeley DB Java Edition Utilities

The Oracle Berkeley DB Java Edition (JE) itself provides a number of utilities that can be used for performing various types of low-level debugging in the database environment. These utilities should generally not be used unless you are advised to do so by your authorized support provider, but they provide access to information about the underlying database environment that is not available through any other means.

Troubleshooting Resources for Java Applications

Because the PingDirectory Server is written entirely in Java, it is possible to use standard Java debugging and instrumentation tools when troubleshooting problems with the Directory Server. In many cases, obtaining the full benefit of these tools requires access to the Directory Server source code. These Java tools should be used under the advisement of your authorized support provider.

Java Troubleshooting Tools

The Java Development Kit provides a number of very useful tools to obtain information about Java applications and diagnosing problems. These tools are not included with the Java Runtime Environment (JRE), so the full Java Development Environment (JDK) should always be installed and used to run the PingDirectory Server.

jps

The **jps** tool is a Java-specific version of the UNIX **ps** tool. It can be used to obtain a list of all Java processes currently running and their respective process identifiers. When invoked by a non-root user, it will list only Java processes running as that user. When invoked by a root user, then it lists all Java processes on the system.

This tool can be used to see if the Directory Server is running and if a process ID has been assigned to it. This process ID can be used in conjunction with other tools to perform further analysis.

This tool can be run without any arguments, but some of the more useful arguments that include:

- **-v** – Includes the arguments passed to the JVM for the processes that are listed.
- **-m** – Includes the arguments passed to the main method for the processes that are listed.
- **-l** – (lowercase L). Include the fully qualified name for the main class rather than only the base class name.

jstack

The **jstack** tool is used to obtain a stack trace of a running Java process, or optionally from a core file generated if the JVM happens to crash. A stack trace can be extremely valuable when trying to debug a problem, because it provides information about all threads running and exactly what each is doing at the point in time that the stack trace was obtained.

Stack traces are helpful when diagnosing problems in which the server appears to be hung or behaving slowly. Java stack traces are generally more helpful than native stack traces, because Java threads can have user-friendly names (as do the threads used by the PingDirectory Server), and the frame of the stack trace may include the line number of the source file to which it corresponds. This is useful when diagnosing problems and often allows them to be identified and resolved quickly.

To obtain a stack trace from a running JVM, use the command:

```
jstack {processID}
```

where **{processID}** is the process ID of the target JVM as returned by the **jps** command. To obtain a stack trace from a core file from a Java process, use the command:

```
jstack {pathToJava} {pathToCore}
```

where **{pathToJava}** is the path to the java command from which the core file was created, and **{pathToCore}** is the path to the core file to examine. In either case, the stack trace is written to standard output and includes the names and call stacks for each of the threads that were active in the JVM.

In many cases, no additional options are necessary. The **"-l"** option can be added to obtain a long listing, which includes additional information about locks owned by the threads. The **"-m"** option can be used to include native frames in the stack trace.

jmap

The **jmap** tool is used to obtain information about the memory consumed by the JVM. It is very similar to the native **pmap** tool provided by many operating systems. As with the **jstack** tool, **jmap** can be invoked against a running Java process by providing the process ID, or against a core file, like:

```
jmap {processID}
jmap {pathToJava} {pathToCore}
```

Some of the additional arguments include:

- **-dump:live,format=b,file=filename** – Dump the live heap data to a file that can be examined by the **jhat** tool
- **-heap** – Provides a summary of the memory used in the Java heap, along with information about the garbage collection algorithm in use.
- **-histo:live** – Provides a count of the number of objects of each type contained in the heap. If the “:live” portion is included, then only live objects are included; otherwise, the count include objects that are no longer in use and are garbage collected.

jhat

The **jhat** (Java Heap Analysis Tool) utility provides the ability to analyze the contents of the Java heap. It can be used to analyze a heap dump file, which is generated if the Directory Server encounters an out of memory error (as a result of the “-XX:+HeapDumpOnOutOfMemoryError” JVM option) or from the use of the **jmap** command with the “-dump” option.

The **jhat** tool acts as a web server that can be accessed by a browser in order to query the contents of the heap. Several predefined queries are available to help determine the types of objects consuming significant amounts of heap space, and it also provides a custom query language (OQL, the Object Query Language) for performing more advanced types of analysis.

The **jhat** tool can be launched with the path to the heap dump file, like:

```
jhat /path/to/heap.dump
```

This command causes the **jhat** web server to begin listening on port 7000. It can be accessed in a browser at <http://localhost:7000> (or <http://address:7000> from a remote system). An alternate port number can be specified using the “-port” option, like:

```
jhat -port 1234 /path/to/heap.dump
```

To issue custom OQL searches, access the web interface using the URL <http://localhost:7000/oql/> (the trailing slash must be provided). Additional information about the OQL syntax may be obtained in the web interface at <http://localhost:7000/oqlhelp/>.

jstat

The **jstat** tool is used to obtain a variety of statistical information from the JVM, much like the **vmstat** utility that can be used to obtain CPU utilization information from the operating system. The general manner to invoke it is as follows:

```
jstat {type} {processID} {interval}
```

The `{interval}` option specifies the length of time in milliseconds between lines of output. The `{processID}` option specifies the process ID of the JVM used to run the Directory Server, which can be obtained by running **jps** as mentioned previously. The `{type}` option specifies the type of output that should be provided. Some of the most useful types include:

- **-class** – Provides information about class loading and unloading.
- **-compile** – Provides information about the activity of the JIT complex.
- **-printcompilation** – Provides information about JIT method compilation.
- **-gc** – Provides information about the activity of the garbage collector.

- **-gccapacity** – Provides information about memory region capacities.

Java Diagnostic Information

In addition to the tools listed in the previous section, the JVM can provide additional diagnostic information in response to certain events.

JVM Crash Diagnostic Information

If the JVM itself should happen to crash for some reason, then it generates a fatal error log with information about the state of the JVM at the time of the crash. By default, this file is named `hs_err_pid{processID}.log` and is written into the base directory of the Directory Server installation. This file includes information on the underlying cause of the JVM crash, information about the threads running and Java heap at the time of the crash, the options provided to the JVM, environment variables that were set, and information about the underlying system.

Troubleshooting Resources in the Operating System

The underlying operating system also provides a significant amount of information that can help diagnose issues that impact the performance and the stability of the Directory Server. In some cases, problems with the underlying system can be directly responsible for the issues seen with the Directory Server, and in others system, tools can help narrow down the cause of the problem.

Identifying Problems with the Underlying System

If the underlying system itself is experiencing problems, it can adversely impact the function of applications running on it. To look for problems in the underlying system view the system log file (`/var/log/messages` on Linux). Information about faulted or degraded devices or other unusual system conditions are written there.

Examining CPU Utilization

Observing CPU utilization for the Directory Server process and the system as a whole provides clues as to the nature of the problem.

System-Wide CPU Utilization

To investigate CPU consumption of the system as a whole, use the `vmstat` command with a time interval in seconds, like:

```
vmstat 5
```

The specific output of this command varies between different operating systems, but it includes the percentage of the time the CPU was spent executing user-space code (user time), the percentage of time spent executing kernel-space code (system time), and the percentage of time not executing any code (idle time).

If the CPUs are spending most of their time executing user-space code, the available processors are being well-utilized. If performance is poor or the server is unresponsive, it can indicate that the Directory Server is not optimally tuned. If there is a high system time, it can indicate that the system is performing excessive disk and/or network I/O, or in some cases, there can be some other system-wide problem like an interrupt storm. If the system is mostly idle but the Directory Server is performing poorly or is unresponsive, there can be a resource constraint elsewhere (for example, waiting on disk or memory access, or excessive lock contention), or the JVM can be performing other tasks like stop-the-world garbage collection that cannot be run heavily in parallel.

Per-CPU Utilization

To investigate CPU consumption on a per-CPU basis, use the `mpstat` command with a time interval in seconds, like:

```
mpstat 5
```

On Linux systems, it might be necessary to add `"-P ALL"` to the command, like:

```
mpstat -P ALL 5
```

Among other things, this shows the percentage of time each CPU has spent in user time, system time, and idle time. If the overall CPU utilization is relatively low but `mpstat` reports that one CPU has a much higher utilization than the others, there might be a significant bottleneck within the server or the JVM might be performing certain types of garbage collection which cannot be run in parallel. On the other hand, if CPU utilization is relatively even across all CPUs, there is likely no such bottleneck and the issue might be elsewhere.

Per-Process Utilization

To investigate CPU consumption on a per-process basis, use a command such as the `top` utility on Linux. If a process other than the Java process used to run the Directory Server is consuming a significant amount of available CPU, it might be interfering with the ability of the Directory Server to run effectively.

Examining Disk Utilization

If the underlying system has a very high disk utilization, it can adversely impact Directory Server performance. It could delay the ability to read or write database files or write log files. It could also raise concerns for server stability if excessive disk I/O inhibits the ability of the cleaner threads to keep the database size under control.

The `iostat` tool may be used to obtain information about the disk activity on the system.

On Linux systems, `iostat` should be invoked with the `"-x"` argument, like:

```
iostat -x 5
```

A number of different types of information will be displayed, but to obtain an initial feel for how busy the underlying disks are, look at the `"%util"` column on Linux. This field shows the percentage of the time that the underlying disks are actively servicing I/O requests. A system with a high disk utilization likely exhibits poor Directory Server performance.

If the high disk utilization is on one or more disks that are used to provide swap space for the system, the system might not have enough free memory to process requests. As a result, it might have started swapping blocks of memory that have not been used recently to disk. This can cause very poor server performance. It is important to ensure that the server is configured appropriately to avoid this condition. If this problem occurs on a regular basis, then the server is likely configured to use too much memory. If swapping is not normally a problem but it does arise, then check to see if there are any other processes running, which are consuming a significant amount of memory, and check for other potential causes of significant memory consumption (for example, large files in a `tmpfs` file system).

Examining Process Details

There are a number of tools provided by the operating system that can help examine a process in detail.

ps

The standard `ps` tool can be used to provide a range of information about a particular process. For example, the command can be used to display the state of the process, the name of the user running the process, its process ID and parent process ID, the priority and nice value, resident and virtual memory sizes, the start time, the execution time, and the process name with arguments:

```
ps -fly -p {processID}
```

Note that for a process with a large number of arguments, the standard `ps` command displays only a limited set of the arguments based on available space in the terminal window.

pstack

The `pstack` command can be used to obtain a native stack trace of all threads in a process. While a native stack trace might not be as user-friendly as a Java stack trace obtained using `jstack`, it includes threads that are not available in a Java stack trace. For example, the command displays those threads

used to perform garbage collection and other housekeeping tasks. The general usage for the `pstack` command is:

```
pstack {processID}
```

dbx / gdb

A process debugger provides the ability to examine a process in detail. Like `pstack`, a debugger can obtain a stack trace for all threads in the process, but it also provides the ability to examine a process (or core file) in much greater detail, including observing the contents of memory at a specified address and the values of CPU registers in different frames of execution. The GNU debugger `gdb` is widely-used on Linux systems.

Note that using a debugger against a live process interrupts that process and suspends its execution until it detaches from the process. In addition, when running against a live process, a debugger has the ability to actually alter the contents of the memory associated with that process, which can have adverse effects. As a result, it is recommended that the use of a process debugger be restricted to core files and only used to examine live processes under the direction of your authorized support provider.

pfiles / lsof

To examine the set of files that a process is using (including special types of files, like sockets), you can use a tool such as `lsof` on Linux systems, (

```
lsof -p {processID}
```

)

Tracing Process Execution

If a process is unresponsive but is consuming a nontrivial amount of CPU time, or if a process is consuming significantly more CPU time than is expected, it might be useful to examine the activity of that process in more detail than can be obtained using a point-in-time snapshot. For example, if a process is performing a significant amount of disk reads and/or writes, it can be useful to see which files are being accessed. Similarly, if a process is consistently exiting abnormally, then beginning tracing for that process just before it exits can help provide additional information that cannot be captured in a core file (and if the process is exiting rather than being terminated for an illegal operation, then no core file may be available).

This can be accomplished using the `strace` tool on Linux (

```
strace -f -p {processID}
```

).

Consult the `strace` manual page for additional information.

Problems with SSL Communication

Enable TLS debugging in the server to troubleshoot SSL communication issues:

```
$ dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name
com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose \
  --set include-throwable-cause:true
```

```
$ dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true \
  --set default-debug-level:disabled
```

In the `java.properties` file, add `-Djavax.net.debug=ssl` to the `start-server` line, and run `bin/dsjavaproperties` to make the option take effect on a scheduled server restart.

Examining Network Communication

Because the PingDirectory Server is a network-based application, it can be valuable to observe the network communication that it has with clients. The Directory Server itself can provide details about its interaction with clients by enabling debugging for the protocol or data debug categories, but there may be a number of cases in which it is useful to view information at a much lower level. A network sniffer, like the `tcpdump` tool on Linux, can be used to accomplish this.

There are many options that can be used with these tools, and their corresponding manual pages will provide a more thorough explanation of their use. However, to perform basic tracing to show the full details of the packets received for communication on port 389 with remote host 1.2.3.4, the following command can be used on Linux:

```
tcpdump -i {interface} -n -XX -s 0 host 1.2.3.4 and port 389
```

It does not appear that the `tcpdump` tool provides support for LDAP parsing. However, it is possible to write capture data to a file rather than displaying information on the terminal (using "`-w {path}`" with `tcpdump`), so that information can be later analyzed with a graphical tool like Wireshark, which provides the ability to interpret LDAP communication on any port.

Note that enabling network tracing generally requires privileges that are not available to normal users and therefore may require root access.

Common Problems and Potential Solutions

This section describes a number of different types of problems that can occur and common potential causes for them.

General Methodology to Troubleshoot a Problem

When a problem is detected, Ping Identity recommends using the following general methodology to isolate the problem:

1. Run the `bin/status` tool or look at the server status in the Administrative Console. The `status` tool provides a summary of the server's current state with key metrics and a list of recent alerts.
2. Look in the server logs. In particular, view the following logs:
 - `logs/errors`
 - `logs/failed-ops`
 - `logs/expensive-ops`
3. Use system commands, such as `vmstat` and `iostat` to determine if the server is bottle-necked on a system resource like CPU or disk throughput.
4. For performance problem (especially intermittent ones like spikes in response time), enabling the `periodic-stats-logger` can help to isolate problems, because it stores important server performance information on a per-second basis. The `periodic-stats-logger` can save the information in a csv-formatted file that can be loaded into a spreadsheet. The information this logger makes available is very configurable. You can create multiple loggers for different types of information or a different frequency of logging (for example, hourly data in addition to per-second data). For more information, see "Profiling Server Performance Using the Periodic Stats Logger".
5. For replication problem, run `dsreplication status` and look at the `logs/replication` file.
6. For more advanced users, run the `collect-support-data` tool on the system, unzip the archive somewhere, and look through the collected information. This is often useful when administrators most familiar with the PingData Platform do not have direct access to the systems where the production servers are running. They can examine the `collect-support-data` archive on a different server. For more information, see Using the Collect Support Data Tool.

i Important: Run the `collect-support-data` tool whenever there is a problem whose cause is not easily identified, so that this information can be passed back to your authorized support provider before corrective action can be taken.

