Release Notes.....	15
Directory Server Release Notes.....	15
PingDirectory Server 8.1.0.6 release notes.....	15
PingDirectory Server 8.1.0.5 release notes.....	16
PingDirectory Server 8.1.0.4 release notes.....	18
PingDirectory Server 8.1.0.3 release notes.....	22
PingDirectory Server 8.1.0.2 Release Notes.....	22
PingDirectory Server 8.1 Release Notes.....	28
Release Notes Archive.....	44
PingDirectoryProxy Server Release Notes.....	221
PingDirectoryProxy Server 8.1.0.6 release notes.....	221
PingDirectoryProxy Server 8.1.0.5 release notes.....	221
PingDirectoryProxy Server 8.1.0.4 release notes.....	223
Release Notes Archive.....	225
PingDataMetrics Release Notes.....	341
PingDataMetrics Server 8.1.0.6 release notes.....	341
PingDataMetrics 8.1.0.5 release notes.....	341
Release Notes Archive.....	343
Delegated Admin Release Notes.....	391
Delegated Admin 4.2.0 Release Notes.....	391
Delegated Admin Release Notes archive.....	393
PingDataSync Server Release Notes.....	398
PingDataSync Server 8.1.0.6 release notes.....	398
PingDataSync Server 8.1.0.5 release notes.....	398
PingDataSync Server Release Notes archive.....	400
PingDirectory Server Administration Guide.....	478
PingDirectory™ Product Documentation.....	478
Overview of the Server.....	478
Server Features.....	479
Administration Framework.....	480
Server Tools Location.....	480
Preparing Your Environment.....	480
Before You Begin.....	480
Preparing the Operating System (Linux).....	482
Running as a Non-Root User (Linux).....	487
Installing the Server.....	487
Getting the Installation Packages.....	487
About the Layout of the Directory Server Folders.....	488
make-ldif Template Format.....	489
About the Server Installation Modes.....	500
Before You Begin.....	501
Ping license keys.....	502
Setting Up the Directory Server in Interactive Mode.....	502
Installing the Directory Server in Non-Interactive Mode.....	504
Installing a Lightweight Server.....	505
Running the Status Tool.....	506
Where To Go From Here.....	507

Working with Multiple Backends.....	508
Importing Data.....	508
Running the Server.....	509
Stopping the Directory Server.....	511
Run the Server as a Microsoft Windows Service.....	512
Uninstalling the Server.....	513
Upgrading the Server.....	515
Upgrade Overview and Considerations.....	515
Update servers in a topology.....	515
To Upgrade the Directory Server.....	518
Revert an update.....	518
Tuning the Server.....	520
About Minimizing Disk Access.....	520
Memory Allocation and Database Cache.....	520
Database Preloading.....	523
Databases on Storage Area Networks, Network-Attached Storage, or running in Virtualized Environments.....	525
Database Cleaner.....	525
Compacting Common Parent DNSs.....	526
Import Thread Count.....	526
JVM Properties for Server and Command-Line Tools.....	526
JVM Garbage Collection Using CMS.....	527
Tuning For Disk-Bound Deployments.....	530
Uncached Attributes and Entries.....	530
Configuring the Server.....	532
About the Configuration Tools.....	532
About dsconfig Configuration Tool.....	533
Using dsconfig in Interactive Command-Line Mode.....	533
Using dsconfig in Non-Interactive Mode.....	535
Getting the Equivalent dsconfig Non-Interactive Mode Command.....	536
Using dsconfig Batch Mode.....	537
Syncing Passwords to PingOne.....	538
Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth Tokens.....	539
About Recurring Tasks and Task Chains.....	540
Exec Tasks.....	542
Topology Configuration.....	543
Servers and Certificates.....	545
Using the Configuration API.....	592
Working with the Directory REST API.....	605
Configuring Server Groups.....	607
Configure the Server Using the Administrative Console.....	608
Generating a Summary of Configuration Components.....	611
About Root User, Administrator, and Global Administrators.....	612
Managing Root Users Accounts.....	612
Default Root Privileges.....	612
Configuring Administrator Accounts.....	614
Configuring a Global Administrator.....	617
Configuring Server Groups.....	618
Configuring Client Connection Policies.....	620
Securing the Server with Lockdown Mode.....	629
Configuring Maximum Shutdown Time.....	630
Working with Referrals.....	630
Configuring a Read-Only Server.....	632
Configuring HTTP Access for the Directory Server.....	633
Domain Name Service (DNS) Caching.....	641

IP Address Reverse Name Lookups.....	642
Configuring Traffic Through a Load Balancer.....	642
Working with the Referential Integrity plugin.....	643
Working with the Unique Attribute plugin.....	643
Working with the Purge Expired Data plugin.....	644
Configuring Uniqueness Across Attribute Sets.....	646
Working with the Last Access Time plugin.....	647
Working with the Pass-Through Authentication plugin.....	648
Supporting Unindexed Search Requests.....	652
Server Performance Issues.....	652
Sun/Oracle Compatibility.....	655
Configuring Soft Deletes.....	656
About Soft Deletes.....	656
General Tips on Soft Deletes.....	657
Configuring Soft Deletes on the Server.....	659
Searching for Soft Deletes.....	661
Undeleting a Soft-Deleted Entry Using the Same RDN.....	663
Undeleting a Soft-Deleted Entry Using a New RDN.....	663
Modifying a Soft-Deleted Entry.....	664
Hard Deleting a Soft-Deleted Entry.....	665
Disabling Soft Deletes as a Global Configuration.....	666
Configuring Soft Deletes by Connection Criteria.....	666
Configuring Soft Deletes by Request Criteria.....	667
Configuring Soft Delete Automatic Purging.....	668
Summary of Soft and Hard Delete Processed.....	669
Summary of Soft Delete Controls and Tool Options.....	670
Monitoring Soft Deletes.....	671
Importing and Exporting Data.....	675
Importing Data.....	675
Running an Offline Import.....	676
Running an Online LDIF Import.....	677
Adding Entries to an Existing Directory Server.....	678
Filtering Data Import.....	679
Exporting Data.....	679
Encrypting LDIF Exports and Signing LDIF Files.....	680
Filtering Data Exports.....	681
Scrambling Data Files.....	682
Backing Up and Restoring Data.....	683
Backing Up and Restoring Data.....	683
Retaining Backups.....	684
Moving or Restoring a User Database.....	688
Comparing the Data in Two Directory Servers.....	688
Revert or Replay Changes.....	691
Working with Indexes.....	693
Overview of Indexes.....	693
General Tips on Indexes.....	693
Index Types.....	695
System Indexes.....	695
Managing Local DB Indexes.....	696
Working with Composite Indexes.....	698
Working with JSON Indexes.....	699
Working with Local DB VLV Indexes.....	700
Working with Filtered Indexes.....	701
Tuning Indexes.....	703
Managing Entries.....	706
Searching Entries.....	706

Working with the Matching Entry Count Control.....	711
Adding Entries.....	712
Deleting Entries Using Idapdelete.....	715
Deleting Entries Using Idapmodify.....	715
Modifying Entries Using Idapmodify.....	716
Working with the Parallel-Update Tool.....	720
Working with the Watch-Entry Tool.....	722
Working with LDAP Transactions.....	722
Working with Virtual Attributes.....	723
Overview of Virtual Attributes.....	723
Viewing Virtual Attribute Properties.....	725
Enabling a Virtual Attribute.....	725
Creating User-Defined Virtual Attributes.....	726
Creating Mirror Virtual Attributes.....	728
Editing a Virtual Attribute.....	729
Deleting a Virtual Attribute.....	730
Working with Composed Attributes.....	730
Virtual Attribute Limitations.....	730
Overview of Composed Attributes.....	731
Composed Attribute Plugin Configuration Properties.....	731
Populate Composed Attribute Values Task.....	736
Composed Attribute Dependency Considerations.....	736
Schema Validation Considerations.....	737
Replication Considerations.....	737
Synchronization Server Considerations.....	738
Directory Proxy Server Considerations.....	738
Troubleshooting Considerations.....	738
Security Considerations.....	738
Limitations of Composed Attributes Relative to Virtual Attributes.....	738
Working with Groups.....	739
Overview of Groups.....	739
About the isMemberOf and isDirectMemberOf Virtual Attribute.....	740
Using Static Groups.....	741
Using Dynamic Groups.....	745
Using Virtual Static Groups.....	749
Creating Nested Groups.....	751
Maintaining Referential Integrity with Static Groups.....	752
Monitoring the Group Membership Cache.....	753
Using the Entry Cache to Improve the Performance of Large Static Groups.....	754
Tuning the Index Entry Limit for Large Groups.....	755
Summary of Commands to Search for Group Membership.....	756
Migrating Sun/Oracle Groups.....	756
Encrypting Sensitive Data.....	759
Encrypting and Protecting Sensitive Data.....	759
Backing Up and Restoring the Encryption-Settings Definitions.....	764
Configuring Sensitive Attributes.....	767
Configuring Global Sensitive Attributes.....	769
Excluding a Global Sensitive Attribute on a Client Connection Policy.....	770
Working with the LDAP Changelog.....	771
Overview of the LDAP Changelog.....	771
Viewing the LDAP Changelog Properties.....	774
Enabling the LDAP Changelog.....	775
Changing the LDAP Changelog Database Location.....	776
Viewing the LDAP Changelog Parameters in the Root DSE.....	777
Viewing the LDAP Changelog Using Idapsearch.....	778
Indexing the LDAP Changelog.....	780

Tracking Virtual Attribute Changes in the LDAP Changelog.....	781
Managing Access Control.....	781
Overview of Access Control.....	782
Working with Targets.....	792
Examples of Common Access Control Rules.....	797
Validating ACIs Before Migrating Data.....	798
Migrating ACIs from Sun/Oracle to PingDirectory Server.....	800
Working with Privileges.....	802
Working with Proxied Authorization.....	806
Working with Parameterized ACIs.....	813
Managing the Schema.....	814
About the Schema.....	814
About the Schema Editor.....	814
Default Directory Server Schema Files.....	815
Extending the Directory Server Schema.....	816
Managing Attribute Types.....	817
Creating a New Attribute over LDAP.....	820
Managing Object Classes.....	822
Managing an Object Class over LDAP.....	824
Creating a New Object Class Using the Schema Editor.....	825
Extending the Schema Using a Custom Schema File.....	826
Managing Matching Rules.....	827
Managing Attribute Syntaxes.....	833
Using the Schema Editor Utilities.....	837
Modifying a Schema Definition.....	838
Deleting a Schema Definition.....	838
Schema Checking.....	838
Managing Matching Rule Uses.....	839
Managing DIT Content Rules.....	840
Managing Name Forms.....	841
Managing DIT Structure Rules.....	842
Managing JSON Attribute Values.....	842
Configuring JSON Attribute Constraints.....	844
Managing Password Policies.....	848
Viewing Password Policies.....	848
About the Password Policy Properties.....	849
Modifying an Existing Password Policy.....	851
Creating a New Password Policy.....	851
Deleting a Password Policy.....	853
Modifying a User's Password.....	853
Enabling YubiKey Authentication.....	855
Enabling Social Login.....	855
Managing User Accounts.....	855
Disabling Password Policy Evaluation.....	858
Managing Password Validators.....	859
Managing Replication.....	864
Overview of Replication.....	864
Replication Versus Synchronization.....	865
Replication Terminology.....	866
Replication Architecture.....	868
Replication Deployment Planning.....	869
Enabling Replication.....	871
Deploying a Basic Replication Topology.....	873
A Deployment with Non-Interactive dsreplication.....	876
Configuring Assured Replication.....	879
Managing the Topology.....	885

Advanced Configuration.....	887
Modifying the Replication Purge Delay.....	887
Configuring a Single Listener-Address for the Replication Server.....	888
Monitoring Replication.....	888
Replication Best Practices.....	889
Replication Conflicts.....	890
Troubleshooting Replication.....	894
Replication Reference.....	897
Advanced Topics Reference.....	915
Managing Logging.....	922
Default Directory Server Logs.....	922
Types of Log Publishers.....	923
Managing Access and Error Log Publishers.....	925
Managing File-Based Access Log Publishers.....	926
Generating Access Logs Summaries.....	929
About Log Compression.....	931
About Log Signing.....	931
About Encrypting Log Files.....	931
Creating New Log Publishers.....	933
Configuring Log Rotation.....	934
Configuring Log Rotation Listeners.....	935
Configuring Log Retention.....	935
Configuring Filtered Logging.....	936
Managing Admin Alert Access Logs.....	937
Managing Syslog-Based Access Log Publishers.....	938
Managing the File-Based Audit Log Publishers.....	940
Managing the JDBC Access Log Publishers.....	941
Managing the File-Based Error Log Publisher.....	945
Managing the Syslog-Based Error Log Publisher.....	946
Creating File-Based Debug Log Publishers.....	947
Managing Monitoring.....	947
The Monitor Backend.....	947
Monitoring Disk Space Usage.....	949
Monitoring with the PingDataMetrics Server.....	950
About the Collection of System Monitoring Data.....	950
Monitoring Key Performance Indicators by Application.....	951
Configuring the External Servers.....	951
Preparing the Servers Monitored by the PingDataMetrics Server.....	951
Configuring the Processing Time Histogram Plugin.....	952
Setting the Connection Criteria to Collect SLA Statistics by Application.....	953
Updating the Global Configuration.....	953
Proxy Considerations for Tracked Applications.....	953
SNMP Implementation.....	953
Configuring SNMP.....	954
Monitoring with the Administrative Console.....	956
Accessing the Processing Time Histogram.....	956
Monitoring with JMX.....	956
Running JConsole.....	956
Monitoring the Directory Server Using JConsole.....	957
Monitoring Using the LDAP SDK.....	959
Profiling Server Performance Using the Stats Logger.....	960
StatsD monitoring endpoint.....	962
Adding Custom Logged Statistics to a Periodic Stats Logger.....	963
Monitoring Using SNMP.....	965
MIBS.....	965
Monitoring over LDAP.....	966

Managing Notifications and Alerts.....	966
Working with Account Status Notifications.....	966
Working with Administrative Alert Handlers.....	969
Configuring the JMX Connection Handler and Alert Handler.....	970
Configuring the SMTP Alert Handler.....	971
Configuring the SNMP Subagent Alert Handler.....	971
E-mail Account Status Notification Handler.....	972
Working with the Alerts Backend.....	979
Working with Alarms, Alerts, and Gauges.....	980
Testing Alerts and Alarms.....	981
Managing SCIM Servlet Extensions.....	984
Managing the SCIM 1.1 and 2.0 Servlet Extensions.....	984
Managing Server SDK Extensions.....	1015
About the Server SDK.....	1015
Available Types of Extensions.....	1015
DevOps and infrastructure-as-code.....	1016
Limitations when automating PingDirectory Server deployments.....	1016
Server profiles.....	1016
Topology-management tools.....	1021
Deployment automation.....	1022
Troubleshooting the Server.....	1026
Working with the Collect Support Data Tool.....	1026
Directory Server Troubleshooting Information.....	1029
About the Monitor Entries.....	1033
Directory Server Troubleshooting Tools.....	1034
Troubleshooting Resources for Java Applications.....	1036
Command-Line Tools.....	1055
Available Command-Line Tools.....	1055
Saving Options in a File.....	1061
Running Task-based Tools.....	1063

PingDirectoryProxy Server Administration Guide..... 1065

PingDirectory™ Product Documentation.....	1065
Introduction.....	1065
Overview of the PingDirectoryProxy Server Features.....	1065
Overview of the Directory Proxy Server Components and Terminology.....	1066
Server Component Architecture.....	1071
Directory Proxy Server Configuration Overview.....	1072
Installing the Directory Proxy Server.....	1073
Before You Begin.....	1073
Preparing the Operating System.....	1075
Getting the Installation Packages.....	1079
Ping license keys.....	1080
Installing the Directory Proxy Server.....	1080
About the Layout of the Directory Proxy Server Folders.....	1085
Running the Server.....	1086
Stopping the Directory Proxy Server.....	1088
Run the Server as a Microsoft Windows Service.....	1089
Uninstalling the Server.....	1090
Updating the Directory Proxy Server.....	1091
Configuring the Directory Proxy Server.....	1095
About the Configuration Tools.....	1095
Using the create-initial-proxy-config Tool.....	1096
Configuring a Standard Directory Proxy Server Deployment.....	1096
About dsconfig Configuration Tool.....	1099

Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth Tokens.....	1102
Topology Configuration.....	1103
Using the Configuration API.....	1113
Working with the Directory REST API.....	1126
Generating a Summary of Configuration Components.....	1127
Configuring Server Groups.....	1128
Domain Name Service (DNS) Caching.....	1129
IP Address Reverse Name Lookups.....	1130
Configuring Traffic Through a Load Balancer.....	1130
Managing Root Users Accounts.....	1130
Configuring Locations.....	1132
Configuring Batched Transactions.....	1136
Configuring Server Health Checks.....	1137
Configuring LDAP External Servers.....	1140
Configuring Load Balancing.....	1144
Configuring HTTP Connection Handlers.....	1153
Configuring Proxy Transformations.....	1158
Configuring Request Processors.....	1159
Configuring Server Affinity.....	1161
Configuring Subtree Views.....	1162
Configuring Client Connection Policies.....	1163
Configuring Globally Unique Attributes.....	1168
Configuring the Global Referential Integrity plugin.....	1169
Configuring an Active Directory Server Back-end.....	1170
Managing Access Control.....	1171
Overview of Access Control.....	1171
Working with Targets.....	1182
Examples of Common Access Control Rules.....	1187
Validating ACIs Before Migrating Data.....	1188
Migrating ACIs from Sun/Oracle to PingDirectory Server.....	1190
Working with Privileges.....	1192
Deploying a Standard Directory Proxy Server.....	1196
Introduction.....	1196
Automatic Server Discovery.....	1197
Creating a Standard Multi-Location Deployment.....	1207
Expanding the Deployment.....	1214
Merging Two Data Sets Using Proxy Transformations.....	1219
Deploying an Entry-Balancing Directory Proxy Server.....	1227
Deploying an Entry-Balancing Proxy Configuration.....	1227
Rebalancing Your Entries.....	1238
Managing the Global Indexes in Entry-Balancing Configurations.....	1241
Working with Alternate Authorization Identities.....	1246
Managing Entry-Balancing Replication.....	1248
Overview of Replication in an Entry-Balancing Environment.....	1249
Replication Prerequisites in an Entry-Balancing Deployment.....	1249
About the --restricted Argument of the dsreplication Command-Line Tool.....	1250
Checking the Status of Replication in an Entry-Balancing Deployment.....	1250
Example of Configuring Entry-Balancing Replication.....	1251
Managing the Directory Proxy Server.....	1255
Managing Logs.....	1256
Types of Log Publishers.....	1260
Creating New Log Publishers.....	1260
About Log Compression.....	1261
About Log Signing.....	1262
About Encrypting Log Files.....	1262

Configuring Log Rotation.....	1264
Configuring Log Rotation Listeners.....	1265
Configuring Log Retention.....	1265
Setting Resource Limits.....	1266
Monitoring the Directory Proxy Server.....	1267
Working with Alarms, Alerts, and Gauges.....	1270
Working with Administrative Alert Handlers.....	1274
Working with Virtual Attributes.....	1276
Managing Monitoring.....	1276
The Monitor Backend.....	1276
Monitoring Disk Space Usage.....	1278
Monitoring with the PingDataMetrics Server.....	1279
Monitoring Using SNMP.....	1282
Monitoring with the Administrative Console.....	1285
Accessing the Processing Time Histogram.....	1285
Monitoring with JMX.....	1285
Monitoring Using the LDAP SDK.....	1288
Monitoring over LDAP.....	1289
Profiling Server Performance Using the Stats Logger.....	1289
StatsD monitoring endpoint.....	1293
DevOps and Infrastructure as Code.....	1294
Server Profiles.....	1295
Troubleshooting the Directory Proxy Server.....	1300
Garbage Collection Diagnostic Information.....	1300
Working with the Troubleshooting Tools.....	1301
Directory Proxy Server Troubleshooting Tools.....	1302
Troubleshooting Resources for Java Applications.....	1303
Managing the SCIM 1.1 and 2.0 Servlet Extensions.....	1319
Overview of SCIM 1.1 Fundamentals.....	1319
Creating Your Own SCIM 1.1 Application.....	1321
Configuring SCIM 1.1.....	1321
Configuring Advanced SCIM 1.1 Extension Features.....	1325
Configuring the Identity Access API.....	1331
Monitoring the SCIM Servlet Extension.....	1333
Managing the SCIM 2.0 Servlet Extension.....	1336
Managing Server SDK Extensions.....	1345
About the Server SDK.....	1345
Available Types of Extensions.....	1346
Command-Line Tools.....	1346
Available Command-Line Tools.....	1346
Saving Options in a File.....	1352
Running Task-based Tools.....	1354
Consent Solution Guide.....	1355
PingDirectory™ Product Documentation.....	1355
Introduction to the Consent Service and Consent API.....	1355
Consent Service overview.....	1355
Consent API overview.....	1356
How consents are collected.....	1356
How consents are enforced.....	1356
How applications use the Consent API.....	1357
Consent Service configuration.....	1357
Configuration overview.....	1357
Example configuration scenarios.....	1357
Set up with the configuration scripts.....	1358

Setup in a replicated PingDirectory Server environment.....	1359
Configuration reference.....	1359
Authorization.....	1366
Manage consents.....	1367
Overview of consent management.....	1367
Consent definitions and localizations.....	1367
Perform an audit on consents.....	1368
Logging.....	1371
Correlating user and consent data.....	1372
Troubleshooting.....	1373

Delegated Admin Application Guide..... 1374

PingDirectory™ Product Documentation.....	1374
Delegated Admin overview.....	1374
Introduction.....	1375
Features.....	1375
Install Delegated Admin.....	1375
Installation locations.....	1375
Prerequisites.....	1375
Supported browsers.....	1376
Obtain the installation files.....	1376
Before you install.....	1377
Install the application.....	1377
Next steps.....	1380
Configure Delegated Admin.....	1381
Configuration overview.....	1381
Authentication configuration.....	1381
Configure delegated administrator rights on PingDirectory Server.....	1383
Parameterized Delegated Administrator Rights.....	1385
Configure user self-service.....	1385
Configure attributes and attribute search on PingDirectory Server.....	1387
Users and groups.....	1389
Generic resource types.....	1394
Differentiate resource types within the same subtree.....	1395
Customize UI form fields.....	1396
Set up email invitations for a new user.....	1397
Enable Password Policy State Virtual Attribute.....	1400
Enable the referential integrity plugin.....	1400
Enable log tracing.....	1400
Specify a custom hostname and port for your Directory Server.....	1401
Change the application logo.....	1401
Configure the session timeout.....	1401
Verify the installation.....	1401
Upgrade Delegated Admin.....	1402
Upgrade PingDirectory Server.....	1402
Upgrade the application.....	1404
Compatibility matrix.....	1405
Configure PingFederate Server.....	1406
Configure PingFederate as the identity provider.....	1406
Configure the OAuth server.....	1408
Configure PingDirectory Server as the token validator (create OAuth client for PingDirectory).....	1410
Configure Delegated Admin as a new client (create OAuth client for Delegated Admin)....	1411
Set Cross-Origin Resource Sharing (CORS) settings.....	1412
Configure PingFederate as a new client (create OAuth client for PingFederate).....	1412

Optional configuration tasks.....	1413
PingDataSync Administration Guide.....	1413
Introduction.....	1413
Overview of PingDataSync Server.....	1414
Data synchronization process.....	1414
Synchronization modes.....	1416
PingDataSync Server operations.....	1416
Configuration components.....	1418
Sync flow examples.....	1419
Sample synchronization.....	1422
Install PingDataSync Server.....	1423
System requirements.....	1424
Install the JDK.....	1425
Optimize the Linux operating system.....	1425
Ping license keys.....	1428
Installing PingDataSync Server.....	1429
Log on to the Administrative Console.....	1431
Server folders and files.....	1431
Start and stop the server.....	1432
Run the server as a Microsoft Windows service.....	1433
Uninstall the server.....	1434
Update servers in a topology.....	1435
Revert an update.....	1437
Install a failover server.....	1438
Administrative accounts.....	1439
Configure PingDataSync Server.....	1440
Configuration checklist.....	1440
Sync user account.....	1442
Configure PingDataSync Server in Standard mode.....	1443
Use the Configuration API.....	1447
Configuration with the dsconfig tool.....	1460
Topology configuration.....	1462
Domain Name Service (DNS) caching.....	1472
IP address reverse name lookups.....	1472
Configure the synchronization environment with dsconfig.....	1473
Prepare external server communication.....	1474
HTTP connection handlers.....	1475
Resync tool.....	1480
Realtime-sync tool.....	1484
Configure the PingDirectory Server backend for synchronizing deletes.....	1488
Configure DN maps.....	1488
Configure synchronization with JSON attribute values.....	1490
Configure fractional replication.....	1494
Configure failover behavior.....	1496
Configure traffic through a load balancer.....	1501
Configure authentication with a SASL external certificate.....	1501
Configure an LDAPv3 Sync Source.....	1503
Server SDK extensions.....	1503
Synchronize with PingOne for Customers.....	1503
Prerequisites.....	1504
Synchronize changes to a PingOne for Customers environment.....	1505
Synchronize changes from a PingOne for Customers environment.....	1507
Synchronize with Active Directory systems.....	1508
Overview of configuration tasks.....	1508

Configuring synchronization with Active Directory.....	1509
Active Directory sync user account.....	1510
Prepare external servers.....	1510
Configure sync pipes and sync classes.....	1511
Configure password encryption.....	1512
Password sync agent.....	1513
Synchronize with relational databases.....	1515
Use the server SDK.....	1516
RDBMS synchronization process.....	1516
DBSync example.....	1517
Configure DBSync.....	1518
Create the JDBC extension.....	1518
Configure the database for synchronization.....	1521
Considerations for synchronizing to database destination.....	1522
Configure a directory-to-database sync pipe.....	1523
Considerations for synchronizing from a database source.....	1526
Synchronize a specific list of database elements.....	1526
Synchronize with Apache Kafka.....	1527
Restrictions.....	1527
Configure a Kafka sync destination.....	1527
Message format.....	1528
Synchronize through PingDirectoryProxy servers.....	1531
Synchronization through a Proxy Server overview.....	1531
Example configuration.....	1533
Configure the source PingDirectory Server.....	1534
Configure a proxy server.....	1535
Configure PingDataSync Server.....	1537
Test the configuration.....	1538
Index the LDAP changelog.....	1540
Changelog synchronization considerations.....	1541
Synchronize in Notification Mode.....	1541
Notification mode overview.....	1541
Notification mode architecture.....	1543
Configure notification mode.....	1545
Implementing the server extension.....	1547
Configure the Notification sync pipe.....	1548
Access control filtering on the sync pipe.....	1550
Configure synchronization with SCIM.....	1551
Synchronize with a SCIM sync destination overview.....	1551
Configure synchronization with SCIM.....	1553
Map LDAP schema to SCIM resource schema.....	1557
Identify a SCIM resource at the destination.....	1562
Manage logging, alerts, and alarms.....	1563
Logs and log publishers.....	1563
Synchronization logs and messages.....	1565
Sync log message types.....	1566
Create a new log publisher.....	1567

Release Notes

Directory Server Release Notes

PingDirectory Server 8.1.0.6 release notes

The release notes for the 8.1.0.6 release of PingDirectory Server.

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-42961	To help with replication backlog analysis, the replication summary monitor now includes a 'replica-partial-backlog' attribute that shows how each origin replica contributes partial backlog with the 'per-origin-replication-backlog' property. The 'replica-partial-backlog' attribute also shows the change numbers used for the calculation.
DS-43898	Addressed an issue where the backend would store an incorrect count for a database key that had exceeded the index entry limit. This only happened for composite indexes when the server started up after not being shut down cleanly. Normal search processing was unaffected, but the matching entry count request control processing would return incorrect results.
DS-43959, DS-44924	<p>Added new global configuration properties that can be used to impose limits on the maximum number of attributes that can be present in an add request and the maximum number of modifications in a modify request, which can be used to avoid potential denial of service attacks.</p> <p>Both limits are set to 1000 by default, which is likely to be adequate for all legitimate use cases, and neither property affects the number of values that can be provided for an attribute.</p>

PingDirectory Server 8.1.0.5 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the on-replay-failure-wait-for-dependent-ops-timeout configuration property on a replication domain.
DS-44037	Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDirectory Server 8.1.0.4 release notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.
DS-43064	Fixed an issue that caused the server to return an objectClassViolation result code instead of the more appropriate attributeOrValueExists result code when trying to modify an entry to add an object class that already exists in that entry.

Ticket ID	Description
DS-43288	<p data-bbox="850 218 1455 338">Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p data-bbox="850 359 1455 768">To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p data-bbox="850 789 1455 1010">Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul data-bbox="850 1031 1464 1852" style="list-style-type: none"><li data-bbox="850 1031 1464 1220">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.<li data-bbox="850 1241 1464 1482">* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.<li data-bbox="850 1503 1464 1852">* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43576	Added the ability to retry operation failures from replication if the failures are likely due to dependent writes being played out of order. This issue only affected environments that were sending writes to different servers, and also were not able to use the appropriate level of replication assurance. To enable this setting, update the on-replay-failure-wait-for-dependent-ops-timeout configuration property on a replication domain.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43999	Updated the server to allow the operation purpose control to be used for operations that are part of an LDAP transaction.
DS-44037	Avoid lockdown due to missing changes during enable caused by a missing timestamp that indicates the enable time. The problem resulted in change numbers and error messages with dates around the year 1970.

PingDirectory Server 8.1.0.3 release notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.

PingDirectory Server 8.1.0.2 Release Notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default.

Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

- Fixed in: 8.1.0.2
- Introduced in: 8.1.0.0
- Support identifiers: DS-42790 SF#00695648
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.3.0.0
 - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 8.0.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.0.1.3
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.6
 - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the

entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.

- Fixed in: 7.0.0.0
- Introduced in: 2.0.0.0
- Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746

- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
 - Fixed in: 6.0.0.0
 - Introduced in: 4.6.0.0
 - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
 - Fixed in: 5.0.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
 - Fixed in: 5.0.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
 - Fixed in: 4.6.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-10470

- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
 - Fixed in: 4.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
 - Fixed in: 4.0.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
 - Fixed in: 3.6.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-5656
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.1.0.0
 - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42438	Fixed an issue that could cause the remove-defunct-server tool to not remove certain replication attributes when run with a topology json file.
DS-42687	Upgrade to Jetty 9.4.30
DS-42790	Fixed an issue where new replicas incorrectly went into lockdown mode after initialization. This issue would happen when trying to initialize a newly-added replica to a topology that had been created some time ago. This amount of time had to exceed the replication purge delay, which is 24 hours by default. Before this fix was introduced, you could get past this by running "leave-lockdown-mode" on the new replica, then re-running "dsreplication initialize" on it.

PingDirectory Server 8.1 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectory Server:

Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

- If you have upgraded a server that is in a cluster (that has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you can create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- The `bypass-pw-policy` privilege was intended to provide a way for administrators to bypass certain password restrictions that would normally be imposed when managing passwords for other users. A user with this privilege could use it to bypass password validation for their own entry. The `bypass-pw-`

policy privilege now only applies when changing another user's password (that is, an administrative password reset), and only in the following scenarios:

- A user with this privilege will be permitted to set pre-encoded passwords.
- A user with this privilege will be permitted to set passwords that would otherwise be rejected by one or more password validators.
- A user with this privilege will be permitted to set passwords that match the current password or that are in the password history.

The privilege will only apply when changing the password for another user, and it will have no effect for a self password change. Further, a user with this privilege will no longer be exempted from any other restrictions in their own password policy. Before upgrading, you should search for users that have the `bypass-pw-policy` privilege and check for compatibility issues. You can use the existing password validators and a custom password policy to enforce passwords for administrative users.

- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. When in this particular missing-changes state the local replica will not accept changes from the local replication server.
- Fixed an issue in which the server could incorrectly evaluate a matched values request control containing an extensible match filter that specified both an attribute type and a matching rule. The server incorrectly used the attribute type's equality matching rule instead of the matching rule specified in the filter.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.
- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-41762 SF#00675207 SF#00683777
- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301

- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.3.0.0
 - Support identifiers: DS-40955
- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 8.0.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
 - The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been

inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

- When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers

are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing

backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
 - Fixed in: 7.0.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-35790 SF#00625942

What's New

These are new features for this release of PingDirectory Server:

- The `collect-support-data` tool will now collect additional files if Delegated Admin is configured within PingDirectory Server. These files include the `config.js` configuration file, the version file, and any custom files used to create customized UI fields. This information can be useful when troubleshooting issues with the Delegated Admin application.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:
 - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - For the `collect-support-data` tool, you can now specify either a path, a file name, or a path and file name for the resulting `csd` file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
 - The `manage-profile` command used for creating server profiles can also be run as a recurring task from the Administration Console. Running `manage-profile` as a task creates an archive

file that can be downloaded with the HTTP File Servlet. This allows updated server profiles to be created from PingDirectory Server running in a container.

- A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this and the --remoteServer option added to the `collect-support-data` tool itself can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- The SCIMv2 REST API was added to PingDirectory Server 8.0. Now developers can "join" separate objects into one query that allows PingDirectory Server to present distinct objects in LDAP as a single SCIM Resource object. There are two general scenarios where this functionality will be used:
 - Primary and Secondary resources, where the secondary resource is represented as a field of the primary resource
 - Composite resources, where the SCIM endpoint server stitches together scattered data into a coherent resource with which the user can interact
- PingDirectory Server has a Consent REST API that allows users to create and store consents. This new feature now allows users to search for consents that have been granted to them by another party.
- PingDirectory Server now supports the ability to create composed attributes that are derived from other attributes like virtual attributes. However, composed attributes can be stored in the backend, they are persistent and can be indexed.
- To address the need for clients to obtain information about account and password policy states, a new virtual attribute Password Policy State JSON, that is a JSON object, provides read-only access to a number of account state and password policy state properties. Since the value is a JSON object, it should be easily consumable by HTTP clients using SCIM and the Directory REST API.
- PingDirectory Server currently has an HTTP file servlet extension that can be used to access files on the server filesystem. This can be used for several purposes such as serving static HTML pages. In this version, the HTTP file servlet now supports basic authentication. Users can authenticate with either a distinguished name or username. Additionally, a new file servlet will be configured automatically when creating a PingDirectory Server instance. This servlet will have as the base directory the install directory for the instance and can be used to access items such as configuration, log files, and backups.. Directory indexing is enabled so you can browse available files. When using this file servlet, authentication is required, and access is restricted to users with the file-servlet-access privilege.
- To assist with recovering from the split-brain state the "dsreplication initialize" command will have a new "--force" option that overrides the lockdown check.
- Missing changes will now be detected when the backend is reverted and there are insufficient changes in the changelog database. While in this particular missing-changes state, the local replica will not accept changes from the local replication server.

Known Issues/Workarounds

The following are known issues in the current version of PingDirectory Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	<p>Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.</p>
DS-1103,DS-41138,DS-41956,DS-41957	<p>Updated the password policy configuration to add support for alternate failure lockout actions, which can customize the behavior the server exhibits for an account with too many outstanding authentication failures. Available implementations include:</p> <ul style="list-style-type: none"> * A "Lock Account" action that will prevent the user from authenticating or from being used as an alternate authorization identity. This matches the behavior that the server exhibited in the past when the password policy was configured to lock accounts after too many failed authentication attempts, and it remains the default behavior unless an alternative is configured. * A "Delay Bind Response" action that will allow the user to authenticate if they provide the correct credentials and their account is not otherwise unusable, but it will delay the bind response (regardless of its ultimate success or failure) by a specified duration to limit the rate at which an attacker can attempt to guess the password. The account will be permitted as an alternate authorization identity without any delay imposed for those operations. * A "No Operation" action that will not prevent or otherwise interfere with the ability to use the account to authenticate or as an alternate authorization identity, but it will still be reported as having too many failed authentication attempts for the purposes of account status notifications, the password policy state extended operation, and the password policy state JSON virtual attribute.
DS-10216	<p>Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.</p>

Ticket ID	Description
DS-11505	<p>Changed the behavior the server exhibits for users with the bypass-pw-policy privilege. Although this privilege was primarily intended to allow administrators to be exempted from certain password policy restrictions while managing other user accounts, it also previously exempted the user from restrictions that should be imposed by their own password policy.</p> <p>As a result of these changes, the bypass-pw-policy privilege now only permits the following:</p> <ul style="list-style-type: none"> * An account with this privilege will be permitted to set pre-encoded passwords in other user entries, regardless of the value of the allow-pre-encoded-passwords setting in the target user's password policy. This does not apply when the privileged user is changing their own password. * An account with this privilege will be permitted to set passwords in other user entries that would otherwise be rejected by one or more password validators configured in the target user's password policy. This does not apply when the privileged user is changing their own password. * An account with this privilege will be permitted to set passwords in other user entries when the new password is in the target user's password history. This does not apply when the privileged user is changing their own password. <p>If the previous behavior (in which a privileged user is not subject to password policy restrictions for their own account) is desired, the user should be assigned a password policy that is not configured with the restrictions that are not wanted.</p>
DS-36573	<p>The minimum required heap size for installing PingDirectory Server has been increased to 768 MB. Other product sizes are unchanged.</p>
DS-36726	<p>Improved performance when adding entries that match very large composite index keys.</p>
DS-37829	<p>The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.</p>

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-38585	Added gauge "Replication Purge Delay" in order to protect against missing changes. The new gauge will have a warning and critical threshold with respect to the effective purge delay, which can be configured by selecting "Gauges" in dsconfig.
DS-38790	Added support for a new ds-pwp-state-json virtual attribute, whose value is a JSON object that provides information about the state and configuration for the password policy with which that entry is associated.
DS-38879	Added a populate composed attribute values task that can be used to update existing entries with composed attribute values without the need to export data to LDIF and re-import. A command-line tool to invoke the task is also provided.
DS-38879	Added a "composed attribute" plugin that allows creating attributes whose values are constructed from the values of other attributes in the same entry. Its behavior is similar to that of the constructed virtual attribute, but composed values are actually stored in the entry rather than being dynamically generated at the time the entry is retrieved, and therefore may be indexed. Composed attribute values may be generated when entries are created by LDAP add operations or in an LDIF import, and their values may be updated if the source attributes are changed by modify or modify DN operations.
DS-39238	Updated the attribute value password validator to provide the ability to specify a minimum substring length when determining whether to reject a proposed password because it contains the value of another attribute in the entry.
DS-39442	Added the X-Frame-Options header in the Administrative console to prevent clickjacking attacks.

Ticket ID	Description
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-39649,DS-40115	Optimized the searches for replication data performed by the status tool.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39911	Updated the character set password validator to make it possible to require that a proposed password contain characters from at least a specified minimum number of character sets. For example, you may define four optional sets containing lowercase letters, uppercase letters, numeric digits, and symbols, and then require that proposed passwords include characters from at least three of those sets.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40379	Fixed an issue that could cause the load-balancing-algorithm-name configuration property of a directory server instance to be lost when joining a topology.
DS-40530	Fixed XSS vulnerabilities in the Administrative console.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.

Ticket ID	Description
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the schemas attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40869	Made JSON the default SCIM 1.1 response content type for requests that did not specify an accept content type.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne for Customers pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-40955	Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.

Ticket ID	Description
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 10% of that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41056	Updated the dictionary of commonly used passwords to include new values from studies released at the end of 2019.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.

Ticket ID	Description
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41221	A new collaborator field has been added to consents. This field is for storing users with whom the consent has been shared with, in order to search consents that have been shared with a user.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41239	Missing changes are now detected for new replicas that have not yet had any changes.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41270	Fixed an intermittent hang in dsreplication initialize due to replication failing to send an internal replication message. When the hang happens a message containing "the destination server is currently unavailable" is logged on the target of the initialize. The fix is to retry sending the internal replication message.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41441	Changed a validator error to a warning since it was deemed to be relatively harmless. The validator error was "Validator Error: The server experienced an unexpected error. Please report this problem and include this log file. Received an update requiring replication assurance, but without a location option"
DS-41465	Obsolete replicas will no longer be purged by default. To turn on the purging of obsolete replicas use "dsconfig" to set "replication-purge-obsolete-replicas" to true in the global configuration.
DS-41471	Added a global ACI that grants clients access to the pre-read and post-read request controls by default. The server will only process these controls if the requester has permission to perform the associated write operation, and the entries returned will only include attributes the requester has permission to read.
DS-41516	Added a --addBaseEntry argument to dsreplication enable. This argument can be used to add a base entry when enabling replication for an empty base DN.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.

Ticket ID	Description
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41763	Updated the server behavior when returning entries in response to a search request in which the client explicitly specified a list of attributes to be returned. If any of the requested attributes exists in the entry but is not defined in the server schema, the server would have previously returned that attribute with a name formatted in all lowercase characters. The attribute will now be returned with a name that uses the same capitalization that the client used for it in the list of requested attributes.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and PingDirectoryProxy Server.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.
DS-41941	Fixed an issue that prevented enabling the LDAP changelog backend with the manage-profile replace-profile tool.

Ticket ID	Description
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

Release Notes Archive

Release notes for previous versions of PingDirectory Server are included for reference.

PingDirectory Server 8.0.0.5 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectory Server 8.0.0.3 release notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-42373	Fixed an issue where unindexed LDAP searches filtered on virtual attributes sometimes omitted objectClass from the returned result.
DS-42922	Fixed a bug where restoring an incremental backup could result in the server not being able to start.

Ticket ID	Description
DS-43288	<p data-bbox="850 218 1455 338">Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p data-bbox="850 359 1455 768">To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p data-bbox="850 789 1455 1010">Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul data-bbox="850 1031 1464 1854" style="list-style-type: none"><li data-bbox="850 1031 1464 1220">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.<li data-bbox="850 1241 1464 1482">* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.<li data-bbox="850 1503 1464 1854">* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDirectory Server 8.0.0.2 Release Notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-39539,DS-41417,DS-41478	Fixed an issue where the manage-profile replace-profile subcommand was unable to create new local DB backends through dsconfig. Also fixed an issue where replace-profile could not export and re-import data from a server with multiple backends.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41033	Before starting replication calculates the total backlog for each replica by adding up the outstanding changes for each remote replica. With this change obsolete replicas will no longer be included in the calculation.
DS-41051	Improved the logic used to determine an appropriate replication database cache size. The previous fixed size of 5MB was found to be too small in some cases, and the replication database could grow larger than expected. In deployments in which the JVM has access to at least 500MB of memory, the replication database cache will now be permitted to use up to 1% of that memory. The former 5MB cache size will still be used in deployments with access to less than 500MB of memory.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41079	Trimming of replication changes database no longer gets stuck when the sequence number of the first change is greater than the sequence number of the last change, which can happen when "dsreplication initialize" is used to initialize a target with changes that are older than the changes the target previously had.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.

Ticket ID	Description
DS-41215	Updated the manage-profile replace-profile subcommand to check for encryption-related arguments in setup-arguments.txt when determining if an export and re-import of user data is necessary.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41252	Obsolete changes are now removed from the replication database of the target system when the target system is initialized.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41658	Fixed an issue where schema changes to a user-defined object class with one or more subordinate classes were not written to the schema file until additional schema changes were made.
DS-41939	Fixed an issue with in which the server may not generate an account status notification for the account-updated notification type for modify operations unless the operation also qualifies for other types of account status notifications.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30
DS-42815	<p>Added a remove-attribute-type-from-schema tool that can be used to safely remove an attribute type definition from the server schema. It will ensure that the attribute type is not in use, and it will clean up metadata references to that attribute type that could have previously required re-importing the data before the attribute type could actually be removed from the schema.</p> <p>The remove attribute type processing can also be requested programmatically through an administrative task.</p>
DS-43043	Fixed an issue where paged subtree searches posted to the Directory Rest API failed with error message: "Unable to decode the cookie in the simple paged results control value", whenever the search returned entries with DN length approaching or exceeding 127 characters.

PingDirectory Server 8.0.0.1 Release Notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDirectory Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 8.0.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Furthermore, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any

other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

The following enhancements were made to the topology manager to make it easier to diagnose connection errors:

- Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
- Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed the following two issues in which the server could have exposed some clear-text passwords in files on the server file system:
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-

config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
 - Fixed in: 7.0.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074

- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
 - Server B had not received changes directly from a client for a long time (beyond the purge delay),
 - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 - Server A is shutdown, and
 - While Server A is shutdown, the Server B processes one or more changes directly from the client.
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where:
 - Server B had not received changes directly from a client for a long time (beyond the purge delay),
 - Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 - Server A is shutdown, and
 - While Server A is shutdown, the Server B processes one or more changes directly from the client.
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
 - Fixed in: 6.0.0.0
 - Introduced in: 4.6.0.0
 - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
 - Fixed in: 5.0.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

Note:

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered

secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
 - Fixed in: 4.6.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
 - Fixed in: 4.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
 - Fixed in: 4.0.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
 - Fixed in: 3.6.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.1.0.0
 - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40902	Fixed an issue that could cause the server to report an error when disabling a PingOne for Customers pass-through authentication plugin.
DS-40951	Improved import-ldif indexing performance.
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41280	The Admin Console is now deployable to an external container running Java 11 with no further downloads or updates necessary.

Ticket ID	Description
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

PingDirectory Server 8.0.0.0 Release Notes

Upgrade considerations

Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

For other upgrade considerations, see [Upgrade overview and considerations](#).

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 8.0.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788

What's New

These are new features for this release of the PingDirectory Server:

- Improved end user experience with several feature additions to user e-mail notifications. Now administrators can configure the server to send multi-part emails, including plain text and HTML. Also, in addition to changes to account state, such as when a user account is locked, administrators can configure notifications to send whenever any configured profile attributes are changed. For example, this can be used for confirmations of self-service account changes, or as notifications for changes made by administrators.
- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Several password-related improvements. A new password validator has been added that rejects passwords known to have been breached or stolen, as collected by the haveibeenpwned.com service. Also, administrators can take advantage of a new Argon2 algorithm and password storage scheme, as well as new options to the PBKDF2 algorithm and password storage scheme.
- New SCIMv2 REST API to create, read, update, and delete (CRUD) users and other resources using JSON over HTTP. This complements the Directory REST API introduced in 7.2. While the Directory REST API is intended for custom application development, the SCIMv2 REST API is more intended for integrations with third party software and services. With SCIMv2, administrators configure the data

conventions used in PingDirectory Server – resource types that map to directory object classes, their attributes, and their locations within the Directory Information Tree (DIT).

- A new tool to easily update the security certificates used by the server. The `replace-certificate` tool allows administrators to replace the certificates presented by the server for external client connections, both HTTPS and LDAPS. If required, the `replace-certificate` also allows the administrator to replace the certificates used for inter-server communication, like replication.

Known Issues/Workarounds

The following are known issues in this version of the PingDirectory Server:

- The following are suggested solutions for problems with slow DNS:
 - Maintain a connection pool in the client app rather than opening new connections for each bind.
 - Add appropriate records, including PTR records, to DNS.
 - Add options `timeout:1` in the `/etc/resolv.conf` file and/or options `single-request`.
 - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- SCIM2 PATCH operations require ACI read permissions for any required attributes in the resource's SCIM schema, even if the operation itself does not modify the required attribute itself. Otherwise, PATCH operations will fail with the error message "Applying patch ops results in an invalid resource". The following is an example of an ACI to grant read permission to the required attributes for Passthrough SCIM resource types of objectClass `inetOrgPerson` for a particular oauthscope:

```
aci: (targetfilter="(objectClass=inetOrgPerson)")
      (targetattr="objectClass||uid||cn||givenName||sn") (version 3.0; acl
      "Allow read access to inetOrgPerson required attributes with OAuth scope
      inetOrgPersonScope"; allow (read) oauthscope="inetOrgPersonScope";)
```
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
 - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
 - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
 - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37042	Added an account status notification handler that can send multi-part email messages (including a plain-text part, HTML part, and optional attachments) in response to notable events affecting user accounts.
DS-37745	Added support for an <code>oauthscope</code> access control bind rule, which can be used to grant or deny access control permissions based on a set of scopes associated with an OAuth token.
DS-37859	Added the <code>--exportImportLocalDBData</code> option to the <code>revert-update</code> tool. This option will perform an export and re-import of any local db backends if there are changes that require it between the two versions. The new option does not handle the LDAP changelog and replication changelog.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38243	Added a password validator that can use the Pwned Passwords service (https://haveibeenpwned.com/) to reject passwords that are known to have been compromised in data breaches.
DS-38371	Added a password storage scheme that uses the Argon2i password hashing algorithm. This scheme requires the free and open source Bouncy Castle library cryptographic, which is not included with the server. This library must be obtained from https://bouncycastle.org/ and placed in the server <code>lib</code> directory before the storage scheme may be used.
DS-38528	Added support for a <code>generate password</code> request control that can be included in an <code>add</code> request to request that the server generate a password for the new entry. The generated password will be provided to the client in a corresponding response control.

Ticket ID	Description
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38699	Avoid sending replication messages for LDAP operations where the required associated replication information is missing.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39099	Fixed an issue where error log notifications were generated regardless of whether the account status notification handler has the property enabled or disabled.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.

Ticket ID	Description
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> ▪ <code>start-ds</code> and <code>stop-ds</code> for PingDirectory Server ▪ <code>start-proxy</code> and <code>stop-proxy</code> for PingDirectoryProxy Server ▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server ▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their pending removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code>), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> ▪ Allow a required attribute to be read-only if it is constructed. ▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. ▪ Handle constructed attributes which reference other constructed attributes.
DS-39589	Fixed an issue that could cause access log messages for bind and StartTLS results to report the client connection policy that had previously been assigned to the connection rather than the new policy that is in place as a result of the operation.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.

Ticket ID	Description
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39787	Fix verify-index errors on multibyte UTF-8 strings.
DS-39796	Added support for two new account status notification types. The account-created notification type can be used to generate a notification whenever a new entry is created in an add request that matches a given set of criteria. The account-updated notification type can be used to generate a notification whenever an entry is updated in a modify or modify DN request that matches a given set of criteria.
DS-39797	<p>Updated the account status notification handler framework to make several new properties available for use in constructing notification messages. These properties provide information about the password policy configuration and the user's password policy state, including:</p> <ul style="list-style-type: none"> ▪ The time the notification was generated ▪ The DN of the account with which the notification is associated ▪ The time the account password was last changed ▪ Whether the account is in a usable state and information about any issues that might affect its usability ▪ Whether the account is administratively disabled ▪ Whether the account is expired or not yet active ▪ Information about any account lockout that may be in effect ▪ Information about password expiration ▪ Whether a new password was generated for a self-change or administrative reset

Ticket ID	Description
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39872	Updated Summarize Access Log Rotation Listener and Copy Log File Rotation Listener to run on a background thread.
DS-39873	Fixed an issue that allowed replicated subtree deletes to cause OutOfMemory errors on replicas. Also fixed a related issue that would cause the replication log to fill up with mild errors.
DS-39882	Fixed an issue that could prevent the simple request criteria from properly evaluating a target entry filter or group membership for a modify DN operation after the change had already been applied to the backend.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40154	Fixed an issue where the restore tool was not restoring all dependencies of an incremental backup.
DS-40177	Fixed an issue that could interfere with the server's ability to purge an earlier, full backup when the following conditions are satisfied: Retention is used. Multiple levels of incremental backups depend on the full backup."
DS-40210	Fixed an issue that prevented uniqueMembers from adding themselves to a groupOfUniqueNames.
DS-40249	Fix an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40317	Created a new function that takes index objects rather than the counts so that we can avoid adding to a <code>long.max_value</code> , creating a long overflow.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.

Ticket ID	Description
DS-40409	Updated the <code>ldif-diff</code> tool so that it provides a <code>--stripTrailingSpaces</code> option that can cause the LDIF parser to strip off illegal trailing spaces rather than reject the associated entry or change record.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile replace-profile</code> to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40561	Fixed an issue that prevented assured replication from working for requests received via SCIM or the REST API.
DS-40674	Added the <code>--addMissingRdnAttributes</code> argument to <code>manage-profile setup</code> . This argument can be used when including LDIF files in the server profile. It will automatically add any missing RDN values to the set of entry attributes when they are not already present.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40744	Fixed an issue with the interaction between deprecated password storage schemes and forced password reset. If a user's password is reset by an administrator using a password storage scheme that is subsequently configured as deprecated, the act of re-encoding the password with the new default scheme would have incorrectly cleared the password reset flag.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.
DS-40788	Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
DS-40799	Fixed an issue in which an account that had been temporarily locked after too many failed authentication attempts could become re-locked with fewer than the expected number of subsequent failed attempts after the previous lockout period had elapsed.

PingDirectory Server 7.3.0.10 release notes

Critical fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
 - Fixed in: 7.3.0.10
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-41762 SF#00675207 SF#00683777

Resolved issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectory Server 7.3.0.7 Release Notes

Critical Fixes

This release of PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
 - Fixed in: 7.3.0.5
 - Introduced in: 7.3.0.0
 - Support identifiers: DS-40955
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 7.3.0.5
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.

Fixed in: 7.2.1.0

Introduced in: 7.0.0.0

Support identifiers: DS-38334 SF#00655578

- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an `InvalidKeyException` could occasionally be reported by `import-ldif`. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': `InvalidKeyException`: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like `userRoot`), the LDAP changelog backend, or the replication database.
 - When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include `backup`, `create-initial-config`, `create-initial-proxy-config`, `dsreplication`, `enter-lockdown-mode`, `export-ldif`, `import-ldif`, `ldappasswordmodify`, `leave-lockdown-mode`, `manage-tasks`, `manage-topology`, `migrate-ldap-schema`, `parallel-update`, `prepare-endpoint-server`, `prepare-external-server`, `realtime-sync`, `rebuild-index`, `re-encode-entries`, `reload-http-connection-handler-certificates`, `reload-index`, `remove-defunct-server`, `restore`, `rotate-log`, and `stop-server`. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords

included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

Fixed in: 7.0.1.3

Introduced in: 7.0.0.0

Support identifiers: DS-38897 DS-38908

- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368

- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
 - Fixed in: 7.0.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

- Fixed in: 6.2.0.0
- Introduced in: 2.1.4.0
- Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 1. Server B had not received changes directly from a client for a long time (beyond the purge delay),
 2. Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 3. Server A is shutdown, and
 4. While Server A is shutdown, the Server B processes one or more changes directly from the client.

Fixed in: 6.2.0.0

Introduced in: 3.5.0.0

Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3

 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
 - Fixed in: 6.0.0.0
 - Introduced in: 4.6.0.0
 - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
 - Fixed in: 5.0.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
 - SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols

are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
Introduced in: 2.1.0.0
Support identifiers: DS-11782
- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
 - Fixed in: 4.6.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
 - Fixed in: 4.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
 - Fixed in: 4.0.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing `get-changelog-batch-requests` at the same time that live traffic is happening.
 - Fixed in: 3.6.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054

- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-5656
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.1.0.0
 - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the "Resource" column in the output of "status". This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-39589	Fixed an issue that could cause access log messages for bind and StartTLS results to report the client connection policy that had previously been assigned to the connection rather than the new policy that is in place as a result of the operation.
DS-39799	Allows users who were migrated from the admin backend to the topology to manage the topology. Migrated users are granted the "manage-topology" privilege if they do not already have it.
DS-39882	Fixed an issue that could prevent the simple request criteria from properly evaluating a target entry filter or group membership for a modify DN operation after the change had already been applied to the backend.
DS-40154	Fixed an issue where the restore tool was not restoring all dependencies of an incremental backup.
DS-40263	Fixed an issue that could cause references to old servers to remain in config.ldif files after remove-defunct-server was run.

Ticket ID	Description
DS-40321	Fix verify-index to correctly validate substring indexes containing multi-byte UTF-8 characters.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40561	Fixed an issue that prevented assured replication from working for requests received via SCIM or the REST API.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40771	Added a --duration argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.
DS-40951	Improved import-ldif indexing performance.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDirectory Server 7.3.0.5 Release Notes

Critical Fixes

This release of the Directory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.
 - Fixed in: 7.3.0.5
 - Introduced in: 7.3.0.0
 - Support identifiers: DS-40955
- Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
 - Fixed in: 7.3.0.5
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-40788

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
- Introduced in: 5.2.0.6
- Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
 - Fixed in: 7.0.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the

changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.

- Fixed in: 6.2.0.0
- Introduced in: 2.1.4.0
- Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
 - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 - 3) Server A is shutdown, and
 - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
 - Fixed in: 6.2.0.0

 - Fixed in: 3.6.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-5656

- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854
- Fix a bug where PingDirectory Server could potentially miss some update messages in large topologies after a restart.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.1.0.0
 - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-40788	Fixed an issue that could cause the server to report an "Unable to decode a blacklist key" error while trying to open a local DB backend after an unclean shutdown.
DS-40955	Addressed an issue where replication could incorrectly detect a backlog that never clears when updating from a pre-7.3 to a 7.3 or later version. This issue requires that servers were previously removed from the topology, and it has been seen rarely.

PingDirectory Server 7.3.0.4 Release Notes

Critical Fixes

This release of the PingDirectory Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."
 - Fixed in: 7.2.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-37313
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
 - Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.5
 - Support identifiers: DS-35528 SF#624368
- Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.

The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.

- Fixed in: 7.0.0.0
 - Introduced in: 5.2.0.6
 - Support identifiers: DS-35616 SF#00625189
- Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.
 - Fixed in: 7.0.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-35790 SF#00625942
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216

- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
 - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 - 3) Server A is shutdown, and
 - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612
- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.2.0.3
 - Support identifiers: DS-17074
- Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
 - Fixed in: 6.2.0.0
 - Introduced in: 2.1.4.0
 - Support identifiers: DS-17237 SF#3746
- Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.
 - Fixed in: 6.2.0.0
 - Introduced in: 5.0.0.0
 - Support identifiers: DS-12216
- Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where
 - 1) Server B had not received changes directly from a client for a long time (beyond the purge delay),
 - 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server,
 - 3) Server A is shutdown, and
 - 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
 - Fixed in: 6.2.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-18035 SF#00614612

- Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.1.0
 - Support identifiers: DS-18070
- Fixed an issue where opening the backend database might fail with an `IllegalStateException` that references "exploded-index-background-deletes" when there are several backend exploded indexes.
 - Fixed in: 6.0.0.0
 - Introduced in: 4.6.0.0
 - Support identifiers: DS-15094
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
 - Fixed in: 5.0.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-11720 SF#2453
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a `SECURITY-NEGOTIATION` access log message. The "protocol" element of a `SECURITY-NEGOTIATION` access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any `SECURITY-NEGOTIATION` messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

- Fixed a problem that could interfere with access to an exploded attribute index after performing an online index rebuild for that attribute.
 - Fixed in: 4.6.0.0
 - Introduced in: 4.5.1.0
 - Support identifiers: DS-10470
- Fix a bug in low level protocol buffer that could result in "uncaught exception" errors.
 - Fixed in: 4.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-9268 SF#2002
- Improve server stability by disabling explicit garbage collections that were being caused by JMX connections.
 - Fixed in: 4.0.0.0
 - Introduced in: 3.5.0.0
 - Support identifiers: DS-7633
- Fix a bug in the LDAP Changelog where the changelog index manager could capture new changes for an attribute in one index after already hitting the end of another index. This created the possibility for changes to be missed when processing get-changelog-batch-requests at the same time that live traffic is happening.
 - Fixed in: 3.6.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-7422
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Address an issue where a directory server might resend duplicate changes when processing a GetChangelogBatch request in an environment that is under heavy load.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-5656
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854
- Fix a bug where PingDirectory Servers could potentially miss some update messages in large topologies after a restart.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.1.0.0
 - Support identifiers: DS-3592

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-40744	Fixed an issue with the interaction between deprecated password storage schemes and forced password reset. If a user's password is reset by an administrator using a password storage scheme that is subsequently configured as deprecated, the act of re-encoding the password with the new default scheme would have incorrectly cleared the password reset flag.
DS-40799	Fixed an issue in which an account that had been temporarily locked after too many failed authentication attempts could become re-locked with fewer than the expected number of subsequent failed attempts after the previous lockout period had elapsed.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

PingDirectory Server 7.3.0.3 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
PDSTAGING-840	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-40327	Fixed an issue in which an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search now returns 52 (unavailable) in this situation.

PingDirectory Server 7.3.0.1 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectory Server:

The file `remove-sample-directory-data-aci.ldif`, which is provided with the Delegated Admin installation package, was updated in version 3.5.0 to reinstate permissions for users to change their own passwords (self-service password reset). If you have used an earlier version of this LDIF file, consider manually adding the following ACI from the updated version:

```
dn: dc=example,dc=com
changetype: modify
add: aci
```

```
aci: (targetattr="userPassword") (version 3.0; acl "Allow users to update
their own password"; allow (write) userdn="ldap:///self");)
```

Resolved Issues

The following issues have been resolved with this release of PingDirectory Server:

Ticket ID	Description
DS-17278	<p>Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps.</p> <p>Updated the LDAP external server monitor to include attributes that track health-check state changes for external servers. The new attributes include the following information:</p> <ul style="list-style-type: none"> ▪ Number of times a health-check transition has occurred ▪ Timestamps of the most recent transitions ▪ Messages associated with the most recent transitions
DS-39176, DS-39308	<p>Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 Release Notes.</p> <p>As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code>, download the appropriate JAR file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.</p>
DS-39347	<p>Fixed an issue in which Delegated Admin did not work properly if the name of the REST resource type was not the same as the resource endpoint.</p>
DS-39510	<p>Fixed an issue in which the Management Console was improperly sanitizing a server's host name, which prevented switching servers in the console's Server drop-down list.</p>

Ticket ID	Description
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> Allow a required attribute to be read-only if it is constructed. Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. Handle constructed attributes that reference other constructed attributes.
DS-39693	<p>Fixed an issue in which Delegated Admin search results were truncated and invalid upon encountering a Directory entry that contained a Boolean or Integer syntax attribute whose values did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results, and a warning message is logged to the server errors log.</p>
DS-39873	<p>Fixed an issue that allowed replicated subtree deletes to cause <code>OutOfMemory</code> errors on replicas. Also fixed a related issue that caused the replication log to fill up with mild errors.</p>

PingDirectory Server 7.3.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Server:

Important:

If you plan to upgrade servers using a mixed-version environment where one version is earlier than 7.0 and some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. You cannot remove any existing servers (using `dsreplication disable`) or add new servers (using `dsreplication enable`) when in this transitional state of partially-updated servers. When a topology has been completely migrated to a 7.0 or later version with the topology registry, changes to the topology size are allowed, even in mixed-version environments (for example, mixed 7.3 and 8.3).