The Server Will Not Run Setup

If the `setup` tool does not run properly, some of the most common reasons include the following:

A Suitable Java Environment Is Not Available

The PingDirectory Server requires that Java be installed on the system and made available to the server, and it must be installed prior to running `setup`. If the `setup` tool does not detect that a suitable Java environment is available, it will refuse to run.

To ensure that this does not happen, the `setup` tool should be invoked with an explicitly-defined value for the `JAVA_HOME` environment variable that specifies the path to the Java installation that should be used. For example:

```
env JAVA_HOME=/ds/java ./setup
```

If this still does not work for some reason, then it can be that the value specified in the provided `JAVA_HOME` environment variable can be overridden by another environment variable. If that occurs, try the following command, which should override any other environment variables that can be set:

```
env UNBOUNDID_JAVA_HOME="/ds/java" UNBOUNDID_JAVA_BIN="" ./setup
```

Oracle Berkeley DB Java Edition Is Not Available

If the version of the Directory Server that you are using was not provided with the Oracle Berkeley DB Java Edition library, then it must be manually downloaded and the appropriate JAR file placed in the `lib` directory before running `setup`. See the `lib/downloading-je.txt` file for instructions on obtaining the appropriate library.

Unexpected Arguments Provided to the JVM

If the `setup` script attempts to launch the `java` command with an invalid set of Java arguments, it might prevent the JVM from starting. By default, no special options are provided to the JVM when running `setup`, but this might not be the case if either the `JAVA_ARGS` or `UNBOUNDID_JAVA_ARGS` environment variable is set. If the `setup` tool displays an error message that indicates that the Java environment could not be started with the provided set of arguments, then invoke the following command before trying to re-run `setup`:

```
unset JAVA_ARGS UNBOUNDID_JAVA_ARGS
```

The Server Has Already Been Configured or Used

The `setup` tool is only intended to provide the initial configuration for the Directory Server. It refuses to run if it detects that the `setup` tool has already been run, or if an attempt has been made to start the Directory Server prior to running the `setup` tool. This protects an existing Directory Server installation from being inadvertently updated in a manner that could harm an existing configuration or data set.

If the Directory Server has been previously used and if you want to perform a fresh installation, it is recommended that you first remove the existing installation, create a new one and run `setup` in that new installation. However, if you are confident that there is nothing of value in the existing installation (for example, if a previous attempt to run `setup` failed to complete successfully for some reason but it will refuse to run again), the following steps can be used to allow the `setup` program to run:

- Remove the `config/config.ldif` file and replace it with the `config/update/config.ldif.{revision}` file containing the initial configuration.
- If there are any files or subdirectories below the `db` directory, then remove them.
- If a `config/java.properties` file exists, then remove it.

- If a `lib/setup-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) exists, then remove it.

The Server Will Not Start

If the Directory Server does not start, then there are a number of potential causes.

The Server or Other Administrative Tool Is Already Running

Only a single instance of the Directory Server can run at any time from the same installation root. If an instance is already running, then subsequent attempts to start the server will fail. Similarly, some other administrative operations can also prevent the server from being started. In such cases, the attempt to start the server should fail with a message like:

```
The Directory Server could not acquire an exclusive lock on file
/ds/PingDirectory/locks/server.lock: The exclusive lock requested for file
/ds/PingDirectory/locks/ server.lock was not granted, which indicates
that another process already holds a shared or exclusive lock on that
file. This generally means that another instance of this server is already
running
```

If the Directory Server is not running (and is not in the process of starting up or shutting down) and there are no other tools running that could prevent the server from being started, and the server still believes that it is running, then it is possible that a previously-held lock was not properly released. In that case, you can try removing all of the files in the `locks` directory before attempting to start the server.

If you wish to have multiple instances running at the same time on the same system, then you should create a completely separate installation in another location on the file system.

There Is Not Enough Memory Available

When the Directory Server is started, the JVM attempts to allocate all memory that it has been configured to use. If there is not enough free memory available on the system, then the Directory Server generates an error message that indicates that the server could not be started with the specified set of arguments. Note that it is possible that an invalid option was provided to the JVM (as described below), but if that same set of JVM arguments has already been used successfully to run the server, then it is more likely that the system does not have enough memory available.

There are a number of potential causes for this:

- If the amount of memory in the underlying system has changed (for example, system memory has been removed, or if the Directory Server is running in a zone or other type of virtualized container and a change has been made to the amount of memory that container will be allowed to use), then the Directory Server might need to be re-configured to use a smaller amount of memory than had been previously configured.
- Another process running on the system is consuming a significant amount of memory so that there is not enough free memory available to start the server. If this is the case, then either terminate the other process to make more memory available for the Directory Server, or reconfigure the Directory Server to reduce the amount of memory that it attempts to use.
- The Directory Server was just shut down and an attempt was made to immediately restart it. In some cases, if the server is configured to use a significant amount of memory, then it can take a few seconds for all of the memory that had been in use by the server, when it was previously running, to be released back to the operating system. In that case, run the `vmstat` command and wait until the amount of free memory stops growing before attempting to restart the server.
- If the system is configured with one or more memory-backed file systems, verify whether any large files might be consuming a significant amount of memory in any of those locations. If so, remove them or relocate them to a disk-based file system.
- For Linux systems only, if a mismatch exists between the huge pages setting for the JVM and the huge pages reserved in the operating system.

If nothing else works and there is still not enough free memory to allow the JVM to start, then as a last resort, try rebooting the system.

An Invalid Java Environment or JVM Option Was Used

If an attempt to start the Directory Server fails with an error message indicating that no valid Java environment could be found, or indicates that the Java environment could not be started with the configured set of options, then you should first ensure that enough memory is available on the system as described above. If there is a sufficient amount of memory available, then other causes for this error can include the following:

- The Java installation that was previously used to run the server no longer exists (for example, an updated Java environment was installed and the old installation was removed). In that case, update the `config/java.properties` file to reference to path to the new Java installation and run the `bin/dsjavaproperties` command to apply that change.
- The Java installation used to run the server has been updated and the server is trying to use the correct Java installation but one or more of the options that had worked with the previous Java version no longer work with the new version. In that case, it is recommended that the server be re-configured to use the previous Java version, so that it can be run while investigating which options should be used with the new installation.
- If an `UNBOUNDID_JAVA_HOME` or `UNBOUNDID_JAVA_BIN` environment variable is set, then its value may override the path to the Java installation used to run the server as defined in the `config/java.properties` file. Similarly, if an `UNBOUNDID_JAVA_ARGS` environment variable is set, then its value might override the arguments provided to the JVM. If this is the case, then explicitly unset the `UNBOUNDID_JAVA_HOME`, `UNBOUNDID_JAVA_BIN`, and `UNBOUNDID_JAVA_ARGS` environment variables before trying to start the server.

Note that any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration. If a problem with the previous Java configuration prevents the `bin/dsjavaproperties` tool from running properly, then it can be necessary to remove the `lib/set-java-home` script (or `lib\set-java-home.bat` file on Microsoft Windows) and invoke the `bin/dsjavaproperties` tool with an explicitly-defined path to the Java environment, like:

```
env UNBOUNDID_JAVA_HOME=/ds/java bin/dsjavaproperties
```

An Invalid Command-Line Option Was Provided

There are a small number of arguments that are provided when running the `bin/start-server` command, but in most cases, none are required. If one or more command-line arguments were provided for the `bin/start-server` command and any of them is not recognized, then the server provides an error message indicating that an argument was not recognized and displays version information. In that case, correct or remove the invalid argument and try to start the server again.

The Server Has an Invalid Configuration

If a change is made to the Directory Server configuration using an officially-supported tool like `dsconfig` or the Administrative Console, the server should validate that configuration change before applying it. However, it is possible that a configuration change can appear to be valid at the time that it is applied, but does not work as expected when the server is restarted. Alternately, a change in the underlying system can cause a previously-valid configuration to become invalid.

In most cases involving an invalid configuration, the Directory Server displays (and writes to the error log) a message that explains the problem, and this can be sufficient to identify the problem and understand what action needs to be taken to correct it. If for some reason the startup failure does not provide enough information to identify the problem with the configuration, then look in the `logs/config-audit.log` file to see what recent configuration changes have been made with the server online, or in the `config/archived-configs` directory to see if there might have been a recent configuration change resulting from a direct change to the configuration file itself that was not made through a supported configuration interface.

If the server does not start as a result of a recent invalid configuration change, then it can be possible to start the server using the configuration that was in place the last time that the server started

successfully (for example, the "last known good" configuration). This can be achieved using the `--useLastKnownGoodConfig` option:

```
$ bin/start-server --useLastKnownGoodConfig
```

Note that if it has been a long time since the last time the server was started and a number of configuration changes have been made since that time, then the last known good configuration can be significantly out of date. In such cases, it can be preferable to manually repair the configuration.

If there is no last known good configuration, if the server no longer starts with the last known good configuration, or if the last known good configuration is significantly out of date, then manually update the configuration by editing the `config/config.ldif` file. In that case, you should make sure that the server is offline and that you have made a copy of the existing configuration before beginning. You might wish to discuss the change with your authorized support representative before applying it to ensure that you understand the correct change that needs to be made.

i Note: In addition to manually-editing the config file, you can look at previous achieved configurations to see if the most recent one works. You can also use the `ldif-diff` tool to compare the configurations in the archive to the current configuration to see what is different.

You Do Not Have Sufficient Permissions

The Directory Server should only be started by the user or role used to initially install the server. In most cases, if an attempt is made to start the server as a user or role other than the one used to create the initial configuration, then the server will fail to start, because the user will not have sufficient permissions to access files owned by the other user, such as database and log files. However, if the server was initially installed as a non-root user and then the server is started by the root account, then it can no longer be possible to start the server as a non-root user because new files that are created would be owned by root and could not be written by other users.

If the server was inadvertently started by root when it is intended to be run by a non-root user, or if you wish to change the user account that should be used to run the server, then it should be sufficient to simply change ownership on all files in the Directory Server installation, so that they are owned by the user or role under which the server should run. For example, if the Directory Server should be run as the "ds" user in the "other" group, then the following command can be used to accomplish this (invoked by the root user):

```
chown -R ds:other /ds/PingDirectory
```

The Server Has Crashed or Shut Itself Down

You can first check the current server state by using the `bin/server-state` command. If the Directory Server was previously running but is no longer active, then the potential reasons include the following:

- The Directory Server was shut down by an administrator. Unless the server was forcefully terminated (for example, using "kill -9"), then messages are written to the `error` and `server.out` logs explaining the reason for the shutdown.
- The Directory Server was shut down when the underlying system crashed or was rebooted. If this is the case, then running the `uptime` command on the underlying system shows that it was recently booted.
- The Directory Server process was terminated by the underlying operating system for some reason (for example, the out of memory killer on Linux). If this happens, then a message will be written to the system error log.
- The Directory Server decided to shut itself down in response to a serious problem that had arisen. At present, this should only occur if the server has detected that the amount of usable disk space has become critically low, or if significant errors have been encountered during processing that left the server without any remaining worker threads to process operations. If this happens, then messages are written to the `error` and `server.out` logs (if disk space is available) to provide the reason for the shutdown.

- The JVM in which the Directory Server was running crashed. If this happens, then the JVM should dump a fatal error log (a `hs_err_pid{processID}.log` file) and potentially a core file.

In the event that the operating system itself crashed or terminated the process, then you should work with your operating system vendor to diagnose the underlying problem. If the JVM crashed or the server shut itself down for a reason that is not clear, then contact your authorized support provider for further assistance.

Conditions for Automatic Server Shutdown

All PingDirectory Server servers will shutdown in an out of memory condition, a low disk space error state, or for running out of file descriptors. The Directory Server will enter lockdown mode on unrecoverable database environment errors, but can be configured to shutdown instead with this setting:

```
$ dsconfig set-global-configuration-prop \
    --set unrecoverable-database-error-mode:initiate-server-shutdown
```

The Server Will Not Accept Client Connections

You can first check the current server state by using the `bin/server-state` command. If the Directory Server does not appear to be accepting connections from clients, then potential reasons include the following:

- The Directory Server is not running.
- The underlying system on which the Directory Server is installed is not running.
- The Directory Server is running but is not reachable as a result of a network or firewall configuration problem. If that is the case, then connection attempts should time out rather than be rejected.
- If the Directory Server is configured to allow secure communication via SSL or StartTLS, then a problem with the key manager and/or trust manager configuration can cause connections to be rejected. If that is the case, then messages should be written to the server access log for each failed connection attempt.
- If the Directory Server has been configured with a maximum allowed number of connections, then it can be that the maximum number of allowed client connections are already established. If that is the case, then messages should be written to the server access log for each rejected connection attempt.
- If the Directory Server is configured to restrict access based on the address of the client, then messages should be written to the server access log for each rejected connection attempt.
- If a connection handler encounters a significant error, then it can stop listening for new requests. If this occurs, then a message should be written to the server error log with information about the problem. Another solution is to restart the server. A third option is to restart the connection handler using the LDIF connection handler to make it available again. To do this, create an LDIF file that disables and then re-enables the connection handler, create the `config/auto-process-ldif` directory if it does not already exist, and then copy the LDIF file into it.

The Server is Unresponsive

You can first check the current server state by using the `bin/server-state` command. If the Directory Server process is running and appears to be accepting connections but does not respond to requests received on those connections, then potential reasons for this behavior include:

- If all worker threads are busy processing other client requests, then new requests that arrive will be forced to wait in the work queue until a worker thread becomes available. If this is the case, then a stack trace obtained using the `jstack` command shows that all of the worker threads are busy and none of them are waiting for new requests to process.

A dedicated thread pool can be used for processing administrative operations. This thread pool enables diagnosis and corrective action if all other worker threads are processing operations. To request that operations use the administrative thread pool, using the `ldapsearch` command for example, use the `--useAdministrativeSession` option. The requester must have the `use-admin-session` privilege (included for root users). By default, eight threads are available for this purpose. This can be

changed with the `num-administrative-session-worker-threads` property in the work queue configuration.

Note: If all of the worker threads are tied up processing the same operation for a long time, the server will also issue an alert that it might be deadlocked, which may not actually be the case. All threads might be tied up processing unindexed searches.