- To ensure correct search results with Delegated Admin, disable client caching by updating the Delegated Admin HTTP Servlet Extension to return response headers, and then stop and restart the server, as follows:

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin" --set "response-header:Cache-Control: no-cache, no-store, must-revalidate" --set "response-header:Expires: 0" --set "response-header:Pragma: no-cache"
```

What's New

These are new features for this release of the Directory Server:

- Introduced a new capability called Server Profiles to manage PingDirectory instances following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of a PingDirectory instance to a directory of text files called a Server Profile, track changes to these files in version control like Git, and install new instances of PingDirectory or update existing instances of PingDirectory from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.
- Several improvements to support highly automated or orchestrated environments. Replication management tools have been improved to support typical workflows such as: simultaneous automated initialization of multiple instances such as during a scale out operation; automated initialization of instances despite other instances being unavailable such as during a replacement of a failed instance; automated planned removal of an instance such as during a scale down. Additionally, an HTTP status endpoint has been added to report overall instance health and availability to a cluster orchestrator like Kubernetes or to a network load balancer like AWS Network Load Balancer.
- New features for delegated administration: using REST Resource Types, administrators can delegate management of new resource types, like groups and organizations, in addition to the user management features available previously. Using Delegated Access Rights, administrators now have independent controls over delegation of search, view, update, and create per resource type.
- New plugin for pass-through authentication to PingOne for Customers. Pass-through authentication allows passwords to be managed by users and administrators in PingOne for Customers while still supporting legacy LDAP application connections on-prem.
- New features for data encryption in transit and at rest: added support for TLS 1.3, ability to encrypt and automatically decrypt sensitive files such as tools.properties and keystore pin files using the server data encryption keys, and the ability to more easily and securely separate master keys from data encryption keys by protecting the server encryption settings database using either Amazon Key Management Service (AWS KMS) or HashiCorp Vault.
- Improved replication resiliency to extended network partitions or downtime. The retention period for the replication changelog now supports a disk usage threshold in addition to an age limit for change retention. In combination, this means changes under typical load can be retained for longer than the age limit as long as the disk usage threshold is not exceeded.
- Added support for Amazon Corretto JDK 8, Windows Server 2019, Red Hat Enterprise Linux 7.6, CentOS 7.6, Amazon Linux 2, and Docker 18.09.0 on Ubuntu 18.04 LTS.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Server:

- When dsreplication is run to add a server to the topology using another node that is not the topology master, it may fail with the following error:

```
"Error updating replication configuration on base DN dc=example,dc=com of server 'ds3' (ldaps://localhost:3636). See /Users/<name>/installs/7.2/s3/logs/tools/dsreplication.log for a detailed log of this operation. Details: A communication problem occurred while contacting the server: The connection to server localhost:3389 was closed while waiting for a response to an add request AddRequest(dn='cn=dc_example_dc_com,cn=domains,cn=Multimaster Synchronization,cn=Synchronization Providers,cn=config', attrs={Attribute(name=objectclass, values={'top', 'ds-cfg-replication-domain'}), Attribute(name=cn, values={'dc_example_dc_com'}), Attribute(name=ds-cfg-server-id, values={'11443'}), Attribute(name=ds-cfg-base-dn, values={'dc=example,dc=com'})}): A request sent on this client connection caused an internal error in the server. This connection will be terminated."
```

The workaround for this issue is to use the topology master for the --host1 parameter of dsreplication to add the new server into the topology.

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
PDSTAGING-570,DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:</p> <ul style="list-style-type: none"> - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections. - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
PDSTAGING-570,DS-38344	<p>The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.</p>
PDSTAGING-570,DS-38335	<p>The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.</p>
DS-6401	<p>Added a target-database-size parameter to the Changelog Backend and the Replication Server configuration objects to allow the corresponding changelogs to grow on disk beyond the purge delay up to the specified total disk size.</p> <p>It is possible that the changelog database size on disk exceeds this configured value since changes are never purged before the configured purge delay</p> <p>A new "Changelog Database Target Size (Percent)" gauge is also included, which will raise an alarm if a changelog grows on disk above the specified limit.</p> <p>So that the server can more easily achieve the target database disk size, the default log file size for both database environments has been reduced from 100MB to 10MB.</p>
DS-15734	<p>Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a key from the Amazon Key Management Service.</p>
DS-17630	<p>Enabled secure JMX connections. Clients must specify the truststore when running applications, and possibly the type and password for the truststore.</p>

Ticket ID	Description
DS-18060	<p>Added an HTTP servlet extension that can be used to retrieve the server's current availability state. It accepts any GET, POST, or HEAD request sent to a specified endpoint and returns a minimal response whose HTTP status code may be used to determine whether the server considers itself to be AVAILABLE, DEGRADED, or UNAVAILABLE. The status code for each of these states is configurable, and the response may optionally include a JSON object with an "availability-state" field with the name of the current state.</p> <p>Two instances of this servlet extension are now available in the default configuration. A request sent to /available-state will return an HTTP status code of 200 (OK) if the server has a state of AVAILABLE, and 503 (Service Unavailable) if the server has a state of DEGRADED or UNAVAILABLE. A request sent to the /available-or-degraded-state will return an HTTP status code of 200 for a state of AVAILABLE or DEGRADED, and 503 for a state of UNAVAILABLE. The former may be useful for load balancers that you only want to have route requests to servers that are fully available. The latter may be useful for orchestration frameworks if you wish to destroy and replace any instance that is completely unavailable.</p>
DS-36474	<p>Updated the ldapdelete command-line tool to improve robustness and add features. Some of the new features include support for client-side subtree delete, deleting entries that match search filters, following referrals, writing failures to a rejects file, rate limiting, and support for a variety of additional controls.</p>
DS-36685	<p>Improved the diagnostic message the server returns when rejecting a proxied authorization attempt because the target account's password policy state does not permit that user to authenticate.</p>
DS-37063	<p>Added a plugin that can allow users to authenticate to the Directory Server with credentials from corresponding accounts in the PingOne for Customers service.</p>

Ticket ID	Description
DS-37063,DS-38012,DS-38497	<p>Updated the pass-through authentication plugin to add a bind-dn-pattern configuration property that allows constructing the DN of the remote user from information in the local user entry. Alternately, if the remote server supports simple authentication with a bind DN value that is not actually a valid LDAP distinguished name, this property can be used to supply that identifier. For example, when passing through authentication to Microsoft Active Directory, this property can be used to construct a bind DN that is actually the user principal name (UPN) for the remote account.</p> <p>Also, updated the pass-through authentication plugin to add an included-local-entry-base-dn configuration property that can be used to indicate which local entries are eligible for pass-through authentication. By default, pass-through authentication is automatically enabled for all users contained in any public backend, but this property can be used to restrict that set of users without the need to define a request criteria. This change also ensures that the server no longer attempts to pass through authentication attempts for root users or topology administrators by default (although if that ability is desired, it can be re-enabled by adding "cn=config" as an included-local-entry-base-dn value).</p>
DS-37164	<p>Replication now removes references to obsolete replicas, in both LDAP and in the BDB database. A replica is obsolete when it has been disabled and all changes are older than the replication purge delay.</p>
DS-37363	<p>Updated the server to make the replication missing changes state persist across restarts. If a server is offline for longer than the configured purge delay, then replication cannot automatically bring the server back in-sync with the rest of the topology. To avoid serving stale data, the server enters lockdown mode when it has missed changes. Prior to this change, restarting the server would incorrectly clear this missing changes state, and it would not enter lockdown mode, which could lead to it serving stale data. Now the server must be reinitialized either from a recent backup or by using "dsreplication initialize" to clear the missing changes state.</p>
DS-37430	<p>Added logging for DNS lookups that take longer than a warning threshold. The default warning threshold is 10 seconds. Added the DNS Resolution monitor to track DNS lookup speed.</p>

Ticket ID	Description
DS-37617	HTTP Connection Handlers now accept client-provided correlation IDs by default. To adjust the set of HTTP request headers that may include a correlation ID value, change the HTTP Connection Handler's correlation-id-request-header property.
DS-37757	Fixed an issue that could cause entryUUID mismatches on replicas configured to automatically use entryUUID as the naming attribute for add requests matching a given set of connection or request criteria.
DS-37805	Updated the server to better sanitize information included in diagnostic messages included in responses to clients. In some cases (for example, in the event of a unique attribute conflict), a response diagnostic message could disclose the existence of another entry in the server.
DS-37839	Make Fingerprint Certificate Mapper and Subject DN to User Attribute Certificate Mapper disabled by default on fresh installations. This will not affect upgrades from installations where these mappers are enabled.
DS-37842	Fixed an issue that allowed a modify operation to alter an entry in a way that left it without one or more superior object classes.

Ticket ID	Description
DS-37959	<p data-bbox="850 216 1455 275">Added support for insignificant configuration archive attributes.</p> <p data-bbox="850 296 1455 926">The configuration archive is a collection of the configurations that have been used by the server at some time. It is updated whenever a change is made to data in the server configuration, and it is very useful for auditing and troubleshooting. However, because the entries that define root users and topology administrators reside in the configuration, changes to those entries will also cause a new addition to the configuration archive. This is true even for changes that affect metadata for those entries, like updates to the password policy state information for one of those users. For example, if last login time tracking is enabled for one of those users, especially with high-precision timestamps, a new configuration may be generated and added to the configuration archive every time that user authenticates to the server. While it is important for this information to be persisted, it is not as important for it to be part of the server's configuration history.</p> <p data-bbox="850 947 1455 1199">This update can help avoid the configuration archive from storing information about updates that only affect this kind of account metadata. If a configuration change only modifies an existing entry, and if the only changes to that entry affect insignificant configuration archive attributes, then that change may not be persisted in the server's configuration archive.</p> <p data-bbox="850 1220 1455 1308">By default, the following attributes are now considered insignificant for the purpose of the configuration archive:</p> <p data-bbox="850 1329 1455 1671">* ds-auth-delivered-otp * ds-auth-password-reset-token * ds-auth-single-use-token * ds-auth-totp-last-password-used * ds-last-access-time * ds-pwp-auth-failure * ds-pwp-last-login-ip-address * ds-pwp-last-login-time * ds-pwp-password-changed-by-required-time * ds-pwp-reset-time * ds-pwp-retired-password * ds-pwp-warned-time * modifiersName * modifyTimestamp * pwdAccountLockedTime * pwdChangedTime * pwdFailureTime * pwdGraceUseTime * pwdHistory * pwdReset</p>

Ticket ID	Description
DS-37960	<p>The Delegated Admin configuration has changed significantly. Delegated Admin Resource Types were removed and replaced by REST Resource Types. Delegated Administrators and Delegated Group Administrators were removed and replaced by Delegated Admin Rights and Delegated Admin Resource Rights. Previous configurations are converted to the new configuration definitions by the update tool when the server is updated.</p>
DS-38021	<p>Enabled assured replication by default for all add, delete, and modify DN operations. Enabled assured replication by default for all modify operations that alter passwords or key password policy state attributes.</p> <p>The server will now wait (up to a maximum of one second) for these types of changes to be replicated to all available local servers before returning the response to the client. This can help avoid issues that may arise if a client sends a write request, and then immediately sends another request that depends on that previous request. If the two requests are routed to different servers, then the second operation may fail or yield an unexpected result if the change from the first request has not yet been replicated.</p> <p>This change will only take effect for new installations. It will not apply to existing installations that are updated to the new release.</p>
DS-38050	<p>Updated the server to support encrypting the contents of the PIN files needed to unlock certificate key and trust stores. If data encryption is enabled during setup, then the default PIN files will automatically be encrypted.</p> <p>Also, updated the command-line tool framework so that the tools.properties file (which can provide default values for arguments not provided on the command line), and passphrase files (for example, used to hold the bind password) can be encrypted.</p>
DS-38072	<p>Updated the server to enable TLSv1.3 by default on JVMs that support it (Java 11 and higher).</p>
DS-38077	<p>Servers that are removed from replication with the "dsreplication disable" command are now also removed from the topology when the last non-schema domain is disabled. This allows the state of the servers after the disable to be closer to the pre-enabled state.</p>

Ticket ID	Description
DS-38083	Fixed ordering of consent-service-cfg.dsconfig commands so that bearer token authentication is enabled after its dependency, unprivileged consent.
DS-38085	Fixed an issue in the installer where the Administrative Console's trust store type would be incorrectly set if it differed from the key store type.
DS-38090,DS-38564,DS-38567	The response header used for correlation IDs may now be set at the HTTP Servlet Extension level using the correlation-id-response-header configuration property. If set, this property overrides the HTTP Connection Handler's correlation-id-response-header property.
DS-38109	Added the --skipHostnameCheck command line option to the setup script, which bypasses validation of the provided host name for the server.
DS-38190	Fixed a problem that could cause a negative etime to appear in the access log when using assured replication.

Ticket ID	Description
DS-38193	<p>Updated the behavior the server exhibits if an attribute type definition is removed from the schema while it is still referenced by a local DB backend's compaction dictionary.</p> <p>In an attempt to minimize the amount of disk space and memory needed to store information in the database, the server compacts the data in several ways. One of its compaction techniques is to reference attribute types by tokens rather than their full name. It maintains a dictionary of these tokens so that it can quickly translate between an attribute type and its corresponding token. If an attribute has been used in at least one entry in the backend since the last LDIF import, then this dictionary should include a token for that attribute type.</p> <p>On startup, the server will read this compaction dictionary into memory. Previously, if it encountered a reference to an attribute type that had been used in the backend but is no longer defined in the schema, it would abort the startup process. This behavior has been changed so that it will instead generate an administrative alert to warn administrators of the problem and provide information about how to address the issue, but it will no longer abort the startup process. The server will also generate an administrative alert if it encounters an entry whose encoded representation includes a token that is associated with an undefined attribute type.</p> <p>In addition, the server has also been updated so that it will no longer permit attribute types or object classes to be removed from the schema if they are referenced in a compaction dictionary.</p>
DS-38202	<p>Fixed an issue that could cause an error during an LDIF export of a data set with a large number of non-leaf entries. In such cases, the data is written to multiple files that are merged at the end of the export process. If the LDIF export was encrypted with a passphrase or an encryption settings definition, the merge process could fail, leaving the export spread across multiple files instead of aggregated into a single file.</p> <p>This issue did not affect the usability or integrity of the export data. It could still be imported, although the administrator would need to list each of the export files in the correct order when performing the import.</p>

Ticket ID	Description
DS-38205	Addressed potential parsing errors in the periodic stats logger when the server is deployed in a non-English locale.
DS-38272	Fixed a Windows stop-server.bat issue where locales using commas for decimal separators could not shut down.
DS-38273	Fixed an issue where changes to a dynamic group's member URL sometimes did not take effect until the next server restart.
DS-38283	Updated ACI processing for modify DN requests. The "export" and "import" rights are no longer required if the superior DN is provided, but has not changed.
DS-38291	Fixed an issue with the client-side validation properties that the haystack password validator would return in a get password quality requirements extended response.
DS-38336	Updated the result code map to allow overriding the default result code that the server returns when a client tries to perform a password-based bind as a user who doesn't have a password.
DS-38403	Fixed an issue that could prevent certain types of initialization failures from appearing in the server error log by default.

Ticket ID	Description
DS-38415,DS-38418,DS-38419,DS-38420	<p data-bbox="849 216 1419 279">Addressed several issues with the pass-through authentication plugin.</p> <p data-bbox="849 296 1443 359">USE SEPARATE CONNECTIONS FOR SEARCH AND BIND REQUESTS</p> <p data-bbox="849 375 1464 753">If the plugin is configured with a search filter pattern, then it may perform a search to find the entry in the external server that corresponds to the entry for the local user that is trying to bind. In such cases, search requests may have been issued over the same connections that were also been used to process bind operations. The change in authorization identity resulting from those bind attempts may interfere with the ability to perform the searches. The plugin has been updated to ensure that search and bind requests are now issued over separate connections.</p> <p data-bbox="849 770 1398 833">ALLOW RETRY ATTEMPTS WITH A SINGLE EXTERNAL SERVER</p> <p data-bbox="849 850 1464 1455">If the plugin is configured with multiple external servers, then it can use some or all of those servers in a pass-through authentication attempt. If a search or bind attempt fails against the first server, and if that failure indicates that there may have been a problem with the server or the connection to it, then the plugin would have re-tried the operation in other servers until the attempt succeeds, the attempt fails in a way that does not indicate a problem with the server or the connection, or all servers have been tried. However, if only a single external server had been configured, then no retry attempt would have been made. The plugin has been updated so that if it is only configured with a single external server, and if a failure is encountered while communicating with that server that may benefit from retrying that operation, then the plugin will attempt to establish a new connection to that server and retry the operation.</p> <p data-bbox="849 1472 1341 1535">UTILIZE ALL CONFIGURED EXTERNAL SERVERS</p> <p data-bbox="849 1551 1464 1992">If PingDirectory Server is configured with a location, then the pass-through authentication plugin will use that information to determine the order in which the external servers should be accessed. It will first attempt external servers in the same location as PingDirectory Server, followed by servers in the most preferred failover location, the second-most preferred failover location, and so on. However, the plugin might have used external servers that did not have a location assigned, or that were assigned to a location that is not one of PingDirectory Server's preferred failover locations. The plugin has been updated to ensure that these servers may be used, albeit with a lower priority than the other servers.</p> <p data-bbox="849 2009 1451 2072">IMPROVE VISIBILITY OF PLUGIN PROCESSING RESULTS</p>

Ticket ID	Description
DS-38421	Updated the file retention recurring task to no longer log an informational message if there are no log matching files to delete.
DS-38430	To efficiently export entries from a backend with a large number of non-leaf entries, the export-ldif command produces multiple intermediate LDIF files that are merged after all entries have been processed. The tool now skips merging these files if sufficient disk space is unavailable to accommodate the intermediate files and the final merged file. The import-ldif command can accept multiple files as input, so merging the files is not essential.
DS-38512	Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a secret passphrase obtained from a HashiCorp Vault instance.
DS-38524	Fixed a problem in which a member could not be added to a group via SCIM unless the group's object class was groupOfUniqueNames.
DS-38525	Made changes to reduce potential lock conditions in proxy replication LDAP health checks.
DS-38550	Fixed an issue in which backups of the encryption settings database could be encrypted with a key from the encryption settings database.
DS-38643	The "dsreplication disable" command now correctly removes replica IDs (ds-cfg-replication-domain-server-id values) from the topology data when a subset of the replication domains is disabled.
DS-38663	Updated performBackendDeregistrationProcessing and performBackendRegistrationProcessing to ignore disabled notification managers instead of throwing a null error.
DS-38670	Fixed a bug where the startIndex value for SCIM requests would be incorrect if the used LDAPSearch element had more than one baseDN defined in the scim-resources XML file.
DS-38722	Fixed an issue where a constructed virtual attribute could not be configured for an attribute that was marked as SINGLE-VALUE in the LDAP schema.
DS-38737	Fixed an issue where inter-server bind requests would fail if the cipher used reported a maximum unencrypted block size of 0.

Ticket ID	Description
DS-38739	Updated the encrypt-file tool to display a notice recommending the use of the --decompress-input argument when decrypting a file that also appears to be GZIP-compressed.
DS-38839	The Amazon Corretto JRE is now supported. Prior to being supported, the Amazon Corretto JRE resulted in a warning that the JRE was "unrecognized and is likely untested and unsupported."
DS-38849	Added an indent-ldap-filter tool that can make it easier to visualize the structure and components of a complex search filter.
DS-38864	Changed the default value of the HTTP Configuration property include-stack-traces-in-error-pages from 'true' to 'false'. Disabling this property prevents information about exceptions thrown by servlet or web application extensions from being revealed in HTTP error responses.
DS-38873	Internal connections created by HTTP requests are now associated with one of the configured client connection policies. A client connection policy may be selected using simple client connection criteria matching the client address, the user performing the request, and the protocol "HTTP/1.1". This change affects the following HTTP interfaces: SCIM, Directory REST API, Consent API and Delegated Admin API.
DS-38874	<p>Updated the server to prevent creating virtual attributes that use the "aci" or "ds-cfg-global-aci" attribute types. Also, updated the server to prevent creating virtual attributes that use the "member" or "uniqueMember" attribute types unless the virtual attribute is one that will provide the membership list for a virtual static group.</p> <p>Virtual attributes cannot be used to define access control rules or assign static group membership. Previously, the server silently ignored any access control rules or static group members defined through virtual attributes, which may have caused an administrator to mistakenly believe that they were in effect.</p>
DS-38892	Fixed an issue that could cause the server to encounter an internal error when processing a set subtree accessibility extended operation against an empty backend.

Ticket ID	Description
DS-38893	Fixed an issue that interfered with assigning privileges using a mirror virtual attribute. If the values to mirror in the ds-privilege-name attribute were contained in another entry, then the privileges would have only been granted if the source attribute could be retrieved by unauthenticated clients.

Ticket ID	Description
DS-38897,DS-38908	<p>Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.</p> <p>* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.</p> <p>* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.</p> <p>In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.</p> <p>We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.</p>

Ticket ID	Description
DS-38913	Added a set of message types to Trace Log Publishers that records events related to access token validation.
DS-38957	Fixed an issue that would throw an exception when trying to delete an entry containing uncached attributes if the LDAP changelog was enabled and using reversible form.
DS-39086	Removed the version information page from the docs/build-info.txt endpoint. This information is now available in build-info.txt, which is located in the root directory.

PingDirectory Server 7.2.1.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Server

- To ensure correct search results with Delegated Admin, disable client caching by updating the Delegated Admin HTTP Servlet Extension to return response headers, and then stop and restart the server, as follows:

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin" --set "response-header:Cache-Control: no-cache, no-store, must-revalidate" --set "response-header:Expires: 0" --set "response-header:Pragma: no-cache"
```

Known Issues/Workarounds

The following are known issues in the current version of the Directory Server

- When dsreplication is run to add a server to the topology using another node that is not the topology master, it may fail with the following error:

```
"Error updating replication configuration on base DN dc=example,dc=com of server 'ds3' (ldaps://localhost:3636). See /Users/<name>/installs/7.2/s3/logs/tools/dsreplication.log for a detailed log of this operation. Details: A communication problem occurred while contacting the server: The connection to server localhost:3389 was closed while waiting for a response to an add request AddRequest(dn='cn=dc_example_dc_com,cn=domains,cn=Multimaster Synchronization,cn=Synchronization Providers,cn=config', attrs={Attribute(name=objectclass, values={'top', 'ds-cfg-replication-domain'}), Attribute(name=cn, values={'dc_example_dc_com'}), Attribute(name=ds-cfg-server-id, values={'11443'}), Attribute(name=ds-cfg-base-dn, values={'dc=example,dc=com'})}): A request sent on this client connection caused an internal error in the server. This connection will be terminated."
```

The workaround for this issue is to use the topology master for the --host1 parameter of dsreplication to add the new server into the topology.

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-37063,DS-38012,DS-38497	<p>Updated the pass-through authentication plugin to add a bind-dn-pattern configuration property that allows constructing the DN of the remote user from information in the local user entry. Alternately, if the remote server supports simple authentication with a bind DN value that is not actually a valid LDAP distinguished name, this property can be used to supply that identifier. For example, when passing through authentication to Microsoft Active Directory, this property can be used to construct a bind DN that is actually the user principal name (UPN) for the remote account.</p> <p>Also, updated the pass-through authentication plugin to add an included-local-entry-base-dn configuration property that can be used to indicate which local entries are eligible for pass-through authentication. By default, pass-through authentication is automatically enabled for all users contained in any public backend, but this property can be used to restrict that set of users without the need to define a request criteria. This change also ensures that the server no longer attempts to pass through authentication attempts for root users or topology administrators by default (although if that ability is desired, it can be re-enabled by adding "cn=config" as an included-local-entry-base-dn value).</p>
DS-37363	<p>Updated the server to make the replication missing changes state persist across restarts. If a server is offline for longer than the configured purge delay, then replication cannot automatically bring the server back in-sync with the rest of the topology. To avoid serving stale data, the server enters lockdown mode when it has missed changes. Prior to this change, restarting the server would incorrectly clear this missing changes state, and it would not enter lockdown mode, which could lead to it serving stale data. Now the server must be reinitialized either from a recent backup or by using "dsreplication initialize" to clear the missing changes state.</p>
DS-37430	<p>Added logging for DNS lookups that take longer than a warning threshold. The default warning threshold is 10 seconds. Added the DNS Resolution monitor to track DNS lookup speed.</p>
DS-37757	<p>Fixed an issue that could cause entryUUID mismatches on replicas configured to automatically use entryUUID as the naming attribute for add requests matching a given set of connection or request criteria.</p>

Ticket ID	Description
DS-37960	<p>The Delegated Admin configuration has changed significantly. Delegated Admin Resource Types were removed and replaced by REST Resource Types. Delegated Administrators and Delegated Group Administrators were removed and replaced by Delegated Admin Rights and Delegated Admin Resource Rights. Previous configurations are converted to the new configuration definitions by the update tool when the server is updated.</p>
DS-38202	<p>Fixed an issue that could cause an error during an LDIF export of a data set with a large number of non-leaf entries. In such cases, the data is written to multiple files that are merged at the end of the export process. If the LDIF export was encrypted with a passphrase or an encryption settings definition, the merge process could fail, leaving the export spread across multiple files instead of aggregated into a single file.</p> <p>This issue did not affect the usability or integrity of the export data. It could still be imported, although the administrator would need to list each of the export files in the correct order when performing the import.</p>
DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:</p> <ul style="list-style-type: none"> - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections. - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
DS-38335	<p>The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.</p>
DS-38344	<p>The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.</p>

Ticket ID	Description
DS-38415,DS-38418,DS-38419,DS-38420	<p data-bbox="849 216 1419 279">Addressed several issues with the pass-through authentication plugin.</p> <p data-bbox="849 296 1443 359">USE SEPARATE CONNECTIONS FOR SEARCH AND BIND REQUESTS</p> <p data-bbox="849 375 1468 753">If the plugin is configured with a search filter pattern, then it may perform a search to find the entry in the external server that corresponds to the entry for the local user that is trying to bind. In such cases, search requests may have been issued over the same connections that were also been used to process bind operations. The change in authorization identity resulting from those bind attempts may interfere with the ability to perform the searches. The plugin has been updated to ensure that search and bind requests are now issued over separate connections.</p> <p data-bbox="849 770 1398 833">ALLOW RETRY ATTEMPTS WITH A SINGLE EXTERNAL SERVER</p> <p data-bbox="849 850 1468 1455">If the plugin is configured with multiple external servers, then it can use some or all of those servers in a pass-through authentication attempt. If a search or bind attempt fails against the first server, and if that failure indicates that there may have been a problem with the server or the connection to it, then the plugin would have re-tried the operation in other servers until the attempt succeeds, the attempt fails in a way that does not indicate a problem with the server or the connection, or all servers have been tried. However, if only a single external server had been configured, then no retry attempt would have been made. The plugin has been updated so that if it is only configured with a single external server, and if a failure is encountered while communicating with that server that may benefit from retrying that operation, then the plugin will attempt to establish a new connection to that server and retry the operation.</p> <p data-bbox="849 1472 1341 1535">UTILIZE ALL CONFIGURED EXTERNAL SERVERS</p> <p data-bbox="849 1551 1468 1992">If the Directory Server is configured with a location, then the pass-through authentication plugin will use that information to determine the order in which the external servers should be accessed. It will first attempt external servers in the same location as the Directory Server, followed by servers in the most preferred failover location, the second-most preferred failover location, and so on. However, the plugin might have used external servers that did not have a location assigned, or that were assigned to a location that is not one of the Directory Server's preferred failover locations. The plugin has been updated to ensure that these servers may be used, albeit with a lower priority than the other servers.</p> <p data-bbox="849 2009 1451 2072">IMPROVE VISIBILITY OF PLUGIN PROCESSING RESULTS</p>

PingDirectory Server 7.2.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Server

- The Delegated Admin web app now supports creation of new users. Installations created using older versions of the install script require a command like the following to be run after upgrade. The 'sn' attribute is a required attribute for inetOrgPerson entries.

```
dsconfig create-delegated-admin-attribute --type-name users --attribute-type sn --set "display-name:Last Name"
```

To enable user creation, one of the new configuration properties org-entry-dn or org-search-filter must be set on the Delegated Admin resource type.

What's New

These are new features for this release of the Directory Server

- Introduced a Directory REST API to create, read, update and delete (CRUD) any object in the directory using JSON over HTTP. Compared to the SCIM-based Identity Access API (introduced in 4.0), the Directory REST API offers more capability without the configuration overhead and SCIM protocol limitations. See the Directory REST API documentation included in the “docs” folder for more information.
- Overhauled the way in which the directory evaluates and processes search expressions. The new search planner leverages index statistics in order to process search expressions in the most effective order. The search planner now considers the overall size of each index, specific values that have too many matches, and the relative distribution of values.
- Improved composite indexes. Composite indexes are used to improve performance for searches where attributes are often searched together, like a customer tenant identifier alongside a person's name. Whereas previously you could only index a combination of the DN of ancestor objects with a single attribute of descendant objects, now you can define a composite index using a pattern that combines equality expressions and at most one substring expression. For example, you can create a composite index covering the entire expression (&#amp;#amp;(tenantId=?)(cn= \ *? \ *)).
- Improved integration with some third-party software. Now the changelog backend (which makes available all recent changes to directory entries) supports paging over LDAP using the Simple Paged Results Control (RFC 2696). This enables third-party data integration software to more efficiently obtain a list of recent changes over LDAP. Previously the Simple Paged Results Control only worked for LDAP searches against user data stored in backends like userRoot.
- Improved the scheduled tasks feature designed to help automate maintenance tasks on the directory server. Now you can schedule the execution of whitelisted commands on the directory server host, create routine LDIF exports for multiple backends, make the server administratively enter or leave “lockdown” mode, and clean up old files from disk, like historical log files and LDIF exports.
- Improved user and group management in the delegated user administration web app (packaged separately.) Administrators can configure the presentation order and groupings of profile attributes, improving delegated admin usability for large user profiles. Also, delegated admins can now create new users, and add and remove entire sub-groups of users to and from groups.
- Added support for Oracle Java JDK 11 and OpenJDK 11. Added support for RedHat 7.5, CentOS 7.5, and Ubuntu 18.04 LTS. <p> When running on JDK 11, we now configure G1GC as the default garbage collection algorithm. This eliminates long garbage collection pauses in most environments.
- Improved event tracing across coordinating HTTP and directory servers. For example, admins can now trace requests to HTTP-based services, like the Directory REST API, through the log files to the LDAP access log of the Directory Server. All HTTP-based services (e.g. SCIM, Consent API) can be configured to accept and/or generate HTTP request headers with correlation identifiers. These identifiers are logged in trace logs, HTTP access logs, and LDAP access logs.
- Added a new command line tool, extract-data-recovery-log-changes, to assist in replaying or reverting data changes, for example, to aid in disaster recovery or to back out changes made in error. The

new tool extracts relevant changes from the server's audit logs and produces an LDIF file that can be imported by ldapmodify. Admins can select or filter changes based on numerous criteria.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Server

- There are known issues when running the server with Java 11.0.0. These are addressed in Java 11.0.1. In general, when using Java 11, we recommend using the latest available release.
- The Identity Access API has been deprecated and will not be supported in the next major release.
- On Microsoft Windows systems, JVM arguments for verbose GC logging do not work as expected. So these arguments are not added to any of the server or client tools.

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-1132	Fixed an issue causing unexpected crashes in dsconfig when backing out of certain screens.
DS-5964	Updated the server to allow delaying the response to failed bind operations by a specified length of time. While the response is delayed, no other operations will be allowed on the connection. This can be used instead of, or in addition to, account lockout as a means of limiting the rate at which an attacker may try to guess user passwords.
DS-6930	Fixed an issue where an entry could be added to the server with invalid privileges.
DS-14799	To facilitate testing in multiple GC (garbage collection) environments, GC JVM options having been moved to separate Java properties in the java.properties file. The new ".gc-type" suffix will select the GC type to use, and the new ".gc-<GC type>-args" suffix will have the JVM options for that GC type.
DS-17771	Updated the server to support sending persistent search results asynchronously, which protects against a blocked persistent search client from interfering with write operation processing.
DS-17771	Fixed an issue preventing third-party tasks from loading correctly.

Ticket ID	Description
DS-18261,DS-35906	Added an extract-data-recovery-log-changes tool that can be used to examine a server audit log file (preferably the data recovery log file, which is preconfigured for optimal compatibility) to extract changes matching a given set of criteria, including change time, operation type, requester DN, client address, change content, and more. The extracted changes can be formatted as they were originally requested so that they can be replayed, or they can be inverted so that they can be backed out.
DS-35516	Fixed an issue where the server would not prevent an invalid entry with more than one structural object class from being added, if any of those classes was a groupOfURLs.
DS-35553	Fixed bug where named pipe can't be used as log file.
DS-35567	Updated the server to expose information about the duration of lengthy phases of server startup. The longest phases are logged to the error log and more detail is provided in the "cn=Startup Phase Times,cn=monitor" monitor entry. Starting the server with the --verbose option will show fine-grained timing information for all phases of server startup.

Ticket ID	Description
DS-35652,DS-36559	<p>Added support for a new file retention task that can identify files in an indicated directory that match a given pattern and remove any matching files that fall outside of the specified retention criteria. You can specify the minimum number of files that should be retained, the minimum age of files that should be retained, the minimum aggregate size of files that should be retained, or any combination thereof. The files that match the pattern will be sorted by timestamp so that if any files are to be removed, the most recent files will be retained and the oldest files will be deleted.</p> <p>The file retention task can be scheduled as a standalone task or as a recurring task. Two instances of the file retention recurring task have been defined in the default configuration: one that can clean up old expensive operation dump files, and another that can clean up old work queue backlog thread dump files. In each case, the recurring task is configured to keep at least the 100 most recent files, and no files less than 30 days old will be removed. While these recurring tasks are defined in the out-of-the-box configuration, they are not part of any recurring task chain and therefore will not actually be invoked unless they are configured as part of a chain.</p> <p>The Directory Server and Directory Proxy Server now include recurring tasks in the out-of-the-box configuration that can clean up old expensive operation dump log files or work queue backlog thread dump log files if too many of them have collected in the server logs directory. For each type of file, if there are more than 100 of them in the server logs directory, then any of the remaining files that are more than 30 days old are candidates for removal. A recurring task chain will perform this cleanup every day at 12:05 a.m. in the JVM's default time zone.</p>
DS-35865	<p>Multiple instances of the SCIM HTTP Servlet Extension may now be created, allowing for multiple SCIM 1.1 service configurations per server instance. For more information, please refer to the "Managing the SCIM Servlet Extension" chapter of the Administration Guide.</p>

Ticket ID	Description
DS-35873	Added support for an exec task that can invoke commands on the server. There are several safeguards in place to prevent unauthorized users from invoking arbitrary commands on the server system, including a new exec-task privilege and a whitelist file that must be updated to include the absolute paths of the allowed commands. A new schedule-exec-task tool helps create an exec task from the command line, and the LDAP SDK has also been updated to allow interacting with exec tasks programmatically.
DS-35873	Added support for recurring exec tasks.
DS-35909	HTTP Connection Handlers will now raise an alarm during initialization if a context path conflict is detected.
DS-36023,DS-37686	A new --topologyFilePath argument has been added to remove-defunct-server, making it possible to remove a defunct server cleanly from the topology using one of the servers in the provided topology file. The topology file may be obtained by running the manage-topology export command.
DS-36030	Fixed an issue that could prevent the server from imposing the correct size and time limits for search requests with an alternate authorization identity.
DS-36132	Fixed an issue in the backup tool where --signHash could be used without --hash.

Ticket ID	Description
DS-36209	<p>A header containing a correlation ID is now added to outgoing HTTP servlet responses, allowing HTTP responses to be correlated with log messages across server instances. The name of the correlation ID response header defaults to "Correlation-Id" but may be changed by setting the HTTP Connection Handler's correlation-id-response-header property. By default, the server will generate a globally unique correlation ID automatically, but the correlation-id-request-header configuration property may be used to optionally specify one or more request headers that provide an existing correlation ID value from the requesting client. The correlation ID header can be disabled on a per-HTTP Connection Handler basis using the use-correlation-id-header configuration property.</p> <p>For Server SDK extensions that have access to the current HttpServletRequest, the correlation ID can be retrieved as a String via the HttpServletRequest's "com.pingidentity.pingdata.correlation_id" attribute. For example: <code>(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");</code></p>
DS-36433	<p>Added a Mock Access Token Validator, which accepts access tokens without validating the authenticity of the tokens using a trusted authorization server or signing certificate. When enabled, a Mock Access Token Validator accepts bearer tokens in the form of a plain text JSON object containing an arbitrary set of claims. Mock Access Token Validators are intended for test or demonstration use only and should never be enabled in production deployments or used to access sensitive data.</p>

Ticket ID	Description
DS-36453	<p>Updated the server to enable automatic LDIF exports by default for new installations. Every day at 1:05 a.m. (in the JVM's default time zone, which is generally the time zone configured for the underlying system), the server will export the contents of each non-administrative backend to a file in the "ldif" directory immediately below the server root. The LDIF exports will always be compressed, and they will be encrypted if the global configuration is set to encrypt LDIF exports by default (which will be enabled if encryption is configured during setup). The LDIF exports will be rate limited to ten megabytes per second to minimize the impact on server performance, and exports will be retained for seven days.</p> <p>Daily LDIF exports will only be enabled by default for new installations. The recurring task chain will be created in instances that are updated to this release, but that chain will not be enabled.</p>
DS-36483	<p>Fixed a defect where the compression-mechanism and compression-parameter properties were not hidden in ReplicationServerConfiguration.xml.</p>
DS-36510	<p>Added support for a delay task, which can be used on its own or as a recurring task. It is primarily intended to be used as a spacer between other tasks, and can sleep for a specified period of time, wait for the server to be idle (that is, there are no outstanding operations and all worker threads are idle), or wait for sets of search criteria to match at least one entry (for example, until a monitor entry indicates that the server is in a desired state).</p>
DS-36511	<p>Added a plugin that supports encrypting the values of operational attributes intended to hold sensitive information, including TOTP shared secrets, delivered one-time passwords, password reset tokens, and single-use tokens.</p>
DS-36519	<p>Bearer token authentication for the Consent API may now be enabled or disabled using the bearer-token-auth-enabled property of the Consent HTTP Servlet Extension.</p>

Ticket ID	Description
DS-36585	Updated the client connection policy configuration to add a maximum-concurrent-operations-per-connection-exceeded-behavior property that specifies the behavior that the server should exhibit if a client tries to exceed the limit set by the maximum-concurrent-operations-per-connection property. Previously, any requests in excess of the maximum-concurrent-operations-per-connection limit would have been rejected with a busy result. The server now offers additional choices for the result code to use when rejecting requests (including admin limit exceeded, constraint violation, unavailable, unwilling to perform, or other), and the server can also be configured to close the connection and abandon all outstanding operations on that connection.
DS-36592	Enhanced rebuild-index performance, especially in environments with encrypted data. This prevents work queue backlogs that could occur when rebuild-index runs with the server online.
DS-36694	Replication now sends heartbeat and monitoring information less frequently to reduce the high network overhead that had been observed in topologies with more than fifty servers. The interval between monitoring data updates is now configurable through the remote-monitor-update-interval property on the Replication Server configuration object.
DS-36729	Added an attributes-modifiable-with-ignore-no-user-modification-request-control global configuration property that will a select set of operational attributes declared with the NO-USER-MODIFICATION constraint to be updated in a modify request that includes the ignore NO-USER-MODIFICATION request control. At present, this is only supported for the creatorsName, createTimestamp, modifiersName, and modifyTimestamp attributes.
DS-36801	Fixed an issue with the Dictionary Password Validator where configuring case-sensitive-validation=false would only work if the input file included the lower-case version of all passwords. The server now automatically converts the passwords to lower-case in memory when configured with case-sensitive-validation=false.

Ticket ID	Description
DS-36834	All tools will now enforce a minimum heap size requirement. Overriding the heap size for the system, using the --maxHeapSize argument of the dsjavaproperties tool, is only effective if the provided value is greater than the minimum required heap size for the tool.
DS-36910	Fixed an issue in which the server could return an incorrect result code for add and modify DN requests that included a malformed DN.
DS-36988	The SCIM v1 servlet extension is no longer enabled by default for new installations. Existing installations will be unaffected on an upgrade. Customers are encouraged to use the new "Directory REST API" for REST access from now on.
DS-37018	Added a Constructed Virtual Attribute that can be used to dynamically construct values for a virtual attribute using a combination of fixed text and values of other attributes from the entry. As with most virtual attributes, searching on the attribute is not indexed.
DS-37037	Updated the recurring LDIF export task to support exporting the contents of multiple backends.
DS-37053	Fixed an issue where manage-extension could install files outside of the installation directory.
DS-37066	Added recurring task support for placing the server in lockdown mode and taking the server out of lockdown mode. While in lockdown mode, the server reports itself as unavailable to the Directory Proxy Server and only accepts requests from a restricted set of clients.
DS-37131	Fixed an issue in which the HTTP Servlet Config Monitor could cause an exception in an HTTP Servlet Extension when attempting to determine its context paths. This caused the status tool and the Administrative Console to potentially omit the HTTP Servlet Extension from the list of active HTTP extensions.
DS-37134	The "dsreplication" command now has a "--topologyLockWaitSeconds" option that controls how long subcommands will wait for the topology lock. This is helpful when running multiple subcommands that each require the topology lock. Without this option, subcommands that require the topology lock will fail if it is not available.

Ticket ID	Description
DS-37176	Added three new matching rules that can be used to customize equality matching for attributes with a JSON object syntax. Previously, it was only possible to perform equality matching with case-sensitive field names and case-insensitive string values. The new matching rules add support for other permutations of case sensitivity for field names and string values.
DS-37181	Updated the out-of-the-box configuration to clean up old lock conflict details log files if too many of them have accumulated. If there are more than 100 of them in the server logs directory, then any of the remaining files that are more than 30 days old are candidates for removal. The cleanup will occur every day at 12:05 a.m. in the JVM's default time zone.
DS-37251	The exploded-index-entry-threshold configuration property on Local DB Backend and Local DB Indexes has been hidden because it is poorly understood and often misconfigured. The effective value of this property is now 50000 since it allows good search performance and high bursts of write throughput.
DS-37262	Updated num-worker-threads and *-worker-thread-percent-busy attributes to exclude admin queue threads from the worker thread count. These attributes will now better reflect the actual number of worker threads available.
DS-37313	Addressed an issue where an InvalidKeyException could occasionally be reported by import-ldif. The error message for this problem resembles, "An unexpected error occurred during merge processing for index 'dc_example_dc_com_sn.equality': InvalidKeyException: The provided passphrase is invalid."

Ticket ID	Description
DS-37352	<p>Updated the audit log to provide the option to include a number of additional fields, including:</p> <ul style="list-style-type: none"> * The server product name. * The server instance name. * The OIDs of any controls include in the request. * Details of any intermediate client or operation purpose request controls include in the request. * Whether the operation was replicated. * Whether the operation was an internal operation. * Whether the operation was processed by an administrative session worker thread. <p>In addition, operation-specific log messages can include the following additional fields:</p> <ul style="list-style-type: none"> * For add operations, the log can now indicate whether the operation was an undelete. * For delete operations, the log can now indicate whether the operation was a soft delete, whether the operation was a delete of a soft-deleted entry, and whether the operation was the base or a subordinate entry of a subtree delete. Further, virtual attributes are separated from real attributes in the record of the deleted entry. * For modify operations, the log can now indicate whether the entry was a modify of a soft-deleted entry.
DS-37356	<p>The replication server now has a configuration property "replication-purge-minimum-retain-count," which is similar to the existing configuration property "replication-purge-delay" except that a minimum number of changes are enforced instead of a maximum age. The "replication-purge-minimum-retain-count" property may be helpful in those cases where a replication server will experience long delays, (exceeding the "replication-purge-delay") of infrequent traffic while not connected to the other replication servers.</p>
DS-37389	<p>Added support for the simple paged results control to the changelog backend.</p>

Ticket ID	Description
DS-37416	Fixed an issue in support for the get effective rights request control that could cause the server to incorrectly report that an anonymous user could have read access to an entry if there are any ACIs that make use of the "ldap:///all" bind rule. The issue affected only get effective rights processing and did not actually expose any server data to unauthorized users.
DS-37420	Addressed an issue that prevented adding or removing users with Identify References virtual attributes if those attributes were included in the changelog backend.
DS-37480	Replication now waits more reliably on startup for missing changes by waiting until there is replica information for all operational replication servers. Also, the server will now wait if a remote server has more recent changes for a local replica.
DS-37492	Added a time limit retention policy to support removing log files older than a specified age.
DS-37515	Updated the server to include a data recovery log in the default configuration. This is an audit log with a configuration optimized for enabling replay or reversion of changes should the need arise. The logger will be defined in the configuration for all new installations and updates of existing installations, but it will only be enabled by default for new installations. The log will always be compressed, and it will be encrypted if data encryption is enabled in the server.
DS-37597	Fixed a bug where the totalResults value for SCIM requests using page parameters would be incorrect if the used LDAPSearch element had more than one baseDN defined in the scim-resources XML file.
DS-37660	Updated the Work Queue to increase the number of internal queues when num-queues is configured with the default of 0 (i.e., the server automatically determines the value). An internal queue is now created for every two worker threads rather than eight. This can reduce thread contention and increase throughput when under extreme load.

Ticket ID	Description
DS-37713	<p>Updated the Consent API to infer actor and/or subject values where possible:</p> <ul style="list-style-type: none"> * The /consent/v1/consents endpoint no longer requires query parameters to be provided. If neither the subject parameter nor the actor parameter is specified, then the subject will be assumed to be the authenticated identity's user ID. * When creating or updating consent records, a client is no longer required to provide subject or actor values; these values will be inferred from the authenticated identity. For unprivileged clients, these values are always set automatically and are ignored when set explicitly. Privileged clients may explicitly specify subject and/or actor values, however. * The Consent Service consent-record-identity-mapper configuration property is no longer needed to support unprivileged clients and is now only needed to support privileged clients that manage consent records on behalf of other users.
DS-37723	<p>Added an optional "titleText" field to Consent API consent definition localization objects. This field may be used to store a localized title or summary for a consent request. A corresponding "titleText" field has also been added to consent record objects.</p>
DS-37778	<p>Updated the Purge Expired Data Plugin to allow the subtree beneath an expired entry to be deleted as well. This is configured by setting the purge-behavior property to subtree-delete-entries.</p>
DS-37823	<p>Fixed an issue where Sensitive Attributes defined on the Global Configuration were incorrectly evaluated for replicated operations. This could lead to failed replicated operations and servers becoming out-of-sync.</p>
DS-37898	<p>Replicated password changes no longer cause password-reset notifications on receiving servers.</p>

PingDirectory Server 7.0.1.0 Release Notes

What's New

These are new features for this release of the Directory Server

- New capabilities have been added to the Delegated Admin application (packaged separately). Now directory administrators can delegate the responsibility of managing group memberships for users in PingDirectory Server. Administrators can delegate to individuals or groups of users, and assign authority over one or more groups in PingDirectory Server.

- Added a new mirrored virtual attribute capability that mirrors the value of an attribute from an entry relative to the entry being retrieved. For example, you could include an attribute from the parent entry. This can eliminate a second search request to the server when a client needs a user entry as well as information from some related entry.
- Improved the way the PingDirectoryProxy Server distributes requests in the failover load-balancing configuration. This is especially helpful for multi-tenant environments to better distribute requests per tenant. Now you can configure a load-spreading base DN such that requests to DIT branches below the load-spreading base DN are balanced among the PingDirectory Servers. The proxy will automatically maintain affinity between servers and DIT branches.
- Added new monitoring data points and data history to aid in performance tuning and troubleshooting. Now the monitoring backend stores occurrences and time spent for several operations, including a histogram distribution of time spent. Operations tracked include time waiting on file system synchronization and time spent at the proxy per directory server operation.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Server

- An ACI starting with "GENERATED D-ADMIN ACCESS" is generated automatically by the server from Delegated Admin configuration. Do not create your own custom ACI with the same prefix, for example by copying and pasting from the generated ACI. A custom ACI with this prefix will be deleted when the server is restarted, and whenever a Delegated Admin configuration change causes the Delegated Admin ACI to be regenerated.
- While upgrading servers in a mixed-version environment, where some of the servers are still using the admin backend while others have been updated to the topology registry, do not attempt to make size changes to the topology. No existing servers may be removed (using dsreplication disable), or new servers added (using dsreplication enable) when in this transitional state of partially-updated servers. When all of the servers have been updated to the topology registry, sizing changes can be made. This restriction is temporary only while crossing the admin backend to topology registry boundary. In post 7.0.1 releases, changes to the topology size will be allowed, even in mixed-version environments.
- It is not possible to add a new server to an existing replication topology of 7.0.0.0 servers. The problem is addressed in 7.0.1.0. In order to add a new server, all existing servers must be updated to at least 7.0.1.0.
- Servers to be monitored by the PingDataMetrics Server must have an instance name of less than 256 characters. A server's instance name is specified during setup.

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-16766	Added the Replication State Detail (ds-sync-state-detail) virtual attribute, which provides a more detailed version of "ds-sync-state" attribute. The additional information can be used for debugging replication issues.

Ticket ID	Description
DS-36325	<p>Improved the behavior that the server exhibits under certain network conditions when it is not possible to write to a client without blocking. This includes:</p> <ul style="list-style-type: none"> * If the server cannot write data to a client after waiting for a length of time specified by the connection handler's max-blocked-write-time-limit configuration property, the access log message indicating that the client has been disconnected because of an I/O timeout will now more clearly indicate that the reason was the inability to write data to the client. * The server now limits the number of threads that can be blocked while trying to send data to the same client over the same client connection. If too many threads would have been blocked while trying to send data over the same connection, that connection will be terminated, and the disconnect access log message will include the reason for the disconnect. * If the server is trying to send data to the client that it considers optional (for example, certain types of unsolicited notifications), then the server may skip sending that optional data if the write would have caused the server thread to block.
DS-36642	<p>Added a configuration option to allow a null serverFQDN for the GSSAPI SASL mechanism to allow an unbound SASL server connection.</p>
DS-36703	<p>Fixed an issue where the isMemberOf virtual attribute provider would indirectly evaluate other virtual attributes, which could lead to significant slow down in search processing.</p>
DS-36814	<p>Fixed an issue in which an unprivileged Consent API client could modify the actor value of a consent record.</p>
DS-36987	<p>Updated the mirror virtual attribute provider to allow a DN map to identify the entry containing the attribute to mirror.</p>
DS-37021	<p>Delegated Admin operations now appear in the LDAP access log.</p>
DS-37047	<p>Enabling replication for restricted domains now creates a server group for each replication set when replication servers are added. Server groups enable initializing restricted domains interactively.</p>

Ticket ID	Description
DS-37132	Changed Resource IDs produced by the Delegated Admin API so that they no longer contain percent characters from Base64 padding.
DS-37235	<p>Updated the keys and values used in the monitoring JMX MBeans to conform with best practices. The keys "type" and "name" are now used in place of "Rdn1" and "Rdn2".</p> <p>To maintain backwards compatibility with existing monitoring solutions, installations upgrading to this release will retain the old behavior, but they can revert to the default behavior by changing the Global Configuration property <code>jmx-use-legacy-mbean-names</code> to false.</p>
DS-37292	The Notification Delivery Thread will now log unexpected errors rather than throwing them as exceptions.
DS-37362	Prevent a notification destination from assuming the master notification delivery role if that server is in lockdown mode or replication hasn't finished initialization.

PingDirectory Server 7.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Server

- This release introduces significant changes to the way servers in a topology are configured with information about each other. Once a server has been upgraded from a pre-7.0 version to 7.0 or later, reverting to the previous version is not supported. Before beginning the upgrade process, make sure you have read and understood the Administration Guide's chapter "Upgrading the Server".
- SCIM 2 error responses, including Config API error responses, now represent the "status" field as a JSON string rather than as a number. Clients written to expect the earlier version format will need to be updated. In particular, clients written using the SCIM 2 SDK for Java should upgrade to version 2.2.0 or higher.
- Indexes are now automatically encrypted when data encryption is enabled on the server. For deployments in which data encryption is already enabled, it is recommended that you export the data to LDIF and re-import it to ensure that its indexes are also encrypted.
- The Administrative Console now uses server information found in the topology registry to populate its server selection control. If the Console is used to manage a legacy server that does not use the topology registry, then the server selection control will not be populated. To manage a different server, the administrator will need to log out of the Console and provide the other server's connection details from the login page.

What's New

These are new features for this release of the Directory Server

- Added support for encrypting indexes. Enabling encryption does have a small performance impact. The exact impact varies based on the data set and load. In our testing,
 - The in memory and on disk footprint is increased by about 30%.
 - Search rate is decreased by about 20% (but 50K searches/sec is still achievable in a fully-cached environment)
 - Peak add / delete rate is impacted the most, because more indexes are updated.
- Added a new delegated user administration web application (packaged separately). This web UI enables the server administrator to delegate profile management and some privileged operations to others within the enterprise.
- Made several security improvements for backups, LDIF exports, and log files. Encryption can be done using a specified passphrase, making it easier to decrypt and use files outside of the server cluster, such as when importing them or reviewing them on a different server. Also, servers can be configured to encrypt backups and exports by default, so that administrators do not inadvertently create an unencrypted artifact.
- Added the capability to automatically purge data after the data has expired. This feature can be applied to delete directory entries, like new accounts that have not fully completed the signup process, or PingFederate persistent grants that have expired. This feature can also be applied to delete individual JSON attributes of a directory entry. Purging expired data is enabled through the Purge Expired Data plugin.
- Added new schema and REST API that can be used to build a system to collect, enforce, and manage fine-grained data authorizations or privacy preferences for users stored within the directory.
- Added a new feature for running recurring maintenance tasks, like backup and LDIF export, without the dependency on Linux cron or Windows schedulers.
- Simplified management tasks related to configuring servers in a large cluster topology or in an automated deployment. Most notably, servers can now be added to a cluster while other servers are offline.
- Added a new syntax of Access Control Instructions (ACI) that can dramatically reduce the number of nearly identical ACI used in multi-tenant or multi-organization directories. The new format is parameterized by attributes of the binding user's DN. For example, the server can extract the "HR" value from a binding user such as uid=Fred,o=HR,dc=data, and use that value to check membership within the related privileged group cn=Admins,o=HR,dc=data. A single parameterized ACI can be written to support groups HR, Finance, IT, Development, Marketing, and so on.
- Added management features for SSL/TLS certificates. The default certificates used in inter-server replication can be replaced; validation of client certificates for HTTPS-based services like the SCIM REST API can be configured; and you can reload from the trust store for HTTPS client certificates without restarting the server or the HTTP-based services.
- Added support for these operating system versions: Ubuntu LTS 16.04, CentOS 7.4, RedHat Linux 7.4, SUSE Enterprise 12 SP3

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-426	<p>Added the ability to generate administrative alert notifications when a task starts running, when it completes successfully, or when it fails to complete successfully. Also added the ability to send an email message to a specified set of users when a task starts running or completes successfully, which complements the existing ability to send an email message when a task fails to complete successfully or when it completes with any state, regardless of success or failure.</p>
DS-426	<p>Added support for recurring tasks, which can be used to automatically invoke certain kinds of administrative tasks based on a specified schedule.</p> <p>At present, only certain kinds of tasks can be scheduled as recurring tasks. This includes both backups and LDIF exports, each of which provides retention support to limit the amount of disk space that the backups and LDIF files consume. It also includes support for any kind of task in which each instance of the task should use exactly the same values for all of the task-specific attributes. The Server SDK also provides an API for creating custom third-party recurring task implementations.</p>
DS-4406	<p>Implemented invocation logging for several server tools, which will write to logs/tools/tool-invocation.log by default upon startup and shutdown. Some of the information recorded by log entries include the tool's start and completion times, the command-line arguments used to initialize them, and the name of the system account used to launch the tool. To modify this behavior, edit the config/tool-invocation-logging.properties file.</p>
DS-4570,DS-14281,DS-14282,DS-14283,DS-14284,DS-17197,DS-17366	<p>The admin backend and the tool used to manage it, dsframework, have been replaced by the topology registry and dsconfig, respectively. The topology registry is automatically mirrored across all servers in the topology, so administrative information is kept in-sync on all servers at all times.</p>

Ticket ID	Description
DS-5930	<p>Updated ACIs to add support for parameterized DNs. Using the new syntax, attribute values will be extracted from matching resource DNs and substituted into parameterized target DNs and bind rule group DNs. Parameterized ACIs can be used in a multi-tenant environment, where each tenant has an administrators group. In the past, an ACI needed to be duplicated for each tenant. Now, one parameterized ACI can be used. For example, the parameterized ACI</p> <pre>(target="ldap:///o=(\$1),dc=example,dc=com") (version 3.0; aci "Subtree Admin Group members may search for and read entries in their subtree."; allow (search, read) groupdn="ldap:///cn=Subtree Admin Group,ou=groups,o=(\$1),dc=example,dc=com")</pre> <p>allows members of a group with DN "cn=Subtree Admin Group,ou=groups,o=Customers,dc=example,dc=com" to search for and read entries in the "o=Customers,dc=example,dc=com" subtree, allows members of a group with DN "cn=Subtree Admin Group,ou=groups,o=Partners,dc=example,dc=com" to search for and read entries in the "o=Partners,dc=example,dc=com" subtree, and so on for any substitution value for the "(\$1)" parameter variable.</p>
DS-6850	<p>Added a new Purge Expired Data Plugin that can be used to delete entries or JSON attributes that have expired. The plugin has several configuration properties that include controlling how expired data is identified and how it is purged.</p>
DS-6970	<p>Added support for encrypted logging, using a key generated from an encryption settings definition. Encrypted log files may be decrypted with the encrypt-file tool.</p>
DS-12087	<p>Enhanced the implementation of filters having to do with "changeNumber" in the "changelog" backend so that it now correctly interprets filters that include all changes.</p>

Ticket ID	Description
DS-12157,DS-35896	<p>Made a number of improvements to backend backup and restore, and to LDIF export and import:</p> <ul style="list-style-type: none"> * Added the ability to encrypt backups and LDIF exports with a key generated from a user-supplied passphrase or with a key generated from an encryption settings definition. Previously, encrypted backups and LDIF exports only used a secret key that was known only to servers within the replication topology. The new options make it easier to restore encrypted backups and import encrypted LDIF files in servers outside of the replication topology. The encrypt-file utility can be used to decrypt encrypted backups and LDIF exports, regardless of how the encryption key was obtained. * Added the ability to limit the rate at which backups and LDIF exports will be written to disk, which can help avoid performance problems that result from these operations saturating the disk subsystem. * Added new global configuration properties for automatically encrypting backups and LDIF exports by default, which will be set to true if data encryption is enabled during setup. * Added new global configuration properties that can specify which encryption settings definitions will be used to obtain the encryption keys for automatically encrypted backups and LDIF exports. If not specified, then the server will use its preferred encryption settings definition, or an internal topology key if no encryption settings definitions are available. * Added a new configuration property for automatically compressing encrypted LDIF exports. * Updated the backup tool to add new --promptForEncryptionPassphrase, --encryptionPassphraseFile, and --encryptionSettingsDefinitionID arguments that can be used to specify which key to use for encrypting the backup. Added a new --doNotEncrypt argument that can be used to force a backup to be unencrypted even if automatic encryption is enabled. Added a new --maxMegabytesPerSecond argument that can be used to impose a limit on the rate at which the backup may be written to disk. * Updated the restore tool to add new --promptForEncryptionPassphrase and --encryptionPassphraseFile arguments that can be used to provide a user-supplied passphrase for use in accessing the contents of an encrypted backup. For backups encrypted with an encryption settings definition or an internal topology key, the server will automatically be able to determine the correct key. * Updated the export-ldif tool to add new --promptForEncryptionPassphrase, --encryptionPassphraseFile, and --encryptionSettingsDefinitionID arguments that can

Ticket ID	Description
DS-14242,DS-16519,DS-35778	<p>Made several improvements to the verify-index tool:</p> <ul style="list-style-type: none">* Fixed an issue that could cause the tool to report an inaccurate estimate for the number of records to process.* Fixed an issue that could cause the tool to perform more processing than necessary when verifying JSON or composite indexes without the --clean argument.* Improved performance when verifying composite indexes.* Improved validation for equality indexes configured with an additional filter.* If any validation errors are encountered, it is now much easier to access the details of those validation errors, and the error messages are much clearer.
DS-14248	<p>Changed the default settings for the Directory Changelog to include all entry attributes during a delete so that matching can be more reliable.</p>
DS-15146	<p>Updated the SMTP account status notification handler to add support for extracting email addresses from JSON attributes, including an optional filter that could be used for things like only sending messages to verified and/or preferred addresses.</p>

Ticket ID	Description
DS-15223,DS-35895	<p>Added the ability to configure data encryption during setup using a randomly generated key, a key generated from a user-supplied passphrase, or a key obtained from an export of another server's encryption settings database. When setting up multiple instances, providing the same encryption passphrase to each instance will ensure that all instances have the same encryption key.</p> <p>The encryption-settings tool has also been updated to allow creating encryption settings definitions from a passphrase, to allow providing a description when creating a new encryption settings definition, and to record a create timestamp for new definitions. It is now possible to create ciphers that use the Galois Counter Mode (GCM) cipher mode (for example, using a cipher transformation of "AES/GCM/PKCS5Padding") for authenticated encryption. Definitions created with just a cipher algorithm but no transformation will now use stronger settings.</p> <p>The default encryption settings export format now provides stronger encryption. Newer server instances should be able to import encryption settings exported from other servers without issue. When exporting encryption settings for import into older servers, use the new <code>--use-legacy-export-format</code> argument.</p>
DS-16508	<p>Updated the <code>dsconfig list</code> subcommands to list objects of all complexity levels rather than requiring the <code>--advanced</code> flag to list advanced and expert objects.</p>
DS-17158	<p>Updated the server to add support for new "reject unindexed search" and "permit unindexed search" request controls, which make it possible to have more fine-grained control over when the server should process an unindexed search.</p>
DS-17197	<p>The <code>dsreplication</code> command's <code>remove-defunct-server</code> and <code>cleanup-local-server</code> sub-commands have been replaced by a new command called <code>remove-defunct-server</code>. The new command supports all of the functionality that was provided by the sub-commands.</p>
DS-17883	<p>Added an <code>ldap-debugger</code> tool that acts as a simple LDAP proxy between a client and a directory server and decodes all requests and responses that pass through it.</p>

Ticket ID	Description
DS-17891	Added a new manage-certificates tool that can be used to perform a number of functions related to TLS certificate management.
DS-18203	Addressed an error that occurs if a password policy DN is modified during an operation that is dependent on that password policy.
DS-18204	Fixed a defect where a web application extension's base context path could be set to "/" with no name.
DS-18222	Made the sending of heartbeats between replication servers more efficient.
DS-35494	Fixed an intermittent deadlock in assured replication.
DS-35523	The update tool now enforces specification of a new product license when updating to a new major version. The license can be specified using the --licenseKeyFile command-line options, or by copying the license file to the top-level directory of the server package used to perform the update. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html , or contact sales@pingidentity.com .
DS-35528	Addressed an issue in "dsreplication enable/initialize" that prevented servers from some previous versions (5.2.0.5 and earlier and 6.0.0.*) from initializing newer servers. Servers from these prior versions can now be used to enable replication with current versions of the server.
DS-35534	Added two database checkpoints to be performed in the backend prior to each online backup. If the backup is restored, this limits the database recovery time when the database environment is opened for the first time, which significantly improves the server startup time. Also, incremental backups will not contain redundant files that are unchanged from the base backup.
DS-35536	Support for the IBM JDK has been retired.
DS-35537	Updated how indexes respond to corrupt records. An index with a corrupt record no longer goes offline and degrades its server. The index instead raises an alarm and continues to process requests. Such an index should be rebuilt, but it will continue to be used and will return the correct results for unaffected keys.