- If a request handler is stuck performing some expensive processing for a client connection, then other requests sent to the server on connections associated with that request handler is forced to wait until the request handler is able to read data on those connections. If this is the case, then only some of the connections can experience this behavior (unless there is only a single request handler, in which it will impact all connections), and stack traces obtained using the `jstack` command shows that a request handler thread is continuously blocked rather than waiting for new requests to arrive. Note that this scenario is a theoretical problem and one that has not appeared in production.
- If the JVM in which the Directory Server is running is not properly configured, then it can be forced to spend a significant length of time performing garbage collection, and in severe cases, could cause significant interruptions in the execution of Java code. In such cases, a stack trace obtained from a `pstack` of the native process should show that most threads are idle but at least one thread performing garbage collection is active. It is also likely that one or a small number of CPUs is 100% busy while all other CPUs are mostly idle. The server will also issue an alert after detecting a long JVM pause (due to garbage collection). The alert will include details of the pause.
- If the JVM in which the Directory Server is running has hung for some reason, then the `pstack` utility should show that one or more threads are blocked and unable to make progress. In such cases, the system CPUs should be mostly idle.
- If a network or firewall configuration problem arises, then attempts to communicate with the server cannot be received by the server. In that case, a network sniffer like `snoop` or `tcpdump` should show that packets sent to the system on which the Directory Server is running are not receiving TCP acknowledgement.
- If the system on which the Directory Server is running has become hung or lost power with a graceful shutdown, then the behavior is often similar to that of a network or firewall configuration problem.

If it appears that the problem is with the Directory Server software or the JVM in which it is running, then you need to work with your authorized support provider to fully diagnose the problem and determine the best course of action to correct it.

The Server is Slow to Respond to Client Requests

If the Directory Server is running and does respond to clients, but clients take a long time to receive responses, then the problem can be attributable to a number of potential problems. In these cases, use the Periodic Stats Logger, which is a valuable tool to get per-second monitoring information on the Directory Server. The Periodic Stats Logger can save the information in csv format for easy viewing in a spreadsheet. For more information, see "Profiling Server Performance Using the Periodic Stats Logger". The potential problems that cause slow responses to client requests are as follows:

- The server is not optimally configured for the type of requests being processed, or clients are requesting inefficient operations. If this is the case, then the access log should show that operations are taking a long time to complete and they will likely be unindexed. In that case, updating the server configuration to better suit the requests, or altering the requests to make them more efficient, could help alleviate the problem. In this case, view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second. You can also run the `bin/status` command or view the status in the Administrative Console to see the Directory Server's Work Queue information (also see the next bullet point).
- The server is overwhelmed with client requests and has amassed a large backlog of requests in the work queue. This can be the result of a configuration problem (for example, too few worker thread configured), or it can be necessary to provision more systems on which to run the Directory Server software. Symptoms of this problem appear similar to those experienced when the server is asked to process inefficient requests, but looking at the details of the requests in the access log show that they are not necessarily inefficient requests. Run the `bin/status` command to view the Work Queue

information. If everything is performing well, you should not see a large queue size or a server that is near 100% busy. The %Busy statistic is calculated as the percentage of worker threads that are busy processing operations.

```

--- Work Queue ---
: Recent : Average : Maximum
-----:-----:-----:-----
Queue Size : 10 : 1 : 10
% Busy      : 17 : 14 : 100

```

You can also view the expensive operations access log in `logs/expensive-ops`, which by default logs operations that take longer than 1 second.

- The server is not configured to fully cache all of the data in the server, or the cache is not yet primed. In this case, `iostat` reports a very high disk utilization. This can be resolved by configuring the server to fully cache all data, and to load database contents into memory on startup. If the underlying system does not have enough memory to fully cache the entire data set, then it might not be possible to achieve optimal performance for operations that need data which is not contained in the cache. For more information, see [Disk-Bound Deployments](#).
- If the JVM is not properly configured, then it will need to perform frequent garbage collection and periodically pause execution of the Java code that it is running. In that case, the server error log should report that the server has detected a number of pauses and can include tuning recommendations to help alleviate the problem.
- If the Directory Server is configured to use a large percentage of the memory in the system, then it is possible that the system has gotten low on available memory and has begun swapping. In this case, `iostat` should report very high utilization for disks used to hold swap space, and commands like `cat /proc/meminfo` on Linux can report a large amount of swap memory in use. Another cause of swapping is if `swappiness` is not set to 0 on Linux. For more information, see [Disable File System Swapping](#).
- If another process on the system is consuming a significant amount of CPU time, then it can adversely impact the ability of the Directory Server to process requests efficiently. Isolating the processes (for example, using processor sets) or separating them onto different systems can help eliminate this problem.

The Server Returns Error Responses to Client Requests

If a large number of client requests are receiving error responses, then view the `logs/failed-ops` log, which is an access log for only failed operations. The potential reasons for the error responses include the following:

- If clients are requesting operations that legitimately should fail (for example, they are targeting entries that do not exist, are attempting to update entries in a way that would violate the server schema, or are performing some other type of inappropriate operation), then the problem is likely with the client and not the server.
- If a portion of the Directory Server data is unavailable (for example, because an online LDIF import or restore is in progress), then operations targeting that data will fail. Those problems will be resolved when the backend containing that data is brought back online. During the outage, it might be desirable to update proxies or load balancers or both to route requests away from the affected server. As of Directory Server version 3.1 or later, the Directory Server will indicate that it is in a degraded status and the Directory Proxy Server will route around it.
- If the Directory Server work queue is configured with a maximum capacity and that capacity has been reached, then the server begins rejecting all new requests until space is available in the work queue. In this case, it might be necessary to alter the server configuration or the client requests or both, so that they can be processed more efficiently, or it might be necessary to add additional server instances to handle some of the workload.
- If an internal error occurs within the server while processing a client request, then the server terminates the connection to the client and logs a message about the problem that occurred. This should not happen under normal circumstances, so you will need to work with your authorized support provider to diagnose and correct the problem.

- If a problem is encountered while interacting with the underlying database (for example, an attempt to read from or write to disk failed because of a disk problem or lack of available disk space), then it can begin returning errors for all attempts to interact with the database until the backend is closed and reopened and the database has been given a change to recover itself. In these cases, the `je.info.*` file in the database directory should provide information about the nature of the problem.

The Server Must Disconnect a Client Connection

If a client connection must be disconnected due to the expense of the client's request, such as an unindexed search across a very large database, perform the following:

- Find the client's connection ID by looking in the `cn=Active Operations,cn=monitor monitor` entry.

```
$ bin/ldapsearch -baseDN cn=monitor "cn=active operations" \
  --bindDN "cn=directory manager" \
  --bindPassword password
```

- The monitor entry will contain attribute values for `operation-in-progress`, which look like an access log message. Look for the value of `conn` in the client request that should be disconnected. In the following example, the client to be disconnected is requesting a search for `(description=expensive)`, which is on connection 6.

```
dn: cn=Active Operations,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-active-operations-monitor-entry
objectClass: extensibleObject
cn: Active Operations
num-operations-in-progress: 2
operation-in-progress: [15/Dec/2014:10:55:35 -0600] SEARCH conn=6 op=3
msgID=4
  clientIP="10.8.4.21" authDN="cn=app1,ou=applications,dc=example,dc=com"
  base="dc=example,dc=com" scope=wholeSubtree filter="(description=expensive)"
  attrs="A
    LL" unindexed=true
operation-in-progress: [15/Dec/2014:10:56:11 -0600] SEARCH conn=7 op=1
msgID=2
  clientIP="127.0.0.1" authDN="cn=Directory Manager,cn=Root
  DNs,cn=config" base="cn=monitor" scope=wholeSubtree filter="(cn=active operations)"
  attrs="ALL"
  num-persistent-searches-in-progress: 0
```

- With the connection ID value, create a file with the following contents, named `disconnect6.ldif`.

```
dn: ds-task-id=disconnect6,cn=scheduled Tasks,cn=tasks
objectClass: top
objectClass: ds-task
objectClass: ds-task-disconnect
ds-task-disconnect-connection-id: 6
ds-task-id: disconnect6
ds-task-class-name:
  com.unboundid.directory.server.tasks.DisconnectClientTask
```

- This LDIF file represents a task entry. The connection ID value 6 is assigned to `ds-task-disconnect-connection-id`. The value for `ds-task-id` value does not follow a specific convention. It must be unique among other task entries currently cached by the server.
- Disconnect the client and cancel the associated operation by adding the task entry to the server:

```
$ bin/ldapmodify --filename disconnect6.ldif \
  --defaultAdd --bindDN "cn=directory manager" \
  --bindPassword password
```

The Server is experiencing problems with replication

If replication does not appear to be functioning properly, then first check the `dsreplication status` command, which shows all of the servers that are replicating and whether they are back-logged or not. Next, you can check the server error log, replication repair log, and replication monitor entries may provide information about the nature of the underlying problem. Potential reasons that replication may not be functioning as expected include the following:

- Replication has not yet been configured between systems or has been disabled.
- If a server has been offline for a period of time or has fallen far enough behind such that it is missing changes, which are no longer present in any of the replication databases, then that server must be re-initialized with an up-to-date copy of the data from another server.
- If the environment is comprised of a heterogeneous set of systems, then it is possible that some of the systems might not be able to keep up with the maximum throughput achieved by other servers in the topology. In such cases, the slower servers might not be fast enough to remain in sync with the other servers in the environment.
- If the environment contains systems in multiple data centers and the network links between the data centers are insufficient for the volume of changes that must be processed, then servers might not be able to remain in sync under a high volume of changes.
- A network or firewall configuration problem has arisen, which prevents or interferes with communication between servers.
- An internal problem within the server has caused replication to stop functioning properly. The Directory Server logs the event in the error log in this case. Run the `collect-support-data` tool, so that the details of the problems can be passed to your authorized support provider. Then, try restarting the Directory Server.

How to Regenerate the Server ads-certificate

At setup time, the server generates a private key and certificate for use when secure communication between servers is required. This certificate, `ads-certificate`, is stored in `config/ads-truststore` and should typically remain unchanged for the life of the server deployment. If the need arises for a new `ads-certificate` to be created, say because the server-root has been copied to a new host, then the private key and certificate will be recreated by the startup process if the `config/ads-truststore` and `config/ads-truststore.pin` files are first manually removed while the server is offline. Note that if replication is enabled, the server must have replication disabled before regeneration of the `ads-certificate`.

For example, the Directory Server allows easy copying of its installation, which can then be used to install another server instance. If a server (`ldap1.example.com:389`) is enabled with its own copy (`ldap2.example.com:389`), `dsreplication` will exit with the following error message:

```
Replication cannot be enabled between servers ldap1.example.com:389 and
  ldap2.example.com:389
because they are using the same instance key.
```

The solution is to stop the server, remove `config/adstruststore` and `config/adstruststore.pin` and re-start the server. Upon startup, a new `adstruststore`, containing the server's instance key, will be generated. Then, you can re-run `dsreplication enable` to set up replication between the two servers.

The Server behaves differently from Sun/Oracle

After migrating from a Sun/Oracle configuration to a PingDirectory Server, follow the tuning procedures in [Sun/Oracle Compatibility](#) if the Directory Server behaves differently from the Sun/Oracle server.

Troubleshooting ACI Evaluation

The Directory Server provides the ability to collect debug information related to ACI evaluation for any operation by enabling the Debug ACI Logger. The Debug ACI Logger is highly configurable and can be scoped to trace very specific request operations in order to narrow on any ACI issue that may arise in the field. Parameters for non-request operations, such as `log-connects`, `log-disconnects`, `log-security-negotiation`, `log-results`, `log-assurance-completed`, `log-search-entries`, `log-`

`search-references`, `log-intermediate-responses` are set to `false` by default and should remain so.

Here is an example to enable the Debug ACI Logger:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set enabled:true
```

Using this debug tracer is often more efficient by limiting the output using request and result criteria to match specific types of operations. An example result criteria for operations that fail due to insufficient access rights can be added to the logger as follows:

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "Debug ACI Logger" \
  --set "result-criteria:Insufficient Access Rights"
```

Once the logger is enabled, all matching operations begin writing ACI evaluation traces to the log file. The amount of information is quite large for each evaluation that is done. However, this information is useful if there is an ACI issue that is difficult to resolve. Most operations result in multiple "ACI DEBUG" traces in the log, since it usually requires multiple ACI rights to perform an operation, each of which requires a separate evaluation. In particular, you can expect a lot of debug tracing when dealing with ACIs for controls, extended operations, and proxied authorization.

The ACI DEBUG traces contain the following pieces of information:

- **Operation.** Specifies a dump of the operation object that you can use to correlate to the original request operation.
- **ACI Container.** Specifies the context of the ACI evaluation being performed.
 - **Client Entry.** Specifies an LDIF dump of the client request access.
 - **Resource Entry.** Specifies an LDIF dump of the target resource.
 - **isProxiedAuth.** Specifies if the client is attempting to proxy as another user.
 - **Original Auth.** Specifies the original client DN if authorization is currently via the proxy.
 - **Rights.** Specifies a list of the ACI rights being requested on the resource entry.
 - **Control.** Specifies the OIDs when evaluating ACIs for a control.
 - **ExtOp.** Specifies the OIDs when evaluating ACIs for an extended operation.
- **ACI Candidates.** Specifies a list of all the ACIs known to this operation, sorted by origin.
- **Applicable ACIs.** Specifies a list of ACIs relevant to the current evaluation. These ACIs are separated by type into "Denies" and "Allows".
- **Deny ACI Evaluations.** Specifies the results of evaluating each "deny" ACI. If any of these evaluate to TRUE, then the operation will be denied.
- **Allow ACI Evaluations.** Specifies the results of evaluating each "allow" ACI. At least one of these must evaluate to "TRUE" or the operation will be denied.

For users with the `bypass-acl` privilege, the Debug ACI Logger will not provide any ACI debug tracing since evaluations are not done for those operations. However, you will see the following trace if you have ACI debugging enabled (`debug-aci-enabled` is set to TRUE) for those operations:

```
Bypassing ACL Evaluation for Operation
```

To avoid unnecessary tracing of these operations, the "Debug ACI Logger" uses a "Client Connection Criteria" called "Clients subject to Access Control" that excludes requests from users with the `bypass-acl` privilege. It is recommended that you create and use your own criteria which specifically targets the clients that you are trying to debug in order to make analyzing the tracing output easier.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Restricted Clients" \
  --type simple \
```

```
--set none-included-user-privilege:bypass-acl
```

Note: Do not use Result Criteria with the Debug ACI Logger. Result criteria is evaluated after ACIs, so it will not be taken into consideration for this type of debugging.

Problems with the Administrative Console

If a problem arises when trying to use the Administrative Console, then potential reasons for the problem may include the following:

- The web application container used to host the console is not running. If an error occurs while trying to start it, then consult the logs for the web application container.
- If a problem occurs while trying to authenticate to the web application container, then make sure that the target Directory Server is online. If it is online, then the access log may provide information about the reasons for the authentication failure.
- If a problem occurs while attempting to interact with the Directory Proxy Server instance using the Administrative Console, then the access and error logs for that Directory Server instance might provide additional information about the underlying problem.

Problems with the Administrative Console: JVM Memory Issues

Console runs out of memory (PermGen). An inadequate PermSize setting in the server, while hosting web applications like the Administrative Console may result in errors like this in the error log:

```
[02/Mar/2016:07:50:27.017 -0600] threadID=2 category=UTIL
severity=SEVERE_ERROR msgID=-1 msg="The server experienced an unexpected
error. Please report this problem and include this log file.
OutOfMemoryError: PermGen space
() \ncom.unboundid.directory.server.core.DirectoryServer.uncaughtException
(DirectoryServer.java:15783) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1057) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.ThreadGroup.uncaughtException
(ThreadGroup.java:1052) \njava.lang.Thread.dispatchUncaughtException
(Thread.java:1986) \nBuild revision: 22496\n"
```

This is only relevant for servers running Java 7.

Problems with the HTTP Connection Handler

When problems with the HTTP Connection Handler occur, first look at the HTTP connection handler log to diagnose the issue. The following section shows HTTP log examples when various errors occur.

- **Failed Request Due to a Non-Existent Resource.** The server receives a status code 404, which indicates the server could not match the URI.