Ticket ID	Description
DS-35538	Updated JZlib from version 1.0.7 to 1.1.3 to address an <code>ArrayIndexOutOfBoundsException</code> that could occur when replication servers disconnected during a scheduled garbage collection.
DS-35549	Eliminated a misleading error message triggered by sorting entries during a search.
DS-35551	<p>Updated the Directory Server to require a minimum Berkeley DB Java Edition version of 7.5.11.</p> <p>Builds of the server that ship with the Berkeley DB JE jar file actually include a pre-release jar file for version 7.5.12 that fixes an issue that could result in lock conflicts internally within JE under heavy concurrent load in an I/O-bound database. Organizations that receive a Directory Server build that does not include the Berkeley DB Java Edition jar file are recommended to contact Oracle support to obtain this fix under their own JE support contract.</p>
DS-35558	Fixed an issue where a JSON object or attribute could not be deleted if it contained a field with two indexed values differing only in case.
DS-35571	In replicated environments, updating attributes with a very large number of attribute options is now much faster. There is a potential for a 2X increase in storage for these entries, but updating an entry with 1000 attribute options is now 100 times faster.
DS-35576	Updated the JMX connection handler's monitor provider so that when a JMX connection is closed, it is removed from the list of established connections. After a JMX client disconnects, it may take the server a few minutes to detect the closure and update the monitor.
DS-35580	Updated the Frequently Accessed Entries Cache to eliminate cache lock contention when the server is starting, and increased parallelism in general. Also, updated the cache to penalize frequently modified entries to improve garbage collection and reduce heap fragmentation.

Ticket ID	Description
DS-35581	<p>Updated the server to include an instance of the Periodic Stats Logger Plugin that is enabled out-of-the-box to aid in diagnosing support issues. The "Historical Stats Logger" plugin will log performance statistics to logs/monitor-history/historical-dsstats.csv every five minutes. This works in concert with the "Monitor History" plugin, which logs the full contents of cn=monitor to logs/monitor-history every five minutes. The tail of this csv file is automatically included in the output generated by collect-support-data.</p>
DS-35582	<p>Added an "Expensive Write Operations Access Logger" that adds detailed timing information to logs for add, delete, modify, or modify-dn operations that take longer than the configured threshold (one second by default). Log messages include information about the most expensive phases of operation processing, which can help diagnose the cause of performance outliers.</p>
DS-35583	<p>Fixed a defect where configuring a Directory server on a Windows machine with a space in the home directory pathname would cause server setup to fail.</p>
DS-35593	<p>Removed the max-passes option from the Periodic GC Plugin. This setting was sometimes necessary in Java 1.6, but setting it higher than 1 now just increases the amount of time it takes the plugin to complete a full garbage collection.</p>
DS-35601	<p>Added a new Monitor Entry for SSL Cipher Suite and Protocol information. It is available under cn=SSL Context,cn=monitor.</p>
DS-35616	<p>Fixed a very rare race condition with the Frequently Accessed Entry Cache which could lead to an index being marked as degraded and requiring a rebuild.</p> <p>The problem is unlikely to happen outside of testing environments since it requires modifying a single entry over 1000 times per second across multiple servers concurrently.</p>
DS-35648	<p>Added a missing double-quote to bat/transform-ldif.bat, which prevented the command from being invoked successfully on Windows systems.</p>

Ticket ID	Description
DS-35659	Enhanced the ACI handling code to reduce contention when updating the set of active ACIs. In systems that have a very high number of entries that include ACIs, this enhancement significantly improves the throughput of operations that add and delete ACIs.
DS-35694,DS-36189	Added a new Cleanup Expired PingFederate Persistent Access Grants Plugin. An instance of this plugin can be created to automatically delete expired persistent access grant entries that were created by PingFederate. This is preferable to PingFederate's cleanup process since it can be run on multiple servers and throttles the background delete operations to prevent impacting client traffic.
DS-35709	Changed enable-sub-operation-timer on the Global Configuration to be true by default. This exposes operation timing information in the Sub-Operation Timing Monitor and any Operation Timing Access Log Publishers that have been configured. Enabling this tracking has about a 3% impact on operation throughput and latency, which will not be noticeable in most deployments and is an acceptable tradeoff for understanding where operation processing time is spent. However, it can be explicitly set to false to turn this tracking off.
DS-35727,DS-35728	Updated setup to include key usage, extended key usage, and subject alternative name extensions in the self-signed certificates that it generates.
DS-35750	Added support for multiple client connection policies for sensitive attributes. Support for different sensitive attributes per client requires the use of multiple client connection policies with the same names on the Directory Server and the Proxy Server. When a client request is processed by a Proxy Server, the Directory Server looks for a policy in its own configuration with the same name as the one in the Proxy Server. The Directory Server then uses this policy rather than the one associated with the Proxy Server's connection.

Ticket ID	Description
DS-35790	<p>Addressed an issue where an index key could incorrectly be reported as exceeding the index-entry-limit after one billion entries had been imported or added to the directory server. The directory server does not need to contain one billion entries at the same time to be affected by this issue since the entry ID will always increase for each added entry even if entries are deleted. Environments that have experienced this issue should export and reimport their data after applying this patch.</p>
DS-35797	<p>The dsreplication "enable" and "initialize" commands now support adding or initializing a server using a topology file in non-interactive mode. The topology file must contain the list of servers that are already in the topology and may be obtained by running the "manage-topology export" command. An LDAP connection to the first available server in the list is used to add or initialize the new server into the topology.</p>
DS-35797	<p>The dsreplication "enable" and "initialize" commands now support adding or initializing a server using a topology file in non-interactive mode. The topology file must contain the list of servers that are already in the topology, and may be obtained by running the "manage-topology export" command. An LDAP connection to the first available server in the list (preferably in the same location as the new server) is used to add or initialize the new server into the topology.</p>
DS-35868	<p>The create-systemd-script command now suggests placing the script created in "/etc/systemd/system."</p>
DS-35869	<p>Updated the GSSAPI SASL mechanism handler to support alternate authorization identities, to support the "dn:" and "u:" formats for those authorization identities, and to allow the use of different identity mappers for authentication and authorization identities.</p>
DS-35898	<p>Updated the LDIF export task so that the server will now execute the export-ldif command in a separate process. This is safer than the former export task mechanism because it ensures that the exported LDIF file will reflect the contents of the backend at a specific point in time (the time the export-ldif process opened the database).</p>

Ticket ID	Description
DS-35933	Fixed a password policy issue that could arise if a user authenticated with a password that was stored with a deprecated password storage scheme. If the password policy for that user is configured with a force-change-on-reset value of true, then the internal update used to re-encode that password would have incorrectly been classified as an administrative reset and the user would have been required to choose a new password after the next successful bind.
DS-35990	Provided the means to request that the server dynamically reload the certificate key and trust stores used by all HTTP connection handler instances that provide support for HTTPS. The request can be made using a new reload HTTP connection handler certificates task, the reload-http-connection-handler-certificates tool, or programmatically from a Server SDK extension using the <code>ServerContext#reloadHTTPConnectionHandlerCertificates</code> method.
DS-35995	The task that sets the generation ID now waits for the replica to be connected before preceding. This should prevent errors such as "The generation ID could not be reset for domain dc=example,dc=com because it is NOT connected to the replication."
DS-35997	Enhanced schema validation. Backends with compacted attribute types will not open if any of the attribute types are missing from the schema.
DS-36025	Added a close-connections-when-unavailable property to the LDAP Connection Handler configuration. This allows a connection handler to be closed whenever the server sets an unavailable alert type, such as when backend data is unavailable. This should trigger clients to failover to another server. When the unavailable alert type is cleared, the connection handler is started again. When using this configuration setting, we recommend using two connection handlers: one for client traffic, with this option set to true, and one for administration and monitoring, with this option set to false. This allows the server to be visible to administrators but not to clients.

Ticket ID	Description
DS-36054	Added an encrypt-file tool that can encrypt and decrypt data with a user-supplied passphrase, an encryption settings definition, or a topology key shared among server instances. It includes support for decrypting the content in encrypted backups, LDIF exports, and log files.
DS-36070	Fixed an issue with compressed logging that could leave some data buffered in memory and not actually written out to disk until the logger is closed.
DS-36075	Updated tools that interact with log or LDIF files to support reading from input files that are compressed and encrypted and writing to compressed and encrypted output files.
DS-36088	In addition to specifying an exact set of desired cipher suites for the LDAP and HTTP Connection Handlers, administrators can now specify inclusions to, or exclusions from, the set of cipher suites selected by the server.
DS-36092	Updated the rebuild-index tool so that the bulkRebuild argument's usage description and error message make it clear that it cannot be used when running the tool as a task or while server is online.
DS-36093	Added support for TLS1.2 with STARTLS to connect to an SMTP server.
DS-36093	Added support for TLS1.2 with STARTLS to connect to SMTP server
DS-36111	<p>Added support for backup retention. When performing a backup, it is now possible to specify a minimum number of backups to retain or a minimum age of backups to retain. If either or both are specified, and if the new backup completes successfully, then any previous backups in the same directory that do not satisfy that criteria will be removed.</p> <p>The remove-backup tool has also been updated to allow specifying the number of backups to retain or the minimum age for backups to retain as an alternative to providing the specific backup ID for the backup to remove. If retention criteria is specified, then any backups in the target directory that do not satisfy that criteria will be removed.</p>
DS-36230	Improved the server's handling of DNs and RDNs that contain characters whose UTF-8 encodings require more than two bytes.

Ticket ID	Description
DS-36239	Fixed an issue to address null addresses associated with internal connections when used in conjunction with address-based ACI evaluations, such as IP and DNS bind rules.
DS-36272	Fixed an issue that could cause certain special characters in LDAP URLs to be doubly encoded.
DS-36312	Fixed an issue that could cause the server to incorrectly classify some search requests as unindexed.
DS-36328	Updated the server to reduce contention when converting between strings and the bytes that comprise those strings.
DS-36339	The error message for a null changelog token when the current server is the Master has been removed
DS-36360	Increased the default size of the queue used to hold alert notifications so they can be asynchronously processed by a background thread. This makes it less likely that the queue will become full if many alerts are generated in a short period of time, which would cause subsequent attempts to generate alerts to block while the server catches up. Also updated the server to log a message when the queue becomes full so that administrators will be aware of the problem and will have suggestions for addressing it.
DS-36377	Fixed an issue where a configuration change to enable a Delegated Administrator could be incorrectly rejected after a configuration change to the parent Delegated Admin Resource Type.
DS-36403	Changed server behavior so it will now mark a JSON index as corrupt if it can't find a key, instead of having the operation fail.
DS-36439	Fixed a rare race condition that would cause "dsreplication enable" or "dsreplication initialize" to fail. This issue has only been seen in automated testing environments with resource-constrained virtual machines.
DS-36545	Added a sanitize option to the Monitor History Plugin that, if enabled, will redact the small amount of potentially personally identifiable information that could appear in search filters and LDAP DNs within the monitor. This makes it easier to share the monitor history files with the support team in secure environments.

PingDirectory Server 6.2.0.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-35874	The Self-Service Account Manager (SSAM) application is no longer included in the Directory Server zip file. The source code for the application is available at https://github.com/pingidentity/ssam .
DS-17027	Updated the replication status table displayed by "dsreplication status" so that it includes a "Server ID" column. The "Server ID" column is only displayed if the "-a" option is passed.
DS-16702 DS-17261	<p>Updated the authentication failure reasons generated for bind attempts that fail because of an incorrect password when account lockout is enabled. If the account is not yet locked, the authentication failure reason will include the number of remaining failed attempts before the account will be locked. If the failed attempt caused the account to be locked, the authentication failure reason will indicate whether the account is permanently or temporarily locked.</p> <p>Also fixed an issue in the get password policy state issues control implementation in which the server would incorrectly indicate that a temporary lockout was permanent for the failed bind attempt that caused the account to be locked.</p>
DS-811	Added an optional reason parameter for dsconfig changes that will be automatically included in the server's config-audit.log file.
DS-1029	The server now monitors important certificates used for client and inter-server communication. Certificate information is available in the Administrative Console and in the status tool output. An alarm is raised and alerts are sent when a monitored certificate is 30 days from expiration.

Ticket ID	Description
DS-1233	<p>Added the relative time extensible matching rule "relativeTimeExtensibleMatch" (1.3.6.1.4.1.30221.2.4.14) that can be used to match attributes with values using Generalized Time Syntax. The assertion value when using this matching rule should be in this form: an optional comparator, an optional negative '-' sign, and a duration sequence. The '>' comparator may be used to match times that come after the duration sequence. The '<' comparator may be used to match times that come before the provided duration sequence. If no comparator is provided, then matching values are determined by whether they are between the current time and the duration sequence. The optional negative sign indicates that the provided duration sequence is in the past. A duration sequence should be a comma separated list of duration values (a number followed by a unit of time, such as year, week, day, hour, minute, second, or millisecond). Examples:</p> <ul style="list-style-type: none"> ▪ Users who haven't changed password in a year (pwdChangedTime:relativeTimeExtensibleMatch:=-<-1y) ▪ Users who logged in the last 3 and half hours (ds-pwp-last-login-time:relativeTimeExtensibleMatch:=-3 hours, 30 m) ▪ Accounts expiring in the next two weeks (ds-pwp-account-expiration-time:relativeTimeExtensibleMatch:=2 weeks) ▪ Entries modified in the last 700 milliseconds (modifyTimestamp:relativeTimeExtensibleMatch:= - 700 ms)

Ticket ID	Description
DS-2074	<p>Updated the installer to discourage the use of weak root passwords.</p> <p>When run in interactive mode, setup will display a list of password quality recommendations before prompting for the initial root password, suggesting that it should be at least 12 characters long, should not be contained in a dictionary of English words, and should not be contained in a dictionary of commonly-used passwords. If the proposed password does not meet these constraints, then the user will be given the option of proceeding with the provided weak password or choosing a different password.</p> <p>When run in non-interactive mode, setup will exit with an error if the proposed initial root password does not satisfy the above constraints, unless the command line also includes the <code>--allowWeakRootUserPassword</code> argument.</p> <p>In either mode, when a strong initial root password is supplied, setup will also configure the root users' password policy to ensure that subsequent root user passwords will also be required to satisfy these constraints.</p>
DS-3653,DS-17268	<p>The setup tool's GUI mode has been deprecated, and will be removed in a future version of the product. Until then, it can still be accessed using the command <code>'setup --gui.'</code> The <code>--cli</code> option is no longer necessary for starting setup in command-line mode.</p>
DS-3653	<p>The setup tool's GUI mode is no longer available.</p>
DS-4161	<p>Updated PingDirectory Server, PingDirectoryProxy Server, PingDataSync, and PingDataGovernance with the capability to run as Windows Services.</p>
DS-5944	<p>Enhanced the rebuild-index tool with the ability to rebuild all indexes, or all indexes in a specific state using the <code>"--bulkRebuild"</code> argument.</p>

Ticket ID	Description
DS-6511,DS-13576,DS-15809	<p>Added support for equality composite indexes, which combine a mandatory equality filter pattern (for example, "(uid=?)" with an optional base DN pattern (for example, "ou=?,ou=Customers,dc=example,dc=com") to improve the performance of certain types of searches in directories with a very large number of entries, and in particular with a very large number of non-leaf entries. Equality composite indexes offer two distinct advantages over the existing equality attribute indexes in these kinds of deployments:</p> <ul style="list-style-type: none"> - In deployments with a highly branched DIT in which clients often search with a base DN at or below one of these branch points, the use of a base DN pattern allows the server to efficiently maintain an index that is scoped to these branches so that the candidate set will only include entries from the targeted branch rather than from the entire backend. This means that individual index keys are much less likely to have ID sets that exceed the index entry limit, or that could require examining a large number of entries that are outside the scope of the search. - In deployments with any DIT structure, equality composite indexes are much more efficient than equality attribute indexes at maintaining index keys that match a very large number of entries. <p>As with equality attribute indexes, equality composite indexes can be used to efficiently search for entries matching an equality filter or a substring filter with a subinitial component. These filters may be requested by themselves, or they may be inside an AND or OR filter.</p>
DS-8914	<p>Added the only-cache-frequently-accessed option to the FIFO Entry Cache to allow only frequently accessed entries to be cached, and added a new Frequently Accessed Entry Cache to the default server configuration. This can speed up server performance when a few entries are accessed frequently, such as system accounts that are retrieved from the backend for each access that is done by the Directory Proxy Server or for frequently repeated queries over a small subset of data.</p>

Ticket ID	Description
DS-9808	<p>By default, replication no longer replicates entries from subordinate backends. For example, replication enabled for the base DN <code>dc=example,dc=com</code> would also allow replicating changes from another backend if the base DN of that backend was subordinate to <code>dc=example,dc=com</code> (for example, <code>dc=child,dc=example,dc=com</code>). Upgraded installations will not experience a behavior change. See the command help for the new "allow-inherited-replication-of-subordinate-backends" global configuration property.</p>
DS-10694	<p>Updated the Server SDK to provide methods for obtaining a single LDAP connection or an LDAP connection pool with connections established to a specified LDAP external server defined in the server configuration.</p> <p>Also updated the server configuration to add support for obscured values. An obscured value is a general-purpose string that is stored in an obscured form in the configuration so that its plaintext value is not readily discernible to anyone looking at the configuration file and so that the value is not displayed in administrative interfaces. The Server SDK provides a method for obtaining the plaintext representation of an obscured value, and this mechanism can be used to store potentially sensitive values in the configuration for use in Server SDK extensions without the need to store those values in the clear.</p>
DS-10748	<p>Added configuration options for setting the SSL Protocol and/or the SSL Cipher Suites to the HTTPS Connection Handler.</p>
DS-12216	<p>Added an alarm at warning level to notify if any of the important JVM startup arguments are missing or misconfigured.</p>
DS-12322	<p>In order to avoid assured replication timeouts, replication will be disabled during explicit garbage collection.</p>
DS-12520	<p>Updated the Server SDK to include an example plugin that enforces that values of a specified JSON field are unique across entries or across multiple values within the same entry. The plugin can be used in either the Directory Server (for cases in which each server contains a complete copy of the data) or the Directory Proxy Server (for cases in which the data is spread across multiple servers, like when using entry balancing).</p>

Ticket ID	Description
DS-13721	Corrected the port number returned in the error message that is displayed when an administrator is trying to set up a server that is already running.
DS-14650	Enhanced the HTTPS Connection Handler to send a HTTP Strict Transport Security header by default in all responses.
DS-15861,DS-15862	Replaced the ldapsearch and ldapmodify tools with new versions. The new versions are backward-compatible, but offer a number of new features, including better connection handling, better output formatting, better support for bulk operations, support for referrals, support for additional request and response controls, and rate limiting. The ldapsearch tool now offers the ability to output results in JSON, CSV, or tab-delimited text as an alternative to LDIF, and provides support for a number of data transformations. The ldapmodify tool now supports the LDIF control syntax, as well as writing to output and reject files.
DS-15978	Added global configuration property replication-history-limit. When set, replication-history-limit specifies the maximum length of the operational attribute ds-sync-hist in bytes.
DS-16018	Updated the encryption-settings tool to provide the ability to export or import multiple encryption settings definitions with a single command.
DS-16117	Updated the server to use the latest 7.0.6 release of Berkeley DB Java Edition.
DS-16170	Updated support for the GSSAPI SASL mechanism to make it possible to configure whether the server should act as a GSSAPI acceptor or an initiator.

Ticket ID	Description
DS-16361	<p>Updated the server to fix a problem with the way that DNs containing hex-encoded RDN values are treated, which could cause the server to accept certain incorrectly encoded DNs, to incorrectly store DNs provided with hex encoding, and to fail to identify the correct DN when using a non-hex-encoded DN to reference a DN that was stored with a hex-encoded representation or when using a hex-encoded DN to reference a DN that was stored with a non-hex-encoded representation.</p> <p>Using hexadecimal encoding in DNs is very rare in practice, so this should have no effect on most deployments. However, any deployments that contain entries stored with hex-encoded DNs, whether used in the DN of the entry or as a value for an indexed attribute with a DN syntax, may need to export that data before performing an update and re-import that data after the update has completed.</p>
DS-16405	<p>The SNMP context name for the server can now be configured using the new context-name property of the SNMP Subagent Plugin. The server instance name remains the default context name when this property is not set.</p>
DS-16431	<p>Removed the "ssl-encryption" attribute from replication related monitor entries that refer to communication that is internal to the server. Only "Remote Repl Server" entries still have an "ssl-encryption" attribute as that communication is over the network.</p>
DS-16500	<p>Updated "dsreplication initialize" to be more defensive when initializing a remote replica. Errors should be detected and reported much sooner.</p>
DS-16509	<p>Updated the access and audit loggers so that, when logging information about an internal operation that was triggered by an external client request, the log message will include the connection and operation ID for that request. Also updated the error logger so that when logging a message from a thread that is actively processing an operation, the log message will include the connection and operation ID for that operation.</p>
DS-16593	<p>Fixed an issue where incorrect names were displayed in the usage for the start scripts.</p>

Ticket ID	Description
DS-16609	Replicating Directory Servers no longer wait on startup for the replication backlog to drop below startup-min-replication-backlog-count, when the replication backlog is due to replicas containing incorrect generation IDs.
DS-16638	Updated the server to automatically store some JSON field values in a more compact manner in order to reduce the on-disk and in-memory footprint required for that data.
DS-16723	Added validation to the dsreplication command so that it no longer allows a server to be added to a domain when the requested restricted status does not match the restricted status of existing servers in the domain.
DS-16755	<p>Added a new plugin to monitor sub-operation phases and gather diagnostic information. The plugin supports adding a request criteria so that the monitoring can be scoped to a specific set of entries.</p> <p>The information collected is exposed in a monitor entry named cn=Sub-Operation Timing in cn=monitor.</p>
DS-16789	The script files used to stop and start the server have been renamed stop-server and start-server. The older scripts are still present but may be removed in a future release of the product.
DS-16855	Fixed an issue where character set password validators would not retain the values for character sets that differed only by case.
DS-16858	The modifierName and modifyTimestamp attributes are now updated when offline configuration changes are made.
DS-16906	Added a disabled-alert-type configuration property to the Alert Backend that can be used to suppress specific alert types from being added to the backend.
DS-16933	Fixed a race condition that could cause a VLV index to become corrupted with a high concurrent modification rate involving values close to each other in the sort order. The problem was uncovered during internal testing with a configuration that is unlikely to be used in production environments.

Ticket ID	Description
DS-16955	Fixed an issue during upgrade where a backend initialization error could occur for the Changelog Backend indicating "Environment is Read-Only."
DS-16982	Fixed an exception that prevented editing a Replication Synchronization Provider in the PingData Administrative Console.
DS-16990,DS-16994	Fixed an issue that could cause the server to incorrectly report the length of time until an account becomes locked after remaining unused for too long, or until an account becomes locked for failing to choose a new password in a timely manner after an administrative reset. The incorrect information would appear in account usability messages in a password policy state extended response or a get password policy state issues response control, and did not affect the server's ability to correctly enforce password policy.
DS-17002	<p>Updated support for the UNBOUNDID-MS-CHAP-V2 SASL mechanism to make it easier for an intermediate application to support delegating MS-CHAPv2 authentication to the Directory Server. This includes:</p> <ul style="list-style-type: none"> - The client SDK has been updated to make it easier to issue separate bind requests for each phase of the two-step authentication process. Previously, the API only exposed a single bind request that would perform both stages of the process. - A new "proxied MS-CHAPv2 details" request control has been provided, which can be used to allow an intermediate application acting as an MS-CHAPv2 server to generate its own server challenge rather than obtaining one from the Directory Server. - The client SDK has been updated to improve the javadoc documentation. A number of examples are included to demonstrate the process of using the SDK to authenticate with the UNBOUNDID-MS-CHAP-V2 mechanism. The README file has also been updated with instructions for enabling server-side support for the UNBOUNDID-MS-CHAP-V2 mechanism.
DS-17007	Updated the commonly-used passwords dictionary to include many additional values, including known passwords used in several real-world breaches.

Ticket ID	Description
DS-17008	Fixed an issue that could impede the timely replication of subtree-delete requests contained in a transaction.
DS-17011	<p>Updated the password storage schemes using the crypt, PBKDF2, and scrypt algorithms to provide the ability to impose an upper bound on the length of the passwords that they will accept. By default, any attempt to use a password longer than 200 bytes will be rejected, although this limit can be adjusted with the max-password-length property in the password storage scheme configuration.</p> <p>These algorithms involve expensive computation, and encoding or validating a longer password is more expensive than encoding or validating a shorter password. A malicious client may try to launch a denial of service attack by issuing bind requests with exceptionally long passwords (with no expectation that those passwords are correct). Imposing an upper limit on password length can mitigate such attacks by rejecting those bind requests without performing any of the expensive processing required to validate the password.</p> <p>Although the bcrypt algorithm also involves expensive processing, it already provides protection against this type of attack by only evaluating up to 72 bytes of a password, so the server does not need to impose an upper limit for passwords used with this scheme.</p>
DS-17019	The server now requires Java version 8.
DS-17020	Fixed an issue with the dictionary password validator that would cause it to stop processing the dictionary file once it encountered a blank line or a line containing only spaces. Any dictionary entries contained in the file after that point were incorrectly ignored.
DS-17042	Fixed an issue that could cause the server to compute a slightly incorrect password expiration time for an account that is within the password expiration warning interval, based on whether the server had provided an expiration warning to that user.
DS-17046	Fixed an issue where user resource limits defined on the authorization entry were not being enforced after a remote bind using the pass-through authentication plugin.

Ticket ID	Description
DS-17048	Fixed an issue where subtree view restrictions could register "replication replay failed" alerts when attempting to replay a subtree delete operation.
DS-17074	Fixed an issue that could allow users with locked accounts to change their own passwords using the password modify extended operation.
DS-17078	Updated a couple of cases where filtered SCIM searches for groups with missing members were not returned.
DS-17080	Improved error reporting for the manage-extensions tool.
DS-17146	<p>Updated the logic used to select which TLS cipher suites should be enabled by default, and the logic used to prioritize those cipher suites. The selection process has been updated to use the guidelines provided in the OWASP "Transport Layer Protection Cheat Sheet" document.</p> <p>Some of the changes include:</p> <ul style="list-style-type: none"> - The server already preferred cipher suites that support forward secrecy over those that don't. It now prefers DHE over ECDHE, and avoids suites that use non-RSA keys. - The server already avoided cipher suites that used known-weak cryptographic weaknesses, including null encryption, the RC4 symmetric cipher, and the MD5 digest algorithm. It now also avoids anonymous encryption, the single-DES symmetric cipher, the IDEA symmetric cipher, and any suite using export-level encryption. - The server now prefers cipher suites that use the Galois/Counter Mode (GCM) over the Cipher Block Chaining (CBC) mode. - The server now prefers AES-based cipher suites with 256-bit keys over those that use 128-bit keys. For suites with equivalent key sizes, it prefers suites with a stronger message digest algorithm over suites with a weaker digest algorithm (e.g., SHA384 over SHA256 over SHA). - The server now provides better support for selecting and prioritizing ciphers when running on the IBM JVM. The IBM JVM uses somewhat different naming for its cipher suites than the Oracle implementation, which previously allowed certain desirable suites to not be included in the selected set.

Ticket ID	Description
DS-17165	Fixed an exception in the Local DB Index management menu that occurred when abandoning or resuming index creation.
DS-17174	Added the ability to customize the LDAP join size limit, which was previously hard-coded to 1000 entries. The ldap-join-size-limit global configuration property, which has a default value of 10000, can be used to set the default server-wide size limit. This default limit can be overridden on a per-user basis by setting the ds-rlim-ldap-join-size-limit operational attribute in the user's entry. It is also possible to use the maximum-ldap-join-size-limit property in the client connection policy configuration to set an absolute maximum join size limit for all requests received on connections associated with that client connection policy.
DS-17211	Fixed an issue where the milliseconds reported in the modifyTimestamp attribute could be up to 100 ms behind the actual modification time.
DS-17235	Updated the SCIM interface to reliably produce JSON rather than XML in response to a GET operation if an Accept header is not present, or when an Accept header provided by the client does not indicate a preference between JSON and XML.
DS-17237	Addressed an issue specific to entry-balanced environments where changes received through replication are applied in the incorrect backend. This can occur if a restricted domain is disabled prior to disabling the global domain. With the restricted domain disabled, the affected server could apply the changes originally targeted for the restricted domain in the global domain. In addition, other servers in the topology will reset their generation ID for the restricted domain.
DS-17241	The Administrative Console is no longer compatible with older versions of the server.

Ticket ID	Description
DS-17243	<p data-bbox="850 216 1446 405">Added support for a uniqueness request control, which can be included in an add, modify, or modify DN request to indicate that the server should attempt to identify any conflicts that the requested operation might introduce with one or more other entries that exist within the directory topology.</p> <p data-bbox="850 422 1463 737">Criteria for identifying conflicts can be specified with one or more attribute types, with a search filter, or both. If the uniqueness criteria includes multiple attribute types, then a multiple attribute behavior can be used to indicate whether to enforce uniqueness separately for each attribute type, to prevent conflicts across any of the specified attribute types, or to ensure that each entry has a unique combination of the values of those attributes.</p> <p data-bbox="850 753 1463 1262">The server can perform pre-commit validation, in which case it will reject the request without applying any changes if it detects that it would have introduced a conflict, and it can also perform post-commit validation, where it can detect conflicts that may have arisen after changes were applied (for example, because of another change being processed at the same time on a different server). When attached to a request sent through the Directory Proxy Server, the uniqueness request control may include pre-commit and post-commit validation levels to indicate how thoroughly it should work to identify conflicts (for example, to perform the search in a single backend server, in at least one server in each backend set, or in all available backend servers).</p> <p data-bbox="850 1278 1463 1562">The control can also include a base DN that can be used to narrow the scope of conflict detection (for example, to ensure that there will not be any conflicts within one particular branch, while ignoring conflicts with entries that may exist elsewhere in the DIT), and it can detect or ignore conflicts with soft-deleted entries. Multiple uniqueness controls can be included in the same request if multiple uniqueness constraints should be enforced.</p>
DS-17252	<p data-bbox="850 1602 1430 1751">Fixed an issue where repeated modifications to a single entry could result in a replication backlog of all changes. A side effect of this change is that changing the number of replication replay threads now requires a server restart.</p>
DS-17267	<p data-bbox="850 1791 1430 1913">Eliminated a spurious warning message written to the server error log for changes that are part of an LDAP transaction or an atomic multi-update operation while a persistent search is active.</p>

Ticket ID	Description
DS-17270	Updated the SCIM 1.1 interface to treat query parameters (such as sortBy, sortOrder, startIndex) case-insensitively.
DS-17271	The SCIM 1.1 interface has been changed to reject searches specifying a sortBy parameter that cannot be processed, rather than processing the search as if the parameter had not been present.
DS-17275	SCIM 1.1 clients can obtain diagnostic information about how the Directory Server processes a search query, by specifying attributes=debugsearchindex as a query parameter.
DS-17298	HTTP TRACE requests have been disabled, and will now return an HTTP status code of 405 Method not allowed.
DS-17305	Updated the server to dynamically calculate the optimal replication window and queue sizes from the configured num-recent-changes value on the backend. Increasing the num-recent-changes setting can lead to an increased peak server modification rate and reduce the possibility of replication backlogs. Since the combined window and queue sizes must not exceed the num-recent-changes value, the window-size and queue-size configuration settings on the Replication Server are no longer configurable separately.
DS-17306	Fixed an issue that could cause the server to add a second entryUUID value to an entry being imported from LDIF, if that entry used entryUUID as an RDN attribute but didn't include it in the set of attributes for the entry.
DS-17311	Fixed an issue where notification delivery could halt after processing a subtree delete operation within a multi-update request.
DS-17318	Removed the default root password from the out-of-the-box configuration. This password was never actually used because it was replaced by the user-supplied password provided when running setup, and it has been removed for additional security.
DS-17357	Fixed a problem that could cause the backup utility to compute an incorrect hash when performing an online backup.

Ticket ID	Description
DS-17362	Updated the SCIM 1.1 SDK to improve the performance of the User groups and Group members attributes. The virtual attribute "isDirectMemberOf" is used by this enhancement, and should be enabled.
DS-17372	Replication will no longer generate or accept replication changes that have timestamps that are too far in the future.
DS-17374	Improved the error reporting associated with search involving isMemberOf failing when the global size limit is reached.
DS-17427	Updated the Server SDK to provide support for privileges. It is now possible to determine whether a user has a given privilege, and to obtain a list of the privileges that have been assigned to a user.
DS-17428	Updated the Server SDK to provide support for groups. It is now possible to determine whether a user is a member of a specified group, to obtain the set of groups in which a user is a member, and to iterate over the members of a specified group.
DS-17431	The aci and objectClass indexes have enforced minimum index entry limits to ensure proper server performance. The enforced minimum will be used unless a higher value is specified.
DS-17433	When a replicated backend does not contain the expected generation ID an alarm will be raised.
DS-17440	Updated to Berkeley DB Java Edition 7.3.7.
DS-17443	The search-filter-pattern property of the Pass Through Authentication Plugin now allows modifiers (such as "ldapFilterEscape" and "trim") to be used with attribute substitutions. This addresses an issue where binary attributes were not properly escaped in the LDAP filter. See the documentation for the search-filter-pattern property for more information.

Ticket ID	Description
DS-17444	<p>Updated the server to reduce the use of the SHA-1 message digest. The server will now use a 256-bit SHA-2 digest instead of a SHA-1 digest in all of the following cases:</p> <ul style="list-style-type: none"> - When hashing or signing a backup. - When signing an LDIF export. - When signing log data. - When generating MACs for an encrypted collect-support-data archive. - When generating unique identifiers for encryption settings definitions. - When determining whether the configuration changed with the server offline. <p>In all of the above cases, the server includes metadata in the output of the cryptographic processing to indicate the digest or MAC algorithm used for that processing, which ensures that the output remains compatible across server versions. For example, an LDIF export that uses a signature generated with the SHA-2 digest can be successfully imported into older versions of the server.</p> <p>Also, the fingerprint certificate mapper has been updated so that it can use the 256-bit SHA-2 digest when mapping a client certificate to the corresponding user entry. The previous MD5 and SHA-1 digests remain supported.</p> <p>Finally, the example enhanced password storage scheme provided with the UnboundID Server SDK has been updated so that it uses the 256-bit SHA-2 digest instead of a SHA-1 digest.</p>
DS-17466	<p>Fixed a bug where transactions grew read-write locks in the lock table without removing them when no longer needed.</p>
DS-17478	<p>Updated the server so that multiple entryDN virtual attributes can be created with different attribute types.</p>
DS-17480	<p>An LDAP search with indexed and virtual attribute filters will return the indexed results if the virtual attribute fails to return any results, for example, if the virtual results exceed the size limit.</p>
DS-17483	<p>Fixed an issue that could cause the pre-read and post-read response controls to be created with a criticality of true.</p>
DS-17504	<p>If the server is shutting down, replication will not try to connect to other servers in the topology, which can speed up server shutdown when remote servers are unresponsive.</p>

Ticket ID	Description
DS-17523	Fixed an issue that prevented users from using the adminPasswordFile argument with dsreplication.
DS-17526	Updated the memory usage calculation of the group cache to occur in a background thread. This eliminates the possibility of blocking application threads in rare situations where the group cache calculation is expensive. Also, any time that the calculation takes longer than 10 seconds, the server will stop maintaining the memory usage for the group cache since in environments with a very high number of groups, this could lead to garbage collection pauses over 5 seconds.
DS-17531	Fixed an issue that could cause a sync pipe to crash due to missing attributes in the changelog.
DS-17544	The Administrative Console can be deployed in an external web container, such as Tomcat, using the contents of resource/admin-console.zip, located in the server root.
DS-17544	The Administrative Console can be deployed in an external web container, such as Tomcat, using the contents of resource/admin-console.zip, located in the server root.
DS-17554	The virtual attribute "isDirectMemberOf" is now enabled by default in PingDirectory Server.
DS-17554	The virtual attribute "isDirectMemberOf" is now enabled by default in PingDirectory Server.
DS-17576	Updated the Server SDK's ServerContext to expose a ValueConstructor, which can be used to build String values using a value-pattern template that references attribute values within an Entry. See the Javadoc for the ValueConstructor class with the Server SDK packaging for more information.
DS-17576	Updated the Server SDK's ServerContext to expose a ValueConstructor, which can be used to build String values using a value-pattern template that references attribute values within an Entry. See the Javadoc for the ValueConstructor class with the Server SDK packaging for more information.
DS-17596	Fixed an issue where an OR filter involving multiple IsMemberOf clauses would return no matches
DS-17596	Fixed an issue where an OR filter involving multiple IsMemberOf clauses would return no matches

Ticket ID	Description
DS-17606	Fixed an issue in the fingerprint, subject attribute to user attribute, and subject DN to user attribute certificate mappers. When configured for use in processing SASL EXTERNAL bind requests, these certificate mappers would return the target user entry without any operational attributes. This could cause the server to behave incorrectly for any user-specific functionality that depends on operational attributes to function properly. This problem did not affect the subject equals DN certificate mapper, nor any custom certificate mapper implemented with the Server SDK.
DS-17606	Fixed an issue in the fingerprint, subject attribute to user attribute, and subject DN to user attribute certificate mappers. When configured for use in processing SASL EXTERNAL bind requests, these certificate mappers would return the target user entry without any operational attributes. This could cause the server to behave incorrectly for any user-specific functionality that depends on operational attributes to function properly. This problem did not affect the subject equals DN certificate mapper, nor any custom certificate mapper implemented with the Server SDK.
DS-17639	Updated to Berkeley DB Java Edition 7.4.5.
DS-17639	Updated to Berkeley DB Java Edition 7.4.5.
DS-17699,DS-17763	Fixed the task based tools to allow the use of password files and prevent passing a bind DN to the server when using a SASL External bind request.
DS-17699,DS-17763	Fixed the task based tools to allow the use of password files and prevent passing a bind DN to the server when using a SASL External bind request.
DS-17709	Fixed an issue in which the server would incorrectly accept a DN containing an attribute value that started with an unescaped plus sign (for example, "telephoneNumber=+1 800 555 1234,ou=People,dc=example,dc=com"). In a DN, plus signs are used to separate the name-value pairs in a multivalued RDN, and any plus sign contained in an RDN value must be escaped with a backslash (like "telephoneNumber=\\+1 800 555 1234,ou=People,dc=example,dc=com"). These kinds of malformed DNs are likely to cause problems with clients that encounter them, and the server now correctly rejects them.

Ticket ID	Description
DS-17709	<p>Fixed an issue in which the server would incorrectly accept a DN containing an attribute value that started with an unescaped plus sign (for example, "telephoneNumber=+1 800 555 1234,ou=People,dc=example,dc=com"). In a DN, plus signs are used to separate the name-value pairs in a multivalued RDN, and any plus sign contained in an RDN value must be escaped with a backslash (like "telephoneNumber=\\+1 800 555 1234,ou=People,dc=example,dc=com"). These kinds of malformed DNs are likely to cause problems with clients that encounter them, and the server now correctly rejects them.</p>
DS-17775	<p>Replication initialization has been enhanced to allow multiple initializations to run concurrently in some cases. When the initializations are for the same base DN each server may only participate in a single initialization. When the initializations are for different base DNs, there is no such limit.</p>
DS-17775	<p>Replication initialization has been enhanced to allow multiple initializations to run concurrently in some cases. When the initializations are for the same base DN each server may only participate in a single initialization. When the initializations are for different base DNs, there is no such limit.</p>
DS-17783	<p>Added the ability to configure connection or request criteria that can identify add requests for entries that should be named with the server-generated entryUUID value. Although the server provides a name with entryUUID request control that can be included in add requests to specifically indicate that the entry should use entryUUID as the naming attribute, it may also be desirable to use criteria to identify requests from clients that cannot use the control, but that may benefit from this functionality.</p>
DS-17783	<p>Added the ability to configure connection or request criteria that can identify add requests for entries that should be named with the server-generated entryUUID value. Although the server provides a name with entryUUID request control that can be included in add requests to specifically indicate that the entry should use entryUUID as the naming attribute, it may also be desirable to use criteria to identify requests from clients that cannot use the control, but that may benefit from this functionality.</p>

Ticket ID	Description
DS-17850	Updated the isMemberOf virtual attribute provider to add an optional included-group-filter configuration property. If provided, the virtual attribute will only include the DNs of groups in which the associated user is a member and that also match the given filter. For example, configuring an included-group-filter of "(objectClass=groupOfURLs)" would ensure that only dynamic groups are listed in the values of the virtual attribute.
DS-17850	Updated the isMemberOf virtual attribute provider to add an optional included-group-filter configuration property. If provided, the virtual attribute will only include the DNs of groups in which the associated user is a member and that also match the given filter. For example, configuring an included-group-filter of "(objectClass=groupOfURLs)" would ensure that only dynamic groups are listed in the values of the virtual attribute.
DS-17886	Replication no longer hangs when disabled for some, but not all, servers for a restricted domain.
DS-17886	Replication no longer hangs when disabled for some, but not all, servers for a restricted domain.
DS-17912	A check was added to make sure a search with a vlv sort doesn't exceed the search time limit.
DS-17912	A check was added to make sure a search with a vlv sort doesn't exceed the search time limit.
DS-17921	<p>Added a new salt-length-bytes configuration property to the Salted MD5, Salted SHA-1, Salted SHA-256, Salted SHA-384, and Salted SHA-512 password storage schemes. If configured, this property will specify the size of the salt generated for new encoded passwords. If it is not defined, the server will continue to use the default size of eight bytes (64 bits).</p> <p>This property only controls the size of the salt used when encoding new passwords. The server already had the ability to interpret encoded passwords with different salt lengths, so any existing passwords encoded with a different salt length will continue to work.</p>

Ticket ID	Description
DS-17921	<p>Added a new salt-length-bytes configuration property to the Salted MD5, Salted SHA-1, Salted SHA-256, Salted SHA-384, and Salted SHA-512 password storage schemes. If configured, this property will specify the size of the salt generated for new encoded passwords. If it is not defined, the server will continue to use the default size of eight bytes (64 bits).</p> <p>This property only controls the size of the salt used when encoding new passwords. The server already had the ability to interpret encoded passwords with different salt lengths, so any existing passwords encoded with a different salt length will continue to work.</p>
DS-17927	<p>The Pass Through Authentication Plugin will now record Last Login Time and Last Login IP Address in the event of a successful remote bind, regardless of the value of try-local-bind.</p>
DS-17927	<p>The Pass Through Authentication Plugin will now record Last Login Time and Last Login IP Address in the event of a successful remote bind, regardless of the value of try-local-bind.</p>
DS-17928	<p>Fixed an issue that could cause different versions of the same schema elements to appear in the server's subschema subentry. If a schema element was defined in an earlier file but then overridden in a later schema file, or if an existing schema element was changed on the fly with the add schema file task (or the load-ldap-schema-file tool, which uses that task behind the scenes), then the schema entry would incorrectly show both the previous and updated versions of the schema element.</p>
DS-17928	<p>Fixed an issue that could cause different versions of the same schema elements to appear in the server's subschema subentry. If a schema element was defined in an earlier file but then overridden in a later schema file, or if an existing schema element was changed on the fly with the add schema file task (or the load-ldap-schema-file tool, which uses that task behind the scenes), then the schema entry would incorrectly show both the previous and updated versions of the schema element.</p>
DS-17953	<p>Fixed an issue that could cause the entry in a pre-read or post-read response control to include virtual attributes that don't have any values.</p>

Ticket ID	Description
DS-17968	Limited the ACI search on collect support data tool to only pull 100 entries. This will reduce the time the tool takes to run for organizations with a large number of ACIs.
DS-17999	Sync Attribute Mapping modifier names, such as "jsonEscape", are now case insensitive.
DS-18007	Updated the 'changes' attribute in the changelog backend to use the correct previous value when use-reversible-form is set to true.
DS-18016	Added support for the X-Forwarded-Prefix header to override the context path of operations processed by Http Servlet Extensions.
DS-18018	<p>Added support for the password update behavior request control, which allows requesters with the password-reset privilege to override certain behaviors that the server would normally exhibit when setting a user's password. The control can be included in an add request, modify request, or password modify extended request and can be used to override the server's normal behavior for any or all of the following:</p> <ul style="list-style-type: none"> - Whether the password update is a self change or an administrative reset - Whether to accept or reject pre-encoded passwords - Whether to perform or skip password quality validation for the new password - Whether to check to see if the new password matches the current password or any password in the user's history - Whether to enforce or ignore the minimum password age constraint - Which password storage scheme to use when encoding the new password - Whether the user must be required to choose a new password before being permitted to request any other operations

Ticket ID	Description
DS-18030	<p>Updated the password policy state extended operation to make it possible to determine whether the target user has a static password. Also, updated the server's support for the get password policy state issues functionality so that it will include an account usability notice if the target user does not have a static password. Either of these can be used to determine whether the user may authenticate with a mechanism that requires a static password (for example, using an LDAP simple bind or a SASL PLAIN bind).</p>
DS-18035	<p>Addressed an issue where a server could incorrectly report missed replication changes at startup in rare circumstances. Server A could report missed changes at startup where</p> <ol style="list-style-type: none"> 1) Server B had not received changes directly from a client for a long time (beyond the purge delay), 2) Since the last successful change, Server B had processed an operation from a client that made it deep enough in the operation processing to generate a change sequence number (CSN) but that operation was later rejected by the server, 3) Server A is shutdown, and 4) While Server A is shutdown, the Server B processes one or more changes directly from the client.
DS-18061	<p>Updated the audit log publisher to include the replication change ID in applicable changes by default.</p>
DS-18070	<p>Fixed an issue that could prevent the server from properly closing a database transaction under a sustained load of heavily conflicting write operations on a system that is processing those operations at an abnormally slow rate (for example, if the database is not cached and the disk subsystem is completely saturated).</p>
DS-18082	<p>Fixed an incompatibility between password modify extended operations and the changelog encryption plugin.</p>
DS-18087	<p>The dsreplication initialize-all option now correctly uses the host name, port, and connection security of the replica servers that were provided during dsreplication enable, rather than the values provided during server setup.</p>

Ticket ID	Description
DS-18100	A license key is required when setting up a server for the first time. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com .
DS-18112	Modified the server to not examine recent changes within the backend when initially started by the updater to look for post-update errors. This can speed the update process by several minutes in some environments.
DS-18134	Updated license files for 3rd party libraries
DS-18144	Update the default global ACIs so that a user can modify their own password when the Changelog Password Encryption Plugin is enabled.
DS-18188	Removed the ability to create custom HTTP trace loggers using the Server SDK.
DS-18191	Updated the NotificationManager class within the Server SDK to provide access to the entry before and after the change rather than only the raw request object.
DS-18229	Fixed an issue where the Self-Service Account Manager (SSAM) sample would not install.
DS-35012	Added a safeguard to limit the size of the buffer used to create a notification of a transaction. The notification will be discarded if some of the changes could not be found and the limit is reached.
DS-35495	Updated dsconfig batch mode to operate more efficiently over the WAN by consolidating the number of LDAP searches required to retrieve the full configuration when pre-validating configuration changes.
DS-35496	Fixed an issue where a subtree delete operation could stall operation processing (SalesForce Case 00623381).
DS-35524	Addressed an issue that could cause a server to never clear its replication backlog after being initialized with "dsreplication initialize".

PingDirectory Server 6.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Server

- ⓘ **Note:** The product names have been updated to reflect the UnboundID acquisition by Ping Identity. This is a naming and branding change only; the code base is the same as in prior releases and will continue to be maintained into the future.
- If upgrading the server that was running an older version of the JDK, run the `dsjavaproperties --initialize` command after the software upgrade to compare the settings of the older JDK with requirements for the new server software. Apply any necessary changes to the upgraded server based on previous performance settings.
- The 6.0 release makes these changes to supported platforms:
 - CentOS 7.2 and RedHat 7.2 are now supported operating system versions.
 - SUSE 11 SP4 is now supported; SUSE 11 SP2 support has been retired.
 - Linux KVM and VMWare ESXi 6.x have been added as supported virtual machine environments.
 - Deprecation of JDKs 7.x. Customers are strongly advised to use JDK 8 with this release. A later release of the platform will remove support for JDK versions 7.x. At that time customers will be required to upgrade to JDK 8.x when upgrading servers. This will apply to all of our JDK flavors (OpenJDK, OracleJDK, IBM JDK) on all platforms.
 - WildFly 9.x (renamed from JBoss) is now a supported application server for all web applications, including the Administrative Console and sample applications. Support for JBoss 7.x has been retired. Tomcat support remains unchanged in this release.
- PBKDF2 is now the default encoding for root passwords. This only affects new installations.
- In addition to changing the default password storage scheme for root users to PBKDF2, the default password storage scheme for regular users has been changed to salted 256-bit SHA-2.
- HTTPS defaults to ON: servers now default to use HTTPS for console and API connections including the SCIM API. This may affect automation scripts and development environments where HTTPS has not been in use before.
- Generated user passwords, for example those created by the server during a password reset sequence, are now created as pass-phrases instead of random character strings. This makes them easier to type and remember. This change will not affect upgrades.
- The `/config` directory file permissions have been changed so that they are only accessible by the server user.
- Customers who choose to use the optional encryption algorithms provided by the third-party BouncyCastle library are encouraged to upgrade to BouncyCastle 1.54.
- The Self Service Account Manager (SSAM) application is now included in the distribution image and may be optionally installed as desired.
- Updated commons-beanutils from version 1.8.3 to 1.9.2 to improve security.
- Updated Spring Boot artifact to v1.2.8 so transitive Spring library dependencies use v4.1.9.
- Updated the HTTP/HTTPS connection handler to Jetty 9.2.15.v20160210.
- The encryption-settings tool in a previous version of the PingDirectory Server will not be able to import settings generated by this version of the PingDirectory Server, if there are multiple settings exported at once.

What's New

These are new features for this release of the Directory Server

- Added a new control for very large result sets `'maximum-sort-size-limit-without-ylv-index,'` which allows client applications to request that the server gracefully degrades to unsorted results in cases where sorting a very large result set would have caused a time-out.
- Added LDAP support for applications that authenticate users with Yubikey one-time passwords. The extensions include the UNBOUNDID-YUBIKEY-OTP SASL handler configuration object, extended operations and command line tools for registering a user's Yubikey device, deregistering, and supporting authentication using either the one-time password (OTP) only, or the OTP together with a static password. The server can be configured to use the public Yubico validation service, or a different validation service. The Yubikey FIDO U2F, OATH HOTP, and PGP modes are not supported.

- Added new "generate TOTP shared secret" and "revoke TOTP shared secret" extended operations to make it easier for applications to enable TOTP authentication for users. While these operations are primarily intended to be invoked programmatically, a generate-totp-shared-secret tool can be used to invoke these operations from the command line.
- A new transform-ldif tool is available to read an LDIF file and write an updated file with a number of changes applied. The transformations include:
 - Scramble, replace, redact, or exclude a specified set of attributes.
 - Replace values of a specified attribute with a generated value that includes a sequential counter.
 - Replace values of a specified attribute with a generated value that includes a sequential counter.
 - Add a given set of attribute values to entries matching a provided set of criteria.
 - Exclude entries matching a provided set of criteria.
 - Rename attributes.
 - Replace the base DN for entries in a specified subtree.
- A new load-ldap-schema-file tool is available for loading LDAP schemas while a server is active and on-line.
- A new register-yubikey-otp-device tool is available for creating or changing associations between users and specific OTP devices.
- The *rate performance testing tools now includes some additional sample rate pattern files: hockey stick, step-function, sine, triangle, sawtooth and square wave patterns.
- The setup command now logs its input arguments, making it easier to confirm or duplicate a setup process. This changes the content of the log and may affect automated scripts that read these log files.
- The config-diff tool, which makes it easy to compare and reconcile settings between server instances, now also supports the --pretty-print option which adds line breaks to the generated lists of dsconfig commands.
- The manage-account tool has been enhanced significantly to make it easier to perform operations that affect large sets of user accounts including bulk lock-outs, parallel processing of updates, support for input filter criteria and DN lists. In particular, the manage-account tool now supports explicitly setting user accounts to the "locked-out" state. This is an improvement over earlier versions which required manipulation of operational attributes. See the command help for a complete list of the options and new sub-commands.
- For easier consumption by third-party analysis tools, the Directory and Proxy Servers can now output JSON log formats. Similar support will be added to the Data Sync and Governance Brokers in a later release.
- To help avoid issues when indexes near their index-entry-limit, the verify-indexes command now has the following two options:--listKeysNearestIndexEntryLimit, and --listKeysExceedingIndexEntryLimit. The Admin Guide includes a new section, "Monitoring Index Entry Limits", which explains how to set, track, and tune the server's Index Entry Limit values.
- Monitor entries have been added for a number of related metrics, all of which can be set to trigger alarms:
 - index-unique-keys-near-entry-limit-accessed-by-search-since-db-open
 - ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open
 - ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open
 - ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open
 - ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open
- The Pass-Through Authentication plugin has a new "allowLaxPassThroughAuthenticationPasswords" option that permits password changes that do not comply with the Directory Server's password policy. This facilitates integration in cases where the pass-through system has less-strict rules for new passwords.
- For Java developers whose tools and workflows make use of Maven, the Server SDK jar has been deployed to Maven Central so that a developer can now add the Server SDK as a project dependency by adding a few lines to a project's pom.xml. Also, developers can now generate a Server SDK project

that Maven-aware IDEs such as IntelliJ IDEA can package into an extension bundle with no special configuration needed. This benefit extends similarly to continuous integration systems such as Jenkins.

- The dsconfig tool provides the ability to search for and quickly navigate to configuration objects and properties in which the name, synopsis, or description matches a provided pattern.
- A new rotate-log tool and task have been added, which can be used to trigger rotation of one or more log files.
- The Configuration API is now fully supported for all servers. In this release, the API was changed to match SCIM conventions for attribute naming, resource modeling, and the standard HTTP verbs. The UnboundID SCIM 2 SDK (available through GitHub) can now be used with the Configuration API.
- All servers have an updated web Administrative Console, which includes:
 - New layouts for operational statistics, processing time, queues, all monitors, and the list of installed extensions.
 - New layouts for operational statistics, processing time, queues, all monitors, and the list of installed extensions.
 - Alert and alarm displays, summarizing the data in cn=alerts and cn=alarms and based on the configured gauges. Plus, filtering and searching for these.
 - A new LDAP Schema Editor for importing schema files, validity checking, creation and editing of object classes and attribute types. The editor also supports viewing of the attribute syntaxes, inheritance, and indexes that exist for each attribute and the dependencies between object classes and attributes.
- The new Administrative Console can also be deployed to independent application servers instead of being co-hosted by the servers. This simplifies deployment models and increases separation between data and application layers.
- To assist with situations where a very large number of changes may cause disk, memory, and server start time to increase unexpectedly, alerting and gauge features have been added to the Recent Changes Database.
- Servers can now trigger events whenever log file rotation occurs. This includes "copy on rotate" and "summarize on rotate" listeners, as well as Server SDK support for creating custom log file rotation listeners.
- It is now possible to create, change, and remove root user accounts across the topology using the dsconfig tool and Administrative Console.
- Made a number of improvements to way the server handles the encryption settings database:
 - When running setup, the server no longer overwrites the encryption settings PIN file if it already exists.
 - When configured to use a file-based cipher stream provider (which is now the default), anything needing access to the encryption settings database would fail immediately if the password file was missing. The server now waits for the password file to become available, for example if kept on removable storage. This behavior can be controlled through the wait-for-password-file configuration property.
 - When configured to use a file-based cipher stream provider (which is now the default), anything needing access to the encryption settings database would fail immediately if the password file was missing. The server now waits for the password file to become available, for example if kept on removable storage. This behavior can be controlled through the wait-for-password-file configuration property.
 - When backing up the contents of the encryption settings database, when a file-based cipher stream provider is configured, the output now includes a warning that indicates the PIN file is not included in the backup and should be archived separately.
 - When restoring a backup of the encryption settings database, the restore will fail if the encryption settings database contained in the backup was protected with a different cipher stream provider, or

if the cipher stream provider is configured with a different encryption key. The restore process will warn if it cannot verify compatibility.

- The server now provides a better error message when it fails to open the encryption settings database, especially when the encryption settings database was created before running setup, which results in a less secure configuration.
- Updated the search-logs tool to support JSON formatted logs.
- The dsreplication initialize command now ignores the adminUID and adminPassword property values in the tools.properties file, as these values may not necessarily be correct for the new server being added to the replication topology. The command now always prompts for the administrative credentials.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Server

- When deploying the Administrative Console in Tomcat 8, and accessing the Administrative Console application using Tomcat's Web Application Manager, some browsers (including Safari and Firefox) will generate a path URL that encodes the dash in ubid-console. This results in a path such as `http://localhost:8888/ubid%2Dconsole/`, which causes session management errors. To workaround this issue, copy and paste the generated link into a browser, and replace the encoded dash with a dash (-) character.
- The PermSize and MaxPermSize JVM properties are no longer supported in JDK 8, and will safely be ignored. These properties can be removed by modifying the `config/java.properties` file and running "bin/dsjavaproperties" while the server is offline.
- Security criteria for root passwords with the default configuration will be increased in a future release. This might affect automated installation scripts that currently use less secure passwords. This will not affect existing root accounts.
- The `dsconfig` tool and the Administrative Console enables creating and managing new Root DN users in this release. However, there is a limitation with changing the password of the currently logged in administrator. The `ldappasswordmodify` command can be used to change the administrator's password by providing the current and new password.
- For version 5.2.0.1 to pre-6.0.0.0 servers configured to use the IBM version of Java, an extraneous `$(INSTANCE_ROOT)` directory is created under the server root. This is fixed on a fresh install of 6.0.0.0, but if updating to 6.0.0.0, this directory still exists and can be deleted before or after the update.

Resolved Issues

The following issues have been resolved with this release of the Directory Server:

Ticket ID	Description
DS-247	<p>Improved visibility of the use of index keys near or in excess of the index entry limit. These changes include:</p> <ul style="list-style-type: none"> ▪ If the server accessed any index keys near the index entry limit while processing an add, delete, modify, modify DN, or search operation, the access log message for that operation will include an <code>indexesWithKeysAccessedNearEntryLimit</code> field that holds the names of the appropriate indexes. If the operation accessed any index keys that exceeded the index entry limit, those indexes will be named in the <code>indexesWithKeysAccessedExceedingEntryLimit</code> field in the access log message. ▪ If the server accessed any index keys near or in excess of the index entry limit while processing a search operation that requested the <code>debugsearchindex</code> attribute or that requested matching entry count debug information, the resulting debug messages will include information about those indexes. <p>The index monitor entry includes new attributes that track the number of such keys accessed by search or write operations:</p> <ul style="list-style-type: none"> ▪ <code>ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open</code> ▪ <code>ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open</code> ▪ <code>ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open</code> ▪ <code>ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open</code>
DS-247	<p>Updated the <code>verify-index</code> tool to add a <code>"--listIndexKeysNearestIndexEntryLimit"</code> argument to obtain information about the keys whose ID lists are closest to (but have not yet exceeded) the index entry limit, including the number of matching entries and how close they are to reaching the limit.</p>
DS-979	<p>Added the ability to search for configuration objects and their properties by name with the <code>dsconfig</code> tool.</p>

Ticket ID	Description
DS-4235	Added support for log file rotation listeners, which allow for custom processing whenever a log file is rotated out of service so that the server will no longer write to it. A copy listener (which will copy the rotated log file to an alternate location, optionally compressing it in the process), and a summarize listener (which will invoke the summarize-access-log tool on the rotated log file) are included. The Server SDK also includes an API for creating custom log file rotation listeners.
DS-7017	Added support for authenticating with one-time passwords generated by YubiKey devices. The server may be configured to require static passwords in conjunction with YubiKey one-time passwords as a form of two-factor authentication, or it may be configured so that a one-time password alone is sufficient for authentication.
DS-7505,DS-13571,DS-13860	<p>Updated the default file permissions for new installations on UNIX-based systems. Files and directories included in the zip file will be only be accessible to their owner (the user that unzipped the file) by default.</p> <p>Newly-created files and directories will also be assigned permissions that allow them to be accessed only by the account used to run the server. Existing configuration options for setting file permissions (the log-file-permissions and db-directory-permissions properties) will continue to behave as before. The new config/server.umask file will control the default permissions for all other newly-created files and directories.</p>

Ticket ID	Description
DS-9407,DS-15183,DS-15220	<p>Updated the initial server configuration to improve security and usability. These changes apply only to new installations and will not be applied when updating an existing installation. Changes include:</p> <ul style="list-style-type: none"> ▪ Updated the default password policy to use a default password storage scheme that uses a salted 256-bit SHA-2 digest rather than a salted SHA-1 digest. ▪ Updated the root password policy to use a default password storage scheme of PBKDF2 rather than salted 512-bit SHA-2. ▪ Updated the secure password policy to use a default password storage scheme of PBKDF2 rather than a CRYPT variant that uses multiple rounds of 256-bit SHA-2. ▪ Updated the password policy import plugin so that it will attempt to use the default password policy to select the password storage scheme(s) to use for entries that do not explicitly specify a password policy. The plugin will also fall back to using a salted 256-bit SHA-2 scheme instead of a salted SHA-1 scheme. ▪ A number of weaker password storage schemes have been disabled by default, including base64, clear, unsalted MD5, salted MD5, 3DES, RC4, and unsalted SHA-1. ▪ The default password policy has been updated to use a password generator that generates very strong yet memorable passphrases rather than a shorter and less-memorable string of randomly-selected characters. ▪ Many of the server loggers have been updated to include additional log elements by default, including the instance name, requester DN, requester IP address, and request controls. ▪ The exact match identity mapper has been updated to look at the mail attribute in addition to the uid attribute. When targeting a user with an authentication ID value (as when using SASL authentication or the proxied authorization v2 request control), it is now possible to specify an email address as an alternative to a user ID. ▪ The UNBOUNDID-TOTP SASL mechanism handler has been updated to prevent TOTP password reuse by default. ▪ Added new request criteria that make it possible to identify requests that target the root DSE or the subschema subentry. The global configuration has been updated so that requests targeting these entries will be in the default exceptions lists if the server is configured to reject insecure or unauthenticated requests. ▪ Updated the template that setup generates for creating sample data to use a more logical and user-friendly numeric range. When the user requests N entries, setup would previously number the entries 0 through N-1 (for example, if the user requested 1000 entries, they would

Ticket ID	Description
DS-10312	Added the server's process ID to the output of the status tool.
DS-10464	Added a new rotate-log tool to request the rotation of one or more log files.
DS-10466,DS-10765,DS-14479,DS-15318,DS-16154	Addressed a few issues in config-diff. In some situations, config-diff would not generate commands in an order that respected all dependencies. This has been fixed. Most expected warnings are now excluded by default but can be included in the output with the --includeAllWarnings option. The --sourceBindPasswordFile and --targetBindPassword are now applied in conjunction with the --targetConfigGroup and --sourceConfigGroup options.
DS-10946	Added a --dry-run option to dsconfig, which can be used in batch mode to validate the configuration changes in a batch file without applying them.
DS-11927	Updated the Local DB Backend to detect the database being only partially initialized via a "dsreplication initialize" command. If the backend is started with a partially initialized environment, then the incomplete database files will be deleted, and an alarm will be raised to signal to the administrator that the backend must be reinitialized.
DS-12191	Added support for setting the request header size in the Jetty http configuration server properties.
DS-12309	Updated the offline mode of the rebuild-index tool to improve performance and reduce disk utilization.
DS-12310	Updated the verify-index tool to improve performance and reduce disk utilization.
DS-13401	Improved the collect-support-data tool to include information provided by systemd on platforms that support it.
DS-13417	Updated replication host name checking with support for certificate alternative subject names and dnsname extensions checking.
DS-13478	Improved the dsconfig tool to validate that there is only one enabled entry cache per entry cache level.

Ticket ID	Description
DS-13700	<p>Updated command-line tools based on the LDAP SDK tool APIs to add the following features:</p> <ul style="list-style-type: none"> ▪ Tools can obtain default values for any arguments not provided on the command line from a properties file. If it exists, the server's config/tools.properties file will be used by default. Command-line arguments can be used to specify an alternate properties file or to indicate that no properties file should be used. ▪ Tools can be launched in an interactive mode, in which the user is prompted for arguments used to establish and authenticate the connection, and for any other required arguments. The user can then use an interactive menu to specify values for any remaining arguments.
DS-13823	<p>Collect-support-data tool now captures Kerberos config and log information.</p>
DS-13870,DS-13940	<p>The configuration framework now trims leading and trailing spaces from distinguished names.</p>
DS-13976	<p>Added a warning during startup for any invalid group entries that are encountered and cannot be used.</p>
DS-14213	<p>Added the ability to create local constants in LDIF template files using the new 'local' keyword.</p>
DS-14424	<p>Added a passphrase password generator that concatenates randomly-selected words from a dictionary file to construct a password that can be both secure and easy to remember.</p>
DS-14430	<p>Updated the Apache commons collections library to address the security vulnerability described by CVE 2015-4852.</p>
DS-14548	<p>Added a monitor entry for each Server SDK extension.</p>
DS-14658	<p>Improved the log message for memory pools with an undefined maximum size when priming a server.</p>
DS-14690	<p>The replication target of the Directory Server now correctly handles the connection being lost during initialization.</p>
DS-14694	<p>Added a --prettyPrint option to the config-diff tool to make the output more human-readable.</p>

Ticket ID	Description
DS-14704	Updated the restore command so that it can no longer be used to restore a backup of the config backend. The command now points the administrator for safer ways to revert configuration changes, including using config-diff.
DS-14749	Updated the server's support for the Twilio Messaging Service so that it uses the newer "Messages" API when sending SMS messages instead of the older "SMS" API. The older API has been deprecated, and Twilio now imposes a 120-character limit for messages sent via that API. The messages API allows the server to take advantage of the full 160 characters per SMS message.
DS-14796	Added a new global configuration property, unrecoverable-database-error-mode, which enables configuration of an action to take when an unrecoverable database error occurs.
DS-14820	Improved the logic the server uses when leveraging indexes to identify the set of candidate entries that are expected to match the search criteria. Also, dramatically improved the information about index usage that the server provides when issuing a search that requests the special debugsearchindex attribute, or that includes the matching entry count request control.
DS-14855	Added a maximum-sort-size-limit-without-vlv-index property to the client connection policy configuration. If this property is given a nonzero value, the server will not attempt to sort a result set if the number of candidate entries is greater than this number, unless it can do so using a VLV index. If the server refuses to sort a result set because of this setting, then it will either reject the search (if the server-side sort control is marked critical), or it will return the results unsorted (if the server-side sort control is not critical).
DS-14857	Fixed an issue with the dsjavaproperties tool where java properties for PermSize and MaxPermSize could be added when using JDK 8, which no longer supports these options.
DS-14863	Updated the FIFO Entry Cache's max-memory-percent property to specify the maximum percentage of JVM memory the cache can use. Previously the property specified the maximum percentage of memory that must be consumed in the JVM by the application overall before the cache begins to shrink.

Ticket ID	Description
DS-14878	Improved memory utilization when processing entries with very large attributes, to prevent possible data retention in memory.
DS-14919	Added support for JSON-formatted access and error log messages.
DS-14923	Updated the bcrypt, crypt, PBKDF2 and scrypt password storage schemes so they can be used to create new instances.
DS-14979	Fixed a case where attribute syntax configuration changes would not apply to undefined attributes, which rely on default attribute types.
DS-14986	Fixed a formatting issue in ldap-diff which could result in multiple progress messages being printed on the same line.
DS-14996	Updated the server to use the latest 6.4.25 release of Berkeley DB Java Edition.
DS-15007,DS-15083	Updated the pass-through authentication plugin to allow replacing passwords for migration from legacy directory products.
DS-15009	Fixed an issue with the summarize-access-log tool where it would appear to hang due to slow processing of large complex filters.
DS-15015	Server SDK extensions are now built with a Java source version of 1.7 by default.
DS-15079	Improved the message used to indicate when the replication server startup minimum replication backlog processing completes. The message now states that the calculation was done when the server was started, and any missing local replicas that were unavailable for the calculation are listed.
DS-15082	Updated the default set of global ACLs to permit requests that include the simple paged results control.

Ticket ID	Description
DS-15088	<p>The former suite of Administrative Console applications, each of which were tied to a particular product (for example the dsconsole.war for the Directory Server) are no longer available, and have been superceded by a new version of the Administrative Console capable of managing any server product. You can choose to access the Administrative Console by hosting it within a server, or by deploying it in an external servlet container. For the former, enable an HTTP Connection Handler and add the Administrative Console Web Application Extension to the handler. For the latter, download and unzip the management-console-[version].zip file, and install the ubid-console.war file according to your container's instructions.</p>
DS-15094	<p>Fixed an issue where opening the backend database might fail with an IllegalStateException that references "exploded-index-background-deletes" when there are several backend exploded indexes.</p>
DS-15096	<p>Updated the pass-through authentication plugin to suppress the "force change on reset" behavior if the user's local password is replaced with a password that was accepted by a backend server.</p>
DS-15108	<p>Replaced the scramble-ldif tool with a more powerful transform-ldif tool with support for a number of additional transformation types. The new transform-ldif tool is backward compatible with the former scramble-ldif tool, and the scramble-ldif shell script and batch file are still included with the server to ensure compatibility with scripts that depend on that tool.</p>
DS-15132	<p>Improved the locking strategy for multi-update requests to better accommodate delete and add requests for the same entry. This also enables graceful failures for bad requests, instead of lock timeouts.</p>
DS-15159	<p>Updated the manage-account tool to display labels for recently added password policy extended operation types.</p>
DS-15175	<p>The Configuration API now returns unquoted, native Javascript values for integer, real number, and boolean properties. Duration and size property values, for example '1 w' or '100 G', continue to be represented as Javascript string types.</p>

Ticket ID	Description
DS-15178	Improved the error messages and examples for create-rc-script and create-systemd-script by explicitly suggesting the use of sudo so that the scripts can modify protected files.
DS-15221	Changed interactive setup default value for HTTPS enablement.
DS-15222	Changed interactive setup default value for entry cache priming.
DS-15227	Added new options to the matching entry count request control to allow the client to better control the balance between how quickly the server obtains the matching entry count estimate and how accurate that estimate is.
DS-15284	Updated the server to reject baseObject searches that request the debugsearchindex attribute.
DS-15286	Updated mirror virtual attribute provider implementation to read values from additional entries when the source entry dn attribute has more than one value.
DS-15337	Improved the error messages for create-rc-script and create-systemd-script when the directory in which the script will be created does not exist.
DS-15349	Added support for a "generate TOTP shared secret" extended operation that allows a client to request that the server generate a shared secret for a specified user that will be stored in the user's entry and returned to the client. That shared secret can be used to generate time-based one-time passwords for use in the course of authenticating to the server through the UNBOUNDID-TOTP SASL mechanism. A "revoke TOTP shared secret" extended operation was also added to allow a shared secret to be eliminated if it is no longer needed or may have been compromised. The password policy state extended operation and the manage-account command-line tool have also been updated to provide support for manipulating the set of TOTP shared secrets for a user.
DS-15361,DS-15363,DS-15434	Updated interactive setup to display default values, and improved the overall layout and appearance.
DS-15366	Fixed a bug that could cause the same filter index to be evaluated multiple times when processing a search operation.

Ticket ID	Description
DS-15400	Addressed an issue where dsconfig incorrectly allowed certain configuration objects to be deleted.
DS-15412	Improved the error messages produced by the manage-extensions tool when attempting to install invalid extensions.
DS-15415	Increased the default cache size set by the installer for JVM heaps smaller than 8GB.
DS-15417	Updated the global ACIs that ship with the server to use a separate ACI for each control or extended request to allow by default, rather than grouping all desired controls together in one ACI and all desired extended requests together in a second ACI. This change will only be reflected in new installations, and not when updating an existing deployment.
DS-15422	Root DN User configuration entries can now be fully managed through the configuration management interfaces such as dsconfig and the Administrative Console.
DS-15437	Provided a graphical tool, watch-entry, that is intended to demonstrate replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, then the background of modified attributes will temporarily be red. Attributes can also be directly modified as well.
DS-15466	Added more logging information when initializing web application and servlet extensions in case an extension causes conflicts or delays.
DS-15470	The backend is no longer locked with an exclusive lock when renaming an entry due to an add conflict during replication.
DS-15471	Updated the changelog backend to report progress and summary information when exporting to LDIF or importing from LDIF. Also fixed a problem that could cause valid entries from being imported because of a mistaken schema violation.
DS-15477	Added the ssl-cert-nickname property to the HTTP Connection Handler. If multiple public-private key pairs are in a JKS keystore, the LDAP Connection Handler enables choosing a specific certificate alias with the ssl-cert-nickname property. The HTTP Connection Handler for HTTPS connections now has the same option for parity.

Ticket ID	Description
DS-15516	Fixed a defect where removing an objectClass value could result in an entry that violates the schema, we will now ensure that the entire entry is valid whenever adding or removing objectClasses.
DS-15521	Updated setup to encode the root password with the PBKDF2 password storage scheme instead of SHA512.
DS-15522	Updater tool will increase PermSize and MaxPermSize parameters to recommended value to prevent Java JVM pauses.
DS-15559	Added support for an UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL mechanism that indicates that an application attempted to verify the identity of a user whose account is stored in the server but that used a form of authentication that is external to the server (for example, via social login). The server will not alter the authentication state of the underlying connection, but may veto a successful external authentication if the user's account is not in a usable state (for example, the account is locked or disabled, or the password is expired), or it may update password policy state for the user to reflect the authentication attempt (for example, updating the last login time and IP address for a successful authentication, or recording the failed attempt and potentially locking the account for an unsuccessful authentication).
DS-15571	Increase the minimum memory requirements for the server process from 256MB to 384MB to accommodate the Administrative Console.
DS-15576	Added a load-ldap-schema-file tool that will allow the server to recognize a new schema file, or an updated version of an existing schema file, and make the definitions immediately available without needing to restart the server.
DS-15578	Changed the dsjavaproperties command so that its --initialize operation now carries over properties that are tool-independent from an existing java.properties file, such as the default java home and the tuning parameters.
DS-15578	Added the default JVM argument "-XX:UseCMSInitiatingOccupancyOnly" to decrease server pauses by forcing the JVM to respect the CMSInitiatingOccupancyFraction.

Ticket ID	Description
DS-15592	Fixed an error that could occur during upgrade when the configuration can not be loaded due to missing custom schema.
DS-15621	Updated the Groovy Scripting Language version to 2.4.6.
DS-15622	Fixed an issue that prevented the deletion of disabled debug loggers.
DS-15672	<p>Added the ability to define an ACI to grant regular users access to the debugsearchindex operational attribute. This attribute can be used to obtain detailed information about the server's use of indexes in the course of processing a search request, and it was previously accessible only to users with either the bypass-acl or bypass-read-acl privilege.</p> <p>To grant this access, you will need to permit access to both the debugsearchindex operational attribute, and to the cn=debugsearch portion of the DIT. For example, if you have a group with DN "cn=debugsearchindex Users,ou=Groups,dc=example,dc=com" and you want to grant the members of that group the ability to use the debugsearchindex feature, you can use the following command to add an appropriate global ACI to permit that access:</p> <pre>dsconfig set-access-control-handler-prop --add "global-aci:(targetattr=\\"debugsearchindex\\") (target=\\"ldap:///cn=debugsearch\\")(version 3.0; aci \\"Allow members of the 'debugsearchindex Users group to request the debugsearchindex operational attribute \\"; allow (read,search,compare) groupdn=\\"ldap:///cn=debugsearchindex Users,ou=Groups,dc=example,dc=com\\");)"</pre> <p>In addition, the server now allows the debugsearchindex attribute to be requested in a case-insensitive manner. Previously, the server would only recognize debugsearchindex in all lowercase. It can now be requested in mixed case, like debugSearchIndex.</p>
DS-15691	Updated the server SDK generated documentation to use the new logo and new icon.
DS-15724	Replaced the tabs in parallel-update log messages for failure with spaces and made the log message timestamps consistent with other logs.

Ticket ID	Description
DS-15753	The Data Services Markup Language (DSML) client and gateway components have been discontinued and are no longer available.
DS-15768	Improved server performance by reducing the cost of determining the transaction settings for interacting with the backend database.
DS-15773	Changed default number of HTTP request handlers from 2 times to 4 times the number of processors available to the Java virtual machine to improve performance. For example, the default has increased from 128 to 256 on a dual-socket, 8-core x64 CPU-based system with hyper-threading enabled.
DS-15789	Updated the server to allow users with expired passwords to authenticate with SASL mechanisms that do not involve passwords.
DS-15791	Updated the unique attribute plugin so that the filter property applies to conflict searches, and matches entries being added or modified.
DS-15792	Added r) option in dsconfig interactive mode which shows how to perform the pending operation through the configuration REST API. Added --rest option to config-diff which changes the output from dsconfig command line arguments to configuration REST API arguments.
DS-15794	Added memory tracking to the FIFO Entry Cache. The memory usage of the FIFO Entry Cache is about 10% less than reported, but is not likely to be higher than reported.

Ticket ID	Description
DS-15849,DS-15850,DS-15851,DS-15852,DS-15853	<p>Rewrote the manage-account tool to provide many new features:</p> <ul style="list-style-type: none"> ▪ Added the following new subcommands: <ul style="list-style-type: none"> ▪ get-account-is-usable ▪ get-account-usability-notice-messages ▪ get-account-usability-warning-messages ▪ get-account-usability-errors-messages ▪ get-account-is-not-yet-active ▪ get-account-is-expired ▪ get-password-is-expired ▪ get-password-expiration-time ▪ get-account-is-failure-locked ▪ set-account-is-failure-locked ▪ get-failure-lockout-time ▪ get-account-is-idle-locked ▪ get-idle-lockout-time ▪ get-account-is-password-reset-locked ▪ get-password-reset-lockout-time ▪ get-account-activation-time ▪ set-account-activation-time ▪ clear-account-activation-time ▪ get-seconds-until-account-activation ▪ get-last-login-ip-address ▪ set-last-login-ip-address ▪ clear-last-login-ip-address ▪ get-password-history-count ▪ Added new ways to target multiple users with a single command. It was already possible to provide a file with the DNs of the users to target. There are now additional options for providing one or more search filters or user IDs to identify which users to target. ▪ Added automatic retry support. If an operation fails in a manner that indicates the connection is no longer valid, the tool will retry the operation on a newly-created connection. It is also possible to provide multiple host name and port values to allow operations to be sent to multiple servers. ▪ Added the ability to use multiple threads to operate more quickly when targeting multiple users. ▪ Added the ability to limit the rate at which the tool operates. The target rate may be specified as a fixed number of operations per second, or it may vary over time. ▪ Changed the output format so that the result of each operation is provided in an LDIF representation. The output remains easy for a person to read, but it is now much easier to consume programmatically. ▪ Added the ability to send the output to a specified file instead of or in addition to standard output. Also added the ability to write a reject file that contains only information about those

Ticket ID	Description
DS-15920	Improved the warnings given when the maximum memory that all server components can consume is greater than the available memory in the JVM.
DS-15968	Updated the isMemberOf virtual attribute implementation so that it preserves the case of the RDN attribute and value in the group DNs.
DS-15993	Updated the changelog backend to better deal with the case in which it encounters information about an orphaned operation in its pending changes map.
DS-16104	Updated the password policy state extended operation and the manage-account tool to provide a way to obtain a list of the SASL mechanisms and OTP delivery mechanisms that are available to a user, to determine whether a user has a TOTP shared secret, and to retrieve and manipulate the set of public IDs for the YubiKey OTP devices registered for a user.
DS-16113	Fixed an issue where update verification fails to catch a problematic update that causes the server to not start.
DS-16137	Improved an error message about a possible database recovery operation that may be triggered after a database restore from an online backup or during replication binary initialization. In rare cases, the database recovery may cause a delay while opening the database.
DS-16149	If a replicated operation has failed multiple times as a result of database lock conflicts resulting from interactions with other operations, the server will now acquire an exclusive lock before making a final attempt at processing that operation to ensure that no other operations will be allowed to conflict with it.

Ticket ID	Description
DS-16150	<p>Updated the local DB backend to provide an option to use a single-writer lock to avoid database lock conflicts between operations by ensuring that only a single write operation may be in progress at any time.</p> <p>By default, write operations do not acquire the single-writer lock and are fully concurrent as long as none of those operations result in database lock conflicts. In the event that a lock conflict does arise between two or more operations (which should be a very rare occurrence in most environments), the server will retry each of those operations one or more times. With the changes included in this update, the server will now also acquire a single-writer lock to ensure that it only processes one of those conflicting operations at a time to reduce the likelihood of a further conflict.</p> <p>In environments with a very large number of database lock conflicts, it may be desirable to configure the server to acquire the single-writer lock even on the first attempt of each write operation. This can be accomplished by setting single-writer-lock-behavior property to always-acquire in the backend configuration. While this can limit the overall write performance that the server can achieve, the server should still be able to process thousands of write operations per second, which is more than enough for most deployments.</p> <p>The use of the single-writer lock does not have any effect on the concurrency of read operations. The server may still process any number of read operations simultaneously, even when the single-writer lock is used to ensure that only one write operation may be processed at any time.</p>
DS-16224	<p>Updated the sanitize-log tool to add support for JSON-formatted access and error log files.</p>
DS-16266	<p>Fixed an issue in which a password modify extended request that included the target user's current password could be seen as an administrative reset rather than a self change and might put the user's account in a "must change password" state if the user's password policy has force-change-on-reset set to true.</p>
DS-16267	<p>Fixed an issue that prevented the server from using the allowed-unauthenticated-request-criteria property to indicate which extended operations would be allowed on an unauthenticated connection when reject-unauthenticated-requests was set to true.</p>

Ticket ID	Description
DS-16282	Fixed an issue that could prevent password reset tokens from being used on locked accounts when the server was configured to permit such changes.
DS-16289	Updated the password modify extended operation to enable a user to provide an expired password, as long as the user has at least one available grace login.
DS-16337	Fixed an issue with JSON field indexing that could occur if the same field value appeared in multiple attribute values in the same entry, when at least one of those field values was removed or changed and at least one remained the same.
DS-16348	Fixed a null-pointer exception error that occurred when performing a bounded range search on an unindexed attribute.
DS-16444	CollectSupportData collects to gc-with-context all log messages for all stop-the-world GC events longer than one second, along with the two previous log messages.
DS-16489	Updated the pass-through authentication plugin to make it possible to search for the appropriate user entry in the external server using a filter constructed from attributes in the local server's copy of the user entry. This makes it possible to use pass-through authentication in cases where the user's entry has a different DN in the external server than in the local server, and where the DN for the external server cannot be constructed from the information contained in the local copy of the user entry.
DS-16589	Fixed an issue in which the server may fail to identify matching entries for an OR JSON object filter that targets an attribute for which at least one JSON field index is defined, but where at least one of the OR filter components is unindexed.

PingDirectory Server 5.2.0.0 Release Notes

What's New

These are new features for this release of the PingDirectory Server:

- Improvements to Datastore's Native JSON Attribute Support - The previous release of the Datastore included native support for compactly storing JSON objects in LDAP attributes, and for evaluating filters to match on fields inside those JSON objects. This release adds support for enforcing constraints on the fields that may be included in JSON objects, for indexing field values for improved search performance and flexibility, and for tokenizing commonly-used string values to further reduce the data footprint.
- New Password Validators - The Datastore now includes the Haystacks Password Validator, based on the Gibson Research Corporation Password Haystacks concept, and the Commonly-Used Passwords

Dictionary Validator, which ensures that a proposed password is not one of 10,000 commonly used passwords.

- Can Request an entryUUID rdn Value when Adding an Entry - When adding a new entry to the server, the client can now request that the server-generated entryUUID be used as the RDN attribute for the entry. This improves privacy by ensuring that the entry DN will not include any personally-identifying information, and it is a convenience for application developers by eliminating the potential need for modify DN operations.
- Implemented a Virtual Attribute Provider - Added an Identify References virtual attribute provider. These virtual attributes will have values that are the DNs of entries that contain a specified attribute with a value equal to the DN of the entry containing the virtual attribute. For example, this could be used to create a virtual 'directReports' attribute whose values are the DNs of the entries that list the target user as their manager.
- Self-Service Account Manager (SSAM) - SSAM is a web application that provides a user interface for performing common account registration, attribute update and password change tasks against the Datastore, with optional integration with PingFederate and PingAccess products.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectory Server:

- When deploying a .war file through the Web Application HTTP Servlet Extension, dependencies bundled in the file may conflict with the server's own dependencies if the server version differs from the version in the .war file. This may cause the Web Application HTTP Servlet Extension or the server itself to not start correctly. For reference, all server dependencies are available in `<server root>/lib`.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-1131,DS-14022	<p>Updated the server's password policy support to make a few account usability enhancements:</p> <ul style="list-style-type: none"> ▪ Added support for a get password policy state issues control that can be included in a bind request to obtain information about notices, warnings, and errors that may impact a user's ability to authenticate or interact with the server. The password policy state extended operation has also been updated to provide methods for retrieving this information. ▪ Added support for an account activation time as a complement to the existing account expiration time functionality. If an activation time is set in a user's account, the user will not be permitted to authenticate until that time has arrived. ▪ Updated the password policy state operation to provide methods for getting, setting, and clearing the user's last login IP address.
DS-1261	<p>The collect-support-data tool now has the option to collect logging information within a specified time range via the '--timeRange' argument.</p>

Ticket ID	Description
DS-1706	Updated interactive dsconfig to include an option to toggle between sorting similar properties together or sorting them alphabetically.
DS-3095	Added a new search-logs tool. Similar to the command line tool 'grep,' this tool searches across log files to extract lines matching the provided pattern(s). The search-logs tool can handle multi-line log messages, extract log messages within a given time range, and include rotated log files.
DS-3186	Added the 'listKeysExceedingIndexEntryLimit' argument to the verify-index tool, which enables listing the keys for indexes that have exceeded their index entry limits.
DS-8739	Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).
DS-9842	Added the ability to configure the Globally-Unique Attribute and Unique Attribute plugins with a filter to limit attribute uniqueness checking to a subset of matching entries.
DS-10010	Reduced the memory overhead of debug logging in high throughput environments by sharing logging buffers across multiple threads.

Ticket ID	Description
DS-10283	<p>Custom HTTP loggers are no longer permitted to modify the requests and responses being logged. Calling a forbidden method will result in a subclass of <code>UnsupportedOperationException</code>. For requests, the forbidden methods are <code>authenticate</code>, <code>getReader</code>, <code>login</code>, <code>logout</code> and <code>setCharacterEncoding</code>. For responses, the forbidden methods are <code>addCookie</code>, <code>addHeader</code>, <code>addIntHeader</code>, <code>flushBuffer</code>, <code>getOutputStream</code>, <code>getWriter</code>, <code>reset</code>, <code>sendError</code>, <code>sendRedirect</code>, <code>setBufferSize</code>, <code>setCharacterEncoding</code>, <code>setContentLength</code>, <code>setContentType</code>, <code>setHeader</code>, <code>setIntHeader</code>, <code>setLocale</code> and <code>setStatus</code>.</p>
DS-10775	<p>Added a new <code>Commonly-Used Passwords</code> instance of the dictionary password validator that uses a dictionary file with 10,000 of the most common user passwords as determined by analysis of data from a number of security breaches. Because these passwords are so popular among end users, they are also very commonly guessed by attackers trying to compromise end user accounts.</p> <p>The <code>Commonly-Used Passwords</code> validator is defined in the out-of-the-box configuration, but is only invoked by the <code>Secure Password Policy</code> by default.</p>
DS-10843	<p>Added support for a "name with entryUUID" request control. If this control is included in an add request, the entry will be added with a distinguished name whose RDN contains only the entryUUID attribute. This offers a number of potential benefits:</p> <ul style="list-style-type: none"> ▪ It can help preserve data privacy by ensuring the entry DN does not include sensitive or personally-identifying information. ▪ It can reduce the need for modify DN operations, since entries are not named with user attributes that have the potential to change. ▪ It can serve as a convenience for entries in which there is no obvious, guaranteed-unique attribute (or combination of attributes) to use for naming those entries.
DS-11067	<p>Added properties to the task backend for limiting the number of log messages retained in task entries, in order to limit the size of the in-memory representation of those entries. All log messages generated by a task will still be recorded in the server error log, even if they are not all retained in the corresponding entry in the task backend.</p>

Ticket ID	Description
DS-11522	<p>Updated the server's JVM arguments to always log garbage collection information to a rotating set of log files stored within logs/jvm/gc.log.N. The file system usage is limited to 300MB. If the server had previously been configured with VERBOSE_GC, then garbage collection logging information will no longer be logged to logs/server.out.</p>
DS-11823,DS-13535,DS-13894	<p>Deprecated the invalid-attribute-syntax-behavior global configuration property in favor of a new permit-syntax-violations-for-attribute global configuration property. The new option makes it possible to allow malformed values for an explicitly-specified set of attribute types, whereas the former option could only be used to enable or disable syntax enforcement for all attribute types.</p> <p>When migrating from a directory service that did not properly enforce attribute syntax compliance, it is strongly recommended that the data be cleaned to correct any malformed values that it may contain. However, in cases where that may not be immediately feasible, it is strongly recommended that syntax validation be relaxed only for attribute types that are known to have problems so that it will still be performed for other attribute types to prevent inadvertently introducing additional malformed values.</p> <p>In the event that an LDIF file contains malformed values, the import-ldif tool will now provide a list of the attribute types with attribute syntax violations and the number of malformed values identified for each attribute type. As before, the specific violations can be identified by instructing the import-ldif tool to generate a rejects file, which will include a comment with each rejected entry to describe the reason the entry was rejected.</p> <p>In addition, the server will now always perform syntax validation for the aci attribute type, regardless of the values of the invalid-attribute-syntax-behavior and permit-syntax-violations-for-attribute properties. This will provide additional assurance that malformed access control instructions cannot be introduced into the server during LDIF import processing. The server will still discover and validate all ACIs on startup, and will still place itself in lockdown mode on finding a malformed ACI rather than attempting to run with an incomplete access control configuration.</p>

Ticket ID	Description
DS-12106	<p>Added support for a new "Haystack" password validator based on the concept of password haystacks as described at https://www.grc.com/haystack.htm. It estimates the strength of a password using a combination of its length and the types of characters that it contains (e.g., a longer password containing only lowercase letters may be stronger than a shorter password containing a mix of uppercase and lowercase letters, numbers, and symbols).</p> <p>The Haystack password validator is defined in the out-of-the-box configuration but is only enabled by default in the secure password policy.</p>
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>
DS-12123	<p>Updated the Configuration API output where properties and their values are listed to include those that are undefined.</p>

Ticket ID	Description
DS-12138	<p>Added support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. Two matching rules have also been added for use in conjunction with the JSON object syntax: <code>jsonObjectExactMatch</code> and <code>jsonObjectFilterExtensibleMatch</code>.</p> <p>The <code>jsonObjectExactMatch</code> equality matching rule is used in evaluating equality filters in search operations, as well as for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. String values will be compared in a case-insensitive manner. The order of elements in arrays will be considered significant.</p> <p>The <code>jsonObjectFilterExtensibleMatch</code> matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation (available in the Commercial Edition of the UnboundID LDAP SDK for Java) for the <code>com.unboundid.ldap.sdk.unboundidds.json.JSONObjectFilter</code> class and its subclasses. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.</p> <p>Indexing is supported only for the <code>jsonObjectExactMatch</code> matching rule. If possible, non-baseObject searches that use the <code>jsonObjectFilterExtensibleMatch</code> matching rule should be wrapped in an LDAP AND filter that also contains one or more indexed components so that the search can be processed more efficiently.</p>

Ticket ID	Description
DS-12139,DS-12917,DS-13476,DS-13538	<p>Enhanced the server's support for storing and interacting with JSON objects.</p> <p>It is now possible to configure indexes for specified fields inside JSON objects to accelerate JSON object filter extensible match search operations. Indexes can be used for fields with boolean, integer, null, and string values and JSON object filters of type equals, equalsAny, greaterThan, lessThan, and substring, as well as AND filters that contain at least one indexed component and OR filters that contain only indexed components. Note that greaterThan and lessThan filters that target string values can only be indexed if they use case-insensitive matching.</p> <p>It is now possible to indicate that the values of specified fields (ideally fields with a relatively small set of distinct values) should be tokenized when they are stored in the database. Tokenized values can be stored more efficiently, and consume less space in memory and on disk.</p> <p>It is now possible to define a number of constraints for the fields that may be included in JSON objects stored in values of a specified attribute type. Constraints that may be imposed on a JSON field include: - Require values of the field to have a specified data type. - Indicate whether the field is required or optional. - Indicate whether the field is permitted to have multiple values in an array. If a field is permitted to have array values, then it is also possible to place restrictions on the number of elements that may be present in the array. - Indicate whether the field is permitted to have a value that is the null primitive as an alternative to values of the indicated data type. - Restrict values of string fields to a predefined set of allowed values, to values matching a given regular expression, or to values of a specified length. - Restrict values of numeric fields with upper and lower bounds.</p>
DS-12178	<p>A new index is now considered trusted if the server can determine that the associated attribute type (or JSON field for a JSON index) is not used in the data already contained in the target backend. If an index is automatically trusted, it is not necessary to use the rebuild-index tool to initialize that index.</p>
DS-12182	<p>The setup tool has been updated to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.</p>

Ticket ID	Description
DS-12218	Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.
DS-12245	The Configuration API has been updated to support filtering, sorting, and paging for object list operations. See the Administration guide for usage.
DS-12263	Updated the local DB backend so that changes to the db-checkpointer-wakeup-interval property no longer require a restart to take effect, and to expose new monitor attributes with useful information about the processing performed by the database cleaner.
DS-12285	Fixed an issue where changes to SMTP External Server configurations did not take effect until after a server restart.
DS-12287	Addressed cases where some messages may be suppressed in logs and alerts.
DS-12312	Updated the report generated by import-ldif to include database cache requirements for each possible cache-mode per backend database (e.g., attribute index). This aids tuning environments that cannot be fully cached.
DS-12313	Changed the default password policy behavior to prevent users from changing their passwords to their current password value. This logic will apply regardless of password history settings.
DS-12318	Added a configuration option to enable a wait period before removing a 'server unavailable' alert after a garbage collection task is performed. This allows sub-systems like replication to restart before the server becomes available again. For the Periodic GC Plugin, this option is 'delay-post-gc.' For a Forced GC Task entry, the attribute is named 'ds-task-delay-post-gc.' Both options take a value in milliseconds, and have a default value equivalent to 20 seconds.
DS-12319	Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.

Ticket ID	Description
DS-12443	Fixed an issue that generated the following error message, but did not impact the current operation: "An unexpected error occurred while notifying a change notification listener of a modify operation: RuntimeException: The specified condition must be true. The error occurred at com.unboundid.directory.server.types.AuthenticationInfo.replaceL
DS-12483	Added support for running on Oracle Java 8 and OpenJDK 8 platforms.
DS-12496	Added logging of all HTTP requests disallowed due to CORS. This should make it easier to debug HTTP 403/Forbidden errors.
DS-12560,DS-12561	Updated the server to avoid the use of the server-side sort and virtual list view request controls in search requests that span multiple subtree views or multiple entry-balanced backend sets. If the server cannot honor a non-critical server-side sort or virtual list view control, then it will process the search operation as if the control had not been included in the request. If the server cannot honor a critical server-side sort or virtual list view control, then it will return an error result to the client.
DS-12576	Update the Detailed HTTP Operation Log Publisher to log the correct return code (404 NOT FOUND) when a request is not handled by defined endpoints.
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12594,DS-12596	<p>Added support for three new extended operations for interacting with single-use tokens:</p> <ul style="list-style-type: none"> ▪ The "get supported OTP delivery mechanisms" operation provides information about which one-time password delivery mechanisms are configured in the server, and which of those are available for a specified user. ▪ The "deliver single-use token" operation can generate a token value and provide it to a specified user through an out-of-band communication mechanism like email, SMS, or voice call. ▪ The "consume single-use token" operation indicates that the user has received a single-use token from the "deliver single-use token" operation, and to consume that token so that it cannot be reused.

Ticket ID	Description
DS-12610	Fixed an issue where configuring numeric IPv4 address filtering by connection criteria in a log publisher performed unnecessary reverse host name lookups.
DS-12618	Updated the notification destination <code>cn=monitor</code> entry (objectclass of <code>ds-notification-destination-monitor-entry</code>) to include an attribute, <code>ds-notification-age-of-next-pending-change-seconds</code> , which tracks how out-of-date the destination is in seconds. Values are only maintained on the master server for that domain (<code>ds-notification-master=true</code>). A value of 0 on the master server for that domain indicates that the destination is up-to-date. This attribute can be used in a gauge to generate alarms if a destination gets too far behind.
DS-12627	Updated the LDAP connection handler to enable the use of multiple threads for accepting connections and preparing them for use. This improves concurrency for deployments in which the process of accepting a new connection may take some time to complete, possibly because of expensive DNS lookups or invoking time-consuming post-connect plugins).
DS-12681,DS-13475	Improved the server's support for selecting TLS cipher suites. When the server is configured to use a specific set of cipher suites, it will now always validate that all of the configured suites are supported by the JVM. When the server is not configured to use a specific set of cipher suites, it will now customize the set of default suites to prioritize those using strong cryptography (especially those that offer forward secrecy), and exclude suites with known weaknesses.
DS-12700	JDBC external servers now give precedence to settings in the <code>jdbc-driver-url</code> property, over other <code>dsconfig</code> JDBC Managed Object settings for <code>host-name</code> , <code>port</code> , and <code>database-name</code> . The <code>jdbc-driver-url</code> property setting can be used instead of the other JDBC Managed Object settings.
DS-12727	Added a gauge to monitor the number of available file descriptors. This Available File Descriptors gauge can detect if a server is running out of file descriptors and degrade the server appropriately.

Ticket ID	Description
DS-12798	MakeLDIF templates now have the ability to escape special characters curly braces, angle brackets, and square brackets using a backslash. See config/MakeLDIF/examples-of-all-tags.template for further examples.
DS-12799	The following UnboundID product names have changed: - Identity Datastore to Datastore - Identity Proxy to Proxy Server - Identity Data Sync Server to Data Sync Server - Identity Broker to Data Broker
DS-12833	Updated the alert handler configuration to indicate whether the alert handler should be invoked asynchronously in a background thread rather than by the thread that generated the alert. For alerts generated during the course of processing an operation, invoking potentially time-consuming alert handlers in a background thread can avoid adversely impacting the response time for that operation while still ensuring that administrators are made aware of the issue that arose.
DS-12833	Updated the server to provide support for SMTP connection pooling. When sending an email message, the server will attempt to reuse an existing SMTP connection rather than establishing a new connection for each message.
DS-12833	Updated the account status notification handler configuration to indicate whether the handler should be invoked asynchronously in a background thread rather than by the thread that triggered the notification. For account status notifications generated during the course of processing an operation, invoking notification handlers in a background thread can avoid adversely impacting the response time for that operation.
DS-12880	Fixed a rare condition that might cause the logger rotation and retention thread to exit under heavy file system load or a network file system outage.
DS-12897	Fixed a bug where using the advanced arguments of some tools would result in changing the saved complexity settings for the dsconfig tool.
DS-12909	Fixed the Local DB Backend configuration help text for deadlock-retry-limit, which incorrectly stated that a value of zero would result in unlimited retry attempts. That value actually results in no retry attempts.

Ticket ID	Description
DS-12933	Updated the server to reject search requests that attempt to make use of an invalid JSON object filter. The server would previously return a success result with no matching entries.
DS-12943	Fixed an issue where the Datastore parsed the last logon time value using the wrong time zone. The incorrect time affected password policy decisions and was delivered in the response to a password policy state extended request.
DS-12969	Improved server locking used by dsconfig in offline batch mode, so that the server lock is held for the entire batch duration, instead of for each invocation. Also, reduced the probability of contention for file locks used by server tools to determine the server status.
DS-12982	Updated the installer to increase the maximum suggested JVM size on Linux systems with at least 48 GB of RAM.
DS-13124	Fixed an issue where debug logging at a fine-level could consume large amounts of memory.
DS-13140	Fixed a problem that could cause the server to incorrectly handle the require-change-by-time property in the password policy configuration.
DS-13163	Addressed an issue where data definition language (DDL) log field mappings for the JDBC error log were not previously documented.
DS-13182	Updated the local DB backend to always try to keep exploded indexes in the database cache, and to always load exploded indexes into the cache on startup if database preloading is enabled, even if the database containing non-exploded index data for the associated index is configured with a lesser cache mode or preload configuration. Because reading from exploded indexes requires much more database interaction than non-exploded indexes, this can dramatically improve the performance of exploded index accesses for deployments in which it is not possible to fully cache all data in the backend.
DS-13206	Updated the server to use the latest 6.3.8 release of the Berkeley DB Java Edition.

Ticket ID	Description
DS-13207	Improved the server shutdown time in situations when there is a database cleaner backlog. This also ensures a faster start up time since database recovery isn't needed.
DS-13426	Updated the server to use the latest 6.3.9 release of the Berkeley DB Java Edition.
DS-13453	Fixed a defect where a deny ACI with target attrs would prevent Modify DN operations from succeeding, even when the target attrs did not include any RDN attrs.
DS-13481	Fixed an edge case problem in which a password change could result in the previous password not being included in the password history.
DS-13484	Fixed a conflict between the Changelog Password Encryption plugin and the replication historical ds-sync-hist attribute that would result in a "historical information for this attribute seems to be corrupt" error message in the logs.
DS-13552	Fixed a log publisher defect that would result in an unreadable file when both compression and signing were enabled at the same time.
DS-13554	Updated the server to allow an initial heap size over 128 GB. Due to limitations of older JVMs, this was previously capped at 128 GB, even when the maximum heap size was larger.
DS-13559	Fixed an issue that could cause the server to overlook attribute options in an indexed search filter.
DS-13644	Fixed an issue with the Pass Through Authentication Plugin where if a DN map was not used, the controls from the native bind operation were included in the pass through authentication request.
DS-13678	Updated the create-systemd-script tool by adding resource limits for available open file descriptors (NOFILE), and shared memory reservations (MEMLOCK). The generated script lists the recommended file descriptors limit and the resource limit setting for enabling large page support. The settings in the create-systemd-script output supersedes prior documentation for setting the number of open file descriptors on non-systemd systems.

Ticket ID	Description
DS-13727	Added an Identify References virtual attribute provider. Virtual attributes of this type will have values that are the DNs of entries that contain a specified attribute with a value that matches the DN of the entry containing the virtual attribute. For example, this could be used to create a virtual directReports attribute whose values are the DNs of the entries that list the target user as their manager.
DS-13748	Updated the Idif-diff tool to ensure that change records for delete operations will be ordered to ensure that a delete for a parent entry will never come before the deletes for its children.
DS-13771	Updated the initial output of export-Idif to report that it is calculating a disk-ordered cursor rather than "Exported 0 entries."
DS-13783	Updated the server to better utilize worker threads and reduce the potential for a work queue backlog when processing multiple concurrent long-running operations.
DS-13794	Updated the server to generate an administrative alert if it detects that a database environment was not closed cleanly and may require a time-consuming recovery process.
DS-13820	Fixed an issue involving transactions sent through a PingDirectoryProxy Server with Entry Balancing configured. If the transaction contained requests that targeted entries that were not in the global index, then duplicate requests were included in the resulting Multi-Update operation forwarded to the Datastore.
DS-13856	Updated the server to use the latest 6.4.9 release of Berkeley DB Java Edition.
DS-13862	Updated the server to discourage conflicts between indexes and virtual attributes. A search that targets an indexed attribute will only identify entries with real values as potential matches, and may omit entries that match the filter if they match because of a virtually-generated value.
DS-13899	Fixed an issue with large password history duration values that may have prevented some passwords in the history from being considered a match when a new password with the same value was added.
DS-13983	Fixed an issue where dynamic group membership searches lead to resource and memory leaks.

Ticket ID	Description
DS-14014	Updated the server to use the latest 6.4.12 release of the Berkeley DB Java Edition. This version addresses a possible data corruption bug in versions 6.3.0 to 6.4.11.
DS-14036	Fixed an issue where password history values could be duplicated in replicated environments.
DS-14060	Fix an issue in the SCIM interface where an attribute required by the SCIM schema could be deleted by a PATCH operation.
DS-14074	Added the ability to protect Velocity templates using the basic authentication scheme.
DS-14099	Fixed an issue where replication would stall while performing searches on LDAP referrals.
DS-14116	Fixed issues pertaining to search references. One caused replication to stall, and the other caused multiple copies of the same reference to be returned in a single search.
DS-14133	Fixed a couple of corner cases in which the server could treat smart referrals improperly. This includes search operations based above smart referrals contained in entries whose DNs contain escaped commas, as well as some search and compare operations based at least one level below a smart referral.
DS-14140	The ldifsearch command now supports the option "--isCompressed" for LDIF files that have been compressed with gzip.
DS-14259	Updated the email OTP delivery mechanism to allow retrieving email addresses from fields contained inside JSON objects, optionally using a JSON object filter to select which of several addresses should be used (e.g., only attempt to use verified email addresses). Similar changes have been made to the Twilio OTP delivery mechanism for obtaining phone numbers for SMS messages.
DS-14311	Fixed a race condition that could arise from simultaneous attempts to add entries with an attribute value that would cause an exploded index key to exceed its index entry limit.
DS-14349	Fixed an issue with the collect-support-data tool when using the --pid argument. Only one jstack was being collected, instead of using the amount specified by the --maxJstacks argument.

Ticket ID	Description
DS-14398,DS-14399	Added password storage schemes that leverage the Bcrypt and scrypt key derivation functions. These storage schemes require the free and open source Bouncy Castle library, which is not included with the server. This library must be obtained from https://bouncycastle.org/ and placed in the server lib directory before these storage schemes can be used.

PingDirectory Server 5.1.5.2 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-14074	Added the ability to protect Velocity templates using the basic authentication scheme.
DS-14099	Fixed an issue where replication would stall while performing searches on LDAP referrals.
DS-14116	Fixed issues pertaining to search references. One caused replication to stall, and the other caused multiple copies of the same reference to be returned in a single search.
DS-14133	Fixed a couple of corner cases in which the server could treat smart referrals improperly. This includes search operations based above smart referrals contained in entries whose DN's contain escaped commas, as well as some search and compare operations based at least one level below a smart referral.

PingDirectory Server 5.1.5.1 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-13484	Fixed a conflict between the Changelog Password Encryption plugin and the replication historical ds-sync-hist attribute that would result in a "historical information for this attribute seems to be corrupt" error message in the logs.
DS-13899	Fixed an issue with large password history duration values that may have prevented some passwords in the history from being considered a match when a new password with the same value was added.

Ticket ID	Description
DS-13983	Fixed an issue where dynamic group membership searches lead to resource and memory leaks.
DS-14015	Updated the server to use the latest 6.3.10 release of the Berkeley DB Java Edition. This version addresses a possible data corruption bug in versions 6.3.0 to 6.3.9.
DS-14036	Fixed an issue where password history values could be duplicated in replicated environments.

PingDirectory Server 5.1.5.0 Release Notes

What's New

These are new features for this release of the PingDirectory Server:

- Data within the backend database is now stored more compactly both on disk and in memory. The exact benefits depend on the data set and indexing, but improvements of 20-40% should be expected in the size on disk, the memory needed to fully cache the database, the time to preload the database at start up, the size and duration of backups, and the time required to remotely initialize a replica. Upgrades of existing environments require an export and reimport of the data to take advantage of these improvements.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-12727	Added a gauge to monitor the number of available file descriptors. This Available File Descriptors gauge can detect if a server is running out of file descriptors and degrade the server appropriately.
DS-12982	Updated the installer to increase the maximum suggested JVM size on Linux systems with at least 48 GB of RAM.
DS-13182	Updated the local DB backend to always try to keep exploded indexes in the database cache, and to always load exploded indexes into the cache on startup if database preloading is enabled, even if the database containing non-exploded index data for the associated index is configured with a lesser cache mode or preload configuration. Because reading from exploded indexes requires much more database interaction than non-exploded indexes, this can dramatically improve the performance of exploded index accesses for deployments in which it is not possible to fully cache all data in the backend.

Ticket ID	Description
DS-13207	Improved the server shutdown time in situations when there is a database cleaner backlog. This also ensures a faster start up time since database recovery isn't needed.
DS-13426	Updated the server to use the latest 6.3.9 release of the Berkeley DB Java Edition.
DS-13481	Fixed an edge case problem in which a password change could result in the previous password not being included in the password history.
DS-13554	Updated the server to allow an initial heap size over 128 GB. Due to limitations of older JVMs, this was previously capped at 128 GB, even when the maximum heap size was larger.
DS-13559	Fixed an issue that could cause the server to overlook attribute options in an indexed search filter.
DS-13644	Fixed an issue with the Pass Through Authentication Plugin where if a DN map was not used, the controls from the native bind operation were included in the pass through authentication request.
DS-13771	Updated the initial output of export-ldif to report that it is calculating a disk-ordered cursor rather than "Exported 0 entries."
DS-13820	Fixed an issue involving transactions sent through a Proxy Server with Entry Balancing configured. If the transaction contained requests that targeted entries that were not in the global index, then duplicate requests were included in the resulting Multi-Update operation forwarded to the Datastore.

PingDirectory Server 5.1.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the PingDirectory Server:

- The summarize-config tool is deprecated, and will be removed in future versions of the product. Use the config-diff tool with the "sourceBaseline" argument to list a summary of changes to the local server configuration.

What's New

These are new features for this release of the PingDirectory Server:

- Password Validators now have added properties for user-friendly descriptions and errors, which can be used by client applications to improve user interfaces.

- The self-service password reset function that uses a one-time password (OTP) is now more streamlined. An OTP token can be sent to an end user through email or SMS, and used for authentication when setting a new password.
- Added initial support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. Indexing options are currently limited. Please see the full release note below for DS-12138.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-3186	Added the 'listKeysExceedingIndexEntryLimit' argument to the verify-index tool, which enables listing the keys for indexes that have exceeded their index entry limits.
DS-8739	Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).
DS-9842	Added the ability to configure the Globally-Unique Attribute and Unique Attribute plugins with a filter to limit attribute uniqueness checking to a subset of matching entries.
DS-10010	Reduced the memory overhead of debug logging in high throughput environments by sharing logging buffers across multiple threads.

Ticket ID	Description
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>
DS-12123	<p>Updated the Configuration API output where properties and their values are listed to include those that are undefined.</p>

Ticket ID	Description
DS-12138	<p>Added support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. Two matching rules have also been added for use in conjunction with the JSON object syntax: <code>jsonObjectExactMatch</code> and <code>jsonObjectFilterExtensibleMatch</code>.</p> <p>The <code>jsonObjectExactMatch</code> equality matching rule is used in evaluating equality filters in search operations, as well as for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. String values will be compared in a case-insensitive manner. The order of elements in arrays will be considered significant.</p> <p>The <code>jsonObjectFilterExtensibleMatch</code> matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation (available in the Commercial Edition of the UnboundID LDAP SDK for Java) for the <code>com.unboundid.ldap.sdk.unboundidds.json.JSONObjectFilter</code> class and its subclasses. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.</p> <p>Indexing is supported only for the <code>jsonObjectExactMatch</code> matching rule. If possible, non-baseObject searches that use the <code>jsonObjectFilterExtensibleMatch</code> matching rule should be wrapped in an LDAP AND filter that also contains one or more indexed components so that the search can be processed more efficiently.</p>
DS-12182	<p>The setup tool has been updated to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.</p>
DS-12218	<p>Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.</p>

Ticket ID	Description
DS-12245	The Configuration API has been updated to support filtering, sorting, and paging for object list operations. See the Administration guide for usage.
DS-12263	Updated the local DB backend so that changes to the db-checkpointer-wakeup-interval property no longer require a restart to take effect, and to expose new monitor attributes with useful information about the processing performed by the database cleaner.
DS-12285	Fixed an issue where changes to SMTP External Server configurations did not take effect until after a server restart.
DS-12287	Addressed cases where some messages may be suppressed in logs and alerts.
DS-12313	Changed the default password policy behavior to prevent users from changing their passwords to their current password value. This logic will apply regardless of password history settings.
DS-12318	Added a configuration option to enable a wait period before removing a 'server unavailable' alert after a garbage collection task is performed. This allows sub-systems like replication to restart before the server becomes available again. For the Periodic GC Plugin, this option is 'delay-post-gc.' For a Forced GC Task entry, the attribute is named 'ds-task-delay-post-gc.' Both options take a value in milliseconds, and have a default value equivalent to 20 seconds.
DS-12319	Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.
DS-12443	Fixed an issue that generated the following error message, but did not impact the current operation: "An unexpected error occurred while notifying a change notification listener of a modify operation: RuntimeException: The specified condition must be true. The error occurred at com.unboundid.directory.server.types.AuthenticationInfo.replaceL
DS-12483	Added support for running on Oracle Java 8 and OpenJDK 8 platforms.
DS-12496	Added logging of all HTTP requests disallowed due to CORS. This should make it easier to debug HTTP 403/Forbidden errors.

Ticket ID	Description
DS-12560,DS-12561	Updated the server to avoid the use of the server-side sort and virtual list view request controls in search requests that span multiple subtree views or multiple entry-balanced backend sets. If the server cannot honor a non-critical server-side sort or virtual list view control, then it will process the search operation as if the control had not been included in the request. If the server cannot honor a critical server-side sort or virtual list view control, then it will return an error result to the client.
DS-12576	Update the Detailed HTTP Operation Log Publisher to log the correct return code (404 NOT FOUND) when a request is not handled by defined endpoints.
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12594,DS-12596	<p>Added support for three new extended operations for interacting with single-use tokens:</p> <ul style="list-style-type: none"> - The "get supported OTP delivery mechanisms" operation provides information about which one-time password delivery mechanisms are configured in the server, and which of those are available for a specified user. - The "deliver single-use token" operation can generate a token value and provide it to a specified user through an out-of-band communication mechanism like email, SMS, or voice call. - The "consume single-use token" operation indicates that the user has received a single-use token from the "deliver single-use token" operation, and to consume that token so that it cannot be reused.
DS-12610	Fixed an issue where configuring numeric IPv4 address filtering by connection criteria in a log publisher performed unnecessary reverse host name lookups.

Ticket ID	Description
DS-12618	Updated the notification destination <code>cn=monitor</code> entry (objectclass of <code>ds-notification-destination-monitor-entry</code>) to include an attribute, <code>ds-notification-age-of-next-pending-change-seconds</code> , which tracks how out-of-date the destination is in seconds. Values are only maintained on the master server for that domain (<code>ds-notification-master=true</code>). A value of 0 on the master server for that domain indicates that the destination is up-to-date. This attribute can be used in a gauge to generate alarms if a destination gets too far behind.
DS-12700	JDBC external servers now give precedence to settings in the <code>jdbc-driver-url</code> property, over other <code>dsconfig</code> JDBC Managed Object settings for <code>host-name</code> , <code>port</code> , and <code>database-name</code> . The <code>jdbc-driver-url</code> property setting can be used instead of the other JDBC Managed Object settings.
DS-12798	MakeLDIF templates now have the ability to escape special characters curly braces, angle brackets, and square brackets using a backslash. See <code>config/MakeLDIF/examples-of-all-tags.template</code> for further examples.
DS-12880	Fixed a rare condition that might cause the logger rotation and retention thread to exit under heavy file system load or a network file system outage.
DS-12909	Fixed the Local DB Backend configuration help text for <code>deadlock-retry-limit</code> , which incorrectly stated that a value of zero would result in unlimited retry attempts. That value actually results in no retry attempts.
DS-12943	Fixed an issue where the Datastore parsed the last login time value using the wrong time zone. The incorrect time affected password policy decisions and was delivered in the response to a password policy state extended request.
DS-12969	Improved server locking used by <code>dsconfig</code> in offline batch mode, so that the server lock is held for the entire batch duration, instead of for each invocation. Also, reduced the probability of contention for file locks used by server tools to determine the server status.
DS-12995	Fixed an issue in the Server SDK where the <code>ServerContext</code> <code>sendAlert</code> method incorrectly generated a <code>Java RuntimeException</code> when attempting to send a third-party extension alert.

PingDirectory Server 5.0.1.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-3186	<p>Added the 'listKeysExceedingIndexEntryLimit' argument to the verify-index tool, which enables listing the keys for indexes that have exceeded their index entry limits.</p>
DS-8739	<p>Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).</p>
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>

Ticket ID	Description
DS-12123	Updated the Configuration API output where properties and their values are listed to include those that are undefined.
DS-12182	The setup tool has been updated to use HTTPS when configuring the HTTP Connection Handler(s). Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.
DS-12218	Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.
DS-12263	Updated the local DB backend so that changes to the db-checkpointer-wakeup-interval property no longer require a restart to take effect, and to expose new monitor attributes with useful information about the processing performed by the database cleaner.
DS-12287	Addressed cases where some messages may be suppressed in logs and alerts.
DS-12313	Changed the default password policy behavior to prevent users from changing their passwords to their current password value. This logic will apply regardless of password history settings.
DS-12318	Added a configuration option to enable a wait period before removing a 'server unavailable' alert after a garbage collection task is performed. This allows sub-systems like replication to restart before the server becomes available again. For the Periodic GC Plugin, this option is 'delay-post-gc.' For a Forced GC Task entry, the attribute is named 'ds-task-delay-post-gc.' Both options take a value in milliseconds, and have a default value equivalent to 20 seconds.
DS-12319	Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.
DS-12443	Fixed an issue that generated the following error message, but did not impact the current operation: "An unexpected error occurred while notifying a change notification listener of a modify operation: RuntimeException: The specified condition must be true. The error occurred at com.unboundid.directory.server.types.AuthenticationInfo.replaceL

Ticket ID	Description
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12618	Updated the notification destination cn=monitor entry (objectclass of ds-notification-destination-monitor-entry) to include an attribute, ds-notification-age-of-next-pending-change-seconds, which tracks how out-of-date the destination is in seconds. Values are only maintained on the master server for that domain (ds-notification-master=true). A value of 0 on the master server for that domain indicates that the destination is up-to-date. This attribute can be used in a gauge to generate alarms if a destination gets too far behind.

PingDirectory Server 5.0.0.0 Release Notes

What's New

These are new features for this release of the PingDirectory Server:

- Java 7 is now required when setting up a new server or upgrading an existing server.
- Added support for extensible match filters that can make assertions about the number of values that a specified attribute has in an entry. For example, the extensible match filter `"(cn:valueCountEquals:=1)"` will match an entry only if that entry has exactly one value for the cn attribute. The following special matching rules have been added to help provide this capability:
 - valueCountEquals - valueCountDoesNotEqual - valueCountGreaterThan - valueCountGreaterThanOrEqualTo - valueCountLessThan - valueCountLessThanOrEqualTo
- Updated the LDAP changelog to support selecting which entries should be included in or excluded from the changelog. Entries can be selected based on the location of the target entry in the DIT, and/or based on whether the changelog entry matches a given filter.