```
[15/Mar/2012:17:39:39 -0500] RESULT requestID=0 from="10.2.1.113:52958"
method="GET" url="https://10.2.1.113:443/Aleph/Users/uid=user.1,ou=people,
dc=example,dc=com" requestHeader="Host: x2270-11.example.lab"
requestHeader="Accept: */*" requestHeader="User-Agent: curl/7.21.6
(i386-pc-centos2.10) libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.22
libssh2/1.2.7" authorizationType="Basic" statusCode=404 etime=81.484
responseContentLength=103 responseHeader="Access-Control-Allow-
Credentials:true"
responseContentType="application/json"
```

- **Failed Request due to a Malformed Request Body.** The server receives a status code 400, which indicates that the request had a malformed syntax in its request body.

```
[15/Mar/2012:17:47:23-0500] RESULT requestID=10 from="10.2.1.113:55284"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:
x2270-11.example.lab" requestHeader="Expect: 100-continue"
requestHeader="Accept: */*" requestHeader="Content-Type: application/json"
requestHeader="User-Agent: curl/ 7.21.6 (i386-pc-centos2.10) libcurl/7.21.6"
```

```
OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2 libssh2/1.2.7"
  authorizationType="Basic"
requestContentType="application/json" requestContentLength=5564
  statusCode=400
etime=15.272 responseContentLength=133 responseContentType="application/
json"
```

- **Failed Request due to an unsupported HTTP method.** The server receives a status code 405, which indicates that the specified method (e.g., "PATCH") in the request line is not allowed for the resource identified in the URI.

```
[15/Mar/2012:17:48:59-0500] RESULT requestID=11 from="10.2.1.113:55763"
method="PATCH" url="https://10.2.1.113:443/Aleph/Users"
  requestHeader="Host:
x2270-11.example.lab" requestHeader="Accept: */*" requestHeader="Content-
Type:
application/json" requestHeader="User-Agent: curl/7.21.6 (i386-pc-
centos2.10)
libcurl/7.21.6 OpenSSL/1.0.0d zlib/1.2.5 libidn/1.2.2 libssh2/1.2.7"
authorizationType="Basic" requestContentType="application/json"
  statusCode=405
etime=6.807 responseContentLength=0 responseHeader="Allow: POST, GET,
OPTIONS, HEAD"
```

- **Failed Request due to an Unsupported Media Type.** The server receives a status code 415, which indicates that the request entity is in a format that is not supported by the requested resource.

```
[15/Mar/2012:17:44:45-0500] RESULT requestID=4 from="10.2.1.113:54493"
method="POST" url="https://10.2.1.113:443/Aleph/Users" requestHeader="Host:

responseContentType="application/json"
```

Virtual Process Size on RHEL6 Linux is Much Larger than the Heap

Red Hat Linux introduced a change in glib 2.11 that creates larger per-thread address spaces aligned at 64MB. This change results in a virtual process size much larger than those seen in previous versions of `glibc`. This is not considered a bug by RedHat, as noted in https://bugzilla.redhat.com/show_bug.cgi?id=640286, and does not affect the physical memory needed by the server process. To see the version of `glibc` on your system, use the command `yum info glibc`.

Providing Information for Support Cases

If a problem arises that you are unable to fully diagnose and correct on your own, then contact your authorized support provider for assistance. To ensure that the problem can be addressed as quickly as possible, be sure to provide all of the information that the support personnel may need to fully understand the underlying cause by running the `collect-support-data` tool, and then sending the generated zip file to your authorized support provider. It is good practice to run this tool and send the ZIP file to your authorized support provider before any corrective action has taken place.

Command-Line Tools

The PingDirectory Server provides a full suite of command-line tools necessary to administer the server. The command-line tools are available in the `bin` directory for UNIX or Linux systems and `bat` directory for Microsoft Windows systems.

This chapter presents the following topics:

Using the Help Option

Each command-line utility provides a description of the subcommands, arguments, and usage examples needed to run the tool. You can view detailed argument options and examples by typing `--help` with the command.

```
bin/dsconfig --help
```

For those utilities that support additional subcommands (for example, `dsconfig`), you can get a list of the subcommands by typing `--help-subcommands`.

```
bin/dsconfig --help-subcommands
```

You can also get more detailed subcommand information by typing `--help` with the specific subcommand.

```
bin/dsconfig list-log-publishers --help
```

Note: For detailed information and examples of the command-line tools, see the *Ping Identity Directory Server Command-Line Tool Reference*.

Available Command-Line Utilities

The Directory Server provides the following command-line utilities, which can be run directly in interactive, non-interactive, or script mode.

Command-Line Utilities

Command-Line Tools	Description
audit-data-security	Performs an internal task that examines all or a subset of entries in the server, writing a series of reports on potential risks with the data. Reports are written to the output directory organized by backend name and audit items.
authrate	Perform repeated authentications against the Directory Server, where each authentication consists of a search to find a user followed by a bind to verify the credentials for that user.

Command-Line Tools	Description
backup	Run full or incremental backups on one or more directory server backends. This utility also supports the use of a properties file to pass predefined command-line arguments. See Managing the tools.properties File for more information.
base64	Encode raw data using the base64 algorithm or decode base64-encoded data back to its raw representation.
collect-support-data	Collect and package system information useful in troubleshooting problems. The information is packaged as a ZIP archive that can be sent to a technical support representative.
config-diff	Generate a summary of the configuration changes in a local or remote server instance. The tool can be used to compare configuration settings when troubleshooting issues, or when verifying configuration settings on new servers.
create-rc-script	Create a Run Control (RC) script that may be used to start, stop, and restart the Directory Server on UNIX-based systems.
create-recurring-task	Create a recurring task to run on the server. Tasks can be created for backups, LDIF exports, a statically defined task, or a third-party task.
create-recurring-task-chain	Create a chain of recurring tasks to run on the server.
dbtest	Inspect the contents of Directory Server backends that store their information in Oracle® Berkeley DB Java Edition databases.
deliver-one-time-password	Submit a "deliver one-time password" extended request, OID 1.3.6.1.4.1.30221.2.6.24, to the server which results in the generation of a one-time password which is delivered out-of-band to the specified user. This tool can be used to test the UNBOUNDID-DELIVERED-OTP SASL mechanism.
dsconfig	View and edit the Directory Server configuration.
dsjavaproperties	Configure the JVM arguments used to run the Directory Server and associated tools. Before launching the command, edit the properties file located in <code>config/java.properties</code> to specify the desired JVM options and <code>JAVA_HOME</code> environment variable.
dsreplication	Manage data replication between two or more Directory Server instances.
dump-dns	Obtain a listing of all of the DNs for all entries below a specified base DN in the Directory Server.
encode-password	Encode user passwords with a specified storage scheme or determine whether a given clear-text value matches a provided encoded password.
encryption-settings	Manage the server encryption settings database.
enter-lockdown-mode	Request that the Directory Server enter lockdown mode, during which it only processes operations requested by users holding the <code>lockdown-mode</code> privilege.
export-ldif	Export data from the Directory Server backend in LDIF form.
identify-references-to-missing-entries	Identify entries containing one or more attributes that reference entries that do not exist. This may require the ability to perform unindexed searches and/or the ability to use the simple paged results control.

Command-Line Tools	Description
identify-unique-attribute-conflicts	Identify unique attribute conflicts. The tool may identify values of one or more attributes that are supposed to exist only in a single entry but are found in multiple entries.
import-ldif	Import LDIF data into the Directory Server backend.
ldap-diff	Compare the contents of two LDAP servers.
ldap-result-code	Display and query LDAP result codes.
ldapcompare	Perform LDAP compare operations in the Directory Server.
ldapdelete	Perform LDAP delete operations in the Directory Server.
ldapmodify	Perform LDAP modify, add, delete, and modify DN operations in the Directory Server.
ldappasswordmodify	Perform LDAP password modify operations in the Directory Server.
ldapsearch	Perform LDAP search operations in the Directory Server.
ldif-diff	Compare the contents of two LDIF files, the output being an LDIF file needed to bring the source file in sync with the target.
ldifmodify	Apply a set of modify, add, and delete operations against data in an LDIF file.
ldifsearch	Perform search operations against data in an LDIF file.
leave-lockdown-mode	Request that the Directory Server leave lockdown mode and resume normal operation.
list-backends	List the backends and base DN's configured in the Directory Server.
make-ldif	Generate LDIF data based on a definition in a template file.
manage-account	Access and alter password policy state properties for user entries.
manage-extension	Install or update extension bundles. An extension bundle is a package of extension(s) that utilize the Server SDK to extend the functionality of the PingDirectory Server. Extension bundles are installed from a zip archive or file system directory. PingDirectory Server will be restarted if running to activate the extension(s).
manage-tasks	Access information about pending, running, and completed tasks scheduled in the Directory Server.
migrate-ldap-schema	Migrate schema information from an existing LDAP server into a PingDirectory Server instance.
migrate-sun-ds-config	Update an instance of the PingDirectory Server to match the configuration of an existing Sun Java System 5.x, 6.x, or 7.x directory instance.
modrate	Perform repeated modifications against a Directory Server.
move-subtree	Move a subtree entries or a single entry from one server to another.
parallel-update	Perform add, delete, modify, and modify DN operations concurrently using multiple threads.
profile-viewer	View information in data files captured by the Directory Server profiler.

Command-Line Tools	Description
re-encode-entries	Initiate a task that causes a local DB backend to re-encode all or a specified subset of the entries that it contains. The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend (e.g., to apply encoding changes if a feature like data encryption or uncached attributes or entries is enabled).
rebuild-index	Rebuild index data within a backend based on the Berkeley DB Java Edition. Note that this tool uses different approaches to rebuilding indexes based on whether it is running in online mode (as a task) rather than in offline mode. Running in offline mode will often provide significantly better performance. Also note that running in online mode will prevent the server from using that index while the rebuild is in progress, so some searches may behave differently while a rebuild is active than when it is not.
remove-backup	Safely remove a backup and optionally all of its dependent backups from the specified Directory Server backend.
restore	Restore a backup of the Directory Server backend.
revert-update	Returns a server to the version before the last update was performed.
review-license	Review and/or indicate your acceptance of the product license.
scramble-ldif	Obscure the contents of a specified set of attributes in an LDIF file.
search-and-mod-rate	Perform repeated searches against an LDAP directory server and modify each entry returned.
searchrate	Perform repeated searches against an LDAP directory server.
server-state	View information about the current state of the Directory Server process.
setup	Perform the initial setup for the Directory Server instance.
start-server	Start the Directory Server.
status	Display basic server information.
stop-server	Stop or restart the Directory Server.
subtree-accessibility	List or update the a set of subtree accessibility restrictions defined in the Directory Server.
sum-file-sizes	Calculate the sum of the sizes for a set of files.
summarize-access-log	Generate a summary of one or more access logs to display a number of metrics about operations processed within the server.
uninstall	Uninstall the Directory Server.
update	Update the Directory Server to a newer version by downloading and unzipping the new server install package on the same host as the server you wish to update. Then, use the <code>update</code> tool from the new server package to update the older version of the server. Before upgrading a server, you should ensure that it is capable of starting without severe or fatal errors. During the update process, the server is stopped if running, then the update is performed, and a check is made to determine if the newly updated server starts without major errors. If it cannot start cleanly, the update will be backed out and the server returned to its prior state. See the <code>revert-update</code> tool for information on reverting an update.

Command-Line Tools	Description
validate-acis	Validates a set of access control definitions contained in an LDAP server (including Sun/Oracle DSEE instances) or an LDIF file to determine whether they are acceptable for use in the Directory Server. Note that the output generated by this tool will be in LDIF format, but each entry in the output will have exactly one ACI, so entries that have more than one ACI will appear multiple times in the output with different ACI values.
validate-file-signature	Validate the signature information in a signed text file, such as a signed log file or a signed LDIF export.
validate-ldif	Validate the contents of an LDIF file against the server schema.
verify-index	Verify that indexes in a backend using the Oracle Berkeley DB Java Edition are consistent with the entry data contained in the database.

Managing the tools.properties File

The PingDirectory Server supports the use of a tools properties file that simplifies command-line invocations by reading in a set of arguments for each tool from a text file. Each property is in the form of name/value pairs that define predetermined values for a tool's arguments. Properties files are convenient when quickly testing the Directory Server in multiple environments.

The Directory Server supports two types of properties file: default properties files that can be applied to all command-line utilities or tool-specific properties file that can be specified using the `--propertiesFilePath` option. You can override all of the Directory Server's command-line utilities with a properties file using the `config/tools.properties` file.

Creating a Tools Properties File

You can create a properties file with a text editor by specifying each argument, or option, using standard Java properties file format (name=value). For example, you can create a simple properties file that define a set of LDAP connection parameters as follows:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
baseDN=dc=example,dc=com
```

Next, you can specify the location of the file using the `--propertiesFilePath /path/to/ File` option with the command-line tool. For example, if you save the previous properties file as `bin/mytool.properties`, you can specify the path to the properties file with `ldapsearch` as follows:

```
$ bin/ldapsearch --propertiesFilePath bin/mytools.properties "(objectclass=*)"
```

Properties files do not allow quotation marks of any kind around values. Any spaces or special characters should be escaped. For example,

```
bindDN=cn=QA\ Managers,ou=groups,dc=example,dc=com
```

The following is not allowed as it contains quotation marks:

```
bindDN=cn="QA Managers,ou=groups,dc=example,dc=com"
```

Tool-Specific Properties

The Directory Server also supports properties for specific tool options using the format: `tool.option=value`. Tool-specific options have precedence over general options. For example, the

following properties file uses `ldapsearch.port=2389` for `ldapsearch` requests by the client. All other tools that use the properties file uses `port=1389`.

```
hostname=server1.example.com
port=1389
ldapsearch.port=2389
bindDN=cn=Directory\ Manager
```

Another example using the `dsconfig` configuration tool is as follows:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
dsconfig.bindPasswordField=/ds/config/password
```

Note: The `.bindPasswordField` property requires an absolute path. If you were to specify `~/ds/config/password`, where `~` refers to the home directory, the server does not expand the `~` value when read from the properties file.

Specifying Default Properties Files

The Directory Server provides default properties files that apply to all command-line utilities used in client requests. A default properties file, `tools.properties`, is located in the `<server-root>/config` directory.

If you place a custom properties file that has a different file name as `tools.properties` in this default location, specify the path by using the `--propertiesFilePath` option. If you make changes to the `tools.properties` file, you do not need the `--propertiesFilePath` option. See the examples in the next section.

Evaluation Order Summary

The Directory Server uses the following evaluation ordering to determine options for a given command-line utility:

- All options used with a utility on the command line takes precedence over any options in any properties file.
- If the `--propertiesFilePath` option is used with no other options, the Directory Server takes its options from the specified properties file.
- If no options are used on the command line including the `--propertiesFilePath` option (and `--noPropertiesFile`), the Directory Server searches for the `tools.properties` file at `<server-root>`
- If no default properties file is found and a required option is missing, the tool generates an error.
- Tool-specific properties (for example, `ldapsearch.port=3389`) have precedence over general properties (for example, `port=1389`).

Evaluation Order Example

Given the following properties file that is saved as `<server-root>/bin/tools.properties`:

```
hostname=server1.example.com
port=1389
bindDN=cn=Directory\ Manager
bindPassword=secret
```

The Directory Server locates a command-line option in a specific priority order.

1. All options presented with the tool on the command line take precedence over any options in any properties file. In the following example, the client request is run with the options specified on the

command line (port and baseDN). The command uses the `bindDN` and `bindPassword` arguments specified in the properties file.