A new ds-changelog-target-attribute attribute has also been added to changelog entries to indicate which attributes were involved in the change. This may be used to select changelog entries for inclusion or exclusion based on changes to specific attributes.

- Enabled support for the SSLv2Hello TLS protocol by default in JVMs that support it. This does not enable support for the insecure SSLv2 protocol, but it can improve compatibility with clients running older versions of Java that may start TLS negotiation with an SSLv2 client hello packet before negotiating to a higher version of the TLS protocol. Support for SSLv2Hello in the initial phase of negotiation does not in any way compromise the strength of the integrity and/or confidentiality protection that is ultimately negotiated between the client and the server.
- Added a Monitor History plugin that periodically records cn=monitor to timestamped files to aid in isolating intermittent problems. By default, it logs the full cn=monitor branch every five minutes to compressed files within logs/monitor-history/. Files are deleted automatically, but a sparse set of older files are kept to provide historical perspective on server performance. The collect-support-data tool has also been updated to collect a few of these files to aid in root cause analysis.
- Updated the server to use the latest 6.2.31 release of the Berkeley DB Java Edition.
- The default SCIM base context path changed from / to /scim. Any clients using the previous base context path will no longer be able to access SCIM services until they are updated. The following dsconfig command may be used to revert to the previous base context path after update:

```
dsconfig set-http-servlet-extension-prop --extension-name SCIM --set base-context-path:/
```

- Introduced the Configuration HTTP Servlet Extension, which can be used for querying and updating the configuration over a REST API. This feature is currently experimental and is subject to change in the future. Your feedback is welcome.
- Improved the diagnostic information the server can provide at startup for any components that take a substantial amount of time to initialize. The server will also generate an alert notification if any component attempts to perform an unindexed internal search operation, in order to warn about potential misconfiguration.
- Added a global configuration setting called `database-on-virtualized-or-network-storage`. This boolean setting must be set to true when database files will be stored on network file systems. It should be set to false if the database is on a local disk since it incurs a performance penalty.

Resolved Issues

The following issues have been resolved with this release of the PingDirectory Server:

Ticket ID	Description
DS-3629	Added a new schema file that contains previously undefined server attributes. The addition of these attributes helps resolve conflicts with user-defined schema.
DS-8368,DS-12120	Updated the HTTP Connection Handler to return a 404 Not Found response to requests for endpoints not handled by any servlet or web application extensions. Previously the handler would return a 200 OK with no response body.
DS-9877,DS-11774	Fixed an issue where replication would not be established for a new replica when it was initialized by importing an LDIF file exported from an existing replica. The issue occurred whether the import was performed before or after enabling replication.
DS-10441	Disabled log rotation during startup to prevent potential problems with rotation dependencies on server components that have not yet been initialized.
DS-10460	Fixed the <code>dsconfig</code> tool to suppress all stray output when run in batch mode with the <code>--quiet</code> option.

Ticket ID	Description
DS-11138	<p>Fixed an issue where deleting values of a multi-valued attribute using SCIM PATCH could silently fail. Modifications in SCIM PATCH are now mapped directly to LDAP modifications to take advantage of the matching rules configured in the Identity Datastore, when matching deleted values. Since the SCIM PATCH is now applied by the Datastore, the Permissive Modify Request Control (1.2.840.113556.1.4.1413) is now required by the SCIM component. This will ensure that adding an existing value or deleting a non-existent value in the PATCH request will not result in an error.</p> <p>To continue using SCIM component after an upgrade of the Identity Datastore or Identity Proxy, access controls and configuration may need to be updated to allow access to the Permissive Modify Request Control.</p> <p>Identity Datastore:</p> <pre>dsconfig set-access-control-handler-prop -- remove 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12") (version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-access-control-handler-prop -- add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12 1.2.840.113556.1.4.1413")(version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <p>Identity Proxy:</p> <pre>dsconfig set-access-control-handler-prop -- remove 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12") (version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-access-control-handler-prop -- add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12 1.2.840.113556.1.4.1413")(version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-request-processor-prop --processor- name dc_example_dc_com-req-processor --add supported-control-oid:1.2.840.113556.1.4.1413</pre> <p>Note that "dc_example_dc_com-req-processor" is the default processor name and it may be different depending on your configuration.</p> <p>Identity Broker: For each Identity Datastore used as</p>

Ticket ID	Description
DS-11297	Simplified the various cache-mode properties within the Local DB Backend configuration. Current values for these properties are "cache-keys-and-values" (formerly "default"), "cache-keys-only" (formerly "evict-leaf-immediately"), and "no-caching" (formerly "evict-bin-immediately"). The old values will continue to work. If the update tool is used to upgrade to this release, the existing values within the configuration will be updated to use the new values.
DS-11396	Updated gauge alert details to include the last threshold value that was crossed.
DS-11406	Added the ability for a Server SDK extension, such as a Plugin, to register for notifications when an operation completes using the <code>OperationContext#registerOperationCompletedListener()</code> method.
DS-11453	Reduced the severity of the "unrecognized alert type" message in the error log from SEVERE_WARNING to NOTICE. The message now states that this is expected if the server is reverted to a version prior to the implementation of these alert types.
DS-11472	Fixed the gauge configuration manager to only re-initialize the gauge that was changed, and not any of the other gauges that did not change.
DS-11483	Updated the set subtree accessibility extended operation handler to support atomically altering the accessibility of multiple subtrees in a single request.
DS-11541	Fixed the alarm manager to generate alarm-cleared alerts when internal alarms are cleared and the alarm manager's generated-alert-types property has the "alarm" value.
DS-11546	Fixed the alarm manager to not include the details of the old alarm, (the alarm being cleared), in the "alarm-cleared" alert message.

Ticket ID	Description
DS-11565	<p>Updated the javadoc for the Example Overload Handler plugin to include the argument "invoke-for-internal-operations" with a value of "false" during the plugin creation. Previously, the plugin, when enabled, would drop internal queries to the monitor backend initiated by the gauge state provider.</p> <p>Fixed an issue in the Example Overload Handler plugin's applyConfiguration method, where when any changes were made to the plugin's configuration itself (such as adding a new pre-parse type), it would drop requests because we were doing an LDAP search for the gauge argument in the config backend over a client connection, instead of using an internal connection.</p> <p>Fixed an issue where when the Example Overload Handler plugin was disabled and then re-enabled, an IllegalStateException occurred because the monitor provider that publishes drop stats was previously registered.</p>
DS-11624	<p>Updated the Web Console so that upon login, the user's old session is always invalidated.</p>
DS-11625	<p>Fixed a rare issue in backend database entry encoding where the server alerted on an "unexpected exception" when encoding large entries with an unusually large number of ds-sync-hist values. The error was reported in the alert message as being a NegativeArraySizeException thrown from the EntryEncoder class.</p>
DS-11629,DS-11645	<p>Updated the Web Console to suppress LDAP responses in user messages, such as when the server is unavailable or for authentication failures. Also added a context parameter to exclude stack traces and detailed error messages from appearing in the application's internal error page.</p>
DS-11637	<p>Updated the alarm manager to not generate "alarm-normal" alert when a gauge's condition abates</p>
DS-11688	<p>Fixed an issue in which tools such as dsconfig, status, and dsreplication could not connect to the server over SSL or StartTLS. This occurred when a certificate was accepted with the 'Manually validate' option, while using the interactive LDAP connection menu.</p>
DS-11719	<p>Updated the alarm manager to not persist normal alarms.</p>

Ticket ID	Description
DS-11719	Updated the ExampleOverloadHandlerPlugin to monitor the alarm backend for delete actions, so that it can react appropriately to abating gauge conditions.
DS-11720	Added a fail safe to the pending changes queue for the Changelog Backend that can detect and ignore recovered changes that do not need to be committed in order to prevent holding up other changes in the queue.
DS-11728	Fixed a bug that resulted in an error message related to performing a modify DN operation against a currently authenticated user entry.
DS-11730	Removed the "alarm-normal" alert.
DS-11738	Updated the server so that alarm-cleared, alarm-warning, alarm-minor, alarm-major, and alarm-critical alerts are not subject to duplicate alert suppression. Separate alert notifications of these types may represent distinct conditions and resources that should not be suppressed.
DS-11751	Fixed incorrect property references for trustStorePassword and keyStorePasswordFile in tools.properties that corresponded to the wrong argument names.
DS-11755	Updated the HTTP Detailed Access logger to use timestamps with millisecond precision.

Ticket ID	Description
DS-11782	<p data-bbox="849 216 1446 468">Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.</p> <p data-bbox="849 485 1463 1213">SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced <code>allowed-insecure-tls-protocol</code> global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.</p> <p data-bbox="849 1230 1463 1829">It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.</p>

Ticket ID	Description
DS-11805	Updated the access logger to include usedPrivileges and/or missingPrivileges fields in result log messages for operations in which the requester used one or more privileges, or in cases where the requested operation required one or more privileges that the requester did not have.
DS-11837	Updated numeric gauges so that their severity changes when the current gauge value equals the threshold's exit value. Previously the value had to be strictly less than the exit value for the severity to change.
DS-11839	Added additional debug information for constraint violations that can happen during replication enable.
DS-11868	Fixed an issue where the server would hang during startup due to a previous unexpected service outage resulting in an empty tasks.Idif file.
DS-11879	Fixed the index rebuild job so that it does not generate redundant "index-degraded" alerts when an index is being rebuilt.
DS-11892	Fixed a replication issue where the changelogDb path on the destination server was incorrect when the following conditions were met: the source and destination shared the same installation path, the source server used a symlink for changelogDb to an external path, the destination server did not have the external path.
DS-11902	Added a workaround for a bug in some versions of Java that could interfere with the ability to restore an encrypted backup.
DS-11908	When using SCIM, the method in which the user name in HTTP Basic authentication are mapped to a user is now configurable using Identity Mappers. After the user name is mapped to a user, a simple BIND request will be used to verify the password.
DS-11913	Computed minimums, averages, maximums in statistics loggers previously processed infinite or out-of-range numbers leading to unprintable character output in comma-separated value (CSV) files. Computed minimums, averages, maximums in statistics loggers now exclude infinite and out-of-range values.

Ticket ID	Description
DS-11919	Fixed an issue that could interfere with rebuilding an attribute index with one or more exploded index keys.
DS-11933	Added change type indexes to the LDAP changelog to improve the efficiency of get changelog batch operations that target records with only a subset of change types.
DS-11959	Updated the HTTP/HTTPS connection handler to Jetty 8.1.16.v20140903.
DS-11993	Added a gauge to the server to track JVM memory usage and alert if the amount of free memory gets low enough that it could impact server performance.
DS-11996	Fixed an issue where a password policy was configured to record the last login time and last login IP address, but those attributes were not being updated when a bind went through the pass-through authentication plugin to a remote server.
DS-12000	Fixed an issue where attempting to cancel many outstanding proxy operations could make the proxy server unresponsive.
DS-12005	Fixed a rare condition where parent DNs stored in compact form for evaluation of group membership could consume a large amount of memory.
DS-12010	Fixed an issue where a password policy was adding login failures when a bind went through the pass-through authentication plugin, and failed locally, but subsequently succeeded against an external server.
DS-12027	Fixed an issue that caused replication to disconnect for up to fifteen minutes when sending on half open connections, typically due an unforeseen network issue.
DS-12032	Updated the configuration properties of the Local DB Backend to indicate which settings require a component (or server) restart to take effect.
DS-12040	Fulfilled an enhancement request to allow access to the additional information properties in alert notifications.
DS-12064	Fixed an issue where the server could hit an unexpected exception when a new attribute index was added while the server was under heavy load.

Ticket ID	Description
DS-12066	Fixed a problem with startup dependencies not being properly honored for Server SDK plugins.
DS-12109	Added a configuration option that can be used to indicate that an attribute index should maintain a matching entry count for keys that exceed the index entry limit. While maintaining a count for these index keys will not improve the efficiency of applicable searches, the count can be used to improve the result the server is able to return for these searches when used in conjunction with the matching entry count request control.
DS-12124	The dsreplication remove-defunct-server subcommand no longer allows the removal of a running server from the replication topology.
DS-12147	Updated the server to make it easier to control the order of values in the ssl-protocol and ssl-cipher-suite properties in the LDAP connection handler and crypto manager configuration objects.
DS-12162	Updated the character set password validator to allow for adding optional character sets that require zero or more matches.
DS-12170	Updated the server's support for filtered indexes so that they can be used for a broader set of search filters.
DS-12174	Fixed an issue where registering a server extension would cause a null-pointer exception at startup preventing the server from starting.
DS-12197	Updated the rebuild-index tool to add offline support for approximate indexes.
DS-12197	Fixed an issue with the verify-index tool that could arise when examining approximate indexes with one or more keys exceeding the index entry limit.
DS-12201	Fixed an issue where updating a component in the web console could generate a missing enabled property error.
DS-12215	Fix an issue where a VLV request specifying a large afterCount value would result in an OutOfMemoryError and cause the Datastore to shut down.

PingDirectoryProxy Server Release Notes

PingDirectoryProxy Server 8.1.0.6 release notes

The release notes for the 8.1.0.6 release of PingDirectoryProxy Server.

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

PingDirectoryProxy Server 8.1.0.5 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDirectoryProxy Server 8.1.0.4 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43288	<p data-bbox="850 218 1455 338">Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p data-bbox="850 361 1455 768">To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p data-bbox="850 791 1455 1010">Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul data-bbox="850 1033 1464 1854" style="list-style-type: none"><li data-bbox="850 1033 1464 1220">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.<li data-bbox="850 1243 1464 1486">* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.<li data-bbox="850 1509 1464 1854">* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43908	Fixed an issue that caused the PingDirectoryProxy Server to return error code 81 (server down) instead of 52 (unavailable) when adding an entry while a dataset was unavailable.

Release Notes Archive

Release notes for previous versions of PingDirectoryProxy Server are included for reference.

PingDirectoryProxy Server 8.1.0.4 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.
DS-43908	Fixed an issue that caused the PingDirectoryProxy Server to return error code 81 (server down) instead of 52 (unavailable) when adding an entry while a dataset was unavailable.

PingDirectoryProxy Server 8.1.0.3 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-42381	Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.

PingDirectoryProxy Server 8.1.0.2 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the directory server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.0.1.3
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
 - Fixed in: 4.5.0.0
 - Introduced in: 4.1.0.7
 - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Update PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

PingDirectoryProxy Server 8.1 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the

new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

- Fixed an issue that could prevent the uninstaller from removing information about the instance from the topology registry.

What's New

These are new features for this release of PingDirectoryProxy Server:

- The SCIM v2 REST API was added to PingDirectory Server in version 8.0. PingDirectoryProxy Server now supports the SCIMv2 REST API to create, read, update and delete (CRUD) users and other resources using JSON over HTTP. PingDirectoryProxy Server supports all the same endpoints and HTTP methods that PingDirectory Server supports.
- In an ongoing effort to improve the use of containers for PingDirectory Server, several features have been implemented:
 - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
 - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectoryProxy Server has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.
- Updated PingDirectoryProxy Server to improve support for the PLAIN, UNBOUNDID-DELIVERED-OTP, UNBOUNDID-TOTP, and UNBOUNDID-YUBIKEY-OTP SASL mechanisms. Previously, PingDirectoryProxy Server itself performed all of the processing for those SASL mechanisms, and it would only work if PingDirectoryProxy Server could retrieve the appropriate encoded credentials from the backend PingDirectory Server. It will now forward the bind request to the backend server for processing, which allows it to work in deployments in which the backend server prevents PingDirectoryProxy Server from accessing the stored credentials.
- Added a new validate-ldap-schema tool that can be used to examine schema definitions in a set of LDIF files and report any issues that it detects.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	<p>Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.</p>
DS-10216	<p>Updated the GSSAPI SASL mechanism handler to support integrity and confidentiality protection for client communication.</p>
DS-37829	<p>The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.</p>
DS-38008,DS-41192	<p>Updated PingDirectoryProxy Server to improve its support for retrying operations that fail in a manner that suggests they may succeed if attempted in a different server or on a newly established connection.</p> <p>Previously, PingDirectoryProxy Server would automatically enable retry support for all types of operations except add. At the time this retry support was initially implemented, retrying an add operation on a different server had the potential to result in a replication conflict if the entry was ultimately created on multiple servers. The Directory Server's replication logic has since been updated to detect and automatically resolve conflicts that result from attempts to add the same entry concurrently on multiple servers. As it is safe to enable automatic retry support for add operations (along with all other types of operations), that is now the default configuration.</p> <p>PingDirectoryProxy Server has also been updated to improve its retry support for the case in which connections to multiple backend servers have become invalidated in a manner that it cannot immediately detect (for example, as the result of an issue with a network switch or hardware load-balancer). As a result of this change, if all of the PingDirectoryProxy Server's usual attempts to process an operation fail in a manner that could indicate that connections are no longer valid, it may now attempt to establish a new connection to a backend server for one additional retry attempt.</p>

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.

Ticket ID	Description
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40817	PATCH operations on SCIM 2 for PingDirectory Server now require that the value of the schemas attribute in the request body to be "urn:ietf:params:scim:api:messages:2.0:PatchOp", in accordance with RFC 7644.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-40953	Added detection for buffer issues that could cause connections to get stuck during TLS handshake.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41136	Enabled SCIM 2 API for PingDirectoryProxy Server.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on PingDirectory Server.

Ticket ID	Description
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where the Ping Directory Proxy could incorrectly return duplicate entries after timing out on an unindexed search.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41622	The use-administrative-operation-request-control property is now hidden on unsupported products.

Ticket ID	Description
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the <code>--zip</code> argument to the <code>manage-profile generate-profile</code> subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to <code>/instance-root</code> by authenticated users with the <code>file-servlet-access</code> privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has <code>memory.swappiness</code> set to a nonzero value.
DS-41851	Enabled Correlated LDAP Data Views for SCIM 2 resource types on PingDirectory Server and Nokia8661DirectoryProxyServerAdministrationGuid.
DS-41987	Updated the PUT request in the consent service to reject requests that have duplicate collaborators to make it consistent with POST and PATCH requests.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a <code>NullPointerException</code> if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

PingDirectoryProxy Server 8.0.0.5 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectoryProxy Server 8.0.0.3 release notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	<p data-bbox="850 216 1455 338">Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p data-bbox="850 359 1455 768">To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p data-bbox="850 789 1455 1010">Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul data-bbox="850 1031 1464 1850" style="list-style-type: none"><li data-bbox="850 1031 1464 1220">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.<li data-bbox="850 1241 1464 1482">* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.<li data-bbox="850 1503 1464 1850">* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDirectoryProxy Server 8.0.0.2 Release Notes

Critical Fixes

This release of PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41299	Fixed an issue where PingDirectoryProxy Server could incorrectly return duplicate entries after timing out on an unindexed search.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

PingDirectoryProxy Server 8.0.0.1 Release Notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-

lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-

NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
 - Fixed in: 4.5.0.0
 - Introduced in: 4.1.0.7
 - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Update the PingDirectoryProxy Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.

Ticket ID	Description
DS-41206	Fixed a memory leak when performing SCIM queries on the PingDirectory Server.

PingDirectoryProxy Server 8.0.0.0 Release Notes

Critical Fixes

This release of the PingDirectoryProxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

What's New

These are new features for this release of the PingDirectoryProxy Server:

- Better insight to server health and the performance of connected applications. Administrators can now push metrics to application insight and monitoring applications such as Splunk using two new methods. A new StatsD monitoring endpoint pushes metrics to StatsD-compatible services. Also, the periodic stats logger has been updated to use JSON-format log files, greatly simplifying the use of log forwarding tools like Splunk's Universal Forwarder or Elastic's FileBeats.
- Better support by Directory Proxy Server for orchestrated Directory Server clusters in automated environments like Kubernetes or AWS EC2 Auto Scaling. Administrators can connect the topology of a PingDirectoryProxy Server cluster to the topology of a PingDirectory Server cluster in order to automatically adapt to cluster changes within the PingDirectory Server cluster. This greatly simplifies the configuration management of PingDirectoryProxy Server when PingDirectory Server clusters are being added, removed, or replaced by automated infrastructure orchestrators.
- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDirectoryProxy Server server to a directory of text files called a Server Profile, track changes to these files in version control like Git, and install new instances of PingDirectoryProxy Server or update existing instances of Directory Proxy Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- The following are suggested solutions for problems with slow DNS:
 - Maintain a connection pool in the client app rather than opening new connections for each bind.
 - Add appropriate records, including PTR records, to DNS.
 - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
 - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in Directory Server's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.

Workaround: Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.

- The working directory value used by exec tasks is not implemented for recurring exec tasks.

- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
 - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
 - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor monitor</code> entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.

Ticket ID	Description
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39155	Updated the default value for <code>maximum-degraded-missing-changes</code> to 1000000, and for <code>minimum-unavailable-missing-changes</code> to 100000. Servers that used the previous default values became unavailable prematurely, leading to outages.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39321	Added support for PingDirectoryProxy Server to the <code>manage-profile</code> tool and its subcommands.

Ticket ID	Description
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> ▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server ▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server ▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server ▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39347	Fixed an issue where Delegated Admin would not work properly if the name of the REST Resource Type was not the same as the resource endpoint.
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code>), this could cause unexpected or incorrect behavior.
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> ▪ Allow a required attribute to be read-only if it is constructed. ▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. ▪ Handle constructed attributes which reference other constructed attributes.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.

Ticket ID	Description
DS-39693	Fixed an issue where Delegated Admin search results were truncated and invalid upon encountering a Directory entry containing a Boolean or Integer syntax attribute whose values were invalid because they did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results and a warning message is logged to the server errors log.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39762	Added support for a "generate password" extended operation that can be used to request that the server generate one or more passwords that may be suggested as possible values when creating a new user or changing the password for an existing user.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40249	Fixed an issue where an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search should return 52 (unavailable) in this situation.
DS-40252	Update the PingDirectoryProxy Server setup process to support joining an existing Ping Identity Platform topology.
DS-40255, DS-40256, DS-40257	Updated the fewest operations and failover load-balancing algorithms to support automatically discovering the set of backend Directory Server instances from the topology registry.
DS-40274	Updated the proxy to check if the proxy's backend has been sufficiently initialized prior to performing a health check.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile</code> <code>replace-profile</code> to copy the tool log file to the server being updated.

Ticket ID	Description
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

PingDirectoryProxy Server 7.3.0.10 release notes

Critical fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
 - Fixed in: 7.3.0.10
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-41762 SF#00675207 SF#00683777

Resolved issues

The following issues have been resolved with this release of the Directory Proxy Server.

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-44204	Fixed an issue in which the Directory Server could incorrectly allow requests to be processed with an alternate authorization identity (for example, using the proxied authorization control, or if the requests pass through a Directory Proxy Server) whose account is in a "must change password" state. The server will now only permit the operation if it attempts to set a new password for the target user.

PingDirectoryProxy Server 7.3.0.7 Release Notes

Critical Fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
 - The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
 - Fixed in: 4.5.0.0
 - Introduced in: 4.1.0.7
 - Support identifiers: DS-9726

- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Update the PingDirectory Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server:

Ticket ID	Description
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the "Resource" column in the output of "status". This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-39799	Allows users who were migrated from the admin backend to the topology to manage the topology. Migrated users are granted the "manage-topology" privilege if they do not already have it.
DS-40274	Updated the proxy to check if the proxy's backend has been sufficiently initialized prior to performing a health check.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40681	Added a cache for password policies stored in user data rather than in the configuration. The cache will hold up to 500 policies by default, but the cache size can be configured (or the cache disabled) using the maximum-user-data-password-policies-to-cache property in the global configuration.
DS-40771	Added a --duration argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDirectoryProxy Server 7.3.0.5 Release Notes

Critical Fixes

This release of the Directory Proxy Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered

secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Update the replication backlog health check so that if a problem is encountered while attempting to retrieve monitor information from a backend server, that server will only be classified as degraded rather than unavailable.
 - Fixed in: 4.5.0.0
 - Introduced in: 4.1.0.7
 - Support identifiers: DS-9726
- Fix a bug that allows users with expired passwords to change attributes in their own entry other than password.
 - Fixed in: 3.5.0.0
 - Introduced in: 3.2.0.0
 - Support identifiers: DS-6054
- Update the PingDirectoryProxy Server to apply access controls when processing the GetAuthorizationEntryRequestControl.
 - Fixed in: 3.5.0.0
 - Introduced in: 2.0.0.0
 - Support identifiers: DS-854

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

PingDirectoryProxy Server 7.3.0.3 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
PDSTAGING-840	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-40327	Fixed an issue in which an LDAP search across entry-balanced server sets sometimes returned 0 (success) even though all servers in one of the sets failed with a timeout. The search now returns 52 (unavailable) in this situation.

PingDirectoryProxy Server 7.3.0.1 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server:

The file `remove-sample-directory-data-aci.ldif`, which is provided with the Delegated Admin installation package, was updated in version 3.5.0 to reinstate permissions for users to change their own passwords (self-service password reset). If you have used an earlier version of this LDIF file, consider manually adding the following ACI from the updated version:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword") (version 3.0; acl "Allow users to update
their own password"; allow (write) userdn="ldap:///self";)
```

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-17278	<p>Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps.</p> <p>Updated the LDAP external server monitor to include attributes that track health-check state changes for external servers. The new attributes include the following information:</p> <ul style="list-style-type: none"> Number of times a health-check transition has occurred Timestamps of the most recent transitions Messages associated with the most recent transitions

Ticket ID	Description
DS-39176, DS-39308	<p>Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 Release Notes.</p> <p>As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code>, download the appropriate JAR file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.</p>
DS-39347	<p>Fixed an issue in which Delegated Admin did not work properly if the name of the REST resource type was not the same as the resource endpoint.</p>
DS-39525, DS-39526	<p>Delegated Admin enhancements for constructed attributes.</p> <ul style="list-style-type: none"> ▪ Allow a required attribute to be read-only if it is constructed. ▪ Add a configured list of "Update Constructed Attributes" on the REST resource type, similar to the "Post Create Constructed Attributes", so that constructed attributes can be updated when dependent attributes change. ▪ Handle constructed attributes that reference other constructed attributes.
DS-39693	<p>Fixed an issue in which Delegated Admin search results were truncated and invalid upon encountering a Directory entry that contained a Boolean or Integer syntax attribute whose values did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results, and a warning message is logged to the server errors log.</p>

PingDirectoryProxy Server 7.3.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server

- To ensure correct search results with Delegated Admin, disable client caching by updating the Delegated Admin HTTP Servlet Extension to return response headers, and then stop and restart the server, as follows:

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin" --set "response-header:Cache-Control: no-cache, no-store, must-revalidate" --set "response-header:Expires: 0" --set "response-header:Pragma: no-cache"
```

What's New

These are new features for this release of PingDirectoryProxy Server

- New features for data encryption in transit and at rest: added support for TLS 1.3, ability to encrypt and automatically decrypt sensitive files such as tools.properties and keystore pin files using the server data encryption keys, and the ability to more easily and securely separate master keys from data encryption keys by protecting the server encryption settings database using either Amazon Key Management Service (AWS KMS) or HashiCorp Vault.
- Added support for Amazon Corretto JDK 8, Windows Server 2019, Red Hat Enterprise Linux 7.6, CentOS 7.6, Amazon Linux 2, and Docker 18.09.0 on Ubuntu 18.04 LTS.
- New load balancing algorithm for performance and improved reliability. By default for new configurations, the load balancing algorithm uses a failover strategy for writes and fewest operations strategy for reads. This means that normally all writes will go to the same server, which reduces replication conflicts or unique attribute conflicts, while all reads are distributed to the servers with lightest load, which distributes server utilization and improves performance. This combination strategy works in tandem with a change to PingDirectoryProxy to use assured replication by default for several types of write operations, which reduces the chances of data consistency issues when write operations are immediately followed by read operations for the same objects and attributes.

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
PDSTAGING-570,DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:</p> <ul style="list-style-type: none"> - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections. - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
PDSTAGING-570,DS-38344	<p>The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.</p>
PDSTAGING-570,DS-38335	<p>The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.</p>
DS-15734	<p>Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a key from the Amazon Key Management Service.</p>

Ticket ID	Description
DS-18060	<p>Added an HTTP servlet extension that can be used to retrieve the server's current availability state. It accepts any GET, POST, or HEAD request sent to a specified endpoint and returns a minimal response whose HTTP status code may be used to determine whether the server considers itself to be AVAILABLE, DEGRADED, or UNAVAILABLE. The status code for each of these states is configurable, and the response may optionally include a JSON object with an "availability-state" field with the name of the current state.</p> <p>Two instances of this servlet extension are now available in the default configuration. A request sent to /available-state will return an HTTP status code of 200 (OK) if the server has a state of AVAILABLE, and 503 (Service Unavailable) if the server has a state of DEGRADED or UNAVAILABLE. A request sent to the /available-or-degraded-state will return an HTTP status code of 200 for a state of AVAILABLE or DEGRADED, and 503 for a state of UNAVAILABLE. The former may be useful for load balancers that you only want to have route requests to servers that are fully available. The latter may be useful for orchestration frameworks if you wish to destroy and replace any instance that is completely unavailable.</p>
DS-36474	<p>Updated the ldapdelete command-line tool to improve robustness and add features. Some of the new features include support for client-side subtree delete, deleting entries that match search filters, following referrals, writing failures to a rejects file, rate limiting, and support for a variety of additional controls.</p>
DS-37174	<p>Made visible the index-priming-idle-listener-timeout property of the Entry Balancing Request Processor configuration object. During global index priming, this property specifies the amount of time an extended operation response listener can be idle while in progress. For example, if the global index is priming and a backend server stops returning results but does not disconnect, this timeout can be used to force a retry of the operation.</p>
DS-37617	<p>HTTP Connection Handlers now accept client-provided correlation IDs by default. To adjust the set of HTTP request headers that may include a correlation ID value, change the HTTP Connection Handler's correlation-id-request-header property.</p>

Ticket ID	Description
DS-37839	<p>Make Fingerprint Certificate Mapper and Subject DN to User Attribute Certificate Mapper disabled by default on fresh installations. This will not affect upgrades from installations where these mappers are enabled.</p>
DS-37959	<p>Added support for insignificant configuration archive attributes.</p> <p>The configuration archive is a collection of the configurations that have been used by the server at some time. It is updated whenever a change is made to data in the server configuration, and it is very useful for auditing and troubleshooting. However, because the entries that define root users and topology administrators reside in the configuration, changes to those entries will also cause a new addition to the configuration archive. This is true even for changes that affect metadata for those entries, like updates to the password policy state information for one of those users. For example, if last login time tracking is enabled for one of those users, especially with high-precision timestamps, a new configuration may be generated and added to the configuration archive every time that user authenticates to the server. While it is important for this information to be persisted, it is not as important for it to be part of the server's configuration history.</p> <p>This update can help avoid the configuration archive from storing information about updates that only affect this kind of account metadata. If a configuration change only modifies an existing entry, and if the only changes to that entry affect insignificant configuration archive attributes, then that change may not be persisted in the server's configuration archive.</p> <p>By default, the following attributes are now considered insignificant for the purpose of the configuration archive:</p> <ul style="list-style-type: none"> * ds-auth-delivered-otp * ds-auth-password-reset-token * ds-auth-single-use-token * ds-auth-totp-last-password-used * ds-last-access-time * ds-pwp-auth-failure * ds-pwp-last-login-ip-address * ds-pwp-last-login-time * ds-pwp-password-changed-by-required-time * ds-pwp-reset-time * ds-pwp-retired-password * ds-pwp-warned-time * modifiersName * modifyTimestamp * pwdAccountLockedTime * pwdChangedTime * pwdFailureTime * pwdGraceUseTime * pwdHistory * pwdReset

Ticket ID	Description
DS-37960	<p>The Delegated Admin configuration has changed significantly. Delegated Admin Resource Types were removed and replaced by REST Resource Types. Delegated Administrators and Delegated Group Administrators were removed and replaced by Delegated Admin Rights and Delegated Admin Resource Rights. Previous configurations are converted to the new configuration definitions by the update tool when the server is updated.</p>
DS-38021	<p>Updated create-initial-proxy-config to change the load-balancing configuration that it generates.</p> <p>Previously, the tool generated a fewest operations load-balancing configuration for all operations. While this may provide the best overall performance throughput, it increases the risk of replication conflicts, unique attribute conflicts, and application issues resulting from replication latency.</p> <p>The tool now generates a criteria-based load-balancing configuration that uses a failover strategy for writes and fewest operations for reads. This ensures that under normal circumstances when all servers are available, all write requests will go to the same server, which eliminates the change for replication conflicts or unique attribute conflicts. When paired with a corresponding change in the Directory Server to use assured replication by default for all add, delete, and modify DN operations, as well as for all modify operations that involve passwords or certain password policy state attributes, the risk of read-after-write issues resulting from replication latency is also dramatically reduced, so it is therefore safe to continue using a fewest operations load-balancing algorithm for read operations.</p>
DS-38050	<p>Updated the server to support encrypting the contents of the PIN files needed to unlock certificate key and trust stores. If data encryption is enabled during setup, then the default PIN files will automatically be encrypted.</p> <p>Also, updated the command-line tool framework so that the tools.properties file (which can provide default values for arguments not provided on the command line), and passphrase files (for example, used to hold the bind password) can be encrypted.</p>
DS-38072	<p>Updated the server to enable TLSv1.3 by default on JVMs that support it (Java 11 and higher).</p>

Ticket ID	Description
DS-38085	Fixed an issue in the installer where the Administrative Console's trust store type would be incorrectly set if it differed from the key store type.
DS-38090,DS-38564,DS-38567	The response header used for correlation IDs may now be set at the HTTP Servlet Extension level using the correlation-id-response-header configuration property. If set, this property overrides the HTTP Connection Handler's correlation-id-response-header property.
DS-38109	Added the --skipHostnameCheck command line option to the setup script, which bypasses validation of the provided host name for the server.
DS-38176	Reduced the default max-connection-age value in LDAP External Server configuration objects to 10 minutes. This should avoid the problems created when firewalls between the proxy and the external server silently close connections that have been open for too long.
DS-38403	Fixed an issue that could prevent certain types of initialization failures from appearing in the server error log by default.
DS-38421	Updated the file retention recurring task to no longer log an informational message if there are no log matching files to delete.
DS-38512	Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a secret passphrase obtained from a HashiCorp Vault instance.
DS-38550	Fixed an issue in which backups of the encryption settings database could be encrypted with a key from the encryption settings database.
DS-38670	Fixed a bug where the startIndex value for SCIM requests would be incorrect if the used LDAPSearch element had more than one baseDN defined in the scim-resources XML file.
DS-38737	Fixed an issue where inter-server bind requests would fail if the cipher used reported a maximum unencrypted block size of 0.
DS-38849	Added an indent-ldap-filter tool that can make it easier to visualize the structure and components of a complex search filter.

Ticket ID	Description
DS-38864	Changed the default value of the HTTP Configuration property include-stack-traces-in-error-pages from 'true' to 'false'. Disabling this property prevents information about exceptions thrown by servlet or web application extensions from being revealed in HTTP error responses.
DS-38873	Internal connections created by HTTP requests are now associated with one of the configured client connection policies. A client connection policy may be selected using simple client connection criteria matching the client address, the user performing the request, and the protocol "HTTP/1.1". This change affects the following HTTP interfaces: SCIM, Directory REST API, Consent API and Delegated Admin API.

Ticket ID	Description
DS-38897,DS-38908	<p>Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.</p> <p>* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.</p> <p>* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.</p> <p>In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.</p> <p>We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.</p>

Ticket ID	Description
DS-38913	Added a set of message types to Trace Log Publishers that records events related to access token validation.
DS-38957	Fixed an issue that would throw an exception when trying to delete an entry containing uncached attributes if the LDAP changelog was enabled and using reversible form.
DS-39086	Removed the version information page from the docs/build-info.txt endpoint. This information is now available in build-info.txt, which is located in the root directory.

PingDirectoryProxy Server 7.2.1.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Proxy Server

- To ensure correct search results with Delegated Admin, disable client caching by updating the Delegated Admin HTTP Servlet Extension to return response headers, and then stop and restart the server, as follows:

```
dsconfig set-http-servlet-extension-prop --extension-name "Delegated Admin" --set "response-header:Cache-Control: no-cache, no-store, must-revalidate" --set "response-header:Expires: 0" --set "response-header:Pragma: no-cache"
```

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server:

Ticket ID	Description
DS-37960	The Delegated Admin configuration has changed significantly. Delegated Admin Resource Types were removed and replaced by REST Resource Types. Delegated Administrators and Delegated Group Administrators were removed and replaced by Delegated Admin Rights and Delegated Admin Resource Rights. Previous configurations are converted to the new configuration definitions by the update tool when the server is updated.

Ticket ID	Description
DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:</p> <ul style="list-style-type: none"> - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections. - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
DS-38335	<p>The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.</p>
DS-38344	<p>The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.</p>

PingDirectoryProxy Server 7.2.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the Directory Proxy Server

- The Delegated Admin web app now supports creation of new users. Installations created using older versions of the install script require a command like the following to be run after upgrade. The 'sn' attribute is a required attribute for inetOrgPerson entries.

```
dsconfig create-delegated-admin-attribute --type-name users --attribute-type sn --set "display-name:Last Name"
```

To enable user creation, one of the new configuration properties org-entry-dn or org-search-filter must be set on the Delegated Admin resource type.

What's New

These are new features for this release of the Directory Proxy Server

- Introduced a Directory REST API to create, read, update and delete (CRUD) any object in the directory using JSON over HTTP. Compared to the SCIM-based Identity Access API (introduced in 4.0), the Directory REST API offers more capability without the configuration overhead and SCIM protocol limitations.
- Improved user and group management in the delegated user administration web app (packaged separately.) Administrators can configure the presentation order and groupings of profile attributes, improving delegated admin usability for large user profiles. Also, delegated admins can now create new users, and add and remove entire sub-groups of users to and from groups.

- Added support for Oracle Java JDK 11 and OpenJDK 11. Added support for RedHat 7.5, CentOS 7.5, and Ubuntu 18.04 LTS. <p> When running on JDK 11, we now configure G1GC as the default garbage collection algorithm. This eliminates long garbage collection pauses in most environments.
- Improved event tracing across coordinating HTTP and directory servers. For example, admins can now trace requests to HTTP-based services, like the Directory REST API, through the log files to the LDAP access log of the Directory Server. All HTTP-based services (e.g. SCIM, Consent API) can be configured to accept and/or generate HTTP request headers with correlation identifiers. These identifiers are logged in trace logs, HTTP access logs, and LDAP access logs.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Proxy Server

- There are known issues when running the server with Java 11.0.0. These are addressed in Java 11.0.1. In general, when using Java 11, we recommend using the latest available release.
- The Identity Access API has been deprecated and will not be supported in the next major release.
- On Microsoft Windows systems, JVM arguments for verbose GC logging do not work as expected. So these arguments are not added to any of the server or client tools.

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server:

Ticket ID	Description
DS-1132	Updated the server to allow delaying the response to failed bind operations by a specified length of time. While the response is delayed, no other operations will be allowed on the connection. This can be used instead of, or in addition to, account lockout as a means of limiting the rate at which an attacker may try to guess user passwords.
DS-6930	To facilitate testing in multiple GC (garbage collection) environments, GC JVM options having been moved to separate Java properties in the java.properties file. The new ".gc-type" suffix will select the GC type to use, and the new ".gc-<GC type>-args" suffix will have the JVM options for that GC type.
DS-35567	Updated the server to expose information about the duration of lengthy phases of server startup. The longest phases are logged to the error log and more detail is provided in the "cn=Startup Phase Times,cn=monitor" monitor entry. Starting the server with the --verbose option will show fine-grained timing information for all phases of server startup.

Ticket ID	Description
DS-35652,DS-36559	<p>Added support for a new file retention task that can identify files in an indicated directory that match a given pattern and remove any matching files that fall outside of the specified retention criteria. You can specify the minimum number of files that should be retained, the minimum age of files that should be retained, the minimum aggregate size of files that should be retained, or any combination thereof. The files that match the pattern will be sorted by timestamp so that if any files are to be removed, the most recent files will be retained and the oldest files will be deleted.</p> <p>The file retention task can be scheduled as a standalone task or as a recurring task. Two instances of the file retention recurring task have been defined in the default configuration: one that can clean up old expensive operation dump files, and another that can clean up old work queue backlog thread dump files. In each case, the recurring task is configured to keep at least the 100 most recent files, and no files less than 30 days old will be removed. While these recurring tasks are defined in the out-of-the-box configuration, they are not part of any recurring task chain and therefore will not actually be invoked unless they are configured as part of a chain.</p> <p>The Directory Server and Directory Proxy Server now include recurring tasks in the out-of-the-box configuration that can clean up old expensive operation dump log files or work queue backlog thread dump log files if too many of them have collected in the server logs directory. For each type of file, if there are more than 100 of them in the server logs directory, then any of the remaining files that are more than 30 days old are candidates for removal. A recurring task chain will perform this cleanup every day at 12:05 a.m. in the JVM's default time zone.</p>
DS-35865	<p>Multiple instances of the SCIM HTTP Servlet Extension may now be created, allowing for multiple SCIM 1.1 service configurations per server instance. For more information, please refer to the "Managing the SCIM Servlet Extension" chapter of the Administration Guide.</p>

Ticket ID	Description
DS-35873	<p>Added support for an exec task that can invoke commands on the server. There are several safeguards in place to prevent unauthorized users from invoking arbitrary commands on the server system, including a new exec-task privilege and a whitelist file that must be updated to include the absolute paths of the allowed commands. A new schedule-exec-task tool helps create an exec task from the command line, and the LDAP SDK has also been updated to allow interacting with exec tasks programmatically.</p>
DS-35873	<p>Added support for recurring exec tasks.</p>
DS-35909	<p>HTTP Connection Handlers will now raise an alarm during initialization if a context path conflict is detected.</p>
DS-36023,DS-37686	<p>A new --topologyFilePath argument has been added to remove-defunct-server, making it possible to remove a defunct server cleanly from the topology using one of the servers in the provided topology file. The topology file may be obtained by running the manage-topology export command.</p>
DS-36209	<p>A header containing a correlation ID is now added to outgoing HTTP servlet responses, allowing HTTP responses to be correlated with log messages across server instances. The name of the correlation ID response header defaults to "Correlation-Id" but may be changed by setting the HTTP Connection Handler's correlation-id-response-header property. By default, the server will generate a globally unique correlation ID automatically, but the correlation-id-request-header configuration property may be used to optionally specify one or more request headers that provide an existing correlation ID value from the requesting client. The correlation ID header can be disabled on a per-HTTP Connection Handler basis using the use-correlation-id-header configuration property.</p> <p>For Server SDK extensions that have access to the current HttpServletRequest, the correlation ID can be retrieved as a String via the HttpServletRequest's "com.pingidentity.pingdata.correlation_id" attribute. For example: <code>(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");</code></p>

Ticket ID	Description
DS-36433	<p>Added a Mock Access Token Validator, which accepts access tokens without validating the authenticity of the tokens using a trusted authorization server or signing certificate. When enabled, a Mock Access Token Validator accepts bearer tokens in the form of a plain text JSON object containing an arbitrary set of claims. Mock Access Token Validators are intended for test or demonstration use only and should never be enabled in production deployments or used to access sensitive data.</p>
DS-36510	<p>Added support for a delay task, which can be used on its own or as a recurring task. It is primarily intended to be used as a spacer between other tasks, and can sleep for a specified period of time, wait for the server to be idle (that is, there are no outstanding operations and all worker threads are idle), or wait for sets of search criteria to match at least one entry (for example, until a monitor entry indicates that the server is in a desired state).</p>
DS-36519	<p>Bearer token authentication for the Consent API may now be enabled or disabled using the bearer-token-auth-enabled property of the Consent HTTP Servlet Extension.</p>
DS-36585	<p>Updated the client connection policy configuration to add a maximum-concurrent-operations-per-connection-exceeded-behavior property that specifies the behavior that the server should exhibit if a client tries to exceed the limit set by the maximum-concurrent-operations-per-connection property. Previously, any requests in excess of the maximum-concurrent-operations-per-connection limit would have been rejected with a busy result. The server now offers additional choices for the result code to use when rejecting requests (including admin limit exceeded, constraint violation, unavailable, unwilling to perform, or other), and the server can also be configured to close the connection and abandon all outstanding operations on that connection.</p>

Ticket ID	Description
DS-36595	<p>Updated the fewest operations load-balancing algorithm configuration to add a <code>balance-requests-across-servers-with-same-operation-count</code> property to specify the behavior the server should exhibit if there are multiple servers of equal preference with the same number of outstanding operations.</p> <p>By default, the property has a value of <code>true</code>, which means that if there are multiple servers that have the same number of operations in progress, then the load-balancing algorithm will randomize the order in which those servers are selected to more evenly spread the requests across those servers.</p> <p>If the property is changed to <code>false</code>, then the request will be sent to the first server encountered with the fewest number of operations. This will ensure that requests are routed more consistently, especially in environments with low utilization, but one server may handle a disproportionately high percentage of requests.</p>
DS-36674	<p>Updated the administrative alert health check to improve error handling and to add safeguards against the possibility of having too many active persistent searches to consume alerts from backend servers.</p>
DS-36834	<p>All tools will now enforce a minimum heap size requirement. Overriding the heap size for the system, using the <code>--maxHeapSize</code> argument of the <code>dsjavaproperties</code> tool, is only effective if the provided value is greater than the minimum required heap size for the tool.</p>
DS-36988	<p>The SCIM v1 servlet extension is no longer enabled by default for new installations. Existing installations will be unaffected on an upgrade. Customers are encouraged to use the new "Directory REST API" for REST access from now on.</p>
DS-37131	<p>Fixed an issue in which the HTTP Servlet Config Monitor could cause an exception in an HTTP Servlet Extension when attempting to determine its context paths. This caused the status tool and the Administrative Console to potentially omit the HTTP Servlet Extension from the list of active HTTP extensions.</p>
DS-37153	<p>Fixed an uncommon issue where unsuccessful searches, with a base DN below the entry balancing point, would remove the data set from the global attribute index.</p>

Ticket ID	Description
DS-37255	Updated the Periodic Stats Logger to include columns for the average response time of operations sent to each LDAP external server.
DS-37492	Added a time limit retention policy to support removing log files older than a specified age.
DS-37660	Updated the Work Queue to increase the number of internal queues when num-queues is configured with the default of 0 (i.e., the server automatically determines the value). An internal queue is now created for every two worker threads rather than eight. This can reduce thread contention and increase throughput when under extreme load.
DS-37723	Added an optional "titleText" field to Consent API consent definition localization objects. This field may be used to store a localized title or summary for a consent request. A corresponding "titleText" field has also been added to consent record objects.

PingDirectoryProxy Server 7.0.1.0 Release Notes

What's New

These are new features for this release of PingDirectoryProxy Server

- New capabilities have been added to the Delegated Admin application (packaged separately). Now directory administrators can delegate the responsibility of managing group memberships for users in PingDirectory Server. Administrators can delegate to individuals or groups of users, and assign authority over one or more groups in PingDirectory Server.
- Improved the way PingDirectoryProxy Server distributes requests in the failover load-balancing configuration. This is especially helpful for multi-tenant environments to better distribute requests per tenant. Now you can configure a load-spreading base DN such that requests to DIT branches below the load-spreading base DN are balanced among the PingDirectory Servers. The proxy will automatically maintain affinity between servers and DIT branches.

Known Issues/Workarounds

The following are known issues in the current version of the Directory Proxy Server

- An ACI starting with "GENERATED D-ADMIN ACCESS" is generated automatically by the server from Delegated Admin configuration. Do not create your own custom ACI with the same prefix, for example by copying and pasting from the generated ACI. A custom ACI with this prefix will be deleted when the server is restarted, and whenever a Delegated Admin configuration change causes the Delegated Admin ACI to be regenerated.
- Servers to be monitored by the PingDataMetrics Server must have an instance name of less than 256 characters. A server's instance name is specified during setup.

Resolved Issues

The following issues have been resolved with this release of the Directory Proxy Server:

Ticket ID	Description
DS-17439	<p>Updated the failover load-balancing algorithm to add support for load spreading. By default, the failover load-balancing algorithm will consistently route all requests to the same server (subject to the health and location of each of the backend servers), which provides the highest level of protection against issues that may result from replication propagation delay. However, it also means that most of the servers are left idle, only to be used if a problem arises with the primary server.</p> <p>Load spreading allows the server to retain many of the consistent routing benefits of the failover load-balancing algorithm's default configuration while also taking better advantage of the available servers in the topology. If the failover load-balancing algorithm is configured with one or more load-spreading base DNs, then requests that target entries below a load-spreading base DN may be balanced across any of the servers with the same health check state and location. Requests targeting a specific portion of the data will consistently be routed to the same server, but requests targeting a different portion of the data may be sent to a different server.</p> <p>Load spreading is primarily beneficial to deployments in which the DIT contains a large number of branches below a common parent, and in which most operations (including search operations, as indicated by the search base DN) only target entries at least one level below that common parent. For example, this may be a good fit for a multi-tenant deployment in which all of the entries for a given tenant are within their own branch, and all of the tenant branches reside below a common parent.</p>

Ticket ID	Description
DS-36325	<p>Improved the behavior that the server exhibits under certain network conditions when it is not possible to write to a client without blocking. This includes:</p> <ul style="list-style-type: none"> * If the server cannot write data to a client after waiting for a length of time specified by the connection handler's max-blocked-write-time-limit configuration property, the access log message indicating that the client has been disconnected because of an I/O timeout will now more clearly indicate that the reason was the inability to write data to the client. * The server now limits the number of threads that can be blocked while trying to send data to the same client over the same client connection. If too many threads would have been blocked while trying to send data over the same connection, that connection will be terminated, and the disconnect access log message will include the reason for the disconnect. * If the server is trying to send data to the client that it considers optional (for example, certain types of unsolicited notifications), then the server may skip sending that optional data if the write would have caused the server thread to block.
DS-36642	<p>Added a configuration option to allow a null serverFQDN for the GSSAPI SASL mechanism to allow an unbound SASL server connection.</p>
DS-36814	<p>Fixed an issue in which an unprivileged Consent API client could modify the actor value of a consent record.</p>
DS-37021	<p>Delegated Admin operations now appear in the LDAP access log.</p>
DS-37132	<p>Changed Resource IDs produced by the Delegated Admin API so that they no longer contain percent characters from Base64 padding.</p>
DS-37141	<p>Updated the external server monitor entry to include a histogram of response times per operation type. This makes it easier to understand the source of response time outliers in the proxy.</p>
DS-37169	<p>Added a getRequestProcessors() method to the ProxyServerContext interface within the Server SDK. This can be used to gain access to an EntryBalancingRequestProcessor, and hence the global index.</p>

Ticket ID	Description
DS-37175	Updated the name of LDAP external server monitor entries to not include product version information, since this can affect integration with JMX monitoring tools.
DS-37235	<p>Updated the keys and values used in the monitoring JMX MBeans to conform with best practices. The keys "type" and "name" are now used in place of "Rdn1" and "Rdn2".</p> <p>To maintain backwards compatibility with existing monitoring solutions, installations upgrading to this release will retain the old behavior, but they can revert to the default behavior by changing the Global Configuration property <code>jmx-use-legacy-mbean-names</code> to false.</p>
DS-37292	The Notification Delivery Thread will now log unexpected errors rather than throwing them as exceptions.
DS-37362	Prevent a notification destination from assuming the master notification delivery role if that server is in lockdown mode or replication hasn't finished initialization.

PingDirectoryProxy Server 7.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDirectoryProxy Server

- This release introduces significant changes to the way servers in a topology are configured with information about each other. Once a server has been upgraded from a pre-7.0 version to 7.0 or later, reverting to the previous version is not supported. Before beginning the upgrade process, make sure you have read and understood the Administration Guide's chapter "Upgrading the Server".
- SCIM 2 error responses, including Config API error responses, now represent the "status" field as a JSON string rather than as a number. Clients written to expect the earlier version format will need to be updated. In particular, clients written using the SCIM 2 SDK for Java should upgrade to version 2.2.0 or higher.
- The Administrative Console now uses server information found in the topology registry to populate its server selection control. If the Console is used to manage a legacy server that does not use the topology registry, then the server selection control will not be populated. To manage a different server, the administrator will need to log out of the Console and provide the other server's connection details from the login page.

What's New

These are new features for this release of PingDirectoryProxy Server

- Simplified management tasks related to configuring servers in a large cluster topology or in an automated deployment. Most notably, servers can now be added to a cluster while other servers are offline.
- Added management features for SSL/TLS certificates. The default certificates used in inter-server replication can be replaced; validation of client certificates for HTTPS-based services like the SCIM

REST API can be configured; and you can reload from the trust store for HTTPS client certificates without restarting the server or the HTTP-based services.

- Added support for these operating system versions: Ubuntu LTS 16.04, CentOS 7.4, RedHat Linux 7.4, SUSE Enterprise 12 SP3

Known Issues/Workarounds

The following are known issues in the current version of PingDirectoryProxy Server:

- Simultaneous cloning multiple PingDirectoryProxy Servers, PingDataSync Servers, and PingDataGovernance Servers from another server of the same type is not currently possible. To create server instances that are identical to a master server, cloning must be performed one at a time.

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-426	Added the ability to generate administrative alert notifications when a task starts running, when it completes successfully, or when it fails to complete successfully. Also added the ability to send an email message to a specified set of users when a task starts running or completes successfully, which complements the existing ability to send an email message when a task fails to complete successfully or when it completes with any state, regardless of success or failure.
DS-426	Added support for recurring tasks, which can be used to automatically invoke certain kinds of administrative tasks based on a specified schedule. At present, only certain kinds of tasks can be scheduled as recurring tasks. This includes both backups and LDIF exports, each of which provides retention support to limit the amount of disk space that the backups and LDIF files consume. It also includes support for any kind of task in which each instance of the task should use exactly the same values for all of the task-specific attributes. The Server SDK also provides an API for creating custom third-party recurring task implementations.
DS-4406	Implemented invocation logging for several server tools, which will write to logs/tools/tool-invocation.log by default upon startup and shutdown. Some of the information recorded by log entries include the tool's start and completion times, the command-line arguments used to initialize them, and the name of the system account used to launch the tool. To modify this behavior, edit the config/tool-invocation-logging.properties file.

Ticket ID	Description
DS-4570,DS-14281,DS-14282,DS-14283,DS-14284,DS-17197,DS-17366	The admin backend and the tool used to manage it, dsframework, have been replaced by the topology registry and dsconfig, respectively. The topology registry is automatically mirrored across all servers in the topology, so administrative information is kept in-sync on all servers at all times.
DS-6970	Added support for encrypted logging, using a key generated from an encryption settings definition. Encrypted log files may be decrypted with the encrypt-file tool.

Ticket ID	Description
DS-12157,DS-35896	<p>Made a number of improvements to backend backup and restore, and to LDIF export and import:</p> <ul style="list-style-type: none"> * Added the ability to encrypt backups and LDIF exports with a key generated from a user-supplied passphrase or with a key generated from an encryption settings definition. Previously, encrypted backups and LDIF exports only used a secret key that was known only to servers within the replication topology. The new options make it easier to restore encrypted backups and import encrypted LDIF files in servers outside of the replication topology. The encrypt-file utility can be used to decrypt encrypted backups and LDIF exports, regardless of how the encryption key was obtained. * Added the ability to limit the rate at which backups and LDIF exports will be written to disk, which can help avoid performance problems that result from these operations saturating the disk subsystem. * Added new global configuration properties for automatically encrypting backups and LDIF exports by default, which will be set to true if data encryption is enabled during setup. * Added new global configuration properties that can specify which encryption settings definitions will be used to obtain the encryption keys for automatically encrypted backups and LDIF exports. If not specified, then the server will use its preferred encryption settings definition, or an internal topology key if no encryption settings definitions are available. * Added a new configuration property for automatically compressing encrypted LDIF exports. * Updated the backup tool to add new --promptForEncryptionPassphrase, --encryptionPassphraseFile, and --encryptionSettingsDefinitionID arguments that can be used to specify which key to use for encrypting the backup. Added a new --doNotEncrypt argument that can be used to force a backup to be unencrypted even if automatic encryption is enabled. Added a new --maxMegabytesPerSecond argument that can be used to impose a limit on the rate at which the backup may be written to disk. * Updated the restore tool to add new --promptForEncryptionPassphrase and --encryptionPassphraseFile arguments that can be used to provide a user-supplied passphrase for use in accessing the contents of an encrypted backup. For backups encrypted with an encryption settings definition or an internal topology key, the server will automatically be able to determine the correct key. * Updated the export-ldif tool to add new --promptForEncryptionPassphrase, --encryptionPassphraseFile, and --encryptionSettingsDefinitionID arguments that can

Ticket ID	Description
DS-15223,DS-35895	<p>Added the ability to configure data encryption during setup using a randomly generated key, a key generated from a user-supplied passphrase, or a key obtained from an export of another server's encryption settings database. When setting up multiple instances, providing the same encryption passphrase to each instance will ensure that all instances have the same encryption key.</p> <p>The encryption-settings tool has also been updated to allow creating encryption settings definitions from a passphrase, to allow providing a description when creating a new encryption settings definition, and to record a create timestamp for new definitions. It is now possible to create ciphers that use the Galois Counter Mode (GCM) cipher mode (for example, using a cipher transformation of "AES/GCM/PKCS5Padding") for authenticated encryption. Definitions created with with just a cipher algorithm but no transformation will now use stronger settings.</p> <p>The default encryption settings export format now provides stronger encryption. Newer server instances should be able to import encryption settings exported from other servers without issue. When exporting encryption settings for import into older servers, use the new --use-legacy-export-format argument.</p>
DS-16508	<p>Updated the dsconfig list subcommands to list objects of all complexity levels rather than requiring the --advanced flag to list advanced and expert objects.</p>
DS-17176	<p>Updated the entry balancing request processor's handling of add operations within an atomic multi-update extended operation. Now, backend servers are not searched for a pre-existing entry if the parent entry was already found to not exist while processing the multi-update request. This eliminates some redundant searches, which reduces the load on the backend servers.</p>
DS-17883	<p>Added an ldap-debugger tool that acts as a simple LDAP proxy between a client and a directory server and decodes all requests and responses that pass through it.</p>
DS-17891	<p>Added a new manage-certificates tool that can be used to perform a number of functions related to TLS certificate management.</p>

Ticket ID	Description
DS-18204	Fixed a defect where a web application extension's base context path could be set to "/" with no name.
DS-35523	The update tool now enforces specification of a new product license when updating to a new major version. The license can be specified using the --licenseKeyFile command-line options, or by copying the license file to the top-level directory of the server package used to perform the update. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html , or contact sales@pingidentity.com .
DS-35536	Support for the IBM JDK has been retired.
DS-35576	Updated the JMX connection handler's monitor provider so that when a JMX connection is closed, it is removed from the list of established connections. After a JMX client disconnects, it may take the server a few minutes to detect the closure and update the monitor.
DS-35581	Updated the server to include an instance of the Periodic Stats Logger Plugin that is enabled out-of-the-box to aid in diagnosing support issues. The "Historical Stats Logger" plugin will log performance statistics to logs/monitor-history/historical-dsstats.csv every five minutes. This works in concert with the "Monitor History" plugin, which logs the full contents of cn=monitor to logs/monitor-history every five minutes. The tail of this csv file is automatically included in the output generated by collect-support-data.
DS-35583	Fixed a defect where configuring a Directory server on a Windows machine with a space in the home directory pathname would cause server setup to fail.

Ticket ID	Description
DS-35596	<p>Updated the Directory Proxy Server to improve performance when detecting that a server has become unavailable, especially when communication is secured with TLS and TLS negotiation is stalled.</p> <p>Also added a new health-check-connect-timeout configuration property for LDAP external servers. This property can be used to specify a shorter timeout when connecting to a server for the purpose of evaluating the health of the server than when creating a connection that will be used to forward client requests to that server. If a health-check-connect-timeout value is not configured, then the Directory Proxy Server will continue to use the value of the connect-timeout property for health check connections as well as for connections used to process client requests.</p>
DS-35601	<p>Added a new Monitor Entry for SSL Cipher Suite and Protocol information. It is available under <code>cn=SSL Context,cn=monitor</code>.</p>
DS-35648	<p>Added a missing double-quote to <code>bat/transform-ldif.bat</code>, which prevented the command from being invoked successfully on Windows systems.</p>
DS-35697	<p>Fixed an issue in which the Directory Proxy Server did not set the correct response timeout for forwarded bind operations. If a backend server did not respond to a bind request, the Directory Proxy Server would have waited for up to five minutes before trying another server or returning an error response to the client.</p>
DS-35709	<p>Changed <code>enable-sub-operation-timer</code> on the Global Configuration to be true by default. This exposes operation timing information in the Sub-Operation Timing Monitor and any Operation Timing Access Log Publishers that have been configured. Enabling this tracking has about a 3% impact on operation throughput and latency, which will not be noticeable in most deployments and is an acceptable tradeoff for understanding where operation processing time is spent. However, it can be explicitly set to false to turn this tracking off.</p>
DS-35727,DS-35728	<p>Updated setup to include key usage, extended key usage, and subject alternative name extensions in the self-signed certificates that it generates.</p>

Ticket ID	Description
DS-35750	Added support for multiple client connection policies for sensitive attributes. Support for different sensitive attributes per client requires the use of multiple client connection policies with the same names on the Directory Server and the Proxy Server. When a client request is processed by a Proxy Server, the Directory Server looks for a policy in its own configuration with the same name as the one in the Proxy Server. The Directory Server then uses this policy rather than the one associated with the Proxy Server's connection.
DS-35868	The create-systemd-script command now suggests placing the script created in "/etc/systemd/system."
DS-35990	Provided the means to request that the server dynamically reload the certificate key and trust stores used by all HTTP connection handler instances that provide support for HTTPS. The request can be made using a new reload HTTP connection handler certificates task, the reload-http-connection-handler-certificates tool, or programmatically from a Server SDK extension using the <code>ServerContext#reloadHTTPConnectionHandlerCertificates</code> method.
DS-36025	Added a close-connections-when-unavailable property to the LDAP Connection Handler configuration. This allows a connection handler to be closed whenever the server sets an unavailable alert type, such as when backend data is unavailable. This should trigger clients to failover to another server. When the unavailable alert type is cleared, the connection handler is started again. When using this configuration setting, we recommend using two connection handlers: one for client traffic, with this option set to true, and one for administration and monitoring, with this option set to false. This allows the server to be visible to administrators but not to clients.
DS-36054	Added an encrypt-file tool that can encrypt and decrypt data with a user-supplied passphrase, an encryption settings definition, or a topology key shared among server instances. It includes support for decrypting the content in encrypted backups, LDIF exports, and log files.
DS-36070	Fixed an issue with compressed logging that could leave some data buffered in memory and not actually written out to disk until the logger is closed.