```
$ bin/ldapsearch --port 2389 --baseDN ou=People,dc=example,dc=com \
  --propertiesFilePath bin/tools.properties "(objectclass=*)" "
```

- Next, if you specify the properties file using the `--propertiesFilePath` option and no other command-line options, the Directory Server uses the specified properties file as follows:

```
$ bin/ldapsearch --propertiesFilePath bin/tools.properties \
  "(objectclass=*)" "
```

- If no options are presented with the tool on the command line and the `--noPropertiesFile` option is not present, the Directory Server attempts to locate any default `tools.properties` file in the following location:

```
<server-root>/config/tools.properties
```

Assume that you move your `tools.properties` file from `<server-root>/bin` to the `<server-root>/config` directory. You can then run your tools as follows:

```
$ bin/ldapsearch "(objectclass=*)" "
```

The Directory Server can be configured so that it does not search for a properties file by using the `--noPropertiesFile` option. This option tells the Directory Server to use only those options specified on the command line. The `--propertiesFilePath` and `--noPropertiesFile` options are mutually exclusive and cannot be used together.

- If no default `tools.properties` file is found and no options are specified with the command-line tool, then the tool generates an error for any missing arguments.

Running Task-based Utilities

The Directory Server has a Tasks subsystem that allows you to schedule basic operations, such as backup, restore, `bin/start-server`, and others. All task-based utilities require the `--task` option that explicitly indicates the utility is intended to run as a task rather than in offline mode. The following table shows the arguments that can be used for task-based operations:

Task-based Utilities

Option	Description
<code>--task</code>	Indicates that the tool is invoked as a task. The <code>--task</code> argument is required. If a tool is invoked as a task without this <code>--task</code> argument, then a warning message will be displayed stating that it must be used. If the <code>--task</code> argument is provided but the tool was not given the appropriate set of authentication arguments to the server, then an error message will be displayed and the tool will exit with an error.
<code>--start</code>	Indicates the date and time, expressed in the format 'YYYYMMDDhhmmss', when the operation starts when scheduled as a server task. A value of '0' causes the task to be scheduled for immediate execution. When this option is used, the operation is scheduled to start at the specified time, after which this utility will exit immediately.
<code>--dependency</code>	Specifies the ID of a task upon which this task depends. A task will not start execution until all its dependencies have completed execution. This option can be used multiple times in a single command.

Option	Description
--failedDependencyAction	Specifies the action this task will take should one of its dependent tasks fail. The value must be one of the following: <code>PROCESS</code> , <code>CANCEL</code> , <code>DISABLE</code> . If not specified, the default value is <code>CANCEL</code> . This option can be used multiple times in a single command.
--completionNotify	Specifies the email address of a recipient to be notified when the task completes. This option can be used multiple times in a single command.
--errorNotify	Specifies the email address of a recipient to be notified if an error occurs when this task executes. This option can be used multiple times in a single command.

Introduction

PingDirectoryProxy™ Server is a fast and scalable LDAPv3 gateway for the PingDirectory® Server. The Directory Proxy Server architecture can be configured to control how client requests are routed to backend servers.

This chapter provides an overview of the Directory Proxy Server features and components. It contains the following sections:

Overview of the PingDirectoryProxy Server Features

The PingDirectoryProxy Server is a fast, scalable, and easy-to-use LDAP proxy server that provides high availability and additional security for the PingDirectory Server, while remaining largely invisible to client applications. From a client perspective, request processing is the same, whether communicating with the Directory Server directly or going through the Directory Proxy Server.

The PingDirectoryProxy Server provides the following set of features:

- **High availability.** The Directory Proxy Server allows you to transparently fail over between servers if a problem occurs, as well as ensuring that the workload is balanced across the topology. If a client does not support following referrals, the Directory Proxy Server can follow them on the client's behalf.
- **Data mapping and transformation.** The Directory Proxy Server can do DN mapping and attribute mapping to allow clients to interact with the server using older names for directory content. It allows clients to continue working when they would not be able to work directly with the Directory Server, either because of changes that have occurred at the data layer or to inherent design limitations in the clients.
- **Horizontal scalability and performance.** Reads can be horizontally scaled using load balancing. In large data centers, if the data set is too large to be cached or to provide horizontal scalability for writes, the Directory Proxy Server can automatically split the data across multiple systems. This feature allows the Directory Proxy Server to improve scalability and performance of the Directory Server environment.
- **Load balancing and failover.** You can spread the workload across multiple proxies in a large data center using load-balancing algorithms. Load balancing is also useful when a server becomes degraded or non-responsive, because client process requesting is directed to a different server.
- **Security and access control.** The Directory Proxy Server can add additional firewall capabilities, as well as constraints and filtering to help protect the Directory Server from attacks. You can use a Directory Proxy Server in a DMZ as opposed to allowing clients to directly access the Directory Proxy Server in the internal network or providing the data in the DMZ. It can help provide secure access to the data and you can define what actions clients are allowed to do. For example, you can prevent clients from making modifications to data when connected via a VPN no matter what their identity or permissions.
- **Tracking of operations across the environment.** In the past, administrators have commonly complained that when they see a request in the access log, they have no idea where it came from and cannot track it back to a particular client. The Directory Proxy Server contains controls that allow administrators to track requests back to the client that issued them. Whenever the Directory Proxy Server forwards a request to the Directory Server, it includes a control in the request so that the Directory Server's access log has the IP address of the client, address and connection ID of the Directory Server. In the response back to the client, it similarly includes information about the Directory Server that processed the request, such as the connection ID and operation ID. This feature makes it easier for administrators to keep track of what is going on in their environment.
- **Monitoring and management tools.** Because the Directory Proxy Server uses many of the components of the PingDirectory Server, it can leverage them to provide protocol support, logging, management tools for configuration and monitoring, schema, and so on. You can use the Data Metrics Server, the `dsconfig` tool and the Administrative Console to manage the Directory Proxy Server.

Overview of the Directory Proxy Server Components and Terminology

The Directory Proxy Server consists of the following components and functionality that provide the proxy capabilities:

- Locations
- LDAP External Servers
- LDAP Health Checks
- Load-Balancing Algorithms
- Data Transformations
- Request Processors
- Server Affinity Providers
- Subtree Views
- Connection Pools
- Client Connection Policies
- Entry Balancing

This section describes each component in more detail.

About Locations

Locations define a group of servers with similar response time characteristics. Each location consists of a name and an ordered list of preferred failover locations. The Directory Proxy Server and each of the backend LDAP external servers can be assigned locations. These locations can be taken into account when deciding how to route requests, so that the server prefers to forward requests to Directory Server in the same data center over those in remote locations. As a rule of thumb, if you have multiple data centers then you should have a separate location for each one. In most environments, all Directory Proxy Server instances should have the same configuration except for the attribute that specifies the location of the Directory Proxy Server itself.

For example, a deployment consists of three data centers, one in New York, another in Chicago, and another in Los Angeles. In the New York data center, applications which reside in this data center prefer communicating with directories in this data center. If none of the servers are available, it prefers to failover to the data center in Chicago rather than the data center in Los Angeles. So the New York location contains an ordered list in which the Chicago location is preferred over the Los Angeles data center for failover.

For information about configuring locations, see [Configuring Locations](#).

About LDAP External Servers

You can configure information about the directory server instances accessed by the PingDirectoryProxy Server. This configuration information includes the following:

- Server connection information, such as IP address, port, and security layer
- Location
- Authentication information
- Methods for authenticating and authorizing clients
- Server-specific health checks
- Types of operations allowed. For example, some LDAP external servers may allow only reads and others allow reads and writes, so the Directory Proxy Server can recognize this and accommodate it.

The PingDirectoryProxy Server allows you to configure different types of LDAP external servers. The default configuration for each type is tuned to be the best possible configuration for each.

For information about configuring LDAP external servers, see [Configuring LDAP External Servers](#).

About LDAP Health Checks

The LDAP health check component provides information about the availability of LDAP external servers. The health check result includes a server state, which can be one of the following:

- **Available.** Completely accessible for use.
- **Degraded.** The server may be used if necessary, but has a condition which may make it less desirable than other servers (for example, it is slow to respond or has fallen behind in replication).
- **Unavailable.** Completely unsuitable for use (for example, the server is offline or is missing critical data).

Health check results also include a numeric score, which has a value between 1 and 10, that can help rank servers with the same state. For example, if two servers are available and one has a score of 8 and the other a score of 7, the Directory Proxy Server can be configured to prefer the server with the higher score.

The Directory Proxy Server periodically invokes health checks to monitor each LDAP external server, and may also initiate health checks in response to failed operations. It checks the health of the LDAP external servers at intervals configured in the LDAP server's `health-check-frequency` property. However, the Directory Proxy Server has safeguards in place to ensure that only one health check is in progress at any time against a backend server to avoid affecting its ability to process other requests.

The results of health checks performed by the Directory Proxy Server are made available to the load-balancing algorithms so that they may be taken into account when determining where to send requests. The Directory Proxy Server will attempt to use servers with a state of available before trying servers with a state of degraded. It will never attempt to use servers with a state of unavailable. Some load-balancing

algorithms may also take the health check score into account, such as the health-weighted load-balancing algorithm, which prefers servers with higher scores over those with lower scores. You configure the algorithms that work best for you environment.

In some cases, an LDAP health check may define different sets of criteria for promoting and demoting the state of a server. So, a degraded server may need to meet more stringent requirements to be reclassified as available than it originally took to be considered degraded. For example, if response time is used in the process of determining the health of a server, then the Directory Proxy Server may have a faster response time threshold for transitioning a server from degraded back to available than the threshold used to consider it degraded in the first place. This threshold difference can help avoid cases in which a server repeatedly transitions between the two states because it is operating near the threshold.

For example, the health check used to measure search response time is configured to mark any server to be marked degraded when the search response time is greater than 1 second. You can then configure that the response time must be less than 500 ms before the server is made available again, so that the Directory Proxy Server does not flip back and forth between available and degraded.

PingDirectoryProxy Server provides the following health checks:

- **Measure the response time for searches and examine the entry contents.** For example, the health check might retrieve a monitoring entry from a server and base the health check result on whether the entry was returned, how long it took to be returned, and whether the value of the returned entry matches what was expected.
- **Monitor the replication backlog.** If a server falls too far behind in replication, then the Directory Proxy Server can stop sending requests to it. A server is classified as degraded or unavailable if the threshold is reached for the number of missing changes, the age of the oldest missing change, or both.
- **Consume Directory Server administrative alerts.** If the Directory Server indicates there is a problem, for example an index that must be rebuilt, then it will flag itself as degraded or unavailable. When the Directory Proxy Server detects this, it will stop sending requests to the server. The Directory Proxy Server detects administrative alerts as soon as they are issued by maintaining an LDAP persistent search for changes within the `cn=alerts` branch of the Directory Server. When the Directory Proxy Server is notified by the Directory Server of a new alert, it immediately retrieves the base `cn=monitor` entry of the Directory Server. If this entry has a value for the `unavailable-alert-type` attribute, then the Directory Proxy Server will consider it unavailable. If this entry has a value for the `degraded-alert-type` attribute, then the Directory Proxy Server will consider it degraded. Clients of the Directory Proxy Server can use a similar mechanism to detect and react when a Directory Proxy Server flags itself as degraded or unavailable.
- **Monitor the busyness of the server.** If a server becomes too busy, then it may be marked degraded or unavailable so that less heavily-loaded servers may be preferred.

For information about configuring health checks, see [Configuring Server Health Checks](#). To associate a health check with an LDAP external server and set the health check frequency, you must configure the `health-check` and `health-check-frequency` properties of the LDAP external server. See “To Configure an External Server Using `dsconfig`” for information about configuring the properties of the external server.

About Load-Balancing Algorithms

Load-balancing algorithms are used to determine which server in a set of similar servers should be used to process a client request. The algorithm can take the following criteria into account:

- **Consider the location of the server.** Servers in the same location as the Directory Proxy Server can be preferred over those in alternate locations.
- **Consider the health of the server.** Servers that are available are preferred over those that are degraded. In some cases, the health check score may also be used to further differentiate between servers with the same health check state.
- **Route requests consistently.** Requests from a single client may be consistently routed to the same directory server instance to avoid problems such as propagation delay from replication.

- **Retry the operation in an alternate server if the request fails or the operation times out.** You can control if the retry is allowed and, if so, how many times to retry and the time out interval.

The PingDirectoryProxy Server provides the following load-balancing algorithms:

- **Fewest operations.** Requests are forwarded to the backend server with the fewest operations currently in progress.
- **Single server.** Requests are always sent to the same server and will not attempt to fail over to another server if the target server is unavailable.
- **Weighted.** Administrators explicitly assign numeric weights to individual servers or sets of servers to control how likely they are to be selected for processing requests relative to other servers.
- **Health-based weighting.** Uses the health check score to assign weights to each of the servers, so that a server with a higher score gets a higher percentage of the traffic than a server with a lower score. The proportion of traffic received is the difference between their health check scores.
- **Failover.** Requests are always sent to a given server first. If that server fails, then the request is sent to another specified server, and so on through an ordered failover server list.

For information about configuring load balancing, see [Configuring Load Balancing](#).

About Proxy Transformations

Proxy transformations are used to rewrite requests and responses as they pass through the Directory Proxy Server. Proxy data transformations are helpful for clients that use an old schema or that contain a hard-coded schema.

Proxy transformations can provide DN and attribute mapping altering both requests to the server as well as responses from the server. For example, a client sends a request to `o=example.com` even though the directory server handling the request uses `dc=example,dc=com`. The Directory Proxy Server can transparently remap the request so that the server can process it, and map it back to the original DN of the client request when the value is returned. Or if a client tries to use the attribute `userID`, the Directory Proxy Server can map it to `uid` before sending the request on to the backend LDAP server. The Directory Proxy Server then remaps the response to `userID` when the value is returned.

The Directory Proxy Server also includes a proxy transformation that can be used to suppress a specified attribute, so that it will never be returned to clients. It can also cause the server to reject requests which target that particular attribute. Another proxy transformation can be used to prevent entries that match a given search filter from being returned to clients.

For information about configuring proxy transformations, see [Configuring Proxy Transformations](#) on page 70.

About Request Processors

A request processor encapsulates the logic for handling an operation, ensuring that a given operation is handled appropriately. The request processor can either process the operation directly, forward the request to another server, or hand off the request to another request processor.

PingDirectoryProxy Server provides the following types of request processor:

- **Proxying request processors**, which forward operations received by the Directory Proxy Server to other LDAP external servers.
- **Entry-balancing request processors**, which split data across multiple servers. They determine which set of servers are used to process a given operation. They then hand off operations to proxying request processors so that requests can be forwarded to one of the servers in the set.
- **Failover request processors**, which perform ordered failover between other types of request processors, sometimes with different behavior for different types of operations.

Directory Proxy Server request processors can be used to forward certain controls, including the batch transaction control and the LDAP join control. The batch transaction control must target a single Berkley DB backend. For more information about the controls, refer to the LDAP SDK for Java documentation.

For information about configuring request processors, see [Configuring Request Processors](#) on page 72.

About Server Affinity Providers

The server affinity provider can be used to establish an affinity to a particular backend server for certain operations. You can configure one of three types of provider:

- **Client connection Server Affinity**, so that requests from the same client connection may consistently be routed to the same backend server.
- **Client IP address Server Affinity**, so that all requests coming from the same client system will be consistently routed to the same backend server.
- **Bind DN Server Affinity**, so that all requests from the same user will be consistently routed to the same backend server.

For information about configuring server affinity, see [Configuring Server Affinity](#).

About Subtree Views

A subtree view can be used to make a portion of the DIT available to a client by associating a request processor with a base DN. Subtree views allow you to route operations concerning one set of data to a particular set of data sources, and operations concerning another set of data to another set of data sources. Multiple subtree views may be involved in processing a request, such as for searches that have a scope that is larger than the subtree view.

The subtree view includes a single base DN used to identify the portion of the DIT. They may have hierarchical relationships, for example one subtree view could be configured for `dc=example,dc=com` and another for `ou=People,dc=example,dc=com`.

For information about configuring a subtree view, see [Configuring Subtree Views](#).

About the Connection Pools

Based on the type of backend server that you are using, the PingDirectoryProxy Server maintains either one or two connection pools to the backend server. It maintains either one pool for all types of operations or two separate pools for processing bind and non-bind operations from clients. When the Directory Proxy Server establishes connections, it authenticates them using whatever authentication mechanism is defined in the configuration of the external server. These connections will be re-used for all types of operations to be forwarded to the backend server. The bind DN and password are configured in the Directory Proxy Server.

Whenever a client sends a bind request to the Directory Proxy Server, the server looks at the type of bind request that was sent. If it is a SASL bind request, then the authentication is processed by the Directory Proxy Server itself and it will not be forwarded to the backend server. However, the Directory Proxy Server may use information contained in the backend server as needed. If the bind request is a simple bind request and the bind DN is within the scope of data supplied by the backend server, then the Directory Proxy Server will forward the client request to the backend server so that it will use the credentials provided by the client.

Regardless of the authentication method that the client uses, the Directory Proxy Server will remember the identity of the client after the authentication is complete and for any subsequent requests sent by that client, it will use the configured authorization method to identify the client to the backend server. Even though the operation is forwarded over a connection that is authenticated as a user defined in the Directory Proxy Server configuration, the request is processed by the backend server under the authority of the end client.

About Client Connection Policies

Client connection policies define the general behavior the server exhibits when communicating with a set of clients. Each policy consists of the following:

- A **set of connection criteria** that define which client is associated with the policy based on information the server has about the client, including client address, protocol used, secure communication mechanism, location of the client's entry in the Directory Server and the contents of the client's entry.

These criteria are the same as those used for filtered logging. For example, different client connection policies could be established for different classes of users, such as root and non-root users.

- A **set of constraints** on the type of operations a client may request. You can specify whether a particular type of operation is allowed for clients. For some operation types, such as extended operations, you can allow only a particular subset of an operation type, such as a particular extended operation.
- A **set of subtree views** that define information about the parts of the DIT the client may access.

When a client connection is established, only one client connection policy is applied. If the criteria for several policies match the same client connection, the evaluation order index is used as a tiebreaker. If no policy matches, the client connection is terminated. If the client binds, changing its identity, or uses StartTLS to convert from an insecure connection to a secure connection, then the connection may be evaluated again to determine if it matches the same or a different client connection policy. The connection can also be terminated if it no longer matches any policy.

For information about configuring a client connection policy, see [Configuring Client Connection Policies](#) on page 77.

About Entry Balancing

Entry balancing allows you to automatically spread entries below a common parent among multiple sets of directory servers for improved scalability and performance. Entry balancing can take advantage of a global index, an in-memory cache used to quickly determine which set or sets of servers should be used to process a request based on the entry DNs and/or the attribute values used in the request.

For information about configuring entry balancing, see [Deploying an Entry-Balancing Proxy Configuration](#) on page 1136.

Server Component Architecture

This section provides an overview of the process flow between the Directory Proxy Server components, for both a simple proxy deployment and an entry-balancing deployment.

Architecture of a Simple Directory Proxy Server Deployment

In a simple Directory Proxy Server deployment, a client request is first processed by a client connection policy as illustrated in Figure 1, “Process Flow for Directory Proxy Server”.

MY TITLE Process Flow for Directory Proxy Server

The client connection policy contains a subtree view, which defines the portion of the DIT available to clients. Once the Directory Proxy Server determines that the DIT is available, it passes the request to the request processor, which defines the logic for processing the request. The request processor then passes the request to a load-balancing algorithm, which determines the server in a set of servers responsible for

handling the request. Finally, the request is passed to the LDAP external server. The LDAP external server contains properties that define the server's location in a topology and the health checks used to determine if the server is functioning properly. This information may be used by the load-balancing algorithm in the course of determining how to route requests.

Architecture of an Entry-Balancing Directory Proxy Server Deployment

Figure 2, "Process Flow for Entry-Balancing Directory Proxy Server" describes how a client request is treated in an entry-balancing deployment.

MY TITLE Process Flow for Entry-Balancing Directory Proxy Server

Entry balancing is typically used when the data set is too large to fully cache on a single server or when the write performance requirements of an environment are higher than can be achieved with a single replicated set of servers. In such cases, the data may be split across multiple sets of servers, increasing the memory available for caching and the overall write performance in proportion to the number of server sets.

As with a simple proxy deployment, the client request is first processed by the client connection policy, which determines how the Directory Proxy Server communicates with a set of clients. It contains a subtree view that represents the base DN for the entire deployment. The data set splits beneath this base DN.

The request is then passed to the entry-balancing request processor. The entry-balancing request processor contains a global attribute index property, which helps the request processor determine which server set contains the entry and how to properly route the request. It also contains a placement algorithm, which helps it select the server set in which to place new entries created by add requests.

Beneath the entry-balancing request processor are multiple proxying request processors that handle multiple unique sets of data. These request processors pass the request to a load-balancing algorithm, which determines which LDAP external server should handle the request. As with a simple proxy deployment, this LDAP external server contains properties that define the server's location and the health checks used to determine if the server is functioning properly.

For information about entry-balancing replication, see [Overview of Replication in an Entry-Balancing Environment](#) on page 1157.

Directory Proxy Server Configuration Overview

The configuration of the Directory Proxy Server involves the following steps:

- **Configuring the locations for your deployment.** A location is a collection of servers that share access and latency characteristics. For example, your deployment might include two data centers, one in the east and one in the west. These data centers would be configured as two locations in the Directory Proxy Server. Each location is associated with a name and an ordered list of failover locations, which could be used if none of the servers in the preferred location are available.
- **Configuring the Directory Proxy Server location.** You need to update the configuration to specify the location of the Directory Proxy Server instance.
- **Configuring health checks for the LDAP external servers.** You can configure at what point the Directory Proxy Server considers an LDAP external server to be available, of degraded availability, or unavailable. Each health check can be configured to be used automatically for all LDAP external servers or for a specified set of servers.
- **Configuring the LDAP external servers.** During this step, you define each of the external directory servers, including the server type. You can configure Ping Identity Directory Servers, Sun Java System Directory Servers, or generic LDAP servers. You also assign the server-specific health checks configured in the previous step.
- **Configuring the load-balancing algorithm.** You configure the load-balancing algorithm used by the Directory Proxy Server to determine which server in a set of similar servers should be used to process a client request. The Directory Proxy Server provides default algorithms. It also steps you through the creation of new algorithms by using an existing algorithm as a template or by creating one from scratch.
- **Configuring the proxying request processor.** In this step, you configure proxying request processors that forward operations received by the Directory Proxy Server to other LDAP external servers.
- **Configuring subtree views.** A subtree view defines the portion of the DIT available to a client. Each subtree view can be associated with a load-balancing algorithm to help distribute the work load.
- **Configuring the client connection policy.** You configure policies to classify how different client connections are managed by the Directory Proxy Server. The client connection policy can be used to control the types of operations that a client may perform and the portion of the DIT that the client can access. Restrictions configured in a client connection policy will take precedence over any capabilities granted by access control or privileges.

Installing the Directory Proxy Server

This section describes how to install PingDirectoryProxy Server. It includes pre-installation requirements and considerations.

It includes the following sections:

Before You Begin

The following sections describe requirements and considerations you should make before installing the software and configuring the PingDirectoryProxy Server objects.

Important:

Each Server Deployment Requires an Execution of Setup - Duplicating a Server-root is not Supported. The installation of the server does not write or require any data outside of the server-root directory. After executing `setup`, copying the server-root to another location or system, in order to *duplicate* the installation, is not a supported method of deployment. The server-root can be moved to another host or disk location if a host or file system change is needed.

It is also highly recommended that a Network Time Protocol (NTP) system be in place so that multi-server environments are synchronized and timestamps are accurate.

System requirements

PingDirectoryProxy Server has qualified the configurations in this section and has certified that they are compatible with the product. Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software is suspected of causing an issue.

Platforms

- Windows Server 2019
- Windows Server 2016
- Red Hat Enterprise Linux ES 8
- Red Hat Enterprise Linux ES 7.6
- Red Hat Enterprise Linux ES 7.5
- CentOS 7.6
- CentOS 7.5
- SUSE Linux Enterprise 15
- SUSE Linux Enterprise 12 SP3
- Ubuntu 18.04 LTS
- Ubuntu 16.04 LTS
- Amazon Linux 2
- Amazon Linux

Note: This product has been tested with the default configurations of all operating system components. If your organization has customized implementations or has installed third-party plugins, the deployment of this product might be affected.

Docker

Version: Docker 18.09.0

Host operating system: Ubuntu 18.04 LTS

Kernel: 4.4.0-1052-aws 7.3

Note: PingDirectoryProxy Server accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment

- Amazon Corretto 8
- OpenJDK 11
- OpenJDK 8
- Oracle Java SE Development Kit 11 LTS
- Oracle Java SE Development Kit 8

Note:

The applies to your Java Runtime Environment.

Browsers

Administration Console

- Chrome
- Firefox
- Internet Explorer 11 and later

End users

- Chrome
- Edge
- Firefox
- Internet Explorer 11 and later
- Safari

Defining a Naming Strategy for Server Locations

The various objects defined in the PingDirectoryProxy Server will be specific to a particular location. Location names are used to define a grouping of PingDirectoryProxy Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.

Software Requirements: Java

For optimized performance, the requires Java for 64-bit architectures. You can view the minimum required Java version on your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

Even if your system already has Java installed, you may want to create a separate Java installation for use by the to ensure that updates to the system-wide Java installation do not inadvertently impact the . This setup requires that the JDK, rather than the JRE, for the 64-bit version, be downloaded.

To Install Java (Oracle/Sun)**Steps**

1. Open a browser and navigate to the Oracle download site.
2. Download the latest version Java JDK. Click the JDK Download button corresponding to the latest Java update.
3. On the Java JDK page, click the Accept Licence Agreement button, then download the version based on your operating system.

Preparing the Operating System

You should make the following changes to your operating system depending on the production environments on which the PingDirectoryProxy Server will run.

Configuring the File Descriptor Limits

The PingDirectoryProxy Server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. If needed, increase the file descriptor limit on the operating system.

If the operating system relies on `systemd`, refer to the Linux operating system documentation for instructions on setting the file descriptor limit.

To Set the File Descriptor Limit (Linux)**About this task**

The Directory Proxy Server allows for an unlimited number of connections by default but is restricted by the file descriptor limit on the operating system. Many Linux distributions have a default file descriptor limit of 1024 per process, which may be too low for the server if it needs to handle a large number of concurrent connections.

Once the operating system limit is set, the number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as, `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the default of 65535 is used. This is strictly optional if wanting to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current hard limit of your system. The hard limit is the maximum server limit that can be set without tuning the kernel parameters in the `proc` file system.

```
ulimit -aH
```

2. Edit the `/etc/sysctl.conf` file. If there is a line that sets the value of the `fs.file-max` property, make sure its value is set to at least 65535. If there is no line that sets a value for this property, add the following to the end of the file:

```
fs.file-max = 65535
```

3. Edit the `/etc/security/limits.conf` file. If the file has lines that sets the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines to the end of the file (before “#End of file”). Also note that you should insert a tab, rather than spaces, between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

4. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

Results

Note: For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits:

```
/etc/security/limits.d/20-nproc.conf
```

Add or edit the following lines if they do not already exist:

```
*          soft    nproc      65536
*          soft    nofile     65536
*          hard    nproc      65536
*          hard    nofile     65536
root      soft    nproc      unlimited
```

Enabling the Server to Listen on Privileged Ports (Linux)

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account. It may be convenient to enable the server to listen on privileged ports while running as a non-root user.

The `setcap` command is used to assign capabilities to an application. The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024). If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), the Java binary can be granted the `cap_net_bind_service` capability with the following command:

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. More strict limitations are imposed on where the operating system will look for shared libraries to load for commands that have capabilities assigned. So it is also necessary to tell the operating system where to look for this library. This can be done by creating the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file. For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

Run the following command for the change to take effect:

```
$ sudo ldconfig -v
```

To Set the File System Flushes

About this task

With the out-of-the-box settings on Linux systems running the ext3 file system, the data is only flushed to disk every five seconds. If the Directory Proxy Server is running on a Linux system using the ext3 file system, consider editing the mount options for that file system to include the following:

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

You should also set the flush frequency to the `/etc/fstab` file. Doing the change via the mount command alone will not survive across reboots.

Disable File System Swapping

About this task

It is recommended that any performance tuning services like `tuned` be disabled. As root, change the current value in the operating system and by adding a line `vm.swappiness = 0` to `/etc/sysctl.conf` to ensure that the correct setting is applied when the system restarts.

If performance tuning is required, `vm.swappiness` can be set by cloning the existing performance profile then adding `vm.swappiness = 0` to the new profile's `tuned.conf` file. This file is located at `/usr/lib/tuned/profile-name/tuned.conf`. The updated profile is then selected by running `tuned-adm profile customized_profile`.

About Editing OS-Level Environment Variables

Certain environment variables can impact the Directory Proxy Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Proxy Server explicitly overrides the values of key environment variables like `PATH`, `LD_LIBRARY_PATH`, and `LD_PRELOAD` to ensure that something set in the environments that are used to start the server does not inadvertently impact its behavior.

If there is a legitimate need to edit any of these environment variables, the values of those variables should be set by manually editing the `set_environment_vars` function of the `lib/_script-util.sh` script. You will need to stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

Install sysstat and pstack (Red Hat)

For Red Hat® Linux systems, you should install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting purposes in the event that a problem occurs. The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect

monitoring, performance statistics, and stack trace information on the server's processes. For Red Hat systems, make sure that these packages are installed, for example:

```
$ sudo yum install sysstat gdb dstat -y
```

Install dstat (SUSE Linux)

The `dstat` utility is used by the `collect-support-data` tool and can be obtained from the OpenSUSE project website. The following example shows how to install the `dstat` utility on SuSE Enterprise Linux 11 SP2:

1. Login as Root.
2. Add the appropriate repository using the `zypper` tool.
3. Install the `dstat` utility.