Ticket ID	Description
DS-36075	Updated tools that interact with log or LDIF files to support reading from input files that are compressed and encrypted and writing to compressed and encrypted output files.
DS-36088	In addition to specifying an exact set of desired cipher suites for the LDAP and HTTP Connection Handlers, administrators can now specify inclusions to, or exclusions from, the set of cipher suites selected by the server.
DS-36093	Added support for TLS1.2 with STARTTLS to connect to an SMTP server.
DS-36093	Added support for TLS1.2 with STARTTLS to connect to SMTP server
DS-36230	Improved the server's handling of DN's and RDN's that contain characters whose UTF-8 encodings require more than two bytes.
DS-36315	Updated the Directory Proxy Server so that if it encounters a problem while trying to follow a referral on behalf of the client (for example, if it can't establish a connection to the server indicated in the referral), it will include additional information about the failure in the access log message for that operation.
DS-36328	Updated the server to reduce contention when converting between strings and the bytes that comprise those strings.
DS-36360	Increased the default size of the queue used to hold alert notifications so they can be asynchronously processed by a background thread. This makes it less likely that the queue will become full if many alerts are generated in a short period of time, which would cause subsequent attempts to generate alerts to block while the server catches up. Also updated the server to log a message when the queue becomes full so that administrators will be aware of the problem and will have suggestions for addressing it.
DS-36377	Fixed an issue where a configuration change to enable a Delegated Administrator could be incorrectly rejected after a configuration change to the parent Delegated Admin Resource Type.

Ticket ID	Description
DS-36455	Updated the proxy server to discard a connection whenever an operation times out rather than reusing it. A new connection is then established. This avoids a cascading error condition when a network problem allows traffic from the proxy server to the directory server but not the reverse.
DS-36545	Added a sanitize option to the Monitor History Plugin that, if enabled, will redact the small amount of potentially personally identifiable information that could appear in search filters and LDAP DNs within the monitor. This makes it easier to share the monitor history files with the support team in secure environments.

PingDirectoryProxy Server 6.2.0.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDirectoryProxy Server:

Ticket ID	Description
DS-811	Added an optional reason parameter for dsconfig changes that will be automatically included in the server's config-audit.log file.
DS-1029	The server now monitors important certificates used for client and inter-server communication. Certificate information is available in the Administrative Console and in the status tool output. An alarm is raised and alerts are sent when a monitored certificate is 30 days from expiration.

Ticket ID	Description
DS-2074	<p>Updated the installer to discourage the use of weak root passwords.</p> <p>When run in interactive mode, setup will display a list of password quality recommendations before prompting for the initial root password, suggesting that it should be at least 12 characters long, should not be contained in a dictionary of English words, and should not be contained in a dictionary of commonly-used passwords. If the proposed password does not meet these constraints, then the user will be given the option of proceeding with the provided weak password or choosing a different password.</p> <p>When run in non-interactive mode, setup will exit with an error if the proposed initial root password does not satisfy the above constraints, unless the command line also includes the --allowWeakRootUserPassword argument.</p> <p>In either mode, when a strong initial root password is supplied, setup will also configure the root users' password policy to ensure that subsequent root user passwords will also be required to satisfy these constraints.</p>
DS-4161	<p>Updated PingDirectory Server, PingDirectoryProxy Server, PingDataSync, and PingDataGovernance with the capability to run as Windows Services.</p>
DS-10694	<p>Updated the Server SDK to provide methods for obtaining a single LDAP connection or an LDAP connection pool with connections established to a specified LDAP external server defined in the server configuration.</p> <p>Also updated the server configuration to add support for obscured values. An obscured value is a general-purpose string that is stored in an obscured form in the configuration so that its plaintext value is not readily discernible to anyone looking at the configuration file and so that the value is not displayed in administrative interfaces. The Server SDK provides a method for obtaining the plaintext representation of an obscured value, and this mechanism can be used to store potentially sensitive values in the configuration for use in Server SDK extensions without the need to store those values in the clear.</p>
DS-10748	<p>Added configuration options for setting the SSL Protocol and/or the SSL Cipher Suites to the HTTPS Connection Handler.</p>

Ticket ID	Description
DS-11217	The Globally-Unique Attribute Plugin has a new multiple-attribute behavior option named "unique-in-combination." When selected, this option ensures the uniqueness of combinations of values for the configured attributes. For example, if no two users may have the same value for both givenName and sn, but users may have the same givenName or the same sn, use unique-in-combination.
DS-12520	Updated the Server SDK to include an example plugin that enforces that values of a specified JSON field are unique across entries or across multiple values within the same entry. The plugin can be used in either the Directory Server (for cases in which each server contains a complete copy of the data) or the Directory Proxy Server (for cases in which the data is spread across multiple servers, like when using entry balancing).
DS-13721	Corrected the port number returned in the error message that is displayed when an administrator is trying to set up a server that is already running.
DS-14650	Enhanced the HTTPS Connection Handler to send a HTTP Strict Transport Security header by default in all responses.
DS-15861, DS-15862	Replaced the ldapsearch and ldapmodify tools with new versions. The new versions are backward-compatible, but offer a number of new features, including better connection handling, better output formatting, better support for bulk operations, support for referrals, support for additional request and response controls, and rate limiting. The ldapsearch tool now offers the ability to output results in JSON, CSV, or tab-delimited text as an alternative to LDIF, and provides support for a number of data transformations. The ldapmodify tool now supports the LDIF control syntax, as well as writing to output and reject files.
DS-15871	Improved support for password modify extended requests processed through the Directory Proxy Server. Those operations will now be processed more reliably and the results will be more consistent with the results obtained from sending the requests directly to a Directory Server instance.

Ticket ID	Description
DS-16361	<p>Updated the server to fix a problem with the way that DNs containing hex-encoded RDN values are treated, which could cause the server to accept certain incorrectly encoded DNs, to incorrectly store DNs provided with hex encoding, and to fail to identify the correct DN when using a non-hex-encoded DN to reference a DN that was stored with a hex-encoded representation or when using a hex-encoded DN to reference a DN that was stored with a non-hex-encoded representation.</p> <p>Using hexadecimal encoding in DNs is very rare in practice, so this should have no effect on most deployments. However, any deployments that contain entries stored with hex-encoded DNs, whether used in the DN of the entry or as a value for an indexed attribute with a DN syntax, may need to export that data before performing an update and re-import that data after the update has completed.</p>
DS-16405	<p>The SNMP context name for the server can now be configured using the new context-name property of the SNMP Subagent Plugin. The server instance name remains the default context name when this property is not set.</p>
DS-16509	<p>Updated the access and audit loggers so that, when logging information about an internal operation that was triggered by an external client request, the log message will include the connection and operation ID for that request. Also updated the error logger so that when logging a message from a thread that is actively processing an operation, the log message will include the connection and operation ID for that operation.</p>
DS-16593	<p>Fixed an issue where incorrect names were displayed in the usage for the start scripts.</p>
DS-16789	<p>The script files used to stop and start the server have been renamed stop-server and start-server. The older scripts are still present but may be removed in a future release of the product.</p>
DS-16858	<p>The modifierName and modifyTimestamp attributes are now updated when offline configuration changes are made.</p>
DS-16906	<p>Added a disabled-alert-type configuration property to the Alert Backend that can be used to suppress specific alert types from being added to the backend.</p>

Ticket ID	Description
DS-17002	<p>Updated support for the UNBOUNDID-MS-CHAP-V2 SASL mechanism to make it easier for an intermediate application to support delegating MS-CHAPv2 authentication to the Directory Server. This includes:</p> <ul style="list-style-type: none"> ▪ The client SDK has been updated to make it easier to issue separate bind requests for each phase of the two-step authentication process. Previously, the API only exposed a single bind request that would perform both stages of the process. ▪ A new "proxied MS-CHAPv2 details" request control has been provided, which can be used to allow an intermediate application acting as an MS-CHAPv2 server to generate its own server challenge rather than obtaining one from the Directory Server. ▪ The client SDK has been updated to improve the javadoc documentation. A number of examples are included to demonstrate the process of using the SDK to authenticate with the UNBOUNDID-MS-CHAP-V2 mechanism. The README file has also been updated with instructions for enabling server-side support for the UNBOUNDID-MS-CHAP-V2 mechanism.
DS-17008	Fixed an issue that could impede the timely replication of subtree-delete requests contained in a transaction.
DS-17019	The server now requires Java version 8.
DS-17078	Updated a couple of cases where filtered SCIM searches for groups with missing members were not returned.
DS-17080	Improved error reporting for the manage-extensions tool.

Ticket ID	Description
DS-17146	<p>Updated the logic used to select which TLS cipher suites should be enabled by default, and the logic used to prioritize those cipher suites. The selection process has been updated to use the guidelines provided in the OWASP "Transport Layer Protection Cheat Sheet" document.</p> <p>Some of the changes include:</p> <ul style="list-style-type: none"> ▪ The server already preferred cipher suites that support forward secrecy over those that do not. It now prefers DHE over ECDHE, and avoids suites that use non-RSA keys. ▪ The server already avoided cipher suites that used known-weak cryptographic weaknesses, including null encryption, the RC4 symmetric cipher, and the MD5 digest algorithm. It now also avoids anonymous encryption, the single-DES symmetric cipher, the IDEA symmetric cipher, and any suite using export-level encryption. ▪ The server now prefers cipher suites that use the Galois/Counter Mode (GCM) over the Cipher Block Chaining (CBC) mode. ▪ The server now prefers AES-based cipher suites with 256-bit keys over those that use 128-bit keys. For suites with equivalent key sizes, it prefers suites with a stronger message digest algorithm over suites with a weaker digest algorithm (e.g., SHA384 over SHA256 over SHA). ▪ The server now provides better support for selecting and prioritizing ciphers when running on the IBM JVM. The IBM JVM uses somewhat different naming for its cipher suites than the Oracle implementation, which previously allowed certain desirable suites to not be included in the selected set.
DS-17241	<p>The Administrative Console is no longer compatible with older versions of the server.</p>

Ticket ID	Description
DS-17243	<p>Added support for a uniqueness request control, which can be included in an add, modify, or modify DN request to indicate that the server should attempt to identify any conflicts that the requested operation might introduce with one or more other entries that exist within the directory topology.</p> <p>Criteria for identifying conflicts can be specified with one or more attribute types, with a search filter, or both. If the uniqueness criteria includes multiple attribute types, then a multiple attribute behavior can be used to indicate whether to enforce uniqueness separately for each attribute type, to prevent conflicts across any of the specified attribute types, or to ensure that each entry has a unique combination of the values of those attributes.</p> <p>The server can perform pre-commit validation, in which case it will reject the request without applying any changes if it detects that it would have introduced a conflict, and it can also perform post-commit validation, where it can detect conflicts that may have arisen after changes were applied (for example, because of another change being processed at the same time on a different server). When attached to a request sent through the PingDirectoryProxy Server, the uniqueness request control may include pre-commit and post-commit validation levels to indicate how thoroughly it should work to identify conflicts (for example, to perform the search in a single backend server, in at least one server in each backend set, or in all available backend servers).</p> <p>The control can also include a base DN that can be used to narrow the scope of conflict detection (for example, to ensure that there will not be any conflicts within one particular branch, while ignoring conflicts with entries that might exist elsewhere in the DIT), and it can detect or ignore conflicts with soft-deleted entries. Multiple uniqueness controls can be included in the same request if multiple uniqueness constraints should be enforced.</p>
DS-17318	<p>Removed the default root password from the out-of-the-box configuration. This password was never actually used because it was replaced by the user-supplied password provided when running setup, and it has been removed for additional security.</p>

Ticket ID	Description
DS-17444	<p>Updated the server to reduce the use of the SHA-1 message digest. The server will now use a 256-bit SHA-2 digest instead of a SHA-1 digest in all of the following cases:</p> <ul style="list-style-type: none"> ▪ When hashing or signing a backup. ▪ When signing an LDIF export. ▪ When signing log data. ▪ When generating MACs for an encrypted collect-support-data archive. ▪ When generating unique identifiers for encryption settings definitions. ▪ When determining whether the configuration changed with the server offline. <p>In all of the above cases, the server includes metadata in the output of the cryptographic processing to indicate the digest or MAC algorithm used for that processing, which ensures that the output remains compatible across server versions. For example, an LDIF export that uses a signature generated with the SHA-2 digest can be successfully imported into older versions of the server.</p> <p>Also, the fingerprint certificate mapper has been updated so that it can use the 256-bit SHA-2 digest when mapping a client certificate to the corresponding user entry. The previous MD5 and SHA-1 digests remain supported.</p> <p>Finally, the example enhanced password storage scheme provided with the UnboundID Server SDK has been updated so that it uses the 256-bit SHA-2 digest instead of a SHA-1 digest.</p>
DS-17463	<p>Updated the Admin Alerts Health Check to tolerate an incorrect LDAP result code returned by Active Directory when testing for the existence of cn=alerts. With this change, having use-for-all-servers=true configured on the Admin Alerts Health Check will no longer cause Active Directory servers to be flagged as UNAVAILABLE.</p>
DS-17544	<p>The Administrative Console can be deployed in an external web container, such as Tomcat, using the contents of resource/admin-console.zip, located in the server root.</p>
DS-17576	<p>Updated the Server SDK's ServerContext to expose a ValueConstructor, which can be used to build String values using a value-pattern template that references attribute values within an Entry. See the Javadoc for the ValueConstructor class with the Server SDK packaging for more information.</p>

Ticket ID	Description
DS-17606	Fixed an issue in the fingerprint, subject attribute to user attribute, and subject DN to user attribute certificate mappers. When configured for use in processing SASL EXTERNAL bind requests, these certificate mappers would return the target user entry without any operational attributes. This could cause the server to behave incorrectly for any user-specific functionality that depends on operational attributes to function properly. This problem did not affect the subject equals DN certificate mapper, nor any custom certificate mapper implemented with the Server SDK.
DS-17716	Addressed an issue where LDAP throughput and response time data were not available for tracked applications configured in the Directory Proxy Server. The problem occurred when the applications were identified by user entries stored in a Directory Server that was referenced by a proxying request processor where a value of 'true' was configured for the assign-client-connection-policy-from-backend-server setting.
DS-17880	Fixed an issue that could prevent an entry-balanced Directory Proxy Server from returning a get password policy state issues response control in response to a failed bind attempt. Also, updated the access logger to include additional details in FORWARD-FAILED messages, including matched DN, referral URLs, and response controls.
DS-17968	Limited the ACI search on collect support data tool to only pull 100 entries. This will reduce the time the tool takes to run for organizations with a large number of ACIs.
DS-18016	Added support for the X-Forwarded-Prefix header to override the context path of operations processed by Http Servlet Extensions.

Ticket ID	Description
DS-18018	<p>Added support for the password update behavior request control, which allows requesters with the password-reset privilege to override certain behaviors that the server would normally exhibit when setting a user's password. The control can be included in an add request, modify request, or password modify extended request and can be used to override the server's normal behavior for any or all of the following:</p> <ul style="list-style-type: none"> ▪ Whether the password update is a self change or an administrative reset ▪ Whether to accept or reject pre-encoded passwords ▪ Whether to perform or skip password quality validation for the new password ▪ Whether to check to see if the new password matches the current password or any password in the user's history ▪ Whether to enforce or ignore the minimum password age constraint ▪ Which password storage scheme to use when encoding the new password ▪ Whether the user must be required to choose a new password before being permitted to request any other operations
DS-18100	<p>A license key is required when setting up a server for the first time. Request a license key through the Ping Identity licensing website https://www.pingidentity.com/en/account/request-license-key.html or contact sales@pingidentity.com.</p>
DS-18142	<p>Round-robin load-balancing algorithm has been deprecated. The fewest-operations load-balancing algorithm should be used instead since it utilizes a pool of servers more efficiently than a simple round-robin algorithm.</p>
DS-18185	<p>Addressed an issue in the Server SDK where internal searches performed by extensions could fail in entry balanced environments. An internal search listener was not properly synchronized and could become corrupted when accessed by multiple threads when doing a broadcast search.</p>
DS-18188	<p>Removed the ability to create custom HTTP trace loggers using the Server SDK.</p>
DS-35495	<p>Updated dsconfig batch mode to operate more efficiently over the WAN by consolidating the number of LDAP searches required to retrieve the full configuration when pre-validating configuration changes.</p>

PingDirectoryProxy Server 6.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the PingDirectoryProxy Server

- Note: The product names have been updated to reflect the UnboundID acquisition by Ping Identity. This is a naming and branding change only; the code base is the same as in prior releases and will continue to be maintained into the future.
- If upgrading the server that was running an older version of the JDK, run the `dsjavaproperties --initialize` command after the software upgrade to compare the settings of the older JDK with requirements for the new server software. Apply any necessary changes to the upgraded server based on previous performance settings.
- The 6.0 release makes these changes to supported platforms:
 - CentOS 7.2 and RedHat 7.2 are now supported operating system versions.
 - SUSE 11 SP4 is now supported; SUSE 11 SP2 support has been retired.
 - Linux KVM and VMWare ESXi 6.x have been added as supported virtual machine environments.
 - Deprecation of JDKs 7.x. Customers are strongly advised to use JDK 8 with this release. A later release of the platform will remove support for JDK versions 7.x. At that time customers will be required to upgrade to JDK 8.x when upgrading servers. This will apply to all of our JDK flavors (OpenJDK, OracleJDK, IBM JDK) on all platforms.
 - WildFly 9.x (renamed from JBoss) is now a supported application server for all web applications, including the Administrative Console and sample applications. Support for JBoss 7.x has been retired. Tomcat support remains unchanged in this release.
- PBKDF2 is now the default encoding for root passwords. This only affects new installations.
- In addition to changing the default password storage scheme for root users to PBKDF2, the default password storage scheme for regular users has been changed to salted 256-bit SHA-2.
- HTTPS defaults to ON: servers now default to use HTTPS for console and API connections including the SCIM API. This may affect automation scripts and development environments where HTTPS has not been in use before.
- Generated user passwords, for example those created by the server during a password reset sequence, are now created as pass-phrases instead of random character strings. This makes them easier to type and remember. This change will not affect upgrades.
- The `/config` directory file permissions have been changed so that they are only accessible by the server user.
- Customers who choose to use the optional encryption algorithms provided by the third-party BouncyCastle library are encouraged to upgrade to BouncyCastle 1.54.

What's New

These are new features for this release of the PingDirectoryProxy Server

- Added a new control for very large result sets `'maximum-sort-size-limit-without-ylv-index,'` which allows client applications to request that the server gracefully degrades to unsorted results in cases where sorting a very large result set would have caused a time-out.
- Added LDAP support for applications that authenticate users with Yubikey one-time passwords. The extensions include the UNBOUNDID-YUBIKEY-OTP SASL handler configuration object, extended operations and command line tools for registering a user's Yubikey device, deregistering, and supporting authentication using either the one-time password (OTP) only, or the OTP together with a static password. The server can be configured to use the public Yubico validation service, or a different validation service. The Yubikey FIDO U2F, OATH HOTP, and PGP modes are not supported.
- Added new "generate TOTP shared secret" and "revoke TOTP shared secret" extended operations to make it easier for applications to enable TOTP authentication for users. While these operations are primarily intended to be invoked programmatically, a `generate-totp-shared-secret` tool can be used to invoke these operations from the command line.

- A new transform-ldif tool is available to read an LDIF file and write an updated file with a number of changes applied. The transformations include:
 - Scramble, replace, redact, or exclude a specified set of attributes.
 - Replace values of a specified attribute with a generated value that includes a sequential counter.
 - Exclude entries matching a provided set of criteria.
 - Add a given set of attribute values to entries matching a provided set of criteria.
 - Rename attributes.
 - Replace the base DN for entries in a specified subtree.
- A new load-ldap-schema-file tool is available for loading LDAP schemas while a server is active and on-line.
- A new register-yubikey-otp-device tool is available for creating or changing associations between users and specific OTP devices.
- The *rate performance testing tools now includes some additional sample rate pattern files: hockey stick, step-function, sine, triangle, sawtooth and square wave patterns.
- The setup command now logs its input arguments, making it easier to confirm or duplicate a setup process. This changes the content of the log and may affect automated scripts that read these log files.
- The config-diff tool, which makes it easy to compare and reconcile settings between server instances, now also supports the --pretty-print option which adds line breaks to the generated lists of dsconfig commands.
- The manage-account tool has been enhanced significantly to make it easier to perform operations that affect large sets of user accounts including bulk lock-outs, parallel processing of updates, support for input filter criteria and DN lists. In particular, the manage-account tool now supports explicitly setting user accounts to the "locked-out" state. This is an improvement over earlier versions which required manipulation of operational attributes. See the command help for a complete list of the options and new sub-commands.
- For easier consumption by third-party analysis tools, the Directory Servers and Directory Proxy Servers can now output JSON log formats. Similar support will be added to the Data Sync and Governance Brokers in a later release.
- To help avoid issues when indexes near their index-entry-limit, the verify-indexes command now has the following two options:--listKeysNearestIndexEntryLimit, and --listKeysExceedingIndexEntryLimit. The Admin Guide includes a new section, "Monitoring Index Entry Limits", which explains how to set, track, and tune the server's Index Entry Limit values.
- Monitor entries have been added for a number of related metrics, all of which can be set to trigger alarms:
 - ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open
 - ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open
 - ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open
 - ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open
- The Pass-Through Authentication plugin has a new "allowLaxPassThroughAuthenticationPasswords" option that permits password changes that do not comply with the Directory Server's password policy. This facilitates integration in cases where the pass-through system has less-strict rules for new passwords.
- For Java developers whose tools and workflows make use of Maven, the Server SDK jar has been deployed to Maven Central so that a developer can now add the Server SDK as a project dependency by adding a few lines to a project's pom.xml. Also, developers can now generate a Server SDK project that Maven-aware IDEs such as IntelliJ IDEA can package into an extension bundle with no special configuration needed. This benefit extends similarly to continuous integration systems such as Jenkins.
- The dsconfig tool provides the ability to search for and quickly navigate to configuration objects and properties in which the name, synopsis, or description matches a provided pattern.
- A new rotate-log tool and task have been added, which can be used to trigger rotation of one or more log files.

- The Configuration API is now fully supported for all servers. In this release, the API was changed to match SCIM conventions for attribute naming, resource modeling, and the standard HTTP verbs. The UnboundID SCIM 2 SDK (available through GitHub) can now be used with the Configuration API.
- All servers have an updated web Administrative Console, which includes:
 - New layouts for operational statistics, processing time, queues, all monitors, and the list of installed extensions.
 - Alert and alarm displays, summarizing the data in `cn=alerts` and `cn=alarms` and based on the configured gauges. Plus, filtering and searching for these.
 - A new LDAP Schema Editor for importing schema files, validity checking, creation and editing of object classes and attribute types. The editor also supports viewing of the attribute syntaxes, inheritance, and indexes that exist for each attribute and the dependencies between object classes and attributes.
- The new Administrative Console can also be deployed to independent application servers instead of being co-hosted by the servers. This simplifies deployment models and increases separation between data and application layers.
- To assist with situations where a very large number of changes may cause disk, memory, and server start time to increase unexpectedly, alerting and gauge features have been added to the Recent Changes Database.
- Servers can now trigger events whenever log file rotation occurs. This includes "copy on rotate" and "summarize on rotate" listeners, as well as Server SDK support for creating custom log file rotation listeners.
- It is now possible to create, change, and remove root user accounts across the topology using the `dsconfig` tool and Administrative Console.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server

- When deploying the Administrative Console in Tomcat 8, and accessing the Administrative Console application using Tomcat's Web Application Manager, some browsers (including Safari and Firefox) will generate a path URL that encodes the dash in `ubid-console`. This results in a path such as `http://localhost:8888/ubid%2Dconsole/`, which causes session management errors. To workaround this issue, copy and paste the generated link into a browser, and replace the encoded dash with a dash (-) character.
- The `PermSize` and `MaxPermSize` JVM properties are no longer supported in JDK 8, and will safely be ignored. These properties can be removed by modifying the `config/java.properties` file and running "bin/dsjavaproperties" while the server is offline.
- Security criteria for root passwords with the default configuration will be increased in a future release. This might affect automated installation scripts that currently use less secure passwords. This will not affect existing root accounts.
- The `dsconfig` tool and the Administrative Console enables creating and managing new Root DN users in this release. However, there is a limitation with changing the password of the currently logged in administrator. The `ldappasswordmodify` command can be used to change the administrator's password by providing the current and new password.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-979	Added the ability to search for configuration objects and their properties by name with the <code>dsconfig</code> tool.

Ticket ID	Description
DS-4235	Added support for log file rotation listeners, which allow for custom processing whenever a log file is rotated out of service so that the server will no longer write to it. A copy listener (which will copy the rotated log file to an alternate location, optionally compressing it in the process), and a summarize listener (which will invoke the summarize-access-log tool on the rotated log file) are included. The Server SDK also includes an API for creating custom log file rotation listeners.
DS-7017	Added support for authenticating with one-time passwords generated by YubiKey devices. The server may be configured to require static passwords in conjunction with YubiKey one-time passwords as a form of two-factor authentication, or it may be configured so that a one-time password alone is sufficient for authentication.
DS-7505,DS-13571,DS-13860	<p>Updated the default file permissions for new installations on UNIX-based systems. Files and directories included in the zip file will be only be accessible to their owner (the user that unzipped the file) by default.</p> <p>Newly-created files and directories will also be assigned permissions that allow them to be accessed only by the account used to run the server. Existing configuration options for setting file permissions (the log-file-permissions and db-directory-permissions properties) will continue to behave as before. The new config/server.umask file will control the default permissions for all other newly-created files and directories.</p>

Ticket ID	Description
DS-9407,DS-15183,DS-15220	<p>Updated the initial server configuration to improve security and usability. These changes apply only to new installations and will not be applied when updating an existing installation. Changes include:</p> <ul style="list-style-type: none"> ▪ Updated the default password policy to use a default password storage scheme that uses a salted 256-bit SHA-2 digest rather than a salted SHA-1 digest. ▪ Updated the root password policy to use a default password storage scheme of PBKDF2 rather than salted 512-bit SHA-2. ▪ Updated the secure password policy to use a default password storage scheme of PBKDF2 rather than a CRYPT variant that uses multiple rounds of 256-bit SHA-2. ▪ Updated the password policy import plugin so that it will attempt to use the default password policy to select the password storage scheme(s) to use for entries that do not explicitly specify a password policy. The plugin will also fall back to using a salted 256-bit SHA-2 scheme instead of a salted SHA-1 scheme. ▪ A number of weaker password storage schemes have been disabled by default, including base64, clear, unsalted MD5, salted MD5, 3DES, RC4, and unsalted SHA-1. ▪ The default password policy has been updated to use a password generator that generates very strong yet memorable passphrases rather than a shorter and less-memorable string of randomly-selected characters. ▪ Many of the server loggers have been updated to include additional log elements by default, including the instance name, requester DN, requester IP address, and request controls. ▪ The exact match identity mapper has been updated to look at the mail attribute in addition to the uid attribute. When targeting a user with an authentication ID value (as when using SASL authentication or the proxied authorization v2 request control), it is now possible to specify an email address as an alternative to a user ID. ▪ The UNBOUNDID-TOTP SASL mechanism handler has been updated to prevent TOTP password reuse by default. ▪ Added new request criteria that make it possible to identify requests that target the root DSE or the subschema subentry. The global configuration has been updated so that requests targeting these entries will be in the default exceptions lists if the server is configured to reject insecure or unauthenticated requests. ▪ Updated the template that setup generates for creating sample data to use a more logical and user-friendly numeric range. When the user requests N entries, setup would previously number the entries 0 through N-1 (for example, if the user requested 1000 entries, they would

Ticket ID	Description
DS-10312	Added the server's process ID to the output of the status tool.
DS-10464	Added a new rotate-log tool to request the rotation of one or more log files.
DS-10466,DS-10765,DS-14479,DS-15318,DS-16154	Addressed a few issues in config-diff. In some situations, config-diff would not generate commands in an order that respected all dependencies. This has been fixed. Most expected warnings are now excluded by default but can be included in the output with the --includeAllWarnings option. The --sourceBindPasswordFile and --targetBindPassword are now applied in conjunction with the --targetConfigGroup and --sourceConfigGroup options.
DS-10946	Added a --dry-run option to dsconfig, which can be used in batch mode to validate the configuration changes in a batch file without applying them.
DS-11076	Updated the Directory Proxy Server to forward Password Policy State and Validate TOTP Password extended operations to the backend Directory Server for processing. Also, the Directory Proxy Server is now able to forward the following extended operations to a backend Directory Server in an entry-balancing configuration: Deliver Password Reset Token, Deliver Single Use Tokens and Get Supported OTP Delivery Mechanisms.
DS-12191	Added support for setting the request header size in the Jetty http configuration server properties.
DS-12555	Changed the Directory Proxy Server search behavior to fail when processing a critical RouteToBackendSetRequestControl with an unknown entry balancing request processor ID included. Non-critical controls will ignore unknown request processor IDs.
DS-13401	Improved the collect-support-data tool to include information provided by systemd on platforms that support it.

Ticket ID	Description
DS-13700	<p>Updated command-line tools based on the LDAP SDK tool APIs to add the following features:</p> <ul style="list-style-type: none"> ▪ Tools can obtain default values for any arguments not provided on the command line from a properties file. If it exists, the server's config/tools.properties file will be used by default. Command-line arguments can be used to specify an alternate properties file or to indicate that no properties file should be used. ▪ Tools can be launched in an interactive mode, in which the user is prompted for arguments used to establish and authenticate the connection, and for any other required arguments. The user can then use an interactive menu to specify values for any remaining arguments.
DS-13823	<p>Collect-support-data tool now captures Kerberos config and log information.</p>
DS-14213	<p>Added the ability to create local constants in LDIF template files using the new 'local' keyword.</p>
DS-14430	<p>Updated the Apache commons collections library to address the security vulnerability described by CVE 2015-4852.</p>
DS-14548	<p>Added a monitor entry for each Server SDK extension.</p>
DS-14694	<p>Added a --prettyPrint option to the config-diff tool to make the output more human-readable.</p>
DS-14699	<p>The server now enforces that attributes referenced in configuration properties are defined explicitly in the local schema. This includes cached attribute types as well, such as, the attribute types that a Proxy Server caches from backend Directory Server instances.</p>
DS-14704	<p>Updated the restore command so that it can no longer be used to restore a backup of the config backend. The command now points the administrator for safer ways to revert configuration changes, including using config-diff.</p>
DS-14749	<p>Updated the server's support for the Twilio Messaging Service so that it uses the newer "Messages" API when sending SMS messages instead of the older "SMS" API. The older API has been deprecated, and Twilio now imposes a 120-character limit for messages sent via that API. The messages API allows the server to take advantage of the full 160 characters per SMS message.</p>

Ticket ID	Description
DS-14805	Improved the admin alert health check system to handle situations where a massive number of admin alerts generated on an external server could result in the server being seen as unavailable.
DS-14807	Tools used to prepare a server for access by another server, such as prepare-external-server, now validate base DN entries before any modifications are performed on the prepared server.
DS-14857	Fixed an issue with the dsjavaproperties tool where java properties for PermSize and MaxPermSize could be added when using JDK 8, which no longer supports these options.
DS-14866	Fixed a race condition in the attribute index's cleanup thread, which was causing the Proxy Server to hang during startup.
DS-14878	Improved memory utilization when processing entries with very large attributes, to prevent possible data retention in memory.
DS-14889	Fixed an issue where the Proxy Server forwarded an atomic multi-update extended operation twice to the same backend set in an entry-balanced configuration, when the operation included a RouteToBackendSet control with absolute routing.
DS-14919	Added support for JSON-formatted access and error log messages.
DS-14922	Improved the subordinate subtree view processing logic to only use the exclude branch request control for subordinate views that are within the scope of the target DN, for search requests processed by the parent subtree view.
DS-14923	Updated the bcrypt, crypt, PBKDF2 and scrypt password storage schemes so they can be used to create new instances.
DS-14979	Fixed a case where attribute syntax configuration changes would not apply to undefined attributes, which rely on default attribute types.
DS-15015	Server SDK extensions are now built with a Java source version of 1.7 by default.

Ticket ID	Description
DS-15059	Fixed an issue with simple paged results that require spanning multiple backend servers through an entry balanced request processor to fill a single page. The operation would return with a 'no such object' result code if one of the backend servers used did not have any matching results.
DS-15088	The former suite of Administrative Console applications, each of which were tied to a particular product (for example the dsconsole.war for the Directory Server) are no longer available, and have been superceded by a new version of the Administrative Console capable of managing any server product. You can choose to access the Administrative Console by hosting it within a server, or by deploying it in an external servlet container. For the former, enable an HTTP Connection Handler and add the Administrative Console Web Application Extension to the handler. For the latter, download and unzip the management-console-[version].zip file, and install the ubid-console.war file according to your container's instructions.
DS-15108	Replaced the scramble-ldif tool with a more powerful transform-ldif tool with support for a number of additional transformation types. The new transform-ldif tool is backward compatible with the former scramble-ldif tool, and the scramble-ldif shell script and batch file are still included with the server to ensure compatibility with scripts that depend on that tool.
DS-15132	Improved the locking strategy for multi-update requests to better accommodate delete and add requests for the same entry. This also enables graceful failures for bad requests, instead of lock timeouts.
DS-15168	Increased the maximum size of the thread pool that is used to process entry balancing broadcast operations. The maximum is now 64 times the number of worker threads with an upper limit of 2048.
DS-15175	The Configuration API now returns unquoted, native Javascript values for integer, real number, and boolean properties. Duration and size property values, for example '1 w' or '100 G', continue to be represented as Javascript string types.

Ticket ID	Description
DS-15178	Improved the error messages and examples for create-rc-script and create-systemd-script by explicitly suggesting the use of sudo so that the scripts can modify protected files.
DS-15186	Fixed a rare condition where priming the Directory Proxy Server would not complete if a backend Directory Server becomes unavailable.
DS-15195	Added support for server affinity using extended operations.
DS-15221	Changed interactive setup default value for HTTPS enablement.
DS-15337	Improved the error messages for create-rc-script and create-systemd-script when the directory in which the script will be created does not exist.
DS-15349	Added support for a "generate TOTP shared secret" extended operation that allows a client to request that the server generate a shared secret for a specified user that will be stored in the user's entry and returned to the client. That shared secret can be used to generate time-based one-time passwords for use in the course of authenticating to the server through the UNBOUNDID-TOTP SASL mechanism. A "revoke TOTP shared secret" extended operation was also added to allow a shared secret to be eliminated if it is no longer needed or may have been compromised. The password policy state extended operation and the manage-account command-line tool have also been updated to provide support for manipulating the set of TOTP shared secrets for a user.
DS-15361,DS-15363,DS-15434	Updated interactive setup to display default values, and improved the overall layout and appearance.
DS-15400	Addressed an issue where dsconfig incorrectly allowed certain configuration objects to be deleted.
DS-15412	Improved the error messages produced by the manage-extensions tool when attempting to install invalid extensions.
DS-15417	Updated the global ACIs that ship with the server to use a separate ACI for each control or extended request to allow by default, rather than grouping all desired controls together in one ACI and all desired extended requests together in a second ACI. This change will only be reflected in new installations, and not when updating an existing deployment.

Ticket ID	Description
DS-15422	Root DN User configuration entries can now be fully managed through the configuration management interfaces such as dsconfig and the Administrative Console.
DS-15466	Added more logging information when initializing web application and servlet extensions in case an extension causes conflicts or delays.
DS-15521	Updated setup to encode the root password with the PBKDF2 password storage scheme instead of SSHA512.
DS-15522	Updater tool will increase PermSize and MaxPermSize parameters to recommended value to prevent Java JVM pauses.
DS-15559	Added support for an UNBOUNDID-EXTERNALLY-PROCESSED-AUTHENTICATION SASL mechanism that indicates that an application attempted to verify the identity of a user whose account is stored in the server but that used a form of authentication that is external to the server (for example, via social login). The server will not alter the authentication state of the underlying connection, but may veto a successful external authentication if the user's account is not in a usable state (for example, the account is locked or disabled, or the password is expired), or it may update password policy state for the user to reflect the authentication attempt (for example, updating the last login time and IP address for a successful authentication, or recording the failed attempt and potentially locking the account for an unsuccessful authentication).
DS-15571	Increase the minimum memory requirements for the server process from 256MB to 384MB to accommodate the Administrative Console.
DS-15576	Added a load-ldap-schema-file tool that will allow the server to recognize a new schema file, or an updated version of an existing schema file, and make the definitions immediately available without needing to restart the server.
DS-15592	Fixed an error that could occur during upgrade when the configuration can not be loaded due to missing custom schema.
DS-15621	Updated the Groovy Scripting Language version to 2.4.6.

Ticket ID	Description
DS-15622	Fixed an issue that prevented the deletion of disabled debug loggers.
DS-15789	Updated the server to allow users with expired passwords to authenticate with SASL mechanisms that do not involve passwords.
DS-15827	Updated the globally-unique attribute plugin so that the filter property applies to conflict searches, and matches entries being added or modified.

Ticket ID	Description
DS-15849,DS-15850,DS-15851,DS-15852,DS-15853	<p>Rewrote the manage-account tool to provide many new features:</p> <ul style="list-style-type: none"> ▪ Added the following new subcommands: <ul style="list-style-type: none"> ▪ get-account-is-usable ▪ get-account-usability-notice-messages ▪ get-account-usability-warning-messages ▪ get-account-usability-errors-messages ▪ get-account-is-not-yet-active ▪ get-account-is-expired ▪ get-password-is-expired ▪ get-password-expiration-time ▪ get-account-is-failure-locked ▪ set-account-is-failure-locked ▪ get-failure-lockout-time ▪ get-account-is-idle-locked ▪ get-idle-lockout-time ▪ get-account-is-password-reset-locked ▪ get-password-reset-lockout-time ▪ get-account-activation-time ▪ set-account-activation-time ▪ clear-account-activation-time ▪ get-seconds-until-account-activation ▪ get-last-login-ip-address ▪ set-last-login-ip-address ▪ clear-last-login-ip-address ▪ get-password-history-count ▪ Added new ways to target multiple users with a single command. It was already possible to provide a file with the DNs of the users to target. There are now additional options for providing one or more search filters or user IDs to identify which users to target. ▪ Added automatic retry support. If an operation fails in a manner that indicates the connection is no longer valid, the tool will retry the operation on a newly-created connection. It is also possible to provide multiple host name and port values to allow operations to be sent to multiple servers. ▪ Added the ability to use multiple threads to operate more quickly when targeting multiple users. ▪ Added the ability to limit the rate at which the tool operates. The target rate may be specified as a fixed number of operations per second, or it may vary over time. ▪ Changed the output format so that the result of each operation is provided in an LDIF representation. The output remains easy for a person to read, but it is now much easier to consume programmatically. ▪ Added the ability to send the output to a specified file instead of or in addition to standard output. Also added the ability to write a reject file that contains only information about those

Ticket ID	Description
DS-15920	Improved the warnings given when the maximum memory that all server components can consume is greater than the available memory in the JVM.
DS-15943	Addressed an issue where jsonObjectFilterExtensibleMatch queries in the proxy would fail if any DN Mappers were configured.
DS-16053	Improved the way we handle unexpected errors and invalid DN's during proxy transformations.
DS-16104	Updated the password policy state extended operation and the manage-account tool to provide a way to obtain a list of the SASL mechanisms and OTP delivery mechanisms that are available to a user, to determine whether a user has a TOTP shared secret, and to retrieve and manipulate the set of public IDs for the YubiKey OTP devices registered for a user.
DS-16224	Updated the sanitize-log tool to add support for JSON-formatted access and error log files.

PingDirectoryProxy Server 5.2.0.0 Release Notes

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server

- When deploying a .war file through the Web Application HTTP Servlet Extension, dependencies bundled in the file may conflict with the server's own dependencies if the server version differs from the version in the .war file. This may cause the Web Application HTTP Servlet Extension or the server itself to not start correctly. For reference, all server dependencies are available in <server root>/lib.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-1261	The collect-support-data tool now has the option to collect logging information within a specified time range via the '--timeRange' argument.
DS-1706	Updated interactive dsconfig to include an option to toggle between sorting similar properties together or sorting them alphabetically.

Ticket ID	Description
DS-3095	Added a new search-logs tool. Similar to the command line tool 'grep,' this tool searches across log files to extract lines matching the provided pattern(s). The search-logs tool can handle multi-line log messages, extract log messages within a given time range, and include rotated log files.
DS-8739	Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).
DS-8794,DS-9652,DS-12704	The setup and initial configuration tools now support offline modes that can be used to bootstrap the server configuration while it is not running. Also, files generated by these tools are now saved to the server's resource directory.
DS-9842	Added the ability to configure the Globally-Unique Attribute and Unique Attribute plugins with a filter to limit attribute uniqueness checking to a subset of matching entries.
DS-10010	Reduced the memory overhead of debug logging in high throughput environments by sharing logging buffers across multiple threads.
DS-10283	Custom HTTP loggers are no longer permitted to modify the requests and responses being logged. Calling a forbidden method will result in a subclass of UnsupportedOperationException. For requests, the forbidden methods are authenticate, getReader, login, logout and setCharacterEncoding. For responses, the forbidden methods are addCookie, addHeader, addIntHeader, flushBuffer, getOutputStream, getWriter, reset, sendError, sendRedirect, setBufferSize, setCharacterEncoding, setContentLength, setContentType, setHeader, setIntHeader, setLocale and setStatus.

Ticket ID	Description
DS-10843	<p>Added support for a "name with entryUUID" request control. If this control is included in an add request, the entry will be added with a distinguished name whose RDN contains only the entryUUID attribute. This offers a number of potential benefits:</p> <ul style="list-style-type: none">▪ It can help preserve data privacy by ensuring the entry DN does not include sensitive or personally-identifying information.▪ It can reduce the need for modify DN operations, since entries are not named with user attributes that have the potential to change.▪ It can serve as a convenience for entries in which there is no obvious, guaranteed-unique attribute (or combination of attributes) to use for naming those entries.
DS-11067	<p>Added properties to the task backend for limiting the number of log messages retained in task entries, in order to limit the size of the in-memory representation of those entries. All log messages generated by a task will still be recorded in the server error log, even if they are not all retained in the corresponding entry in the task backend.</p>
DS-11522	<p>Updated the server's JVM arguments to always log garbage collection information to a rotating set of log files stored within logs/jvm/gc.log.N. The file system usage is limited to 300MB. If the server had previously been configured with VERBOSE_GC, then garbage collection logging information will no longer be logged to logs/server.out.</p>

Ticket ID	Description
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>
DS-12123	<p>Updated the Configuration API output where properties and their values are listed to include those that are undefined.</p>

Ticket ID	Description
DS-12138	<p>Added support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. Two matching rules have also been added for use in conjunction with the JSON object syntax: <code>jsonObjectExactMatch</code> and <code>jsonObjectFilterExtensibleMatch</code>.</p> <p>The <code>jsonObjectExactMatch</code> equality matching rule is used in evaluating equality filters in search operations, as well as for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. String values will be compared in a case-insensitive manner. The order of elements in arrays will be considered significant.</p> <p>The <code>jsonObjectFilterExtensibleMatch</code> matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation (available in the Commercial Edition of the UnboundID LDAP SDK for Java) for the <code>com.unboundid.ldap.sdk.unboundidds.json.JSONObjectFilter</code> class and its subclasses. Although the LDAP SDK can facilitate searches with this matching rule, these searches can be issued through any LDAP client API that supports extensible matching.</p> <p>Indexing is supported only for the <code>jsonObjectExactMatch</code> matching rule. If possible, non-baseObject searches that use the <code>jsonObjectFilterExtensibleMatch</code> matching rule should be wrapped in an LDAP AND filter that also contains one or more indexed components so that the search can be processed more efficiently.</p>
DS-12182	<p>The setup tool has been updated to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.</p>
DS-12218	<p>Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.</p>

Ticket ID	Description
DS-12245	The Configuration API has been updated to support filtering, sorting, and paging for object list operations. See the Administration guide for usage.
DS-12285	Fixed an issue where changes to SMTP External Server configurations did not take effect until after a server restart.
DS-12287	Addressed cases where some messages may be suppressed in logs and alerts.
DS-12319	Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.
DS-12480	SCIM, through proxy, does not support pagination. Pagination requires the use of VLV and Server Side Sort controls, which are not natively supported by the Identity Proxy Server. The SCIM proxy configuration script incorrectly included these controls in the ACI and supported controls sections. These have now been removed.
DS-12483	Added support for running on Oracle Java 8 and OpenJDK 8 platforms.
DS-12496	Added logging of all HTTP requests disallowed due to CORS. This should make it easier to debug HTTP 403/Forbidden errors.
DS-12555	Fixed an issue where using the RouteToBackendSetRequestControl with an incorrect entry-balancing request processor ID could result in a NullPointerException.
DS-12560,DS-12561	Updated the server to avoid the use of the server-side sort and virtual list view request controls in search requests that span multiple subtree views or multiple entry-balanced backend sets. If the server cannot honor a non-critical server-side sort or virtual list view control, then it will process the search operation as if the control had not been included in the request. If the server cannot honor a critical server-side sort or virtual list view control, then it will return an error result to the client.
DS-12576	Update the Detailed HTTP Operation Log Publisher to log the correct return code (404 NOT FOUND) when a request is not handled by defined endpoints.

Ticket ID	Description
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12594,DS-12596	<p>Added support for three new extended operations for interacting with single-use tokens:</p> <ul style="list-style-type: none"> ▪ The "get supported OTP delivery mechanisms" operation provides information about which one-time password delivery mechanisms are configured in the server, and which of those are available for a specified user. ▪ The "deliver single-use token" operation can generate a token value and provide it to a specified user through an out-of-band communication mechanism like email, SMS, or voice call. ▪ The "consume single-use token" operation indicates that the user has received a single-use token from the "deliver single-use token" operation, and to consume that token so that it cannot be reused.
DS-12607	Fixed an issue where the Proxy Server returned an incorrect result code when attempting to add an entry that already exists more than one level below an entry balancing base DN. The Proxy Server in some cases would incorrectly return NO_SUCH_OBJECT rather than ENTRY_ALREADY_EXISTS.
DS-12610	Fixed an issue where configuring numeric IPv4 address filtering by connection criteria in a log publisher performed unnecessary reverse host name lookups.
DS-12616	Updated the prepare-* tools to avoid unnecessary confirmation for trust of the prepared server's certificate when the --trustStorePath argument specifies a trust store that establishes trust.
DS-12627	Updated the LDAP connection handler to enable the use of multiple threads for accepting connections and preparing them for use. This improves concurrency for deployments in which the process of accepting a new connection may take some time to complete, possibly because of expensive DNS lookups or invoking time-consuming post-connect plugins).

Ticket ID	Description
DS-12681,DS-13475	Improved the server's support for selecting TLS cipher suites. When the server is configured to use a specific set of cipher suites, it will now always validate that all of the configured suites are supported by the JVM. When the server is not configured to use a specific set of cipher suites, it will now customize the set of default suites to prioritize those using strong cryptography (especially those that offer forward secrecy), and exclude suites with known weaknesses.
DS-12727	Added a gauge to monitor the number of available file descriptors. This Available File Descriptors gauge can detect if a server is running out of file descriptors and degrade the server appropriately.
DS-12798	MakeLDIF templates now have the ability to escape special characters curly braces, angle brackets, and square brackets using a backslash. See config/MakeLDIF/examples-of-all-tags.template for further examples.
DS-12799	The following UnboundID product names have changed: - Identity Datastore to Datastore - Identity Proxy to Proxy Server - Identity Data Sync Server to Data Sync Server - Identity Broker to Data Broker
DS-12802	Fixed an issue that would result in long server startup when many locations and load balancing algorithms are defined.
DS-12833	Updated the alert handler configuration to indicate whether the alert handler should be invoked asynchronously in a background thread rather than by the thread that generated the alert. For alerts generated during the course of processing an operation, invoking potentially time-consuming alert handlers in a background thread can avoid adversely impacting the response time for that operation while still ensuring that administrators are made aware of the issue that arose.
DS-12833	Updated the server to provide support for SMTP connection pooling. When sending an email message, the server will attempt to reuse an existing SMTP connection rather than establishing a new connection for each message.
DS-12880	Fixed a rare condition that might cause the logger rotation and retention thread to exit under heavy file system load or a network file system outage.

Ticket ID	Description
DS-12897	Fixed a bug where using the advanced arguments of some tools would result in changing the saved complexity settings for the dsconfig tool.
DS-12969	Improved server locking used by dsconfig in offline batch mode, so that the server lock is held for the entire batch duration, instead of for each invocation. Also, reduced the probability of contention for file locks used by server tools to determine the server status.
DS-12982	Updated the installer to increase the maximum suggested JVM size on Linux systems with at least 48 GB of RAM.
DS-13124	Fixed an issue where debug logging at a fine-level could consume large amounts of memory.
DS-13163	Addressed an issue where data definition language (DDL) log field mappings for the JDBC error log were not previously documented.
DS-13242	Updated the prepare-external-server tool to suppress output when run with the --quiet option.
DS-13248	The Proxy Server processing for Third-Party Proxied Extended Operation Handlers has been changed for extended operations containing "Route To Backend Set" request controls. The default behavior is now to process the operation only on backends in the entry-balancing request processors specified in the request controls. The old behavior to process on backends in other request processors too may be obtained through the advanced "route-to-backend-set-behavior" configuration property on the Third-Party Proxied Extended Operation Handler.
DS-13501	Fixed a case where duplicate entry searches performed prior to an ADD operation in an entry-balanced environment may not honor a maximum response timeout.
DS-13552	Fixed a log publisher defect that would result in an unreadable file when both compression and signing were enabled at the same time.
DS-13554	Updated the server to allow an initial heap size over 128 GB. Due to limitations of older JVMs, this was previously capped at 128 GB, even when the maximum heap size was larger.

Ticket ID	Description
DS-13678	Updated the create-systemd-script tool by adding resource limits for available open file descriptors (NOFILE), and shared memory reservations (MEMLOCK). The generated script lists the recommended file descriptors limit and the resource limit setting for enabling large page support. The settings in the create-systemd-script output supersedes prior documentation for setting the number of open file descriptors on non-systemd systems.
DS-13783	Updated the server to better utilize worker threads and reduce the potential for a work queue backlog when processing multiple concurrent long-running operations.
DS-13820	Fixed an issue involving transactions sent through a Proxy Server with Entry Balancing configured. If the transaction contained requests that targeted entries that were not in the global index, then duplicate requests were included in the resulting Multi-Update operation forwarded to the Datastore.
DS-14060	Fix an issue in the SCIM interface where an attribute required by the SCIM schema could be deleted by a PATCH operation.
DS-14074	Added the ability to protect Velocity templates using the basic authentication scheme.
DS-14088	Fixed an issue where there could be missing or duplicated changes when synchronizing through a Proxy Server in an entry-balancing configuration. The issue only affected Proxy Server configurations with multiple entry-balancing request processors referencing the same proxying request processor.
DS-14140	The ldifsearch command now supports the option "--isCompressed" for LDIF files that have been compressed with gzip.
DS-14349	Fixed an issue with the collect-support-data tool when using the --pid argument. Only one jstack was being collected, instead of using the amount specified by the --maxJstacks argument.
DS-14350	Improved processing of abandon requests with subordinate operations by avoiding canceling twice and not waiting for internally canceled operations.
DS-14353	Fixed an issue where configuration changes to an external server would not notify all load-balancing algorithms defined for that server.

PingDirectoryProxy Server 5.1.5.2 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-14074	Added the ability to protect Velocity templates using the basic authentication scheme.

PingDirectoryProxy Server 5.1.5.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server::

Ticket ID	Description
	Fixed a race condition in the LDAP SDK that could result in poor performance when using the separate-connections verify-credentials-method on an external server.
DS-12727	Added a gauge to monitor the number of available file descriptors. This Available File Descriptors gauge can detect if a server is running out of file descriptors and degrade the server appropriately.
DS-12982	Updated the installer to increase the maximum suggested JVM size on Linux systems with at least 48 GB of RAM.
DS-13554	Updated the server to allow an initial heap size over 128 GB. Due to limitations of older JVMs, this was previously capped at 128 GB, even when the maximum heap size was larger.

PingDirectoryProxy Server 5.1.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the PingDirectoryProxy Server:

- The summarize-config tool is deprecated, and will be removed in future versions of the product. Use the config-diff tool with the "sourceBaseline" argument to list a summary of changes to the local server configuration.

What's New

These are new features for this release of the PingDirectoryProxy Server:

- Added initial support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. Indexing options are currently limited. Please see the full release note below for DS-12138.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-8739	<p>Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).</p>
DS-9842	<p>Added the ability to configure the Globally-Unique Attribute and Unique Attribute plugins with a filter to limit attribute uniqueness checking to a subset of matching entries.</p>
DS-10010	<p>Reduced the memory overhead of debug logging in high throughput environments by sharing logging buffers across multiple threads.</p>
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>

Ticket ID	Description
DS-12123	<p>Updated the Configuration API output where properties and their values are listed to include those that are undefined.</p>
DS-12138	<p>Added support for a JSON object attribute syntax, which can be used for attribute types whose values are JSON objects. The syntax requires that each value of this type is a valid JSON object. Two matching rules have also been added for use in conjunction with the JSON object syntax: <code>jsonObjectExactMatch</code> and <code>jsonObjectFilterExtensibleMatch</code>.</p> <p>The <code>jsonObjectExactMatch</code> equality matching rule is used in evaluating equality filters in search operations, as well as for matching performed against JSON object attributes for add, compare, and modify operations. It determines whether two values are logically-equivalent JSON objects. The field names used in both objects must match exactly (although fields may appear in different orders). The values of each field must have the same data types. String values will be compared in a case-insensitive manner. The order of elements in arrays will be considered significant.</p> <p>The <code>jsonObjectFilterExtensibleMatch</code> matching rule can perform more powerful matching against JSON objects. The assertion values for these extensible matching filters should be JSON objects that express the constraints for the matching. These JSON object filters are described in detail in the Javadoc documentation (available in the Commercial Edition of the UnboundID LDAP SDK for Java) for the <code>com.unboundid.ldap.sdk.unboundidds.json.JSONObjectFilter</code> class and its subclasses. DS-12182	<p>The setup tool has been updated to use HTTPS for initial configuration. Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.</p>

Ticket ID	Description
DS-12218	Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.
DS-12245	The Configuration API has been updated to support filtering, sorting, and paging for object list operations. See the Administration guide for usage.
DS-12285	Fixed an issue where changes to SMTP External Server configurations did not take effect until after a server restart.
DS-12287	Addressed cases where some messages may be suppressed in logs and alerts.
DS-12319	Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.
DS-12480	SCIM, through proxy, does not support pagination. Pagination requires the use of VLV and Server Side Sort controls, which are not natively supported by the Identity Proxy Server. The SCIM proxy configuration script incorrectly included these controls in the ACI and supported controls sections. These have now been removed.
DS-12483	Added support for running on Oracle Java 8 and OpenJDK 8 platforms.
DS-12496	Added logging of all HTTP requests disallowed due to CORS. This should make it easier to debug HTTP 403/Forbidden errors.
DS-12555	Fixed an issue where using the RouteToBackendSetRequestControl with an incorrect entry-balancing request processor ID could result in a NullPointerException.
DS-12560,DS-12561	Updated the server to avoid the use of the server-side sort and virtual list view request controls in search requests that span multiple subtree views or multiple entry-balanced backend sets. If the server cannot honor a non-critical server-side sort or virtual list view control, then it will process the search operation as if the control had not been included in the request. If the server cannot honor a critical server-side sort or virtual list view control, then it will return an error result to the client.

Ticket ID	Description
DS-12576	Update the Detailed HTTP Operation Log Publisher to log the correct return code (404 NOT FOUND) when a request is not handled by defined endpoints.
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12594,DS-12596	<p>Added support for three new extended operations for interacting with single-use tokens:</p> <ul style="list-style-type: none"> - The "get supported OTP delivery mechanisms" operation provides information about which one-time password delivery mechanisms are configured in the server, and which of those are available for a specified user. - The "deliver single-use token" operation can generate a token value and provide it to a specified user through an out-of-band communication mechanism like email, SMS, or voice call. - The "consume single-use token" operation indicates that the user has received a single-use token from the "deliver single-use token" operation, and to consume that token so that it cannot be reused.
DS-12607	Fixed an issue where the Proxy Server returned an incorrect result code when attempting to add an entry that already exists more than one level below an entry balancing base DN. The Proxy Server in some cases would incorrectly return NO_SUCH_OBJECT rather than ENTRY_ALREADY_EXISTS.
DS-12610	Fixed an issue where configuring numeric IPv4 address filtering by connection criteria in a log publisher performed unnecessary reverse host name lookups.
DS-12798	MakeLDIF templates now have the ability to escape special characters curly braces, angle brackets, and square brackets using a backslash. See config/MakeLDIF/examples-of-all-tags.template for further examples.
DS-12802	Fixed an issue that would result in long server startup when many locations and load balancing algorithms are defined.
DS-12880	Fixed a rare condition that might cause the logger rotation and retention thread to exit under heavy file system load or a network file system outage.

Ticket ID	Description
DS-12969	Improved server locking used by dsconfig in offline batch mode, so that the server lock is held for the entire batch duration, instead of for each invocation. Also, reduced the probability of contention for file locks used by server tools to determine the server status.
DS-13248	The Proxy Server processing for Third-Party Proxied Extended Operation Handlers has been changed for extended operations containing "Route To Backend Set" request controls. The default behavior is now to process the operation only on backends in the entry-balancing request processors specified in the request controls. The old behavior to process on backends in other request processors too may be obtained through the advanced "route-to-backend-set-behavior" configuration property on the Third-Party Proxied Extended Operation Handler.

PingDirectoryProxy Server 5.0.1.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-8739	Added the ability to reset user passwords with a single-use, time-limited token that is delivered to the end user through some out-of-band mechanism like SMS or email. After determining the identity of the user for whom the password reset token should be generated, an application can use the new "deliver password reset token" extended operation to cause the server to create and deliver the token to the user. This token can then be provided to the "password modify" extended operation in lieu of the user's current password in order to allow that user to select a new password. Password reset tokens can optionally permit users to reset their passwords even if their account is not usable (for example, because their account is locked or their password is expired).

Ticket ID	Description
DS-12107,DS-12137	<p>Added features to allow clients to better determine the set of requirements that the server will impose for user passwords. The get password quality requirements extended operation can be used to retrieve information about the requirements before an attempted password change. Those requirements can be conveyed to the end user, and can potentially be used to enable some types of client-side validation to identify problems with a password before it is sent to the server. The password validation details request control can be included in an add request, a modify request, or a password modify extended request to identify which specific validation requirements may not have been met by the password provided in the request.</p> <p>Password validators can be configured with user-friendly messages that better describe the constraints that the validator will impose for passwords, and that the validator should return if a proposed password does not satisfy those constraints. The server will generate these messages if they are not provided in the configuration.</p>
DS-12123	<p>Updated the Configuration API output where properties and their values are listed to include those that are undefined.</p>
DS-12182	<p>The setup tool has been updated to use HTTPS when configuring the HTTP Connection Handler(s). Unsecure HTTP can be enabled post-setup, or by using non-interactive setup.</p>
DS-12218	<p>Updated the server to automatically monitor and report the length of time each operation spends waiting in the work queue before a worker thread can begin to process it.</p>
DS-12287	<p>Addressed cases where some messages may be suppressed in logs and alerts.</p>
DS-12319	<p>Updated UnboundID work queue processing to log expensive work queue operations and diagnostic thread stack traces when a queue backlog alarm is raised.</p>
DS-12480	<p>SCIM, through proxy, does not support pagination. Pagination requires the use of VLV and Server Side Sort controls, which are not natively supported by the Identity Proxy Server. The SCIM proxy configuration script incorrectly included these controls in the ACI and supported controls sections. These have now been removed.</p>

Ticket ID	Description
DS-12579	The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
DS-12802	Fixed an issue that would result in long server startup when many locations and load balancing algorithms are defined.