```
$ zypper install dstat
```

Omit vm.overcommit_memory

Administrators should be aware that an improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file can cause the `setup` or `start-server` tool to fail.

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, it could lead the operating system to grab too much memory, depriving memory for the `setup` or `start-server` tool.

We recommend omitting the property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing System Entropy

Entropy is used to calculate random data that is used by the system in cryptographic operations. Some environments with low entropy may have intermittent performance issues with SSL-based communication. This is more typical on virtual machines, but can occur in physical instances as well. Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

If necessary, update `$JAVA_HOME/jre/lib/security/java.security` to use `file:/dev/. / urandom` for the `securerandom.source` property.

Set File System Event Monitoring (inotify)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates. The Linux system puts a limit on the number of `inotify` watches a user can receive. To increase the limit, edit `etc/sysctl.conf` to add a line:

```
fs.inotify.max_user_watches = 524288
```

Run the command:

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tune IO Scheduler

Using the correct IO scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load. For file systems running on an SSD, or in a virtualized environment, the `noop` scheduler is recommended. For all other systems, the `deadline` scheduler is recommended. To determine which scheduler is configured on your system, run this command:

```
$ cat /sys/block/<block-device>/queue/scheduler
```

For example:

```
$ cat /sys/block/sda/queue/scheduler
```

Changing the scheduler on a running system can be done with the following command:

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

The change will take effect after the system is restarted. The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Getting the Installation Packages

To begin the installation process, obtain the latest ZIP release bundle from Ping Identity and unpack it in a folder of your choice. The release bundle contains the Directory Proxy Server code, tools, and package documentation.

To Unpack the Build Distribution

Steps

1. Download the latest zip distribution of the Directory Proxy Server software.
2. Unzip the compressed zip archive file in a directory of your choice.

```
$ unzip PingDirectoryProxy-<version>.zip
```

You can now set up the Directory Proxy Server.

Ping license keys

License keys are required to install all Ping products. To obtain a license key, contact your account representative or [Ping Identity](#).

- A license is always required for setting up a new single server instance and can be used site-wide for all servers in an environment. When cloning a server instance with a valid license, no new license is needed.
- A new license must be obtained when updating a server to a new major version, for example from 6.2 to 7.0. Licenses with no expiration date are valid until the server is upgraded to the next major version. A prompt for a new license is displayed during the update process.
- A license may expire on particular date. If a license does expire, obtain a new license and install it using `dsconfig` or the Administrative Console. The server will provide a notification as the expiration date approaches. License details are available using the server's `status` tool.

When installing the server, specify the license key file in one of the following ways:

- Copy the license key file to the server root directory before running `setup`. The interactive `setup` tool will discover the file and not require input. If the file is not in the server root, the setup tool will prompt for its location.
- If the license key is not in the server root directory, specify the `--licenseKeyFile` option for non-interactive setup, and the path to the file.

About the RPM Package

PingDirectory Server supports the PingDirectory Server release bundle in an RPM Package Manager (RPM) package for customers who require it. By default, the RPM unpacks the code at `/opt/ping-identity/ds/PingDirectory`, after which you can run the `setup` command to install the server at that location.

If the RPM install fails for any reason, you can perform an RPM erase if the RPM database entry was created and manually remove the target RPM install directory (e.g., “/opt/ping-identity/ds/PingDirectory” by default). You can install the package again once the system is ready.

To Install the RPM Package

Steps

1. Download the latest RPM distribution of the Directory Server software.
2. Unpack the build using the `rpm` command with the `--install` option. By default, the build is unpacked to `/opt/ping-identity/ds/PingDirectory`. If you want to place the build at another location, use the `--prefix` option and specify the file path of your choice.

```
$ rpm --install PingDirectory-<version>.rpm
```

3. From `/opt/ping-identity/ds/PingDirectory/PingDirectory`, run the `setup` command to install the server on the machine.

Installing the Directory Proxy Server

When you deploy PingDirectoryProxy Server in a topology, you generally deploy them in pairs. These pairs are configured identically except for their host name, port name, and possibly their location.

To help administrators easily install identical proxies, the Directory Proxy Server allows you to clone a proxy configuration. First, you install a Directory Proxy Server using the `setup` tool. Then, you configure it using the `create-initial-proxy-config` tool described in [Using the create-initial-proxy-config Tool](#). Finally, you run the `setup` tool on subsequent servers, indicating that you want to clone the configuration on a peer server.

The following sections describe the setup tool in more detail, and tell you how to install first and subsequent proxies in your topology.

About the setup Tool

One of the strengths of the is the ease with which you can install a server instance using the `setup` tool. The `setup` tool allows you to quickly install and configure a stand-alone instance.

To install a server instance, run the `setup` tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the `setup --cli` command.
- **Non-Interactive Command-Line Mode.** Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, `setup` must be run with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the will run.

Installing the First Directory Proxy Server in Interactive Mode

The `setup` tool provides an interactive text-based interface to install a Directory Proxy Server instance.

To Install the First Directory Proxy Server in Interactive Mode

Steps

1. Change to the server root directory.

```
cd Directory Proxy Server
```

2. Use the `setup` command.

```
$ ./setup
```

3. Read the Ping Identity End-User License Agreement, and type `yes` to continue.

4. Press **Enter** to accept the default of `no` in response to adding this new server to an existing topology.

```
Would you like to add this server to an existing Directory Proxy Server topology? (yes / no) [no]:
```

5. Enter the fully qualified host name for this server, or press **Enter** to accept the default.

6. Create the initial root user DN for this server, or press **Enter** to accept the default.

7. Enter and confirm a password for this account.

8. To enable the Directory Proxy Server services (Configuration, Documentation, and Directory REST API) and Administrative Console over HTTPS, press **Enter** to accept the default. After setup, individual services can be enabled or disabled by configuring the HTTPS Connection Handler.

9. Enter the port on which the Directory Proxy Server should accept connections from HTTPS clients, press **Enter** to accept the default.

10. Enter the port on which the Directory Proxy Server should accept connections from LDAP clients, press **Enter** to accept the default.

11. The next two options enable LDAPS and StartTLS. Press **Enter** to accept the default (`yes`), or type `no`. If either are enabled, certificate options are required. To use the Java Keystore or the PKCS#12 keystore, the keystore path and the key PIN are required. To use the PKCS#11 token, only the key PIN is required.

12. Choose a certificate server option:

```
Certificate server options:
```

- 1) Generate self-signed certificate (recommended for testing purposes only)
- 2) Use an existing certificate located on a Java Keystore (JKS)
- 3) Use an existing certificate located on a PKCS#12 keystore
- 4) Use an existing certificate on a PKCS#11 token

13. Choose the desired encryption for backups and log files from the choices provided:

- Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
- Encrypt data with a key generated from a passphrase read from a file.
- Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
- Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
- Do not encrypt server data.

14. To configure your Directory Proxy Server to use entry balancing, type `yes`, or accept the default `no`.

In an entry balancing environment, entries immediately beneath the balancing base DN are divided into disjoint subsets. Each subset of data is handled by a separate set of one or more directory server instances, which replicate this subset of data between themselves. Choosing `yes` will enable more memory be allocated to the server and tools.

15. Choose the option for the amount of memory to assign to this server.

16. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.

17. After setup is complete, choose the next configuration option.

```
This server is now ready for configuration What would you like to do?
```

- ```

1) Start 'create-initial-proxy-config' to create a basic
 initial configuration (recommended for new users)
2) Start 'dsconfig' to create a configuration from scratch
3) Quit

```

```
Enter choice [1]:
```

## To Install Additional Directory Proxy Server Instances in Interactive Mode

### About this task

The **setup** tool provides an interactive text-based interface to install a Directory Proxy Server instance that clones a previously installed Directory Proxy Server instance.

### Steps

1. Change to the server root directory.

```
cd Directory Proxy Server
```

2. Use the **setup** command.

```
$./setup
```

3. Read the Ping Identity End-User License Agreement, and type *yes* to continue.

4. Enter *yes* in response to add this new server to an existing topology.

```
Would you like to add this server to an existing Directory Proxy Server
topology? (yes / no) [no]: yes
```

5. Enter the host name of the Directory Proxy Server from which configuration settings are copied during setup.

```
Enter the host name of the peer Directory Proxy Server from which you would
like
to copy configuration settings. [proxy.example.com]:
```

6. Type the port number of the peer Directory Proxy Server from which configuration settings are copied during setup. You can press **Enter** to accept the default port, which is 389.

```
Enter the port of the peer Directory Proxy Server [389]:
```

7. Enter the option corresponding to the type of connection you want to use to connect to the peer Directory Proxy Server.

```
How would you like to connect to the peer Directory Proxy Server?
1) None
2) SSL
3) StartTLS
```

```
Enter choice [1]:
```

8. Type the root user DN of the peer Directory Proxy Server, or press **Enter** to accept the default (cn=Directory Manager), and then type and confirm the root user password.

```
Enter the manager account DN for the peer Directory Proxy Server
[cn=Directory Manager]:
Enter the password for cn=Directory Manager:
```

9. Enter the host name of the new local Directory Proxy Server.

```
Enter the fully qualified host name or IP address of the local host
[proxy.example.com]:
```

10. Choose the location of your new Directory Proxy Server instance or enter a new one.

11. Enter an option to set up the server with the current configuration, provide new parameters, or cancel.

12. After setup is complete, choose the next configuration option.

### Installing the First Directory Proxy Server in Non-Interactive Mode

You can run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line. If there is a missing or incorrect argument, the `setup` tool fails and aborts the process.

The `setup` tool automatically chooses the maximum heap size. You can manually tune the maximum amount of memory devoted to the server's process heap using the `--maxHeapSize` option. The `--maxHeapSize` argument is only valid if the `--entryBalancing` or `--aggressiveJVM Tuning` options are also present.

For example, use the `--aggressiveJVM Tuning` option to set the maximum amount of memory used by the Directory Proxy Server and tools as follows:

```
--aggressiveJVM Tuning --maxHeapSize 256m
```

If you are using entry balancing, tune the amount of memory devoted to the Directory Proxy Server using the `--entryBalancing` option as follows:

```
--entryBalancing --maxHeapSize 1g
```

The amount of memory allowed when using the `--entryBalancing` option is calculated and depends on the amount of system memory available. If you are using entry balancing and also want the tools to get more memory, include both the `--entryBalancing` and the `--aggressiveJVM Tuning` options.

```
--entryBalancing --aggressiveJVM Tuning --maxHeapSize 1g
```

If you have already configured a truststore, you can also use the `setup` tool to enable security. The following example enables security, both SSL and StartTLS. It also specifies a JKS Keystore and Truststore that define the server certificate and trusted CA. The passwords for the keystore files are defined in the corresponding `.pin` files, where the password is written on the first line of the file. The values in the `.pin` files will be copied to the `server-root/config` directory in the `keystore.pin` file.

Note that the password to the private key within the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined within the Administrative Console or `dsconfig` by editing the Trust Manager Provider standard configuration object.

```
$ env JAVA_HOME=/ds/java ./setup --cli \
 --no-prompt --rootUserDN "cn=Directory Manager" \
 --rootUserPassword "password" --ldapPort 389 \
 --enableStartTLS --ldapsPort 636 \
 --useJavaKeystore /path/to/devkeystore.jks \
 --keyStorePasswordFile /path/to/devkeystore.pin \
 --certNickName server-cert \
 --useJavaTrustStore /path/to/devtruststore.jks \
 --trustStorePasswordFile /path/to/devtruststore.pin \
 --acceptLicense
```

### To Install the First Directory Proxy Server in Non-Interactive Mode

#### Steps

- Use `setup` with the `--no-prompt` option. The command uses the default root user DN (`cn=Director Manager`) with the specified `--rootUserPassword` option. You must include the `--acceptLicense` option or the `setup` tool will generate an error message.

```
$ env JAVA_HOME=/ds/java ./setup --no-prompt \
 --rootUserDN "cn=Directory Manager" \
```

```
--rootUserPassword "password" --ldapPort 389 \
--acceptLicense
```

### To Install Additional Directory Proxy Server in Non-Interactive Mode

You can run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line. If there is a missing or incorrect argument, the `setup` tool fails and aborts the process.

### To Install Additional Directory Proxy Server in Non-Interactive Mode

#### Steps

- Use `setup` with the `--no-prompt` option.

```
$ env JAVA_HOME=/ds/java ./setup --cli --no-prompt \
--rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" --ldapPort 1389 \
--localHostName proxy2.example.com \
--peerHostName proxy1.example.com --peerPort 389 \
--peerUseNoSecurity --acceptLicense --location austin1
```

### Installing the Directory Proxy Server with a Truststore in Non-Interactive Mode

If you have already configured a trust store, you can also use the `setup` tool to enable security. The following example enables SSL security. It also specifies a JKS Keystore and truststore that define the server certificate and trusted CA. The passwords for the keystore files are defined in the corresponding `.pin` files, where the password is written on the first line of the file. The values in the `.pin` files will be copied to the `server-root/config` directory in the `keystore.pin` and `truststore.pin` files.

**Note:** The password to the private key within the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined within the `dsconfig` by editing the Key Manager Provider standard configuration object.

### To Install the Directory Proxy Server with a Truststore in Non-Interactive Mode

#### Steps

- Run the `setup` tool to install with a truststore.

```
$ env JAVA_HOME=/ds/java ./setup --cli \
--no-prompt --rootUserDN "cn=Directory Manager" \
--rootUserPassword "password" \
--ldapPort 389 --ldapsPort 636 \
--useJavaKeystore /path/to/devkeystore.jks \
--keyStorePasswordFile /path/to/devkeystore.pin \
--certNickName server-cert \
--useJavaTrustStore /path/to/devtruststore.jks \
--acceptLicense
```

In order to update the trust store, the password must be provided

See 'prepare-external-server --help' for general overview

```
Testing connection to ds-east-01.example.com:1636 Done
Testing 'cn=Proxy User,cn=Root DNs,cn=config' access

## About the Layout of the Directory Proxy Server Folders

Once you have unzipped the Directory Proxy Server distribution file, the following folders and command-line utilities are available.