PingDirectoryProxy Server 5.0.0.0 Release Notes

What's New

These are new features for this release of the PingDirectoryProxy Server:

- Java 7 is now required when setting up a new server or upgrading an existing server.
- Added a `poll-backend-servers-for-global-index-changes` configuration property to allow the entry-balancing request processor to retrieve information about changes processed in backend servers and keep the global index up to date. All backend servers must be configured to maintain an LDAP changelog if this feature is enabled.
- Added Server SDK support for creating custom server affinity providers.
- Enabled support for the SSLv2Hello TLS protocol by default in JVMs that support it. This does not enable support for the insecure SSLv2 protocol, but it can improve compatibility with clients running older versions of Java that may start TLS negotiation with an SSLv2 client hello packet before negotiating to a higher version of the TLS protocol. Support for SSLv2Hello in the initial phase of negotiation does not in any way compromise the strength of the integrity and/or confidentiality protection that is ultimately negotiated between the client and the server.
- Added a Monitor History plugin that periodically records `cn=monitor` to timestamped files to aid in isolating intermittent problems. By default, it logs the full `cn=monitor` branch every five minutes to compressed files within `logs/monitor-history/`. Files are deleted automatically, but a sparse set of older files are kept to provide historical perspective on server performance. The `collect-support-data` tool has also been updated to collect a few of these files to aid in root cause analysis.
- The default SCIM base context path changed from `/` to `/scim`. Any clients using the previous base context path will no longer be able to access SCIM services until they are updated. The following `dsconfig` command may be used to revert to the previous base context path after update:

```
dsconfig set-http-servlet-extension-prop --extension-name SCIM --set base-context-path:/
```
- Introduced the Configuration HTTP Servlet Extension, which can be used for querying and updating the configuration over a REST API. This feature is currently experimental and is subject to change in the future. Your feedback is welcome.

Known Issues/Workarounds

The following are known issues in the current version of the PingDirectoryProxy Server:

- For Entry Balancing deployments referencing custom schema in the Global Attribute Index, the attributes should be defined in the Proxy's schema as well as the external Datastore.

Resolved Issues

The following issues have been resolved with this release of the PingDirectoryProxy Server:

Ticket ID	Description
DS-8368,DS-12120	Updated the HTTP Connection Handler to return a 404 Not Found response to requests for endpoints not handled by any servlet or web application extensions. Previously the handler would return a 200 OK with no response body.
DS-10441	Disabled log rotation during startup to prevent potential problems with rotation dependencies on server components that have not yet been initialized.
DS-10460	Fixed the dsconfig tool to suppress all stray output when run in batch mode with the --quiet option.
DS-11068,DS-11784,DS-11887	Updated the setup tools to enable definition of external server instances that are configured to reject unauthenticated requests. Previously the tools would erroneously indicate these servers were unavailable.
DS-11122	The PingDirectoryProxy Server will now periodically persist the global index to a file, and optionally prime the global index from the persisted file when the server is restarted.

Ticket ID	Description
DS-11138	<p>Fixed an issue where deleting values of a multi-valued attribute using SCIM PATCH could silently fail. Modifications in SCIM PATCH are now mapped directly to LDAP modifications to take advantage of the matching rules configured in the Identity Datastore, when matching deleted values. Since the SCIM PATCH is now applied by the Datastore, the Permissive Modify Request Control (1.2.840.113556.1.4.1413) is now required by the SCIM component. This will ensure that adding an existing value or deleting a non-existent value in the PATCH request will not result in an error.</p> <p>To continue using SCIM component after an upgrade of the PingDirectory Server or PingDirectoryProxy Server, access controls and configuration may need to be updated to allow access to the Permissive Modify Request Control.</p> <p>Directory:</p> <pre>dsconfig set-access-control-handler-prop -- remove 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12") (version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-access-control-handler-prop -- add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12 1.2.840.113556.1.4.1413")(version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <p>Proxy:</p> <pre>dsconfig set-access-control-handler-prop -- remove 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12") (version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-access-control-handler-prop -- add 'global-aci:(targetcontrol="1.3.6.1.1.13.2 1.2.840.113556.1.4.473 1.2.840.113556.1.4.319 2.16.840.1.113730.3.4.9 1.3.6.1.1.12 1.2.840.113556.1.4.1413")(version 3.0;aci "Authenticated access to controls used by the SCIM servlet extension"; allow (all) userdn="ldap:///all";)'</pre> <pre>dsconfig set-request-processor-prop --processor- name dc_example_dc_com-req-processor --add supported-control-oid:1.2.840.113556.1.4.1413</pre> <p>Note that "dc_example_dc_com-req-processor" is the default processor name and it may be different depending on your configuration.</p> <p>Identity Broker: For each directory used as an</p>

Ticket ID	Description
DS-11396	Updated gauge alert details to include the last threshold value that was crossed.
DS-11402	Reduced the Proxy Server's global index memory use by tokenizing the attribute type in the RDN index and compacting indexed attribute values for syntaxes that support it, such as integer, hex string, and bit string syntaxes.
DS-11406	Added the ability for a Server SDK extension, such as a Plugin, to register for notifications when an operation completes using the <code>OperationContext#registerOperationCompletedListener()</code> method.
DS-11453	Reduced the severity of the "unrecognized alert type" message in the error log from SEVERE_WARNING to NOTICE. The message now states that this is expected if the server is reverted to a version prior to the implementation of these alert types.
DS-11472	Fixed the gauge configuration manager to only re-initialize the gauge that was changed, and not any of the other gauges that did not change.
DS-11541	Fixed the alarm manager to generate alarm-cleared alerts when internal alarms are cleared and the alarm manager's generated-alert-types property has the "alarm" value.
DS-11546	Fixed the alarm manager to not include the details of the old alarm, (the alarm being cleared), in the "alarm-cleared" alert message.
DS-11564	Updated the uninstall tool so that it unregisters the local server from any configured peer servers.

Ticket ID	Description
DS-11565	<p>Updated the javadoc for the Example Overload Handler plugin to include the argument "invoke-for-internal-operations" with a value of "false" during the plugin creation. Previously, the plugin, when enabled, would drop internal queries to the monitor backend initiated by the gauge state provider.</p> <p>Fixed an issue in the Example Overload Handler plugin's applyConfiguration method, where when any changes were made to the plugin's configuration itself (such as adding a new pre-parse type), it would drop requests because we were doing an LDAP search for the gauge argument in the config backend over a client connection, instead of using an internal connection.</p> <p>Fixed an issue where when the Example Overload Handler plugin was disabled and then re-enabled, an IllegalStateException occurred because the monitor provider that publishes drop stats was previously registered.</p>
DS-11624	<p>Updated the Web Console so that upon login, the user's old session is always invalidated.</p>
DS-11629,DS-11645	<p>Updated the Web Console to suppress LDAP responses in user messages, such as when the server is unavailable or for authentication failures. Also added a context parameter to exclude stack traces and detailed error messages from appearing in the application's internal error page.</p>
DS-11637	<p>Updated the alarm manager to not generate "alarm-normal" alert when a gauge's condition abates</p>
DS-11642	<p>Updated the entry-balancing request processor to reject atomic multi-update requests that have one or more changes targeting entries at or outside of the balancing point.</p>
DS-11688	<p>Fixed an issue in which tools such as dsconfig, status, and dsreplication could not connect to the server over SSL or StartTLS. This occurred when a certificate was accepted with the 'Manually validate' option, while using the interactive LDAP connection menu.</p>
DS-11719	<p>Updated the alarm manager to not persist normal alarms.</p>
DS-11719	<p>Updated the ExampleOverloadHandlerPlugin to monitor the alarm backend for delete actions, so that it can react appropriately to abating gauge conditions.</p>

Ticket ID	Description
DS-11730	Removed the "alarm-normal" alert.
DS-11738	Updated the server so that alarm-cleared, alarm-warning, alarm-minor, alarm-major, and alarm-critical alerts are not subject to duplicate alert suppression. Separate alert notifications of these types may represent distinct conditions and resources that should not be suppressed.
DS-11751	Fixed incorrect property references for trustStorePassword and keyStorePasswordFile in tools.properties that corresponded to the wrong argument names.
DS-11755	Updated the HTTP Detailed Access logger to use timestamps with millisecond precision.

Ticket ID	Description
DS-11782	<p data-bbox="850 216 1464 468">Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.</p> <p data-bbox="850 485 1464 1213">SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced <code>allowed-insecure-tls-protocol</code> global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.</p> <p data-bbox="850 1230 1464 1835">It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.</p>

Ticket ID	Description
DS-11837	Updated numeric gauges so that their severity changes when the current gauge value equals the threshold's exit value. Previously the value had to be strictly less than the exit value for the severity to change.
DS-11850	Updated the PingDirectoryProxy Server to return a "size limit exceeded" result for a baseObject search that matches multiple entries because entries with the same DN exist in multiple entry-balanced backend sets. Previously, the server could return multiple entries, which is undesirable for a baseObject search.
DS-11868	Fixed an issue where the server would hang during startup due to a previous unexpected service outage resulting in an empty tasks.Idif file.
DS-11879	Fixed the index rebuild job so that it does not generate redundant "index-degraded" alerts when an index is being rebuilt.
DS-11959	Updated the HTTP/HTTPS connection handler to Jetty 8.1.16.v20140903.
DS-11993	Added a gauge to the server to track JVM memory usage and alert if the amount of free memory gets low enough that it could impact server performance.
DS-12000	Fixed an issue where attempting to cancel many outstanding proxy operations could make the proxy server unresponsive.
DS-12002	Updated the proxy server to limit the number of parallel threads that will be created to process entry balancing operations that must be broadcast. In configurations with a large number of worker threads or a large number of backend sets, this keeps the server from creating too many threads.
DS-12077	Improved the PingDirectoryProxy Server's handling for the rare case in which a number of backend server connections become invalidated, but that backend server still accepts connections and those newly-established connections can be successfully used to process operations.
DS-12077	Updated the server to perform a health check against an entry-balanced backend server in the event of a failure while processing a broadcast operation.

Ticket ID	Description
DS-12147	Updated the server to make it easier to control the order of values in the ssl-protocol and ssl-cipher-suite properties in the LDAP connection handler and crypto manager configuration objects.

PingDataMetrics Release Notes

PingDataMetrics Server 8.1.0.6 release notes

The release notes for the 8.1.0.6 release of PingDataMetrics Server.

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-44224	Addressed an issue where icons on the dashboards were not properly displayed.

PingDataMetrics 8.1.0.5 release notes

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-43288	<p data-bbox="850 216 1455 338">Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p data-bbox="850 359 1455 766">To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p data-bbox="850 787 1455 1010">Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul data-bbox="850 1031 1464 1854" style="list-style-type: none"><li data-bbox="850 1031 1464 1220">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.<li data-bbox="850 1241 1464 1484">* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.<li data-bbox="850 1505 1464 1854">* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDataMetrics Server 8.1.0.4 release notes

Critical Fixes

This release of the PingDataMetrics Sever addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDataMetrics Server:

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.

PingDataMetrics Server 8.1.0.3 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.

PingDataMetrics Server 8.1.0.2 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.0.1.3
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
 - Fixed in: 5.0.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-42687	Upgrade to Jetty 9.4.30

PingDataMetrics Server 8.1 Release Notes

Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578

- Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of the Data Metrics Server

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the

new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

What's New

These are new features for this release of the Data Metrics Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
 - The --outputFile option has been added to the collect-support-data tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the collect-support-data tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - The collect-support-data tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
 - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the collect-support-data tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the --remoteServer added to the collect-support-data tool can be used to send the request to another server. In other words, you can now run collect-support-data on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

Known Issues/Workarounds

The following are known issues in the current version of the Data Metrics Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the create-systemd-script tool to create a forking systemd service, the service is stopped by the "systemctl stop ping-directory.service" command. At that time, you can see the status using the "systemctl status ping-directory.service" command. That status might contain an indication of failure: "Active: failed (Result: exit-code)". This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.

Ticket ID	Description
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.

Ticket ID	Description
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

PingDataMetrics 8.0.0.5 release notes

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

PingDataMetrics Server 8.0.0.3 release notes

Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PoingDataMetrics Server:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

Ping Data Metrics Server 8.0.0.2 Release Notes

Critical Fixes

This release of the Ping Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Ping Data Metrics Server :

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

Ticket ID	Description
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42812	Upgrade to jetty 9.4.30

PingDataMetrics Server 8.0.0.1 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on .
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that

were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced allowed-insecure-tls-protocol global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition,

if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataMetrics Server 8.0.0.0 Release Notes

Critical Fixes

This release of PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Known Issues and Workarounds

The following are known issues in the current version of PingDataMetrics Server:

- The following are suggested solutions for problems with slow DNS:
 - Maintain a connection pool in the client app rather than opening new connections for each bind.
 - Add appropriate records, including PTR records, to DNS.
 - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`.
 - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.
 - **Workaround:** Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.
- The working directory value used by exec tasks is not implemented for recurring exec tasks.

Resolved Issues

The following issues have been resolved with this release of PingDataMetrics Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38867	Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions. Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 release notes. As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code> , download the appropriate jar file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.

Ticket ID	Description
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> ▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server ▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server ▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server ▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point at the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39373	<p>Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.</p>
DS-39518	<p>Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code>), this could cause unexpected or incorrect behavior.</p>
DS-39592	<p>HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code>, which defines the alias of a specific certificate within their keystore to be used as a client certificate.</p>
DS-39626, DS-40357	<p>The trace log publisher will now record an access token's scopes after the token is successfully validated.</p>
DS-39654	<p>Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.</p>
DS-39715	<p>Updated the Server SDK to add support for sending email messages.</p>
DS-39857	<p>Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.</p>
DS-39908	<p>Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.</p>
DS-40114	<p>Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.</p>
DS-40354	<p>Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.</p>

Ticket ID	Description
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

PingDataMetrics 7.3.0.10 release notes

Critical fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
 - Fixed in: 7.3.0.10
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-41762 SF#00675207 SF#00683777

Resolved issues

The following issues have been resolved with this release of the Data Metrics Server.

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.

Ping Data Metrics Server 7.3.0.8 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF

exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-42265	Upgrade to jetty 9.4
DS-42687	Upgrade to jetty 9.4.30

PingDataMetrics Server 7.3.0.7 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the "Resource" column in the output of "status". This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-39799	Allows users who were migrated from the admin backend to the topology to manage the topology. Migrated users are granted the "manage-topology" privilege if they do not already have it.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40771	Added a --duration argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataMetrics Server 7.3.0.5 Release Notes

Critical Fixes

This release of the Data Metrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782

Resolved Issues

The following issues have been resolved with this release of the Data Metrics Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

PingDataMetrics Server 6.2.0.0 Release Notes

Critical Fixes

This release of the PingDataMetrics Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose `cn=Version,cn=monitor` entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301

- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395

Upgrade Considerations

Important considerations for upgrading to this version of the PingDataMetrics Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.

What's New

These are new features for this release of the PingDataMetrics Server:

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
 - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
 - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the `collect-support-data` tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the `--remoteServer` added to the `collect-support-data` tool can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party.

Known Issues/Workarounds

The following are known issues in the current version of the PingDataMetrics Server:

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.

Resolved Issues

The following issues have been resolved with this release of the PingDataMetrics Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the <code>collect-support-data</code> tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an <code>outputPath</code> argument to allow specifying the path or name to use for the output file.

Ticket ID	Description
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.

Ticket ID	Description
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.

Ticket ID	Description
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.

Ticket ID	Description
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has memory.swappiness set to a nonzero value.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a NullPointerException if a server was configured with a custom global result code map.

PingDataMetrics Server 6.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of the PingDataMetrics Server:

Note: The product names have been updated to reflect the UnboundID acquisition by Ping Identity. This is a naming and branding change only; the code base is the same as in prior releases and will continue to be maintained into the future.

- If upgrading the server that was running an older version of the JDK, run the `dsjavaproperties --initialize` command after the software upgrade to compare the settings of the older JDK with requirements for the new server software. Apply any necessary changes to the upgraded server based on previous performance settings.
- Due to licensing considerations, the Metrics API no longer supports output of the bitmap charts formats `.jpg` and `.png`; data is still available as CSV, XML, and JSON. This does not affect the PingDataMetrics Server dashboards and does not affect the Query Builder.
- The 6.0 release makes these changes to supported platforms:
 - CentOS 7.2 and RedHat 7.2 are now supported operating system versions.
 - SUSE 11 SP4 is now supported; SUSE 11 SP2 support has been retired.
 - Linux KVM and VMWare ESXi 6.x have been added as supported virtual machine environments.
 - Deprecation of JDKs 7.x. Customers are strongly advised to use JDK 8 with this release. A later release of the platform will remove support for JDK versions 7.x. At that time customers will be required to upgrade to JDK 8.x when upgrading servers. This will apply to all of our JDK flavors (OpenJDK, OracleJDK, IBM JDK) on all platforms.
 - WildFly 9.x (renamed from JBoss) is now a supported application server for all web applications, including the Administrative Console and sample applications. Support for JBoss 7.x has been retired. Tomcat support remains unchanged in this release
- PBKDF2 is now the default encoding for root passwords. This only affects new installations.
- In addition to changing the default password storage scheme for root users to PBKDF2, the default password storage scheme for regular users has been changed to salted 256-bit SHA-2.
- HTTPS defaults to ON: servers now default to use HTTPS for console and API connections including the SCIM API. This may affect automation scripts and development environments where HTTPS has not been in use before.
- Generated user passwords, for example those created by the server during a password reset sequence, are now created as pass-phrases instead of random character strings. This makes them easier to type and remember. This change will not affect upgrades.

- The /config directory file permissions have been changed so that they are only accessible by the server user.
- Customers who choose to use the optional encryption algorithms provided by the third-party BouncyCastle library are encouraged to upgrade to BouncyCastle 1.54.

What's New

These are new features for this release of the PingDataMetrics Server:

- For Java developers whose tools and workflows make use of Maven, the Server SDK jar has been deployed to Maven Central so that a developer can now add the Server SDK as a project dependency by adding a few lines to a project's pom.xml. Also, developers can now generate a Server SDK project that Maven-aware IDEs such as IntelliJ IDEA can package into an extension bundle with no special configuration needed. This benefit extends similarly to continuous integration systems such as Jenkins.
- The dsconfig tool provides the ability to search for and quickly navigate to configuration objects and properties in which the name, synopsis, or description matches a provided pattern.
- A new rotate-log tool and task have been added, which can be used to trigger rotation of one or more log files.
- The Configuration API is now fully supported for all servers. In this release, the API was changed to match SCIM conventions for attribute naming, resource modeling, and the standard HTTP verbs. The UnboundID SCIM 2 SDK (available through GitHub) can now be used with the Configuration API.
- All servers have an updated web Administrative Console. This includes the following:
 - New layouts for operational statistics, processing time, queues, all monitors, and the list of installed extensions.
 - Alert and alarm displays, summarizing the data in cn=alerts and cn=alarms and based on the configured gauges. Plus, filtering and searching for these.
 - A new LDAP Schema Editor for importing schema files, validity checking, creation and editing of object classes and attribute types. The editor also supports viewing of the attribute syntaxes, inheritance, and indexes that exist for each attribute and the dependencies between object classes and attributes
- The new Administrative Console can also be deployed to independent application servers instead of being co-hosted by the servers. This simplifies deployment models and increases separation between data and application layers.
- To assist with situations where a very large number of changes may cause disk, memory, and server start time to increase unexpectedly, alerting and gauge features have been added to the Recent Changes Database.
- Servers can now trigger events whenever log file rotation occurs. This includes copy on rotate and summarize on rotate listeners, as well as Server SDK support for creating custom log file rotation listeners.
- It is now possible to create, change, and remove root user accounts across the topology using the dsconfig tool and Administrative Console.

Known Issues/Workarounds

The following are known issues in the current version of the PingDataMetrics Server:

- When deploying the Administrative Console in Tomcat 8, and accessing the Administrative Console application using Tomcat's Web Application Manager, some browsers (including Safari and Firefox) will generate a path URL that encodes the dash in ubid-console. This results in a path such as http://localhost:8888/ubid%2Dconsole/, which causes session management errors. To workaround this issue, copy and paste the generated link into a browser, and replace the encoded dash with a dash (-) character.
- The PermSize and MaxPermSize JVM properties are no longer supported in JDK 8, and will safely be ignored. These properties can be removed by modifying the config/java.properties file and running bin/dsjavaproperties while the server is offline.

- Security criteria for root passwords with the default configuration will be increased in a future release. This might affect automated installation scripts that currently use less secure passwords. This will not affect existing root accounts.
- The `dsconfig` tool and the Administrative Console enables creating and managing new Root DN users in this release. However, there is a limitation with changing the password of the currently logged in administrator. The `ldappasswordmodify` command can be used to change the administrator's password by providing the current and new password.

Resolved Issues

The following issues have been resolved with this release of the PingDataMetrics Server:

Ticket ID	Description
DS-979	Added the ability to search for configuration objects and their properties by name with the <code>dsconfig</code> tool.
DS-4235	Added support for log file rotation listeners, which allow for custom processing whenever a log file is rotated out of service so that the server will no longer write to it. A copy listener (which will copy the rotated log file to an alternate location, optionally compressing it in the process), and a summarize listener (which will invoke the <code>summarize-access-log</code> tool on the rotated log file) are included. The Server SDK also includes an API for creating custom log file rotation listeners.
DS-7505,DS-13571,DS-13860	<p>Updated the default file permissions for new installations on UNIX-based systems. Files and directories included in the zip file will be only be accessible to their owner (the user that unzipped the file) by default.</p> <p>Newly-created files and directories will also be assigned permissions that allow them to be accessed only by the account used to run the server. Existing configuration options for setting file permissions (the <code>log-file-permissions</code> and <code>db-directory-permissions</code> properties) will continue to behave as before. The new <code>config/server.umask</code> file will control the default permissions for all other newly-created files and directories.</p>

Ticket ID	Description
DS-9407,DS-15183,DS-15220	<p>Updated the initial server configuration to improve security and usability. These changes apply only to new installations and will not be applied when updating an existing installation. Changes include:</p> <ul style="list-style-type: none"> ▪ Updated the default password policy to use a default password storage scheme that uses a salted 256-bit SHA-2 digest rather than a salted SHA-1 digest. ▪ Updated the root password policy to use a default password storage scheme of PBKDF2 rather than salted 512-bit SHA-2. ▪ Updated the secure password policy to use a default password storage scheme of PBKDF2 rather than a CRYPT variant that uses multiple rounds of 256-bit SHA-2. ▪ Updated the password policy import plugin so that it will attempt to use the default password policy to select the password storage scheme(s) to use for entries that do not explicitly specify a password policy. The plugin will also fall back to using a salted 256-bit SHA-2 scheme instead of a salted SHA-1 scheme. ▪ A number of weaker password storage schemes have been disabled by default, including base64, clear, unsalted MD5, salted MD5, 3DES, RC4, and unsalted SHA-1. ▪ The default password policy has been updated to use a password generator that generates very strong yet memorable passphrases rather than a shorter and less-memorable string of randomly-selected characters. ▪ Many of the server loggers have been updated to include additional log elements by default, including the instance name, requester DN, requester IP address, and request controls. ▪ The exact match identity mapper has been updated to look at the mail attribute in addition to the uid attribute. When targeting a user with an authentication ID value (as when using SASL authentication or the proxied authorization v2 request control), it is now possible to specify an email address as an alternative to a user ID. ▪ The UNBOUNDID-TOTP SASL mechanism handler has been updated to prevent TOTP password reuse by default. ▪ Added new request criteria that make it possible to identify requests that target the root DSE or the subschema subentry. The global configuration has been updated so that requests targeting these entries will be in the default exceptions lists if the server is configured to reject insecure or unauthenticated requests. ▪ Updated the template that setup generates for creating sample data to use a more logical and user-friendly numeric range. When the user requests N entries, setup would previously number the entries 0 through N-1 (for example, if the user requested 1000 entries, they would

Ticket ID	Description
DS-9591	The ability to request server-generated charts from the Metrics Engine has been removed in this release.
DS-10312	Added the server's process ID to the output of the status tool.
DS-10464	Added a new rotate-log tool to request the rotation of one or more log files.
DS-10466,DS-10765,DS-14479,DS-15318,DS-16154	Addressed a few issues in config-diff. In some situations, config-diff would not generate commands in an order that respected all dependencies. This has been fixed. Most expected warnings are now excluded by default but can be included in the output with the --includeAllWarnings option. The --sourceBindPasswordFile and --targetBindPassword are now applied in conjunction with the --targetConfigGroup and --sourceConfigGroup options.
DS-10946	Added a --dry-run option to dsconfig, which can be used in batch mode to validate the configuration changes in a batch file without applying them.
DS-12191	Added support for setting the request header size in the Jetty http configuration server properties.
DS-12546	The setup tool now creates the Postgres database directory under the server root, instead of the user's current directory. The data directory location can be changed by specifying the --databaseDataDir option when invoking setup.
DS-13401	Improved the collect-support-data tool to include information provided by systemd on platforms that support it.
DS-13700	<p>Updated command-line tools based on the LDAP SDK tool APIs to add the following features:</p> <ul style="list-style-type: none"> ▪ Tools can obtain default values for any arguments not provided on the command line from a properties file. If it exists, the server's config/tools.properties file will be used by default. Command-line arguments can be used to specify an alternate properties file or to indicate that no properties file should be used. ▪ Tools can be launched in an interactive mode, in which the user is prompted for arguments used to establish and authenticate the connection, and for any other required arguments. The user can then use an interactive menu to specify values for any remaining arguments.

Ticket ID	Description
DS-13823	Collect-support-data tool now captures Kerberos config and log information.
DS-13901	The PingDataMetrics Server REST API servlet has a new authentication timeout property to allow a configurable session timeout. Previously, the authentication session timeout was 15 minutes.
DS-14213	Added the ability to create local constants in LDIF template files using the new 'local' keyword.
DS-14430	Updated the Apache commons collections library to address the security vulnerability described by CVE 2015-4852.
DS-14548	Added a monitor entry for each Server SDK extension.
DS-14694	Added a --prettyPrint option to the config-diff tool to make the output more human-readable.
DS-14704	Updated the restore command so that it can no longer be used to restore a backup of the config backend. The command now points the administrator for safer ways to revert configuration changes, including using config-diff.
DS-14749	Updated the server's support for the Twilio Messaging Service so that it uses the newer "Messages" API when sending SMS messages instead of the older "SMS" API. The older API has been deprecated, and Twilio now imposes a 120-character limit for messages sent via that API. The messages API allows the server to take advantage of the full 160 characters per SMS message.
DS-14857	Fixed an issue with the dsjavaproperties tool where java properties for PermSize and MaxPermSize could be added when using JDK 8, which no longer supports these options.
DS-14923	Updated the bcrypt, crypt, PBKDF2 and scrypt password storage schemes so they can be used to create new instances.
DS-14979	Fixed a case where attribute syntax configuration changes would not apply to undefined attributes, which rely on default attribute types.
DS-15015	Server SDK extensions are now built with a Java source version of 1.7 by default.

Ticket ID	Description
DS-15088	The former suite of Administrative Console applications, each of which were tied to a particular product (for example the dsconsole.war for the PingDirectory Server) are no longer available, and have been superceded by a new version of the Administrative Console capable of managing any server product. You can choose to access the Administrative Console by hosting it within a server, or by deploying it in an external servlet container. For the former, enable an HTTP Connection Handler and add the Administrative Console Web Application Extension to the handler. For the latter, download and unzip the management-console-[version].zip file, and install the ubid-console.war file according to your container's instructions.
DS-15175	The Configuration API now returns unquoted, native Javascript values for integer, real number, and boolean properties. Duration and size property values, for example '1 w' or '100 G', continue to be represented as Javascript string types.
DS-15178	Improved the error messages and examples for create-rc-script and create-systemd-script by explicitly suggesting the use of sudo so that the scripts can modify protected files.
DS-15221	Changed interactive setup default value for HTTPS enablement.
DS-15336	The monitored-servers tool now enables specifying a monitoring user bind DN when adding servers.
DS-15337	Improved the error messages for create-rc-script and create-systemd-script when the directory in which the script will be created does not exist.
DS-15361,DS-15363,DS-15434	Updated interactive setup to display default values, and improved the overall layout and appearance.
DS-15400	Addressed an issue where dsconfig incorrectly allowed certain configuration objects to be deleted.
DS-15412	Improved the error messages produced by the manage-extensions tool when attempting to install invalid extensions.

Ticket ID	Description
DS-15417	Updated the global ACIs that ship with the server to use a separate ACI for each control or extended request to allow by default, rather than grouping all desired controls together in one ACI and all desired extended requests together in a second ACI. This change will only be reflected in new installations, and not when updating an existing deployment.
DS-15422	Root DN User configuration entries can now be fully managed through the configuration management interfaces such as dsconfig and the Administrative Console.
DS-15466	Added more logging information when initializing web application and servlet extensions in case an extension causes conflicts or delays.
DS-15521	Updated setup to encode the root password with the PBKDF2 password storage scheme instead of SHA512.
DS-15522	Updater tool will increase PermSize and MaxPermSize parameters to recommended value to prevent Java JVM pauses.
DS-15592	Fixed an error that could occur during upgrade when the configuration can not be loaded due to missing custom schema.
DS-15621	Updated the Groovy Scripting Language version to 2.4.6.
DS-15622	Fixed an issue that prevented the deletion of disabled debug loggers.
DS-15679	Updated the version of the XML serialization library XStream from 1.3.1 to 1.4.9 to address a security vulnerability in the prior version.
DS-16224	Updated the sanitize-log tool to add support for JSON-formatted access and error log files.

Delegated Admin Release Notes

Delegated Admin 4.2.0 Release Notes

Upgrade Considerations

If you are running Delegated Administration application version 3.5 or older, you will need to upgrade it to the latest version if you want to use PingDirectory 8.0 or newer.

What's New

These are new features for this release of PingDirectory Delegated Admin:

- Delegated Admin 4.1
 - For Delegated Admin, administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.
 - REST resource types define the types of objects that can be managed by delegated administrators. Typical REST resource types include users and groups which can be configured based on the subtree and a predefined search filter. A new include-filter property has been added to REST resource types to differentiate different resource types that are within the same subtree and have the same objectclass.
- Delegated Admin 4.2
 - Administrative users can now create and download reports of users, group membership or other generic resource to a CSV file. The users need the proper rights for the resource types on which they wish to report. The information stored in the downloaded file will be based on the attributes configured for the resource type. For group resource types, each report generated will be for a single group.
 - Added a new reference permission to Delegated Admin resource rights configuration which allows the administrator to reference resources when selecting a parent for a new resource. This permission differs from read permission in that the app will not show an option to manage the parent resource type in the Delegated Administrator app.
 - In many circumstances, LDAP attributes within an entry contain multiple values. The application can now display multi-valued attributes which are not handled by custom UI form fields.
 - A privileged administrator for a hosting company can onboard a new tenant administrator to manage resources for the tenant's own organization without requiring additional configuration from the Administrative Console or command line.

Known Issues/Workarounds

The following known issues are in the current version of Delegated Admin:

- Delegated Admin 4.2.0 has an intermittent, infinite spinner issue when signing on. To address the issue and continue using PingDirectory 8.1.0.0, install Delegated Admin 4.2.1. Alternatively, you can upgrade to Delegated Admin 4.4.0 to address the issue; however, that upgrade requires upgrading to PingDirectory 8.2.0.0.
- Delegated Admin does not always show the account locked status correctly if the server password policy is configured to require the user to reset their password after the password has been administratively reset. This can be corrected by enabling the Password Policy State JSON virtual attribute for the user object class. For example:

```
dsconfig set-virtual-attribute-prop --name "Password Policy State JSON" \
--set enabled:true --set require-explicit-request-by-name:true \
--set "filter:(objectClass=person) "
```

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-41819	Fixed an issue where a Delegated Administrator was unable to add or remove themselves to or from a group to which they had rights to manage group membership.
DS-41848	Fixed an issue where edits modifying only the case or capitalization of an attribute value did not take effect.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

Delegated Admin Release Notes archive

Release Notes for earlier versions of Delegated Admin are included for reference.

Delegated Admin 4.1.0 Release Notes

Upgrade Considerations

Upgrade directly to this release from versions prior to 7.0 is not supported. As a workaround, upgrade from a pre-7.0 version to 8.0, and then upgrade to this version.

What's New

These are new features for this release of :

- Administrators can be assigned rights to manage different types of resources such as users and groups. Previously, administrators who can only manage users in specified groups could not create users to put them in the one of the groups they managed. Now, administrators with the ability to manage and create groups can create users within the group(s) they manage.
- When the Delegated admin rights for a User REST resource type have admin scope resources-in-specific-groups, a user is added to one of the configured groups when the user is created.
- An example file for JSON attributes, `example-json.html`, has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of `ubidEmailJSON`, an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the `example-multivalue.html` for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
- Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, `example-multivalue.html`, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

- In environments with Proxy and multiple backend servers, there is a known issue using the fewest-operation load-balancing algorithm with the Delegated Admin app. Constructed attributes sometimes do

not get updated when the attributes they reference are edited. Using a failover load-balancing algorithm is a workaround for this issue. (DS-40977)

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-40938	Fixed an issue when Delegated Admin is installed on the Directory Proxy Server where a constructed attribute that is set to be read-only may not update in the app immediately after one of the attributes it references is updated.
DS-41066	Fixed an issue where JSON object values for attributes caused an application error when attempting to display them in the UI.
DS-41275	It is now a configuration error to enable two REST resource types with the same endpoint (ignoring differences in case) at the same time. It is allowed to have two resource types with the same endpoint if one or both of them are not enabled.
DS-41669	An example file for JSON attributes, example-json.html, has been added and can be located alongside other existing example files for custom UI form fields. This example file supports a single value and uses the expected JSON structure of uidEmailJSON, an available JSON attribute type for Ping Directory. Multiple values are also supported, please see the example-multivalue.html for an example of how to handle that use-case. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, example-multivalue.html, has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Delegated Admin 4.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

PingDirectory 8.0.0.0 is now the minimum required version to use with Delegated Admin 4.0.0. If you are on an older version of PingDirectory, it will be necessary to upgrade to PingDirectory 8.0.0.0 to maintain compatibility.

Delegated Admin 3.5.1 is compatible with PingDirectory Server 8.0.0.0. However, versions of Delegated Admin that are earlier than 4.0.0 will not be compatible with versions of PingDirectory Server that are later than 8.0.0.0.

By default, the display name for the logged in delegated admin will no longer display. To re-configure this functionality, please see the section on enabling the `name` attribute to be returned with the OIDC id token. See the Delegated Admin Guide for more information.

The `delegated-admin-template.dsconfig` file has been updated to allow for `generate-password` extended requests and password validation details request controls. This change is not applied during an update. You must run the following two `dsconfig` commands when updating :

```
dsconfig set-access-control-handler-prop --add \
'global-aci:(extop="1.3.6.1.4.1.30221.2.6.62")(version 3.0; \
acl "Authenticated access to the generate-password extended \
request for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

```
dsconfig set-access-control-handler-prop \
--add 'global-aci:(targetcontrol="1.3.6.1.4.1.30221.2.5.40") \
(version 3.0;acl "Authenticated access to the password validation details \
request \
control for the Delegated Admin API"; allow (read) userdn="ldap:///all";)'
```

What's New

These are new features for this release of :

- Invite new users via e-mail: Taking advantage of the new e-mail notification capabilities of 8.0.0.0, now administrators can configure the service so that when a delegated admin creates a new user, the server can send an HTML e-mail to tell the new user their password and invite them to use their new account. Combine this with PingFederate self-service profile management to invite the new user to complete their profile.
- When creating users or resetting passwords, delegated admins now have the option to type in the new password or have the server generate a password. Previously the application only supported server-generated passwords.
- More flexibility in delegating the management of user profiles: Now administrators can configure the service so that delegated admins of one type, such as Employee, can create and manage users of other types, such as Customers or Members. Previously delegated admins could only create and manage users of their own type.

Known Issues/Workarounds

The following are known issues in this version of Delegated Admin:

-
- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
 - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
 - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin:

Ticket ID	Description
DS-39352	When adding a user to groups and there were no non-member groups to display, the notice text did not use proper context to reflect this state.
DS-39782	Constructed attributes were not updated in the application after their associated attributes were edited. A page refresh or subsequent data request was required to reflect the change for the constructed attribute in the application.
DS-40690	This scenario occurred when a delegated admin only had permission to edit users in certain groups. If the delegated admin then went to a user's profile and removed them from the group which governed permission over that user, this action resulted in an application error.
DS-41715	Multivalue attributes may now be handled as part of custom UI form fields. Contrary to single value attributes, an array of values will need to be sent up to the form when building out the custom field. An example file, <code>example-multivalue.html</code> , has been provided to demonstrate a string-based, multivalue attribute as a custom UI form field and can be located alongside other existing example files. As with any custom UI form field, modifications will likely be necessary and some technical knowledge will be required.

Delegated Admin 3.5.1 Release Notes

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-38745, DS-39639	Previously, when port 443 was used but not specified in the PingFederate Base URL, the system returned an <code>Invalid issuer in token</code> message. With this fix, the value for <code>window.PF_PORT</code> can be left blank in <code>config.js</code> to match the expected Base URL that the PingFederate token supplies.

Delegated Admin 3.5.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of Delegated Admin:

The file `remove-sample-directory-data-aci.ldif`, which is provided with the Delegated Admin installation package, was updated to reinstate permissions for users to change their own passwords (self-

service password reset). If you have used an earlier version of this LDIF file, consider manually adding the following ACI from the updated version:

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr="userPassword")(version 3.0; acl "Allow users to update
their own password"; allow (write) userdn="ldap:///self");)
```

What's New

The following features are new with this release of Delegated Admin:

- Added the ability for developers to customize attribute form fields and form behaviors. Previously, `Delegated User Admin` did not support attributes whose types were neither strings nor numbers, like JSON attribute types. With the ability to override the form fields for any attribute type, developers can now extend `Delegated User Admin` to handle these attribute types and more. Requires PingDirectory Server 7.3.0.0 or later.
- Added more capabilities for attributes that are constructed from other attributes. The *constructed attribute* feature can now be used for attributes that the LDAP schema requires. Further, administrators can configure constructed attributes to update automatically when their referenced attributes change. For example, if `displayName` is constructed from `givenName` and `sn`, the `displayName` attribute updates whenever the delegated administrator updates either `givenName` or `sn`. Requires PingDirectory Server 7.3.0.1 or later.

Known Issues and Workarounds

The following issues are known in this release of Delegated Admin:

- Changes to custom form field HTML files are not displayed.

This issue relates to the browser and server. Because PingDirectory Server does not send the appropriate cache headers for static files, some browsers might cache them aggressively.

Workaround: Refer to the "Next steps" section in [Customize UI form fields](#) on page 1396.
- Constructed attributes do not update automatically when editing a resource.

This issue relates to the user interface (UI). When a constructed attribute is computed and saved in PingDirectory Server, the UI does not immediately display the new value.

Workaround: To verify the changes visually, try one or both of the following suggestions:

 - Refresh the browser.
 - Visit another page, and then navigate back to the edited resource.

Resolved Issues

The following table identifies issues that have been resolved with this release of Delegated Admin.

Ticket ID	Description
DS-39347	Fixed an issue in which Delegated Admin did not work properly if the name of the REST resource type was not the same as the resource endpoint.

Ticket ID	Description
DS-39693	Fixed an issue in which Delegated Admin search results were truncated and invalid upon encountering a Directory entry that contained a Boolean or Integer syntax attribute whose values did not conform to the appropriate syntax. With this fix, the offending values are omitted from the results, and a warning message is logged to the server errors log.

PingDataSync Server Release Notes

PingDataSync Server 8.1.0.6 release notes

The release notes for the 8.1.0.6 release of PingDataSync Server.

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-42049	Fixed an issue with the Data Sync server where retry operations could get the server stuck and unable to process changes at the source.

PingDataSync Server 8.1.0.5 release notes

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-44316	Reduced the JVM memory requirements for many command line tools. This avoids memory pressure when multiple tools, such as a scheduled collect-support-data task, are run concurrently to the server process. For most tools, the initial heap size has been reduced to 128 MB, and for certain tools the maximum heap size has capped at 512 MB. On systems with larger amounts of memory, these tools previously were allotted unnecessarily large heaps. The maximum heap size has not been reduced for any tool that especially benefits from having more memory.

PingDataSync Server Release Notes archive

Release Notes for earlier versions of PingDataSync Server are included for reference.

PingDataSync 8.1.0.4 release notes

Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the PingDataSync Server:

Ticket ID	Description
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43305	Increased the maximum number of RDN components that a DN may have from 50 to 100.
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.
DS-43817	Fixed an issue where Directory Server sometimes reports erroneous warnings about duplicate jar files.

PingDataSync 8.1.0.3 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-37890	Added a new property to sync classes called <code>replace-all-attr-values-limit</code> . The property is only used when <code>replace-all-attr-values</code> is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of <code>replace-all-attr-values-limit</code> , then the modification will use ADD or DELETE operations rather than a REPLACE operation.

Ticket ID	Description
DS-40650	Updated the collect-support-data tool to make it possible to specify how much data should be captured from the beginning and end of each log file to include in the support data archive. You can also specify the capture size when invoking the tool through an administrative task, recurring task, or extended operation.
DS-42527	Fixed an issue that could cause an exception when creating a resource in SCIM 1.1 using certain types of DNTemplate.
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.

PingDataSync 8.1.0.2 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it has been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - Fixed in: 7.0.1.3
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763

- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.
 - Fixed in: 5.0.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.
 - Fixed in: 3.2.0.0
 - Introduced in: 3.0.0.0
 - Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41964	Fixed an issue with the manage-profile tool where files in a server profile's dsconfig/ directory without a ".dsconfig" extension could cause failures in manage-profile replace-profile when validating updated dsconfig files.
DS-42687	Upgrade to Jetty 9.4.30

PingDataSync 8.1 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.1.0.0
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301

- Fixed a memory leak when performing SCIM queries on the Directory Server.
 - Fixed in: 8.1.0.0
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.
 - * When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-

endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

Upgrade Considerations

Important considerations for upgrading to this version of the Data Sync Server:

- If you have upgraded a server that is in a cluster (i.e., has a cluster name set in the Server Instance configuration object) to version 8.1, you will not be able to make cluster configuration changes until all servers with the same cluster name have been upgraded to version 8.1. If needed, you could create temporary clusters based on server versions and modify each of the servers' cluster name appropriately to minimize the impact while you are upgrading.
- Updated the "delay bind response" failure lockout action to provide an option to delay the response to bind requests initiated by non-LDAP clients (for example, when using HTTP basic authentication). This option is disabled by default because delaying the bind response for non-LDAP clients may require temporarily blocking the thread used to process the request, which could increase the risk of a denial-of-service attack. To help mitigate this risk, if you enable delayed bind responses for non LDAP clients, we recommend that you also increase the number of request handler threads for all enabled HTTP connection handlers.
- Updated setup to create a second encryption settings definition if data encryption is enabled. It will continue to create a definition for 128-bit AES encryption for use as the preferred definition to preserve backward compatibility with existing servers in the topology, but it will now also generate a definition for 256-bit AES encryption. The 256-bit AES definition may become the preferred definition in a future release, but you can use it now by first ensuring that any existing instances are updated to contain the new definition (with the "encryption-settings export" and "encryption-settings import" commands) and then making it the preferred definition (with "encryption-settings set-preferred") in all instances.

What's New

These are new features for this release of the Data Sync Server

- In an ongoing effort to improve the use of containers for PingDirectory, several features have been implemented:
 - The `--outputFile` option has been added to the `collect-support-data` tool. You can now specify either a path, a file name, or a path and file name for the resulting CSD file. This means an administrator can run the `collect-support-data` tool and put the output file into a directory outside of the container, allowing access to the file without having to actually connect to the container.
 - The `collect-support-data` tool can now be run as a recurring task. Recurring tasks can be created using the Administration console which means that administrators do not have to connect to the container in order to run the tool.
 - A Collect Support Tool Extended Operation has been added allowing LDAP clients to initiate the `collect-support-data` tool and to receive the output of the request. The LDAP SDK has been updated to support this, and the `--remoteServer` added to the `collect-support-data` tool can be used to send the request to another server. In other words, you can now run `collect-support-data` on the command line and reference another server, possibly in a container, and retrieve the output file remotely.
- PingDirectory has a Consent REST API that allows users to create and store consents. A new feature now allows users to search for consents that have been granted to them by another party
- Updated the server to use `/dev/urandom` (on non-Windows systems where that path exists and is readable) instead of `/dev/random` as the primary source for secure random data. Attempts to read from `/dev/random` can block if the underlying system does not have sufficient entropy, which can have a severe adverse effect on performance. Reads from `/dev/urandom` will not block, and the data that it provides is no less secure than data from `/dev/random` in any way that matters for the server.
- Replaced the `ldapcompare` tool with a new version that offers more functionality, including support for multiple compare assertions, following referrals, additional controls, and multiple output formats (including tab-delimited text, CSV, and JSON).
- Replaced the `ldifsearch`, `ldifmodify`, and `ldif-diff` command-line tools with more full-featured and robust implementations.
- Updated the server to require a minimum key size of 2048 bits when negotiating a TLS cipher suite that uses ephemeral Diffie-Hellman key exchange.
- Replaced the `ldappasswordmodify` tool with a new version that offers more functionality, including support for additional controls, support for multiple password change methods (the password modify extended operation, a regular LDAP modify operation, or an Active Directory-specific modify operation), and the ability to generate the new password on the client.
- Added a `config/sample-dsconfig-batch-files` directory with set of well commented `dsconfig` batch files that may be useful in enabling or configuring a variety of features in the server.

Known Issues/Workarounds

The following are known issues in the current version of the Data Sync Server

- Several known issues can occur when you use the Administrative Console with Tomcat 9.0.31. You can resolve these issues by upgrading to Tomcat 9.0.33 or later.
- If you use the `create-systemd-script` tool to create a forking `systemd` service, the service is stopped by the `"systemctl stop ping-directory.service"` command. At that time, you can see the status using the `"systemctl status ping-directory.service"` command. That status might contain an indication of failure: `"Active: failed (Result: exit-code)"`. This error has to do with the way the service exits. It is harmless.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-1046,DS-1204,DS-36547	Added support for remotely invoking the collect-support-data tool using an administrative task, and for invoking the tool on a regular basis as a recurring task. The tool has also been updated to add an outputPath argument to allow specifying the path or name to use for the output file.
DS-37829	The "create-systemd-script" CLI now creates a "forking" service file since Ping services are started by a process (the "start-server" script) that is different than the actual service process.
DS-38122	Added support for an extended operation that can be used to invoke the collect-support-data tool from a remote system and stream the output and resulting support data archive back to the client. The collect-support-data command-line tool has been updated to support this capability through the new --useRemoteServer argument.
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.
DS-39798	Fixed a bug in which SEMI_AGGRESSIVE and AGGRESSIVE JVM Tuning Parameters were previously allowed to both be selected.
DS-39862	Improved support for the PingOne Sync Source and Destination in the create-sync-pipe-config tool by adding Sync Classes tailored to the PingOne endpoint.
DS-40025,DS-42041	When using an Active Directory Sync Source, the base DN of the Sync Source can now be set to a descendant of the root directory partition of the AD instance(s). When detecting changes, the Sync Source will adjust the value to be the root directory partition if it is not already set to this value, but when synchronizing changes, the Sync Source will only consider changes that have a DN under the base DN provided to the Sync Source.
DS-40241	Updated create-sync-pipe-config to support creating a sync pipe that does not synchronize any attributes. This will be suggested as the default option when either the source or destination is Active Directory or a relational database. The previous default of synchronizing all attributes will still be used when both the source and destination are non-Active Directory LDAP servers.

Ticket ID	Description
DS-40356	Updated the manage-profile tool to prevent displaying warnings about offline config changes when starting the server.
DS-40413	Updated the behavior of the resync tool when an invalid DN is detected. Instead of stopping the process, the offending entry will be reported and skipped, allowing for the remaining entries to be processed. This issue only affected ActiveDirectory and Changelog Sync Sources (LDAP Sync Sources that detect changes using cn=changelog, such as PingDirectory or ODSEE).
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted tools.properties file.
DS-40567	A license is now always required when using the manage-profile replace-profile tool.
DS-40746	Updated the logic that the server uses to select an appropriate default set of TLS cipher suites.
DS-40806	Fixed an issue that could cause the shutdown process to stall if the server is configured to use TCP to communicate with a StatsD endpoint that has become unresponsive.
DS-40889	Fixed an issue with recurring exec tasks where the working-directory attribute was ignored.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.

Ticket ID	Description
DS-41086	Updated the StatsD monitoring endpoint to replace any spaces, commas, or colons with underscores, and remove and single quotes or double quotes in sent metric lines. This simplifies parsing of the produced metrics.
DS-41118	A gauge called HTTP Processing (Percent) is now available. This gauge measures the server's capacity to process new incoming HTTP requests.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41142	Improved debugging support for Server SDK extensions. If debugging is enabled, the server will now generate a debug message whenever it invokes an extension. For some extension methods that return a value, the server will also generate a debug message with that return value.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41263	Updated the README for the Ping Identity Active Directory Password Sync Agent to indicate support for Windows Server 2016 and Windows Server 2019 and the removal of support for Windows Server 2008.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-41301	Addressed an issue that could lead to slow, off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
DS-41333	Added an ssl-client-auth-policy configuration property to the HTTP connection handler to provide support for mutual TLS authentication.
DS-41366	Updated the base monitor entry to include locationName and locationDN attributes if the server is configured with a location.
DS-41396	Updated the Server SDK to add ClientContext and OperationContext methods for obtaining the name and DN of the associated client connection policy.
DS-41400	Updated the file servlet HTTP servlet extension to add support for requiring authentication in order to access the content. Access may optionally be limited to members of a specified set of groups.
DS-41579	Fixes issue with realtime-sync Password Files and Pin Files displaying contents in clear text.
DS-41731	Fixed an issue that could prevent setup from generating a self-signed certificate for systems with non-ASCII hostnames.
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
DS-41784	Fixed a bug that could cause the duration of a sync operation to be miscalculated.
DS-41818	Added the --zip argument to the manage-profile generate-profile subcommand, which can be used to generate a zipped server profile.
DS-41820	Added an administrative task that may be used to generate a server profile and a corresponding recurring task that may be used to invoke the task on a regular basis.
DS-41821	Added an instance root file servlet to the default configuration. HTTPS requests to /instance-root by authenticated users with the file-servlet-access privilege will be granted access to files within the server instance root.

Ticket ID	Description
DS-41850	Servers running on Linux will now log a warning about possible performance impacts if the current memory control group has <code>memory.swappiness</code> set to a nonzero value.
DS-42006	The server now warns the administrator at startup if there are multiple versions of the same jar listed in the classpath, and the first one in the classpath is not the newest one.
DS-42033	Addressed an issue where some tools would throw a <code>NullPointerException</code> if a server was configured with a custom global result code map.
DS-42117	Updated Constructed Attribute Mapping's <code>exclude-value</code> property to accept multiple values with different capitalizations.
DS-42387	Updated the <code>manage-profile generate-profile</code> subcommand to exclude files in the <code>ldif/</code> and <code>bak/</code> directories by default when generating a server profile. If necessary, you can manually include those directories using the <code>--includePath</code> argument.

PingDataSync Server 8.0.0.5 release notes

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified.

PingDataSync 8.0.0.3 release notes

Critical Fixes

This release of PingDataSync addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of PingDataSync:

Ticket ID	Description
DS-38535	Fixed an issue that could cause the server to generate an administrative alert about an uncaught exception when trying to send data on a TLS-encrypted connection that is no longer valid.

Ticket ID	Description
DS-41807	Fixed an issue where LDAP DELETE operations were sometimes not synchronized from an Oracle Unified Directory sync source, due to variations in the format of the 'targetUniqueID' attribute obtained from the Oracle changelog.

Ticket ID	Description
DS-43288	<p>Updated setup and the replace-certificate tool to improve the way we generate self-signed certificates and certificate signing requests to make them more palatable to clients.</p> <p>To reduce the frequency with which administrators had to replace self-signed certificates, we previously used a very long lifetime for self-signed certificates generated by setup or the replace-certificate tool. However, some clients (especially web browsers and other HTTP clients) have started more strenuously objecting to certificates to long lifetimes, so we now generate self-signed certificates with a one-year validity period. The inter-server certificate (which is used internally within the server and does not get exposed to normal clients) is still created with a twenty-year lifetime.</p> <p>Also, the replace-certificate tool's interactive mode has been updated to improve the process that it uses to obtain information to include in the subject DN and subject alternative name extension for self-signed certificates and certificate signing requests. The following changes have been made in accordance with CA/Browser Forum guidelines:</p> <ul style="list-style-type: none">* When selecting the subject DN for the certificate, we listed a number of common attributes that may be used, including CN, OU, O, L, ST, and C. We previously indicated that CN attribute was recommended. We now also indicate that the O and C attributes are recommended as well.* When obtaining the list of DNS names to include in the subject alternative name extension, we previously suggested all names that we could find associated with interfaces on the local system. In many cases, we now omit non-qualified names and names that are associated with loopback interfaces. We will also warn about any attempts to add unqualified or invalid names to the list.* When obtaining the list of IP addresses to include in the subject alternative name extension, we previously suggested all addresses associated with all network interfaces on the system. We no longer suggest any IP addresses associated with loopback interfaces, and we no longer suggest any IP addresses associated in IANA-reserved ranges (for example, addresses reserved for private-use networks). The tool will now warn about attempts to add these addresses for inclusion in the subject alternative name extension.

Ticket ID	Description
DS-43480	Updated the system information monitor provider to restrict the set of environment variables that may be included. Previously, the monitor entry included information about all defined environment variables, as that information can be useful for diagnostic purposes. However, some deployments may include credentials, secret keys, or other sensitive information in environment variables, and that should not be exposed in the monitor. The server will now only include values from a predefined set of environment variables that are expected to be the most useful for troubleshooting problems, and that are not expected to contain sensitive information.
DS-43632	Fixed an issue where the "format" field is omitted from the list of operational attribute schemas in the Directory REST API.
DS-43651	The Security Guide is now available online at pingidentity.com and has been removed from the server packaging.

PingDataSync 8.0.0.2 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-37890	Added a new property to sync classes called <code>replace-all-attr-values-limit</code> . The property is only used when <code>replace-all-attr-values</code> is true and the sync destination is an LDAP server. If a modification would replace more values of the same attribute than the value of <code>replace-all-attr-values-limit</code> , then the modification will use ADD or DELETE operations rather than a REPLACE operation.
DS-40551	Fixed an issue that could prevent some tools from running properly with an encrypted <code>tools.properties</code> file.

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41074	Fixed an issue with the way the server reports memory usage after completing an explicitly requested garbage collection.
DS-41126	Updated the server to make the general monitor entry available to JMX clients.
DS-41235	Updated the cn=Cluster subtree to prevent clustered configuration changes when servers in the cluster have mixed versions. To make clustered configuration changes, either update all servers in the cluster to the same version, or temporarily create separate clusters by server version by changing the cluster-name property on the server instance configuration objects.
DS-41236	To avoid inconsistencies, changing clustered configuration will now require all servers in the cluster to be on the same product version. Servers will not pull any clustered configuration from the master of the cluster if they are on a different product version.
DS-41261	Fixed an issue with manage-profile replace-profile where certain configuration changes for recurring task chains were not being applied.
DS-41289	Fixed an issue that prevented password changes for topology administrators unless their password policy was configured to allow pre-encoded passwords.

Ticket ID	Description
DS-42609	Fixed an issue in which the Directory REST API could fail to decode certain credentials when using basic authentication.
DS-42665	Fixed an issue that caused the resync tool to not take the attribute-comparison-method of the sync class into account. This caused resync to ignore when byte-for-byte comparison was configured.
DS-42812	Upgrade to jetty 9.4.30

PingDataSync 8.0.0.1 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed a memory leak when performing SCIM queries on PingDataMetrics Server.
 - Fixed in: 8.0.0.1
 - Introduced in: 7.2.0.0
 - Support identifiers: DS-41206 SF#00681395
- Addressed an issue that could lead to slow off-heap memory growth. This only occurred on servers whose cn=Version,cn=monitor entry was retrieved frequently.
 - Fixed in: 8.0.0.1
 - Introduced in: 5.2.0.0
 - Support identifiers: DS-41301
- The following enhancements were made to the topology manager to make it easier to diagnose connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578

- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.

- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763

- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can

ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40532	Added a logging-error-behavior property to the log publisher, periodic stats logger plugin, and monitor history plugin configuration that can be used to specify the behavior the server should exhibit if an error occurs while attempting logging-related processing. By default, the server will preserve its previous behavior of writing a message to standard error, but it can be configured to enter lockdown mode on a logging error, in which the server will report itself as unavailable and will only accept requests from accounts with the lockdown-mode privilege and only from clients communicating over a loopback interface.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataSync 8.0.0.0 Release Notes

Critical Fixes

This release of the PingDataSync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

No critical issues have been identified

What's New

These are new features for this release of the PingDataSync Server:

- Use Server Profiles to reduce risk and improve consistency following the DevOps principle of infrastructure-as-code. Administrators can export the configuration of the PingDataSync Server server to a directory of text files called a Server Profile, track changes to these files in version control such as Git, and install new instances of PingDataSync Server or update existing instances of PingDataSync Server from a Server Profile. Server Profiles support variable substitution in order to remove the settings unique to each pre-production or production environment from the Server Profile that is stored in version control.
- Improved consistency for user passwords that are managed in PingOne for Customers. Now when PingDataSync Server recognizes a password change in the source PingOne for Customer environment, the password is removed from the destination PingDirectory. Upon the next on-prem LDAP bind, the validated password is saved in the destination PingDirectory by the pass-through authentication plugin.

Known Issues/Workarounds

The following are known issues in the current version of the PingDataSync Server:

- The following are suggested solutions for problems with slow DNS:
 - Maintain a connection pool in the client app rather than opening new connections for each bind.
 - Add appropriate records, including PTR records, to DNS.
 - Add `options timeout:1` in the `/etc/resolv.conf` file and/or `options single-request`
 - If IPv6 requests specifically are causing issues, add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory's `config/java.properties` file, run `bin/dsjavaproperties`, and restart the server to stop the issuance of IPv6 PTR requests.
- Some server tools, such as `dsreplication`, `collect-support-data`, and `rebuild-index`, will fail with errors if they are run with an encrypted `tools.properties` file.

Workaround: Add the `--noPropertiesFile` argument to the server tools to prevent them from pulling information from the encrypted file.

- Deploying the Admin Console to an external container using JDK 11 requires downloading the following dependencies and making them available at runtime (for example, by copying them to the `WEB-INF/lib` directory of the exploded WAR file).
 - `groupId:jakarta.xml.bind, artifactId:jakarta.xml.bind-api, version:2.3.2`
 - `groupId:org.glassfish.jaxb, artifactId:jaxb-runtime, version:2.3.2`

Workaround: Deploy the Console in an external container using JDK 8.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-17278	Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps. Updated the LDAP external server monitor to include attributes tracking health check state changes for external servers. The new attributes include the number of times a health check transition has occurred, timestamps of the most recent transitions, and messages associated with the most recent transitions.
DS-37881	The PingFederate Access Token Validator will now refresh its cached value of the PingFederate server's token introspection endpoint. A new attribute, <code>endpoint-cache-refresh</code> , has been added to the PingFederate Access Token Validator, which will determine how often this refresh occurs.
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the <code>Resource</code> column in the output of <code>status</code> . This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-38053	The JWT Access Token Validator no longer requires a restart after a change to one of its signing certificates.