### Layout of the Directory Proxy Server Folders

| Directories/Files/Tools | Description                                                                                                                                                                |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| License.txt             | Licensing agreement for the Directory Proxy Server.                                                                                                                        |
| README                  | README file that describes the steps to set up and start the Directory Proxy Server.                                                                                       |
| bak                     | Stores the physical backup files used with the <b>backup</b> command-line tool.                                                                                            |
| bat                     | Stores Windows-based command-line tools for the Directory Proxy Server.                                                                                                    |
| bin                     | Stores UNIX/Linux-based command-line tools for the Directory Proxy Server.                                                                                                 |
| classes                 | Stores any external classes for server extensions.                                                                                                                         |
| collector               | Used by the server to make monitored statistics available to the Data Metrics Server.                                                                                      |
| config                  | Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.                                       |
| docs                    | Provides the product documentation.                                                                                                                                        |
| import-tmp              | Stores temporary imported items.                                                                                                                                           |
| ldif                    | Stores any LDIF files that you may have created or imported.                                                                                                               |
| legal-notice            | Stores any legal notices for dependent software used with the Directory Proxy Server.                                                                                      |
| lib                     | Stores any scripts, jar, and library files needed for the server and its extensions.                                                                                       |
| locks                   | Stores any lock files in the backends.                                                                                                                                     |
| logs                    | Stores log files for the Directory Proxy Server.                                                                                                                           |
| metrics                 | Stores the metrics that can be gathered for this server and surfaced in the Data Metrics Server.                                                                           |
| resource                | Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server. |
| revert-update           | The <b>revert-update</b> tool for UNIX/Linux systems.                                                                                                                      |
| revert-update.bat       | The <b>revert-update</b> tool for Windows systems.                                                                                                                         |
| setup                   | The <b>setup</b> tool for UNIX/Linux systems.                                                                                                                              |
| setup.bat               | The <b>setup</b> tool for Windows systems.                                                                                                                                 |
| scim-data-tmp           | Used to create temporary files containing SCIM request data.                                                                                                               |
| uninstall               | The <b>uninstall</b> tool for UNIX/Linux systems.                                                                                                                          |
| uninstall.bat           | The <b>uninstall</b> tool for Windows systems.                                                                                                                             |
| update                  | The <b>update</b> tool for UNIX/Linux systems.                                                                                                                             |
| update.bat              | The <b>update</b> tool for Windows systems.                                                                                                                                |

| Directories/Files/Tools | Description                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| Velocity                | Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server. |

## Running the Server

To start the Directory Proxy Server, run the `bin/start-server` command on UNIX or Linux systems (an analogous command is in the `bat` folder on Microsoft Windows systems). The `bin/start-server` command starts the Directory Proxy Server as a background process when no options are specified. To run the Directory Proxy Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

### To Start the Directory Proxy Server

#### Steps

Use `bin/start-server` to start the server.

```
$ bin/start-server
```

### To Run the Server as a Foreground Process

#### Steps

1. Enter `bin/start-server` with the `--nodetach` option to launch the Directory Proxy Server as a foreground process.

```
$ bin/start-server --nodetach
```

2. You can stop the Directory Proxy Server by pressing **CTRL+C** in the terminal window where the server is running or by running the `bin/stop-server` command from another window.

### To Start the Server at Boot Time

By default, the PingDirectoryProxy Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command. To configure the Directory Proxy Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

#### Steps

1. Create the service unit configuration file in a temporary location where "ds" is the user the PingDirectoryProxy will run as.

```
$ bin/create-systemd-script \
 --outputFile /tmp/ping-directory.service \
 --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. Reload `systemd` to read the new configuration file.

```
$ systemctl daemon-reload
```

4. To start the PingDirectoryProxy, use the `start` command.

```
$ systemctl start ping-directory.service
```

- To configure the PingDirectoryProxy to start automatically when the system boots, use the **enable** command.

```
$ systemctl enable ping-directory.service
```

- Log out as root.

If on an RC system, this task is done by creating the startup script with **bin/create-rc-script** and moving it to the `/etc/init.d` directory. Create symlinks to it from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and `/etc/rc0.d` directory (starting with a "K" to ensure that the server is stopped).

### Logging into the Administrative Console

After the server is installed, access the Administrative Console, <https://hostname:HTTPport/console/login>, to verify the configuration and manage the server. To log into the Administrative Console, use the initial root user DN specified during setup (by default **cn=Directory Manager**).

The **dsconfig** command or the Administrative Console can be used to create additional root DN users in **cn=Root DNs**, **cn=config**. These new users require the fully qualified DN as the login name, such as **cn=new-admin**, **cn=Root DNs**, **cn=config**. To use a simple user name (with out the **cn=** prefix) for logging into the Administrative Console, the root DN user must have the **alternate-bind-dn** attribute configured with an alternate name, such as "admin."

By default the link to the Administrative Console is <https://hostname:HTTPport/console/login>.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package (`/server-root/resource/admin-console.zip`) can be installed according to that container's documentation.

## Stopping the Directory Proxy Server

The Directory Proxy Server provides a simple shutdown script, `bin/stop-server`, to stop the server. You can run it manually from the command line or within a script.

If the Directory Proxy Server has been configured to use a large amount of memory, then it can take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server can fail because the system does not yet have enough free memory. On UNIX systems, run the **vmstat** command and watch the values in the "free" column increase until all memory held by the Directory Proxy Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process may take.

### To Stop the Server

#### Steps

- Use the `bin/stop-server` tool to shut down the server.

```
$ bin/stop-server
```

### To Schedule a Server Shutdown

#### Steps

- Use the **bin/stop-server** tool with the `--stopTime YYYYMMDDhhmmss` option to schedule a server shutdown.

The Directory Proxy Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing

"Z", for example, 20120606134500Z. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
 --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
 --stopReason "Scheduled offline maintenance"
```

## To Restart the Server

About this task

Re-start the Directory Proxy Server using the `bin/stop-server` command with the `--restart` or `-R` option. Running the command is equivalent to shutting down the server, exiting the JVM session, and then starting up again.

Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

```
$ bin/stop-server --restart
```

## Run the Server as a Microsoft Windows Service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables log out of a machine without the server being stopped.

### To Register the Server as a Windows Service

About this task

Perform the following steps to register the server as a service:

Steps

- Stop the server with `bin/stop-server`. A server cannot be registered while it is running.
- Register the server as a service. From a Windows command prompt, run `bat/register-windows-service.bat`.
- After a server is registered, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

### To Run Multiple Service Instances

About this task

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file. To run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

## To Deregister and Uninstall Services

### About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat/deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

### Log Files for Services

#### About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or due to file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

## Uninstalling the Server

The Directory Proxy Server provides an `uninstall` command-line utility for quick and easy removal of the code base.

To uninstall a server instance, run the `setup` tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode is a text-based interface that prompts the user for input. You can start the command using the `bin/uninstall` command with the `--cli` option. The utility prompts you for input if more data is required.
- **Non-Interactive Command-Line Mode.** Non-interactive mode suppresses progress information from being written to standard output during processing, except for fatal errors. This mode is convenient for scripting and is invoked using the `bin/uninstall` command with the `--no-prompt` option.

**Note:** For stand-alone installations with a single Directory Proxy Server instance, you can also manually remove the Directory Proxy Server by stopping the server and recursively deleting the directory and subdirectories. For example:

```
$ rm -rf /ds/PingDirectoryProxy
```

### To Uninstall the Server in Interactive Mode

#### About this task

Interactive mode uses a text-based, command-line interface to help you remove your instance. If `uninstall` cannot remove all of the Directory Proxy Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Proxy Server.

#### Steps

1. From the server root directory, run the `uninstall` command.

```
$./uninstall --cli
```

2. Select the components to be removed. If you want to remove all components, press **Enter** to accept the default (remove all). Enter the option to specify the specific components that you want to remove.

```
Do you want to remove all components or select the components to remove?
```

```

1) Remove all components
2) Select the components to be removed

q) quit
Enter choice [1]:

```

3. For each type of server component, press **Enter** to remove them or type `no` to keep it.

```

Remove Server Libraries and Administrative Tools? (yes / no) [yes]:
Remove Database Contents? (yes / no) [yes]:
Remove Log Files? (yes / no) [yes]:
Remove Configuration and Schema Files? (yes / no) [yes]:
Remove Backup Files Contained in bak Directory? (yes / no) [yes]:
Remove LDIF Export Files Contained in ldif Directory? (yes / no) [yes]:

```

4. If the Directory Proxy Server is part of a replication topology, type `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a stand-alone server, continue to step 7.
5. Type the Global Administrator ID and password to remove the references to this server in other replicated servers. Then, type or verify the host name or IP address for the server that you are uninstalling.
6. Next, select how you want to trust the server certificate if you have set up SSL or StartTLS. For this example, press **Enter** to accept the default.

```

How do you want to trust the server certificate for the Directory Proxy
Server
on server.example.com:389?

1) Automatically trust
2) Use a trust store
3) Manually validate

Enter choice [3]:

```

7. If your Directory Proxy Server is running, the server is shutdown before continuing the uninstall process. The uninstall processes the removal requests and completes. View the logs for any remaining files. Manually remove any remaining files or directories, if listed.

### To Uninstall the Server in Non-Interactive Mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option. Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command will fail and abort.

#### Steps

1. From the server root directory, run `uninstall` tool with the `--remove-all` option to remove all of the Directory Proxy Server's libraries. The `--quiet` option suppresses output information and is optional. The following command assumes that the Directory Proxy Server is stand-alone and not part of a replication topology.

```
$./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

### To Uninstall Selected Components in Non-Interactive Mode

#### Steps

From the server root directory, run `uninstall` with the `--backup-files` option to remove the Directory Proxy Server's backup files. Use the `--help` or `-H` option to view the other options available to remove specific components.

```
$./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
```

## To Uninstall the RPM Build Package

### Steps

1. From the server root directory, remove the RPM package use the `--erase` option with the `<rpm-id>`. The `<rpm-id>` is `PingDirectory` and removes the files at `/opt/ping-identity/ds/PingDirectory/PingDirectory`.

```
$ rpm --erase PingDirectory
```

2. The `rpm` command specifies if any files or directories require manual deletion. Manually remove any remaining directories or files using `rm -rf <directory>`.

## Updating the Directory Proxy Server

Ping Identity issues new software builds periodically and distributes the software package in zip format. Administrators can use the Directory Proxy Server's `update` utility to update the current server code with the latest features and bug fixes. To update the Directory Proxy Server to a newer version, download the build package, and then unzip the new server package on the same host as the server that you wish to update. Before upgrading a server, you should ensure that it is capable of starting without severe or fatal errors.

During an update process, the updater checks a manifest file that contains a MD5 checksum of each file in its original state when installed from zip. Next, it compares the checksum of the new server files to that of the old server. Any files that have different checksums will be updated. For files that predates the manifest file generation, the file is backed up and replaced. The updater also logs all file changes in the history directory to tell what files have been changed.

For schema updates, the `update` tool preserves any custom schema definitions (`99-user.ldif`). For any default schema element changes, if any, the updater will warn the user about this condition and then create a patch schema file and copy it into the server's schema directory. For configuration files, the update tool preserves the configuration file, `config.ldif`, unless new configuration options must be added to the Directory Proxy Server.

Once the updater finishes its processing, it checks if the newly updated server starts without any fatal errors. If an error occurs during the update process, the `update` tool reverts the server root instance to the server state prior to the update.

### Update servers in a topology

An update to the current PingDirectory Server release includes significant changes as well as the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts. For the admin backend to be migrated, the `update` tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security option requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the `inherit-default-privileges` set to true (such as the `cn=Directory Manager` user) that exists on every server can be used.

After enabling or fixing the configuration of the LDAP connection handler(s) to support the desired connection security mechanism on each server, run the following `dsframework` command on the server being updated so that its admin backend has the most up-to-date information:

```
$ bin/dsframework set-server-properties \
 --serverID serverID \
```

```
--set ldapport:port \
--set ldapsport:port \
--set startTLSEnabled:true
```

The **update** tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The **update** tool will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

```
$ bin/dsconfig set-global-configuration-prop \
--set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under **cn=cluster, cn=config** (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output. For example:

```
$ bin/config-diff --sourceHost hostName \
--sourcePort port \
--sourceBindDN bindDN \
--sourceBindPassword password \
--targetHost hostName \
--targetPort port \
--targetBindDN bindDN \
--targetBindPassword password
```

If any of these conditions are not satisfied, the **update** tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

## To Update the Directory Proxy Server

### About this task

Assume that an existing version of the Directory Proxy Server is stored at PingDirectoryProxy-old, which you want to update.

### Steps

1. Make sure you have complete, readable backup of the existing system before upgrading the Directory Proxy Server build. Also, make sure you have a clear backout plan and schedule.
2. Download the latest version of the PingDirectoryProxy Server software and unzip the file. For this example, let's assume the new server is located in the PingDirectoryProxy-new directory.
3. Check the version number of the newly downloaded Directory Proxy Server instance using the **--version** option on any command-line utility. For example, you should see the latest revision number.

```
$ PingDirectoryProxy-new/setup --version PingDirectoryProxy Server
8.0.0.0
Build 2011043200609Z Revision 9235
```

4. Use the **update** tool of the newly unzipped build to update the Directory Proxy Server code. Make sure to specify the Directory Proxy Server instance that you are upgrading with the `--serverRoot` option. The Directory Proxy Server must be stopped for this update to be applied.

```
$ PingDirectoryProxy-new/update --serverRoot PingDirectoryProxy-old
```

**Note:** The PingDirectoryProxy Server provides a web console called the Administrative Console, to configure and monitor the server. If you update the Directory Proxy Server version, you should also update the Administrative Console.

5. View the log file to see which files were changed. The log file is located in the `<server-root>/history` directory. For example, the file will be labelled with the Directory Proxy Server version number and revision.

```
$ view <server-root>/history/1272307020420-8.0.0.0.9235/update.log
```

## Upgrade the RPM package

### About this task

If the Linux RPM package was used to install PingDirectory Server, perform the following steps to upgrade the server:

### Steps

1. Ensure the new RPM package, `PingDirectory-<new-version>.rpm`, resides in the server root directory.
2. From the server root directory, run the command **rpm** with the option `--upgrade`, as follows:

```
$ rpm --upgrade PingDirectory-<new-version>.rpm
```

The upgrade history is written to `/opt/ping-identity/ds/PingDirectory/PingDirectory/history/<timestamp>/update.log`.

The RPM package does not support a revert option after the build is upgraded.

## Revert an update

After PingDirectoryProxy Server has been updated, you can revert to the last version (one level back) using the **revert-update** tool. The **revert-update** tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the **revert-update** tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the PingDirectoryProxy Server, you can run the **revert-update** command to revert to its previous state, then run the **revert-update** command again to return to its original state.

### Reverting from version 7.x to a version prior to 7.0