Ticket ID	Description
DS-38493	Updated the PingOne for Customer Sync Source to remove a user's password from a destination (for example, PingDirectory) when the corresponding user's password has changed in PingOne for Customers. This behavior requires the <code>password</code> attribute in PingOne for Customers to be mapped to the password attribute (for example, <code>userPassword</code>) in the destination schema.
DS-38560	Updated <code>manage-profile replace-profile</code> to apply configuration changes directly, when possible. If the new server profile used by <code>replace-profile</code> has changed only the <code>dsconfig</code> batch files from the original profile, then only the <code>dsconfig</code> files are applied. If no changes are detected between profiles, <code>replace-profile</code> takes no action. If changes other than <code>dsconfig</code> are detected, the full <code>replace-profile</code> process is followed.
DS-38777	Added support for updating the server version during <code>manage-profile replace-profile</code> . The server must have been originally set up with a server profile.
DS-38832	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.
DS-38863	Updated the <code>manage-profile setup</code> subcommand to set a server's cluster name to match its instance name by default. This prevents servers in the same replication topology from being in the same cluster, reducing the risk of unintentionally overwriting parts of an existing server's configuration in a DevOps environment. The <code>--useDefaultClusterName</code> argument can be used to leave the cluster name unchanged.
DS-38867	<p>Updated the PBKDF2 password storage scheme to add support for variants that use the 256-bit, 384-bit, and 512-bit SHA-2 digest algorithms. At present, the SHA-1 variant remains the default to preserve backward compatibility with older versions.</p> <p>Also, in accordance with the recommendations in NIST SP 800-63B, we have increased the default iteration count from 4096 to 10,000, and the default salt length from 64 bits to 128 bits.</p>
DS-38869	Updated the <code>remove-defunct-server</code> tool's <code>--ignoreOnline</code> option. When using <code>--ignoreOnline</code> in a mixed-version environment, all servers must support the option.
DS-39176, DS-39308	<p>Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 release notes.</p> <p>As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code>, download the appropriate jar file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.</p>

Ticket ID	Description
DS-39191	Updated the <code>auto-mapped-source-attribute</code> property on Sync Class configuration objects to not have a default value since the previous default of <code>-all-</code> caused confusion. Existing <code>dsconfig</code> batch files used for automated deployments might need to be updated to provide a value for this property. A value of <code>-all-</code> is recommended when synchronizing between two systems with the same schema, such as when migrating from a legacy LDAP server to PingDirectory.
DS-39253	Added a <code>replace-certificate</code> tool, which can help an administrator replace the listener or inter-server certificate for a server instance.
DS-39320	Added support for PingDataSync Server to the <code>manage-profile</code> tool and its subcommands.
DS-39325	<p>Removed the legacy product-specific scripts for starting and stopping the server. These include:</p> <ul style="list-style-type: none"> ▪ <code>start-ds</code> and <code>stop-ds</code> for Directory Server ▪ <code>start-proxy</code> and <code>stop-proxy</code> for Directory Proxy Server ▪ <code>start-sync</code> and <code>stop-sync</code> for Data Sync Server ▪ <code>start-metrics-engine</code> and <code>stop-metrics-engine</code> for Data Metrics Server <p>These legacy scripts had been deprecated for several releases in favor of the more general <code>start-server</code> and <code>stop-server</code> scripts, and they displayed a warning message about their upcoming removal if they were invoked.</p> <p>If you still have dependencies on these legacy product-specific scripts, you will need to update them to reference the general <code>start-server</code> and <code>stop-server</code> scripts instead. If it is not feasible to update these references immediately, you may create symbolic links that use the legacy script names and point to the <code>start-server</code> and <code>stop-server</code> scripts.</p>
DS-39373	Preserve the privileges that are explicitly set on the admin user when migrating from the admin backend to the topology registry.
DS-39518	Fixed an issue in which escaped characters in schema extensions may not be handled properly. If used in attribute type constraints (such as <code>X-VALUE-REGEX</code>), this could cause unexpected or incorrect behavior.
DS-39540	Released an updated Password Sync Agent for Active Directory that uses SSHA256 as a default for its password hashing algorithm instead of SSHA, since SSHA is soon to be deprecated in PingDirectory. If SSHA256 is not supported by a directory or if it is not wanted, a registry value was added that can be set to specify the password hashing algorithm.
DS-39592	HTTP External Servers have a new attribute, <code>ssl-cert-nickname</code> , which defines the alias of a specific certificate within their keystore to be used as a client certificate.
DS-39603	Fixed an issue where Server SDK extensions could not be configured by <code>dsconfig</code> batch files in the <code>manage-profile</code> tool.
DS-39626, DS-40357	The trace log publisher will now record an access token's scopes after the token is successfully validated.

Ticket ID	Description
DS-39654	Added support for the <code>--topologyFilePath</code> argument to the <code>manage-topology add-server</code> subcommand.
DS-39671	Updated the <code>manage-topology add-server</code> subcommand to require being run from the older server in a mixed-version environment.
DS-39715	Updated the Server SDK to add support for sending email messages.
DS-39853	Added support for the PingOne for Customers Sync Source and Destination to the <code>create-sync-pipe-config</code> tool.
DS-39857	Added the StatsD monitoring endpoint. When the Stats Collector Plugin is enabled, this endpoint sends metric data from the server in StatsD format to the configured destination.
DS-39908	Added a new JVM-default trust manager provider that can be used to automatically trust any certificate signed by an authority included in the JVM's default set of trusted issuers. Also, updated other trust manager providers to offer an option to use the JVM-default trust addition to the trust that they normally provide.
DS-40020	Fixed an issue in Active Directory Sync Source where the persistent state was updated before applying changes, so changes could be missed when stopping the Sync Pipe.
DS-40114	Added a new <code>cn=Status Health Summary,cn=monitor</code> monitor entry that provides a summary of the server's current assessment of its health. This simplifies monitoring with third party tools that support retrieving monitoring data over JMX. The Periodic Stats Logger has also been updated to allow some of this monitoring information to be logged. No new information is logged by default.
DS-40354	Fixed a problem with <code>config-diff</code> when writing properties that span multiple lines using the <code>--prettyPrint</code> argument.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40377	Added support for logging to a JSON file in the Periodic Stats Logger Plugin.
DS-40517	Added metrics for status summary, replication database, and LDAP changelog to the Stats Collector Plugin.
DS-40543	Updated <code>manage-profile replace-profile</code> to copy the tool log file to the server being updated.
DS-40556	Added support for specifying a working directory for exec tasks.
DS-40730	Updated the <code>encrypt-file</code> tool to prevent using the same path for both the input file and the output file.
DS-40771	Added a <code>--duration</code> argument to <code>collect-support-data</code> . When used, only the log files covering the specified duration before the current time will be collected.

PingDataSync Server 7.3.0.10 release notes

Critical fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.
 - Fixed in: 7.3.0.10
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-41762 SF#00675207 SF#00683777

Resolved issues

The following issues have been resolved with this release of the Data Sync Server.

Ticket ID	Description
DS-41762	Fixed an issue where mirrored subtree polling could produce config archive files that were identical or ignored the configured insignificant attributes list.

PingDataSync Server 7.3.0.7 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.

You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655

- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-37955	To support multiple trace loggers, each trace logger now has its own resource key, which is shown in the "Resource" column in the output of "status". This key allows multiple alarms, due to sensitive message types for multiple trace loggers.
DS-39799	Allows users who were migrated from the admin backend to the topology to manage the topology. Migrated users are granted the "manage-topology" privilege if they do not already have it.
DS-40020	Fixed an issue in Active Directory Sync Source where the persistent state was updated before applying changes, so changes could be missed when stopping the Sync Pipe.
DS-40366	Fixed an issue where the server was attempting to connect by an IP address rather than a hostname when DNS lookup was successful.
DS-40771	Added a --duration argument to collect-support-data. When used, only the log files covering the specified duration before the current time will be collected.
DS-41054	Fixed an issue that stopped new extensions from being installed.
DS-41206	Fixed a memory leak when performing SCIM queries on the Directory Server.

PingDataSync Server 7.3.0.5 Release Notes

Critical Fixes

This release of the Data Sync Server addresses critical issues from earlier versions. Update all affected servers appropriately.

- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38334 PDSTAGING-570 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable

to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38344 PDSTAGING-570 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.3.0.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 PDSTAGING-570 SF#00655578
- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.

* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908

- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes

in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into

the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.

* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.

In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.

We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.

- Fixed in: 7.3.0.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- The following enhancements were made to the topology manager to make it easier to diagnose the connection errors:
 - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections.
 - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
- Fixed in: 7.2.1.0
- Introduced in: 7.0.0.0
- Support identifiers: DS-38334 SF#00655578
- The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38344 SF#00655578
- The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.
 - Fixed in: 7.2.1.0
 - Introduced in: 7.0.0.0
 - Support identifiers: DS-38335 SF#00655578

- Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.
 - * When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. - Fixed in: 7.0.1.3
- Introduced in: 7.0.0.0
- Support identifiers: DS-38897 DS-38908
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- Fixed an issue with the sync connect and response timeouts being set with incorrect units of time.
 - Fixed in: 6.2.0.0
 - Introduced in: 6.0.0.0
 - Support identifiers: DS-18026 SF#00616763
- The server can now detect an "out of file handles" situation on the operating system, and shut down to prevent running in an unreliable state.
 - Fixed in: 5.1.0.0
 - Introduced in: 2.1.0.0
 - Support identifiers: DS-12579 SF#2655
- Disabled support for SSLv3 by default in the LDAP, HTTP, and JMX connection handlers, and for replication communication. The recently-discovered POODLE vulnerability could potentially allow a

network attacker to determine the plaintext behind an SSLv3-encrypted session, which would effectively negate the primary benefit of the encryption.

SSLv3 was initially defined in 1996, but was supplanted by the release of the TLSv1 definition in 1999 (and subsequently by TLSv1.1 in 2006 and TLSv1.2 in 2008). These newer TLS protocols are not susceptible to the POODLE vulnerability, and the server has supported them (and preferred them over SSLv3) for many years. The act of disabling SSLv3 by default should not have any adverse effect on clients that support any of the newer TLS protocols. However, if there are any legacy client applications that attempt to communicate securely but do not support the newer TLS protocols, they should be updated to support the newer protocols. In the event that there are known clients that do not support any security protocol newer than SSLv3 and that cannot be immediately updated to support a newer protocol, SSLv3 support can be re-enabled using the newly-introduced `allowed-insecure-tls-protocol` global configuration property. However, since communication using SSLv3 can no longer be considered secure, it is strongly recommended that every effort be made to update all known clients still using SSLv3.

It is possible to use the server access log to identify LDAP clients that use SSLv3 to communicate with the server. Whenever an LDAP client establishes a secure connection to the server, or whenever a client uses the StartTLS extended operation to secure an existing plaintext connection, the server will generate a SECURITY-NEGOTIATION access log message. The "protocol" element of a SECURITY-NEGOTIATION access log message specifies the name of the security protocol that has been negotiated between the client and the server, and any SECURITY-NEGOTIATION messages with a protocol of "SSLv3" suggest that the associated client is vulnerable to the POODLE attack. In addition, if any connections are terminated for attempting to use the disallowed SSLv3 protocol, the access log message for that disconnect should include a message stating the reason for the termination.

- Fixed in: 5.0.0.0
- Introduced in: 2.1.0.0
- Support identifiers: DS-11782
- Change the default behavior of the Synchronization Server to not lock entries across all Sync Pipes when processing changes.

The Sync Server has a specialized mutex that ensures that changes to the same entry are processed serially. The primary reason for this mutex is to ensure that the server can safely process changes in parallel to achieve high throughput. However, we also use this mutex to ensure that two Sync Pipes don't process the same entry at the same time for deployments that synchronize changes bi-directionally. A consequence of this locking is that if one Sync Pipe is failing (because the destination is unavailable) then it retains the lock on an entry, and when other Sync Pipes try to process changes to that entry they will block that change and all changes that follow it while they wait on the lock.

This change turns off using a shared mutex by default, but adds a new advanced configuration option on the Sync Pipe, `shared-mutex-name`, that specifies the name of a mutex that is shared by other Sync Pipes. This gives greater control over the locking so that two Sync Pipes that share end points can ensure that two changes to the same logical user are not processed concurrently, while not impacting other Sync Pipes.

See the `shared-mutex-name` property for more information.

This property is subject to change in a future release.

- Fixed in: 3.2.0.0
- Introduced in: 3.0.0.0
- Support identifiers: DS-4202 SF#1527

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-40828	Fixed an issue where some state associated with a JMX connection was not freed after the connection was closed. This led to a slow memory leak in servers that were monitored by an application that created a new JMX connection each polling interval.

PingDataSync Server 7.3.0.3 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
PDSTAGING-840	Fixed an issue that could cause the server to leak a small amount of memory each time it failed to establish an LDAP connection to another server.

PingDataSync Server 7.3.0.1 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-17278	<p>Added a <code>cn=Server Status Timeline,cn=monitor</code> monitor entry to track a history of the local server's last 100 status changes and their timestamps.</p> <p>Updated the LDAP external server monitor to include attributes that track health-check state changes for external servers. The new attributes include the following information:</p> <ul style="list-style-type: none"> ▪ Number of times a health-check transition has occurred ▪ Timestamps of the most recent transitions ▪ Messages associated with the most recent transitions
DS-39176, DS-39308	<p>Updated the Groovy scripting language version to 2.5.7. For a list of changes, visit groovy-lang.org and view the Groovy 2.5 Release Notes.</p> <p>As of this release, only the core Groovy runtime and the <code>groovy-json</code> module are bundled with the server. To deploy a Groovy-scripted Server SDK extension that requires a Groovy module not bundled with the server, such as <code>groovy-xml</code> or <code>groovy-sql</code>, download the appropriate JAR file from groovy-lang.org and place it in the server's <code>lib/extensions</code> directory.</p>

PingDataSync Server 7.3.0.0 Release Notes

What's New

These are new features for this release of PingDataSync Server:

- New features for data encryption in transit and at rest: added support for TLS 1.3, ability to encrypt and automatically decrypt sensitive files such as tools.properties and keystore pin files using the server data encryption keys, and the ability to more easily and securely separate master keys from data encryption keys by protecting the server encryption settings database using either Amazon Key Management Service (AWS KMS) or HashiCorp Vault.
- Added support for Amazon Corretto JDK 8, Windows Server 2019, Red Hat Enterprise Linux 7.6, CentOS 7.6, Amazon Linux 2, and Docker 18.09.0 on Ubuntu 18.04 LTS.
- More configuration flexibility. Brand new JSON Attribute Mapping provides a more natural way to construct JSON-based attributes rather than using Constructed Attribute Mapping. Base64 encoding and decoding options are added to allow for synchronizing binary data. LDAP extensible match and approximate match filters can be used to better select changes that require synchronization. Rate limiting has been added per sync pipe using the max-rate-per-second setting.
- Publish changes to Kafka. Sync pipes in notification mode can now be configured to publish changes in PingDirectory to topics in Kafka. Messages are published to Kafka for additions, deletions, modifications, and for resynchronization. Each message contains the JSON-serialized format of the mapped attributes per LDAP object, before and after modification, if applicable.

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
PDSTAGING-570,DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose the connection errors described in PDSTAGING-570:</p> <ul style="list-style-type: none"> - Added monitoring information for all the failed outbound connections (including the time since it's been failing and the last error message seen when the failure occurred) from a server to one of its configured peers and the number of failed outbound connections. - Added alarms/alerts for when a server fails to connect to a peer server within a configured grace period.
PDSTAGING-570,DS-38344	<p>The topology manager will now raise a mirrored-subtree-manager-connection-asymmetry alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared as soon as there is connection symmetry.</p>
PDSTAGING-570,DS-38335	<p>The dsreplication tool has been fixed to work when the node being used to enable replication is currently out-of-sync with the topology master.</p>

Ticket ID	Description
DS-15734	Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a key from the Amazon Key Management Service.
DS-18060	<p>Added an HTTP servlet extension that can be used to retrieve the server's current availability state. It accepts any GET, POST, or HEAD request sent to a specified endpoint and returns a minimal response whose HTTP status code may be used to determine whether the server considers itself to be AVAILABLE, DEGRADED, or UNAVAILABLE. The status code for each of these states is configurable, and the response may optionally include a JSON object with an "availability-state" field with the name of the current state.</p> <p>Two instances of this servlet extension are now available in the default configuration. A request sent to /available-state will return an HTTP status code of 200 (OK) if the server has a state of AVAILABLE, and 503 (Service Unavailable) if the server has a state of DEGRADED or UNAVAILABLE. A request sent to the /available-or-degraded-state will return an HTTP status code of 200 for a state of AVAILABLE or DEGRADED, and 503 for a state of UNAVAILABLE. The former may be useful for load balancers that you only want to have route requests to servers that are fully available. The latter may be useful for orchestration frameworks if you wish to destroy and replace any instance that is completely unavailable.</p>
DS-36269	Added support for using Population names both as a default when configuring the PingOne Customer Sync Destination and in attribute mapping.
DS-36474	Updated the ldapdelete command-line tool to improve robustness and add features. Some of the new features include support for client-side subtree delete, deleting entries that match search filters, following referrals, writing failures to a rejects file, rate limiting, and support for a variety of additional controls.
DS-37617	HTTP Connection Handlers now accept client-provided correlation IDs by default. To adjust the set of HTTP request headers that may include a correlation ID value, change the HTTP Connection Handler's correlation-id-request-header property.

Ticket ID	Description
DS-37839	<p>Make Fingerprint Certificate Mapper and Subject DN to User Attribute Certificate Mapper disabled by default on fresh installations. This will not affect upgrades from installations where these mappers are enabled.</p>
DS-37959	<p>Added support for insignificant configuration archive attributes.</p> <p>The configuration archive is a collection of the configurations that have been used by the server at some time. It is updated whenever a change is made to data in the server configuration, and it is very useful for auditing and troubleshooting. However, because the entries that define root users and topology administrators reside in the configuration, changes to those entries will also cause a new addition to the configuration archive. This is true even for changes that affect metadata for those entries, like updates to the password policy state information for one of those users. For example, if last login time tracking is enabled for one of those users, especially with high-precision timestamps, a new configuration may be generated and added to the configuration archive every time that user authenticates to the server. While it is important for this information to be persisted, it is not as important for it to be part of the server's configuration history.</p> <p>This update can help avoid the configuration archive from storing information about updates that only affect this kind of account metadata. If a configuration change only modifies an existing entry, and if the only changes to that entry affect insignificant configuration archive attributes, then that change may not be persisted in the server's configuration archive.</p> <p>By default, the following attributes are now considered insignificant for the purpose of the configuration archive:</p> <ul style="list-style-type: none"> * ds-auth-delivered-otp * ds-auth-password-reset-token * ds-auth-single-use-token * ds-auth-totp-last-password-used * ds-last-access-time * ds-pwp-auth-failure * ds-pwp-last-login-ip-address * ds-pwp-last-login-time * ds-pwp-password-changed-by-required-time * ds-pwp-reset-time * ds-pwp-retired-password * ds-pwp-warned-time * modifiersName * modifyTimestamp * pwdAccountLockedTime * pwdChangedTime * pwdFailureTime * pwdGraceUseTime * pwdHistory * pwdReset

Ticket ID	Description
DS-38050	<p>Updated the server to support encrypting the contents of the PIN files needed to unlock certificate key and trust stores. If data encryption is enabled during setup, then the default PIN files will automatically be encrypted.</p> <p>Also, updated the command-line tool framework so that the tools.properties file (which can provide default values for arguments not provided on the command line), and passphrase files (for example, used to hold the bind password) can be encrypted.</p>
DS-38072	<p>Updated the server to enable TLSv1.3 by default on JVMs that support it (Java 11 and higher).</p>
DS-38085	<p>Fixed an issue in the installer where the Administrative Console's trust store type would be incorrectly set if it differed from the key store type.</p>
DS-38090,DS-38564,DS-38567	<p>The response header used for correlation IDs may now be set at the HTTP Servlet Extension level using the correlation-id-response-header configuration property. If set, this property overrides the HTTP Connection Handler's correlation-id-response-header property.</p>
DS-38098	<p>Added a max-rate-per-second configuration property to the Sync Pipe, which can be used to throttle the rate that changes are applied to the destination.</p>
DS-38100	<p>Added a Kafka Sync Destination, which can be used to publish changes from PingDirectory Sync Sources to Kafka topics. Changes are represented as the entry contents before and the entry contents after the change in JSON format.</p>
DS-38109	<p>Added the --skipHostnameCheck command line option to the setup script, which bypasses validation of the provided host name for the server.</p>
DS-38253	<p>Added the PingOne for Customers Sync Source to Ping Data Sync. Identities can now be synchronized from PingOne for Customers to on premises identity stores.</p>
DS-38403	<p>Fixed an issue that could prevent certain types of initialization failures from appearing in the server error log by default.</p>
DS-38460	<p>Added 'base64-encode-value' and 'base64-decode-value' properties to direct attribute mappings to facilitate synchronizing binary data.</p>

Ticket ID	Description
DS-38495	Updated the PingDataSync Server to support LDAP filters in Sync Classes that include extensible match or approximate match components. The Data Sync Server supports the same matching rules as the PingDirectory Server.
DS-38512	Added a cipher stream provider that can be used to protect the contents of the encryption settings database with a secret passphrase obtained from a HashiCorp Vault instance.
DS-38550	Fixed an issue in which backups of the encryption settings database could be encrypted with a key from the encryption settings database.
DS-38582	Added attribute-comparison-method configuration option to SyncClass to allow syncing with a syntax-based comparison (default mode) or a byte-for-byte comparison method.
DS-38670	Fixed a bug where the startIndex value for SCIM requests would be incorrect if the used LDAPSearch element had more than one baseDN defined in the scim-resources XML file.
DS-38737	Fixed an issue where inter-server bind requests would fail if the cipher used reported a maximum unencrypted block size of 0.
DS-38833	Added JSON Attribute Mapping and JSON Attribute Mapping Field configuration objects that simplify constructing destination JSON attribute values from source attributes. Compared to using a Constructed Attribute Mapping to build up JSON, using these configuration objects does not requiring providing the JSON structure (braces, colons, and quotes), does not require escaping string values, and automatically omits fields whose values cannot be constructed.
DS-38849	Added an indent-ldap-filter tool that can make it easier to visualize the structure and components of a complex search filter.
DS-38864	Changed the default value of the HTTP Configuration property include-stack-traces-in-error-pages from 'true' to 'false'. Disabling this property prevents information about exceptions thrown by servlet or web application extensions from being revealed in HTTP error responses.

Ticket ID	Description
DS-38897,DS-38908	<p>Fixed two issues in which the server could have exposed some clear-text passwords in files on the server file system.</p> <p>* When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key (which may have been obtained from an encryption settings definition) could have been inadvertently written into the backup descriptor. This problem does not affect local DB backends (like userRoot), the LDAP changelog backend, or the replication database.</p> <p>* When running certain command-line tools with an argument instructing the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. Affected tools include backup, create-initial-config, create-initial-proxy-config, dsreplication, enter-lockdown-mode, export-ldif, import-ldif, ldappasswordmodify, leave-lockdown-mode, manage-tasks, manage-topology, migrate-ldap-schema, parallel-update, prepare-endpoint-server, prepare-external-server, realtime-sync, rebuild-index, re-encode-entries, reload-http-connection-handler-certificates, reload-index, remove-defunct-server, restore, rotate-log, and stop-server. Other tools are not affected. Also note that this only includes passwords contained in files that were provided as command-line arguments; passwords included in the tools.properties file, or in a file referenced from tools.properties, would not have been exposed.</p> <p>In each of these cases, the files would have been written with permissions that make their contents only accessible to the system account used to run the server. Further, while administrative passwords may have been exposed in the tool invocation log, neither the passwords for regular users, nor any other data from their entries, should have been affected. We have introduced new automated tests to help ensure that such incidents do not occur in the future.</p> <p>We recommend changing any administrative passwords you fear may have been compromised as a result of this issue. If you are concerned that the passphrase for an encryption settings definition may have been exposed, then we recommend creating a new encryption settings definition that is preferred for all subsequent encryption operations, exporting your data to LDIF, and re-importing so that it will be encrypted with the new key. You also may wish to re-encrypt or destroy any existing backups, LDIF exports, or other data encrypted with a compromised key, and you may wish to sanitize or destroy any existing tool invocation log files that may contain clear-text passwords.</p>

Ticket ID	Description
DS-38913	Added a set of message types to Trace Log Publishers that records events related to access token validation.
DS-38957	Fixed an issue that would throw an exception when trying to delete an entry containing uncached attributes if the LDAP changelog was enabled and using reversible form.
DS-39014	Addressed an issue in DataSync where LDAP operational attributes (such as isMemberOf) used in a SyncClass include-filter would not be requested from the source LDAP server if the LDAP filter was a nested filter.
DS-39086	Removed the version information page from the docs/build-info.txt endpoint. This information is now available in build-info.txt, which is located in the root directory.
DS-39174	Addressed an issue where a resync command could fail with a SEVERE_ERROR condition when run with multiple passes and the Sync Source was either Active Directory or PingOne for Customers.
DS-39177	Addressed an issue where a resync operation might not synchronize all users if a PingOne Customer Sync Source was configured with a value for population-to-synchronize.

PingDataSync Server 7.2.1.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-38098	Added a max-rate-per-second configuration property to the Sync Pipe, which can be used to throttle the rate that changes are applied to the destination.
DS-38253	Added the PingOne for Customers Sync Source to PingDataSync Server. Identities can now be synchronized from PingOne for Customers to on-premises identity stores.

Ticket ID	Description
DS-38334	<p>The following enhancements were made to the topology manager to make it easier to diagnose connection errors:</p> <ul style="list-style-type: none"> Added monitoring information for all failed outbound connections, including the time since they began failing and the last error message seen when the failures occurred, from a server to one of its configured peers, as well as the number of failed outbound connections. Added alarms and alerts for when a server fails to connect to a peer server within a configured grace period.
DS-38335	<p>The <code>dsreplication</code> tool has been fixed to work when the node being used to enable replication is not synchronized with the topology master.</p>
DS-38344	<p>The topology manager now raises a <code>mirrored-subtree-manager-connection-asymmetry</code> alarm when a server is able to establish outbound connections to its peer servers, but those peer servers are unable to establish connections back to the server within the configured grace period. The alarm is cleared when connection symmetry is achieved.</p>

PingDataSync Server 7.2.0.0 Release Notes

What's New

Introduced a Directory REST API to create, read, update, and delete (CRUD) any object in the directory by using JSON over HTTP. Compared to the SCIM-based Identity Access API, which was introduced in version 4.0, the Directory REST API offers more capability without the configuration overhead and the SCIM protocol limitations. For more information, visit <https://apidocs.pingidentity.com/pingdirectory/directory/v1/api/guide/>.

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-6930	<p>To facilitate testing in multiple garbage collection (GC) environments, GC JVM options have been moved to separate Java properties in the <code>java.properties</code> file. The new <code>.gc-type</code> suffix selects the GC type to use, and the new <code>.gc-<GC type>-args</code> suffix has the JVM options for that GC type.</p>

Ticket ID	Description
DS-35652, DS-36559	<p>Added support for a file-retention task that can identify files in an indicated directory that match a given pattern, and can remove matching files that fall outside the specified retention criteria. You can specify the minimum number, age, and aggregate size of the files to retain. Files that match the pattern are sorted by timestamp. If any files are removed, the most recent files are retained, and the oldest files are deleted.</p> <p>The file-retention task can be scheduled as a standalone or recurring task. The following instances of the file-retention recurring task are defined in the default configuration:</p> <ul style="list-style-type: none"> ▪ Cleans up old, expensive operation dump files ▪ Cleans up old, work-queue backlog thread dump files <p>In each case, the recurring task is configured to retain at least the 100 most recent files. No files that are younger than 30 days old are removed. Although these recurring tasks are defined in the default configuration, they are not part of a recurring task chain. Consequently, they are not invoked unless they are configured as part of a chain.</p> <p>The default configurations of PingDirectory Server and PingDirectoryProxy Server also include recurring tasks that clean up old, expensive operation dump log files or work-queue backlog thread dump log files if too many of them have collected in the server logs directory. For each file type, if more than 100 files are present in the server logs directory, remaining files that are older than 30 days are candidates for removal. A recurring task chain performs this cleanup every day at 12:05 a.m. in the JVM's default time zone.</p>
DS-35873	<p>Added support for an exec task that can invoke commands on the server. Multiple safeguards prevent unauthorized users from invoking arbitrary commands on the server system, including a new exec-task privilege and a whitelist file that must be updated to include the absolute paths of the allowed commands. Additionally, a new schedule-exec-task tool helps create an exec task from the command line, and the LDAP SDK has been updated to allow pragmatic interactions with exec tasks.</p>
DS-35873	<p>Added support for recurring exec tasks.</p>
DS-35909	<p>HTTP Connection Handlers now raise an alarm during initialization if a context path conflict is detected.</p>

Ticket ID	Description
DS-36209	<p>A header that contains a correlation ID has been added to outgoing HTTP servlet responses, allowing the correlation of HTTP responses with log messages across server instances. The name of the correlation ID response header defaults to "Correlation-Id" but can be changed by setting the HTTP Connection Handler's correlation-id-response-header property. By default, the server generates a globally unique correlation ID automatically, but the correlation-id-request-header configuration property can optionally be used to specify one or more request headers that provide an existing correlation ID value from the requesting client. The correlation ID header can be disabled on a per-HTTP Connection Handler basis by using the use-correlation-id-header configuration property.</p> <p>For Server SDK extensions that have access to the current HttpServletRequest, the correlation ID can be retrieved as a string by using the HttpServletRequest's com.pingidentity.pingdata.correlation_id attribute, as follows:</p> <pre data-bbox="850 947 1469 1003">(String) request.getAttribute("com.pingidentity.p</pre>
DS-36433	<p>Added a Mock Access Token Validator that uses a trusted authorization server or signing certificate to accept access tokens without validating their authenticity. When enabled, the Mock Access Token Validator accepts bearer tokens in the form of a plain text JSON object that contains an arbitrary set of claims.</p>
	<p>ⓘ Warning: Mock Access Token Validators are intended for test or demonstration use only. Never enable them in production deployments or use them to access sensitive data.</p>
DS-36434	<p>Added a preFetch method to the LDAPSyncSourcePlugin Server SDK extensions. This method allows extension developers to modify the search request or source entry fetch behavior for LDAP Sync Sources.</p>

Ticket ID	Description
DS-36435	<p>Added Change Detectors as a new type of Server SDK extension. A Change Detector can be used to customize the manner in which a Sync Source detects changes to entries in a source server.</p> <p>As an example, a developer could build a Change Detector that reads messages from a Kafka topic and uses them as the source of changes for an OpenLDAP server that is configured as the Sync Source.</p> <p>Change Detectors are available only for use with the new Generic LDAP Sync Source.</p>
DS-36510	<p>Added support for a delay task that can be used on its own or as a recurring task. It is primarily intended for use as a spacer between other tasks, and can sleep for a specified period of time, wait for the server to become idle (all worker threads are idle, and no operations are outstanding), or wait for sets of search criteria to match at least one entry (for example, until a monitor entry indicates that the server is in a particular state).</p>
DS-37131	<p>Fixed an issue in which the HTTP Servlet Config Monitor could throw an exception in an HTTP Servlet Extension when attempting to determine its context paths. This exception caused the status tool and the Administrative Console to potentially omit the HTTP Servlet Extension from the list of active HTTP extensions.</p>
DS-37492	<p>Added a time limit retention policy to support the removal of log files that are older than a specified age.</p>

PingDataSync Server 7.0.1.3 Release Notes

Resolved Issues

The following issues have been resolved with this release of the Data Sync Server:

Ticket ID	Description
DS-38670	<p>Fixed an issue in which the startIndex value for SCIM requests would be incorrect if the used LDAPSearch element had more than one baseDN defined in the <code>scim-resources</code> XML file.</p>

Ticket ID	Description
DS-38897, DS-38908	<p>Fixed the following issues, in which the server could have exposed some clear-text passwords in files on the server file system:</p> <ul style="list-style-type: none"> When creating an encrypted backup of the alarms, alerts, configuration, encryption settings, schema, tasks, or trust store backends, the password used to generate the encryption key, which might have been obtained from an encryption settings definition, could have been inadvertently written into the backup descriptor. This problem did not affect local DB backends (like <code>userRoot</code>), the LDAP changelog backend, or the replication database. When running certain command-line tools with an argument that instructs the tool to read a password from a file, the password contained in that file could have been written into the server's tool invocation log instead of the path to that file. This issue affected the following tools: <pre> backup create- create- dsreplication initial- initial- config proxy- config enter- export- import- ldappasswordmodify lockdown-ldif ldif leave- manage- manage- migrate- lockdown-tasks topology ldap- mode schema parallel-prepare- prepare- realtime- update endpoint-external-sync server server rebuild- re- reload- reload- index encode- http- index entries connection- handler- certificates remove- restore rotate- stop- defunct- log log server server </pre> <p>Other tools are unaffected. Additionally, this issue included only passwords that were contained in files provided as command-line arguments. Passwords that were included in the <code>tools.properties</code> file, or in a file that <code>tools.properties</code> referenced, were not exposed.</p> <p>In each of these cases, the files were written with permissions that made their contents accessible only to the system account that ran the server. Further, while administrative passwords might have been exposed in the tool invocation log, neither the passwords for regular users nor the data from their entries should have been affected. New automated</p>

PingDataSync Server 7.0.1.2 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-37804	Enhanced LDAP Sync Destinations — such as PingDirectory, DSEE, and Generic LDAP — so that <code>IgnoreNoUserModificationRequestControl</code> is applied to requests by default. This resolution allows Sync Sources to write and update operational attributes, like <code>createtimestamp</code> or <code>modifiersdn</code> . To enable the modification of specific operational attributes, additional configuration might be required on the destination server.

PingDataSync Server 7.0.1.0 Release Notes

Known Issues

The instance name of a server that PingDataMetrics Server will monitor must consist of fewer than 256 characters. A server's instance name is specified during setup.

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-36271 and DS-36797	Added the ability to synchronize pre-encoded passwords to the PingOne for Customers Sync Destination.
DS-36642	Added a configuration option to allow a null <code>serverFQDN</code> for the GSSAPI SASL mechanism to permit an unbound SASL server connection.
DS-37235	Updated the keys and values that are used in the monitoring JMX MBeans to conform with best practices. The keys <code>type</code> and <code>name</code> are now used in place of <code>Rdn1</code> and <code>Rdn2</code> . To maintain backward compatibility with existing monitoring solutions, installations that upgrade to this release will retain the earlier behavior. However, they can revert to the default behavior by setting the global configuration property <code>jmx-use-legacy-mbean-names</code> to <code>false</code> .
DS-37275	Improved supportability by enhancing the logging for the PingOne for Customer Sync Destination to expose all errors from the PingOne API.

PingDataSync Server 7.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDataSync Server:

- This release introduces significant changes to the manner in which servers in a topology are configured with information about each other. After a server has been upgraded from a pre-7.0 version to 7.0 or later, reverting to the previous version is not supported. Before beginning the upgrade process, read "Upgrading the Server" in the *PingDataSync Server Administration Guide*.
- SCIM 2 error responses, including Config API error responses, now represent the status field as a JSON string rather than as a number. Clients that are written to expect the earlier version format must be updated. In particular, clients written by using the SCIM 2 SDK for Java need to upgrade to version 2.2.0 or later.
- The Administrative Console now uses server information from the topology registry to populate its server selection control. If the Console is used to manage a legacy server that does not use the topology registry, the server selection control is not populated. To manage a different server, an administrator must log off from the Console and provide the other server's connection details from the logon page.

What's New

The following features are new with this release of PingDataSync Server:

- Simplified management tasks that are related to configuring servers in a large cluster topology or in an automated deployment. Most notably, servers can now be added to a cluster while other servers are offline.
- Added management features for SSL and TLS certificates. The default certificates that are used in inter-server replication can be replaced, validation of client certificates for HTTPS-based services (like the SCIM REST API) can be configured, and you can reload from the trust store for HTTPS client certificates without restarting the server or the HTTP-based services.
- Added support for the following operating system versions:
 - Ubuntu LTS 16.04
 - CentOS 7.4
 - RedHat Linux 7.4
 - SUSE Enterprise 12 SP3

Known Issues and Workarounds

The simultaneous cloning of multiple PingDirectoryProxy, PingDataSync, and PingDataGovernance Servers from another server of the same type is not currently possible.

Workaround: To create multiple server instances that are identical to a master server, clone the instances one at a time.

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-426	<p>Added the ability to generate administrative alert notifications whenever a task satisfies the following conditions:</p> <ul style="list-style-type: none"> ▪ Starts running ▪ Completes successfully ▪ Fails to complete successfully <p>Also added the ability to send an email message to a specified set of users when a task starts running or completes successfully. This functionality complements the existing ability to send an email message when a task fails to complete successfully or when it completes with any state, regardless of success or failure.</p>
DS-426	<p>Added support for recurring tasks, which can be used to invoke certain kinds of administrative tasks automatically, based on a specified schedule.</p> <p>At present, only certain kinds of tasks can be scheduled as recurring tasks, including backups and LDIF exports, each of which provides retention support to limit the amount of disk space that the backups and LDIF files consume. It also includes support for any kind of task in which each instance of the task uses exactly the same values for all of the task-specific attributes. Additionally, the Server SDK provides an API for creating custom third-party recurring task implementations.</p>
DS-4406	<p>Implemented invocation logging for several server tools, which write to <code>logs/tools/tool-invocation.log</code> by default upon startup and shutdown. Log entries record the following information:</p> <ul style="list-style-type: none"> ▪ The tool's start and completion times ▪ Command-line arguments used to initialize them ▪ Name of the system account used to launch the tool <p>To modify this behavior, edit the <code>config/tool-invocation-logging.properties</code> file.</p>
DS-4570, DS-14281, DS-14282, DS-14283, DS-14284, DS-17197, DS-17366	<p>The admin backend and the tool used to manage it, <code>dsframework</code>, have been replaced by the topology registry and <code>dsconfig</code>, respectively. The topology registry is mirrored automatically across all servers in a topology, so administrative information is synchronized on all servers at all times.</p>
DS-6970	<p>Added support for encrypted logging by using a key that is generated from an encryption settings definition. Encrypted log files can be decrypted by using the <code>encrypt-file</code> tool.</p>

Ticket ID	Description
DS-12157, DS-35896	<p>Made the following improvements to backend backup and restore, as well as to LDIF export and import:</p> <ul style="list-style-type: none"> ▪ Added the ability to encrypt backups and LDIF exports with a key generated from one of the following sources: <ul style="list-style-type: none"> ▪ User-supplied passphrase ▪ Encryption settings definition <p>Previously, encrypted backups and LDIF exports used only a secret key that was known solely to servers within the replication topology. The new options simplify the processes of restoring encrypted backups and importing encrypted LDIF files in servers outside the replication topology. The <code>encrypt-file</code> utility can be used to decrypt encrypted backups and LDIF exports, regardless of the manner in which the encryption key was obtained.</p> <ul style="list-style-type: none"> ▪ Added the ability to limit the rate at which backups and LDIF exports are written to disk, which helps to avoid performance problems that result from these operations saturating the disk subsystem. ▪ Added new global configuration properties for automatically encrypting backups and LDIF exports by default. If data encryption is enabled during setup, these properties are set automatically to true. ▪ Added new global configuration properties that can specify the encryption settings definitions that are used to obtain encryption keys for backups and LDIF exports that are encrypted automatically. If no encryption settings definitions are specified, the server uses its preferred encryption settings definition or, if no encryption settings definitions are available, an internal topology key. ▪ Added a new configuration property for compressing encrypted LDIF exports automatically. ▪ Updated the <code>backup</code> tool to add the following arguments, which can be used to specify which key to use for encrypting a backup: <ul style="list-style-type: none"> ▪ <code>--promptForEncryptionPassphrase</code> ▪ <code>--encryptionPassphraseFile</code> ▪ <code>--encryptionSettingsDefinitionID</code> <p>Added a <code>--doNotEncrypt</code> argument that forces a backup to remain unencrypted even if automatic encryption is enabled.</p> <p>Added a <code>--maxMegabytesPerSecond</code> argument that imposes a limit on the rate at which a backup can be written to disk.</p> <ul style="list-style-type: none"> ▪ Updated the <code>restore</code> tool to add the following arguments, which can be used to provide a user-supplied passphrase when accessing the

Ticket ID	Description
DS-15223, DS-35895	<p>Added the ability to configure data encryption during setup by using a key that is obtained by any of the following methods:</p> <ul style="list-style-type: none"> ▪ Random generation ▪ Generated from a user-supplied passphrase ▪ Obtained from an export of another server's encryption settings database <p>When setting up multiple instances, if the same encryption passphrase is provided to each instance, then all instances share the same encryption key.</p> <p>The encryption-settings tool has also been updated, as follows:</p> <ul style="list-style-type: none"> ▪ Encryption settings definitions can be created from passphrases. ▪ Descriptions can be provided when encryption settings definitions are created. ▪ <code>Create</code> timestamps can be recorded for new definitions. <p>Additionally, you can create ciphers that use the Galois Counter Mode (GCM) cipher mode (for example, a cipher transformation of <code>AES/GCM/PKCS5Padding</code>) for authenticated encryption. Definitions that are created with a cipher algorithm but without a transformation now use stronger settings.</p> <p>The default encryption settings export format also provides stronger encryption. Newer server instances can cleanly import encryption settings that other servers have exported. To export encryption settings for import into earlier servers, use the <code>--use-legacy-export-format</code> argument.</p>
DS-16508	<p>Updated the <code>dsconfig</code> list subcommands to list objects of all complexity levels rather than requiring the <code>--advanced</code> flag to list advanced and expert objects.</p>
DS-17347	<p>Fixed a class loader issue where Sync Source extensions that were written using the Server SDK threw a <code>ClassNotFoundException</code> exception when importing classes not included in the PingDataSync Server base classpath.</p>
DS-17543	<p>Sync Pipe plugins can now be enabled for specific Sync Classes when creating or editing a Sync Class. As before, Sync Pipe plugins that are enabled on the Sync Pipe also run for all associated Sync Classes. If plugins are enabled on the Sync Pipe as well as an associated Sync Class, the plugins on the Sync Pipe run before the plugins on the Sync Class.</p>

Ticket ID	Description
DS-17891	Added a manage-certificates tool that performs multiple functions related to TLS certificate management.
DS-35523	<p>The update tool enforces the specification of a new product license when updating to a new major version. To specify a license, perform either of the following steps:</p> <ul style="list-style-type: none"> ▪ Use the <code>--licenseKeyFile</code> command-line options. ▪ Copy the license file to the top-level directory of the server package that is used to perform the update.
	<div style="border: 1px solid black; padding: 5px;"> <p> Important: To request a license, visit the Ping Identity licensing website or contact sales@pingidentity.com.</p> </div>
DS-35536	Support for the IBM JDK has been retired.
DS-35576	Updated the JMX connection handler's monitor provider so that when a JMX connection is closed, it is removed from the list of established connections. After a JMX client disconnects, the server might require a few minutes to detect the closure and to update the monitor.
DS-35581	Updated the server to include an instance of the Periodic Stats Logger plugin that is enabled by default to aid in diagnosing support issues. The Historical Stats Logger plugin logs performance statistics to <code>logs/monitor-history/historical-dsstats.csv</code> every five minutes. This process works in concert with the Monitor History plugin, which logs the full contents of <code>cn=monitor</code> to <code>logs/monitor-history</code> every five minutes. The output that collect-support-data generates also includes the tail of the <code>.csv</code> file automatically.
DS-35583	Fixed a defect in which configuring PingDirectory Server on a Windows machine with a space in the home directory pathname caused the server setup to fail.
DS-35601	Added a new Monitor Entry for SSL Cipher Suite and Protocol information. The new entry is available under <code>cn=SSL Context,cn=monitor</code> .
DS-35648	Added a missing double-quote to <code>bat/transform-ldif.bat</code> , which prevented the command from being invoked successfully on Windows systems.
DS-35727, DS-35728	Updated setup to include key usage, extended key usage, and subject alternative name extensions in the self-signed certificates that it generates.

Ticket ID	Description
DS-35868	The create-systemd-script command now suggests placing the script created in <code>/etc/systemd/system</code> .
DS-35990	<p>Provided the means to request that the server dynamically reload the certificate key and trust stores used by all HTTP connection handler instances that provide support for HTTPS. To make such a request, use one of the following tasks, tools, or methods:</p> <ul style="list-style-type: none"> ▪ A reload HTTP connection handler certificates task ▪ The reload-http-connection-handler-certificates tool ▪ The ServerContext#reloadHTTPConnectionHandlerCertificates method (to make the request programmatically from a Server SDK extension)
DS-36000	Added the PingOne for Customers Sync Destination for Ping Data Sync. Identities can now be synchronized from on-premises identity stores to PingOne for Customers.
DS-36054	Added an encrypt-file tool that can encrypt and decrypt data with a user-supplied passphrase, an encryption settings definition, or a topology key that is shared among server instances. encrypt-file includes support for decrypting content in encrypted backups, LDIF exports, and log files.
DS-36070	Fixed an issue with compressed logging that could leave data buffered in memory and not actually written out to disk until the logger is closed.
DS-36075	Updated tools that interact with log or LDIF files to support reading from input files that are compressed and encrypted, and to support writing to compressed and encrypted output files.
DS-36088	In addition to specifying an exact set of cipher suites for the LDAP and HTTP Connection Handlers, administrators can now specify inclusions to, or exclusions from, the set of cipher suites that the server selects.
DS-36093	Added support for TLS1.2 with STARTLS to connect to an SMTP server.
DS-36198	Updated the SCIM Sync Destination to always send credentials preemptively when configured to use HTTP basic authentication.

Ticket ID	Description
DS-36326	Fixed a compatibility issue when PingFederate was used as a SCIM Sync Destination, and a PingFederate Server's SCIM schema response that contained the schema for the <code>User</code> resource type could not be parsed.
DS-36328	Updated the server to reduce contention when converting between strings and the bytes that comprise them.
DS-36360	Increased the default size of the queue that holds alert notifications so that they can be processed asynchronously by a background thread. When many alerts are generated in a short period of time, this change reduces the probability of the queue becoming full, and prevents the blocking of subsequent alerts while the server catches up. Also updated the server to log a message when the queue becomes full, so that administrators are made aware of the problem and are provided with suggestions for addressing it.
DS-36466	Fixed an issue in which the password attribute could be deleted when PingDataSync Server was used with an Active Directory Sync Source.
DS-36545	Added a sanitize option to the Monitor History plugin that, if enabled, redacts the small amount of potentially personally identifiable information that could appear in search filters and LDAP DNs within the monitor. This fix facilitates the sharing of monitor history files with the support team in secure environments.

PingDataSync Server 6.2.0.0 Release Notes

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-811	Added an optional reason parameter for <code>dsconfig</code> changes that are automatically included in the server's <code>config-audit.log</code> file.
DS-1029	The server now monitors important certificates that are used for client and inter-server communication. Certificate information is available in the Administrative Console and in the <code>status</code> tool output. When a monitored certificate is 30 days from expiration, an alarm is raised, and alerts are sent.

Ticket ID	Description
DS-1045	<p>Constructed attribute mappings now support multivalued source attributes for conditional (conditional-value-pattern property) and non-conditional (value-pattern property) value patterns. Only one of the source attributes that contribute to a given value pattern can be multivalued.</p>
DS-2074	<p>Updated the installer to discourage the use of weak root passwords.</p> <p>When run in interactive mode, setup displays the following list of quality recommendations before prompting for the initial root password:</p> <ul style="list-style-type: none"> ▪ Make the password at least 12 characters in length. ▪ Verify that the password is not contained in the following dictionary types: <ul style="list-style-type: none"> ▪ English words ▪ Commonly used passwords <p>If the proposed password does not meet these constraints, the user is given the option of proceeding with the provided weak password or choosing a different password.</p> <p>When run in non-interactive mode, setup exits with an error if the proposed initial root password does not satisfy these constraints, unless the command line also includes the <code>--allowWeakRootUserPassword</code> argument.</p> <p>In either mode, when a strong initial root password is supplied, setup configures a root user's password policy to ensure that subsequent root user passwords are also required to satisfy these constraints.</p>
DS-4161	<p>Updated PingDirectory, PingDirectoryProxy, PingDataSync, and PingDataGovernance Servers with the capability to run as Windows Services.</p>
DS-10016	<p>PingDataSync Server now supports Oracle Unified Directory as an external server and as a sync source.</p>

Ticket ID	Description
DS-10694	<p>Updated the Server SDK to provide methods for obtaining a single LDAP connection or an LDAP connection pool with connections established to a specified LDAP external server defined in the server configuration.</p> <p>Also updated the server configuration to add support for obscured values. An <i>obscured</i> value is a general-purpose string that is stored in an obscured form in the configuration so that its plaintext value is not readily discernible to anyone viewing the configuration file. Consequently, the value is not displayed in administrative interfaces.</p> <p>The Server SDK provides a method for obtaining the plaintext representation of an obscured value. This mechanism can be used to store potentially sensitive values in the configuration for use in Server SDK extensions without the need to store those values in the clear.</p>
DS-10748	<p>Added configuration options for setting the SSL Protocol and the SSL Cipher Suites to the HTTPS Connection Handler.</p>
DS-13721	<p>Corrected the port number that is returned in the error message displayed when an administrator attempts to set up a server that is already running.</p>
DS-14650	<p>Enhanced the HTTPS Connection Handler to send an HTTP Strict Transport Security header by default in all responses.</p>
DS-15051	<p>Sync Destination Server SDK Extensions can now ignore a change by calling the <code>setIgnore()</code> method on the provided sync operation. Ignored changes are not included as applied operations in the statistics that are reported for the Sync Pipe through the Management Console, the <code>bin</code> or <code>status</code> command-line utility, or in a raw form under <code>cn=Sync Pipe Monitor: <pipe-name>,cn=monitor</code>.</p>

Ticket ID	Description
DS-15861, DS-15862	<p>Replaced the <code>ldapsearch</code> and <code>ldapmodify</code> tools with new, backward-compatible versions that offer many new features, including the following examples:</p> <ul style="list-style-type: none"> ▪ Improved connection handling ▪ Improved output formatting ▪ Improved support for bulk operations ▪ Support for referrals ▪ Support for additional request and response controls ▪ Rate limiting <p>The <code>ldapsearch</code> tool also offers the following abilities:</p> <ul style="list-style-type: none"> ▪ Output results in the following formats as an alternative to LDIF: <ul style="list-style-type: none"> ▪ JSON ▪ CSV ▪ Tab-delimited text ▪ Supports multiple data transformations <p>Additionally, the <code>ldapmodify</code> tool now supports the LDIF control syntax, as well as writing to output and reject files.</p>
DS-16405	<p>The SNMP context name for the server can now be configured by using the new context-name property of the SNMP Subagent plugin. When this property is not set, the server instance name remains the default context name .</p>
DS-16423	<p>PingDataSync Server now supports OpenDJ as an external server and as a sync source.</p>
DS-16509	<p>Updated the access and audit loggers so that, when information is logged about an internal operation that an external client request triggered, the log message includes the connection and operation ID for the request. Also updated the error logger so that, when a message is logged from a thread that is actively processing an operation, the log message includes the connection and operation ID for that operation.</p>
DS-16593	<p>Fixed an issue in which incorrect names displayed in the usage for the start scripts.</p>
DS-16603	<p>For Active Directory external servers, the bind-dn property can now be a User Principal Name (UPN).</p>
DS-16789	<p>The script files that stop and start the server have been renamed to <code>stop-server</code> and <code>start-server</code>, respectively. Earlier versions of the scripts are still present.</p>

Ticket ID	Description
DS-16858	The modifierName and modifyTimestamp attributes are now updated when offline configuration changes are made.
DS-16906	Added a disabled-alert-type configuration property to the Alert backend. This property suppresses specific alert types from being added to the backend.
DS-17019	The server now requires Java version 8.
DS-17078	Updated some cases in which filtered SCIM searches for groups with missing members were not returned.
DS-17080	Improved error reporting for the manage-extensions tool.
DS-17089	PingDataSync Server now supports generic LDAP servers as sync destinations.

Ticket ID	Description
DS-17146	<p>Updated the logic that selects which TLS cipher suites to enable by default, and the logic that prioritizes the cipher suites. Also updated the selection process to use the guidelines that the OWASP "Transport Layer Protection Cheat Sheet" document provides.</p> <p>The following changes are included:</p> <ul style="list-style-type: none"> ▪ The server already preferred cipher suites that support forward secrecy over suites that do not. It now prefers DHE over ECDHE, and avoids suites that use non-RSA keys. ▪ The server already avoided cipher suites that used known-weak cryptographic weaknesses, including null encryption, the RC4 symmetric cipher, and the MD5 digest algorithm. It now also avoids anonymous encryption, the single-DES symmetric cipher, the IDEA symmetric cipher, and any suite using export-level encryption. ▪ The server now prefers cipher suites that use the Galois/Counter Mode (GCM) over the Cipher Block Chaining (CBC) mode. ▪ The server now prefers AES-based cipher suites with 256-bit keys over those that use 128-bit keys. For suites with equivalent key sizes, it prefers suites with a stronger message digest algorithm over suites with a weaker digest algorithm (for example, SHA384 over SHA256 over SHA). ▪ The server now provides improved support for selecting and prioritizing ciphers when running on the IBM JVM. The IBM JVM uses a different naming convention for its cipher suites than does the Oracle implementation, which previously allowed certain desirable suites to be excluded from the selected set.
DS-17241	<p>The Administrative Console is no longer compatible with earlier versions of the server.</p>
DS-17318	<p>Removed the default root password from the out-of-the-box configuration to provide additional security. This password was never actually used because it was replaced by the user-supplied password provided when running setup.</p>
DS-17356	<p>Added additional logging for ignored synchronization operations.</p>

Ticket ID	Description
DS-17444	<p>Updated the server to reduce the use of the SHA-1 message digest. The server now uses a 256-bit SHA-2 digest instead of a SHA-1 digest in all of the following cases:</p> <ul style="list-style-type: none"> ▪ Hashing or signing a backup ▪ Signing an LDIF export ▪ Signing log data ▪ Generating MACs for an encrypted collect-support-data archive ▪ Generating unique identifiers for encryption settings definitions ▪ Determining whether the configuration changed with the server offline <p>In all of these cases, the server includes metadata in the output of the cryptographic processing to indicate the digest or MAC algorithm used for that processing, which ensures that the output remains compatible across server versions. For example, an LDIF export that uses a signature generated with the SHA-2 digest can be successfully imported into earlier versions of the server.</p> <p>The fingerprint certificate mapper has also been updated to use the 256-bit SHA-2 digest when mapping a client certificate to the corresponding user entry. The previous MD5 and SHA-1 digests remain supported.</p> <p>Additionally, the example enhanced password-storage scheme that the UnboundID Server SDK provides has been updated to use the 256-bit SHA-2 digest instead of a SHA-1 digest.</p>
DS-17531	<p>Fixed an issue that could cause a sync pipe to crash due to missing attributes in the changelog.</p>
DS-17544	<p>The Administrative Console can be deployed in an external web container, such as Tomcat, using the contents of <code>resource/admin-console.zip</code>, located in the server root.</p>
DS-17545, DS-17546, DS-18008	<p>Enhanced Attribute Mapping in PingDataSync Server to allow users to filter or exclude values from entries in the Sync Destination.</p>
DS-17576	<p>Updated the Server SDK's ServerContext to expose a ValueConstructor, which build String values by using a value-pattern template that references attribute values within an entry. For more information, refer to the Javadoc for the <code>ValueConstructor</code> class that is included with the Server SDK packaging.</p>

Ticket ID	Description
DS-17652	Fixed an issue in which attribute matching rules were not applied appropriately during synchronization.
DS-17653	Addressed an issue in which the server would throw a NullPointerException if a <code>com.unboundid.directory.sdk.sync.api.SyncSource</code> implementation did not set a modifier's name in a generated <code>ChangeRecord</code> .
DS-17668	Sync correlation attributes now support correlating using JSON keys within JSON attribute values. A JSON key can be referenced with syntax <code><attribute-name>>.<JSON-key>></code> . If a JSON correlation attribute is used but the JSON key does not exist for the source or destination entry, or if the considered source or destination entry does not possess valid JSON data, the destination entry considered entry is not matched.
DS-17688	PingDataSync Server now supports the synchronization of particular fields within JSON attributes. The JSON Attribute configuration object controls the manner in which fields are synchronized, as well as the manner in which source and destination values are correlated.
DS-17689	Sync constructed attribute mappings now support extracting JSON fields within JSON attributes by appending <code>.</code> , and then the JSON field, to extract to the attribute name. For example, if the JSON attribute is <code>ubidEmailJSON</code> and the <code>value</code> field is to be extracted, then <code>ubidEmailJSON.value</code> can be specified for the attribute name, resulting in <code>{ubidEmailJSON.value}</code> or, if a regular expression is used, <code>{ubidEmailJSON.value:/regex/replacement/flags}</code> .

Ticket ID	Description
DS-17693	<p>Constructed attribute mappings now support modifiers that alter the value of referenced source attributes when added to the end of source attribute references. For example, if the attribute mail is to be included in a constructed JSON value, the modifier jsonEscape can be specified, resulting in <code>{{"userMail":{mail:jsonEscape} }}</code> or, if a regular expression is used, <code>{{"userMail":{mail:/regex/replacement/flags:jsonEscape} }}</code>.</p> <div data-bbox="841 520 1466 590" style="border: 1px solid black; padding: 5px;"> <p> Note: <code>{{ expands to {, and }}}</code> expands to <code>'</code>.</p> </div> <p>The following modifiers are available:</p> <ul style="list-style-type: none"> ▪ jsonEscape — Escapes text for use in a JSON value. ▪ ldapFilterEscape — Escapes text for use in an LDAP filter. ▪ lowerCase — Converts text to lowercase. ▪ trim — Removes leading and trailing whitespace. ▪ upperCase — Converts text to uppercase.
DS-17697	<p>Added additional support to PingDataSync Server for synchronizing Active Directory Groups that contain more than 1,500 members.</p>
DS-17711	<p>PingDataSync Server now logs an error and continues processing if it encounters a corrupted changelog entry. Previously, the server threw an exception continually and stopped processing subsequent changes.</p>
DS-17741	<p>LDAP referral entries are now synchronized as a raw entry rather than trying to follow the referral.</p>
DS-17742	<p>LDAP changelog-based Sync Sources, such as the DSEE Sync Source, no longer fetch source entries when none of the Sync Source's configured base-dn values contains the targetDN in the corresponding changelog entry. This change reduces the load that is placed on the source directory servers.</p>
DS-17936	<p>PingDataSync Server now tries to use the source schema, if available, when the destination schema is unavailable.</p>
DS-17968	<p>Limited the ACI search on the collect support data tool to pull only 100 entries. This change reduces the amount of time the tool requires to run for organizations with a large number of ACIs.</p>
DS-17993	<p>Added additional logging to PingDataSync Server for cases in which attribute mapping fails. The synchronization operation is not halted.</p>

Ticket ID	Description
DS-18003	Updated the Server SDK so that HTTPServletExtensions can be installed on PingDataSync Server instances.
DS-18026	Fixed an issue that involved setting the sync connect and response timeouts with incorrect units of time.
DS-18100	A license key is required when setting up a server for the first time.
	<div style="border: 1px solid black; padding: 5px;"> <p> Important: To request a license, visit the Ping Identity licensing website or contact sales@pingidentity.com.</p> </div>
DS-18136	Enhanced the LDAP Sync Destination to allow administrators to configure options for synchronizing user passwords with clear-text, in cases where the LDAP Server does not support pre-encoded password synchronization. Setting <code>password-synchronization-format:clear-text</code> on the LDAP Sync Destination now enables the clear-text synchronization of passwords. By default, passwords are synchronized only in the clear over a secure connection. To override this option, set <code>require-secure-connection-for-clear-text-passwords:false</code> on the LDAP Sync Destination.
DS-18169	Fixed an incompatibility between Java and PKCS12 trust stores and keystores that caused an error during PingDataSync Server installations.
DS-18188	Removed the ability to create custom HTTP trace loggers by using the Server SDK.
DS-18199	Updated the default configuration of the File-Based Access Logger (logs/access) so that requests from peer PingDataSync instances are no longer suppressed. This approach simplifies the troubleshooting of connection and health-checking issues between server instances.
DS-35495	Updated <code>dsconfig</code> batch mode to operate more efficiently over the WAN by consolidating the number of LDAP searches that are required to retrieve the full configuration when pre-validating configuration changes.

PingDataSync Server 6.0.0.0 Release Notes

Upgrade Considerations

Important considerations for upgrading to this version of PingDataSync Server are as follows:

Note: Product names have been updated to reflect the UnboundID acquisition by Ping Identity. This change affects naming and branding only. The code base is the same as in prior releases.

- If you are upgrading a server that was running an earlier version of the JDK, run the `dsjavaproperties --initialize` command after the software upgrade to compare the settings of the earlier JDK with the requirements for the new server software. Apply necessary changes to the upgraded server, based on the previous performance settings.
- The 6.0 release makes the following changes to supported platforms:
 - CentOS 7.2 and RedHat 7.2 are now supported operating system versions.
 - SUSE 11 SP4 is now supported, and support for SUSE 11 SP2 has been retired.
 - Linux KVM and VMWare ESXi 6.x have been added as supported virtual machine environments.
 - Deprecation of JDKs 7.x. Customers are strongly advised to use JDK 8 with this release.
 - WildFly 9.x, which is renamed from *JBoss*, is now a supported application server for all web applications, including the Administrative Console and sample applications. Support for JBoss 7.x has been retired. Tomcat support remains unchanged in this release.
 - PBKDF2 is now the default encoding for root passwords. This change affects only new installations.
 - In addition to changing the default password-storage scheme for root users to PBKDF2, the default password-storage scheme for regular users has been changed to salted 256-bit SHA-2.
 - HTTPS defaults to ON, and servers now default to use HTTPS for console and API connections, including the SCIM API. This change might affect automation scripts and development environments in which HTTPS has not previously been in use.
 - Generated user passwords, like those created by the server during a password reset sequence, are now created as passphrases instead of as random character strings. This change makes such passwords easier to type and remember but does not affect upgrades.
 - The `/config` directory file permissions have been changed so that only the server user can access them.
 - Customers who use the optional encryption algorithms that the BouncyCastle library provides are encouraged to upgrade to BouncyCastle 1.54.

What's New

The following features are new with this release of PingDataSync Server:

- PingDataSync Server now recognizes and handles changes from Active Directory sources, including the non-standard `range=n-m` suffixes for multi-valued attributes.
- Added the ability to apply attribute maps programmatically in Server Extensions so that specific maps can be applied to a cascading set of changes that the extension generates.
- For Java developers whose tools and workflows make use of Maven, the Server SDK `.jar` file has been deployed to Maven Central. To add the Server SDK as a project dependency, developers need only to add a few lines to a project's `pom.xml`. Also, developers can now generate a Server SDK project that Maven-aware IDEs, such as IntelliJ IDEA, can package into an extension bundle that requires no special configuration. This benefit extends to continuous integration systems, such as Jenkins.
- The `dsconfig` tool provides the ability to search for and quickly navigate to configuration objects and properties in which the name, synopsis, or description matches a provided pattern.
- A new `rotate-log` tool and task have been added, which can be used to trigger the rotation of one or more log files.
- The Configuration API is now fully supported for all servers. In this release, the API was changed to match SCIM conventions for attribute naming, resource modeling, and the standard HTTP verbs. The UnboundID SCIM 2 SDK, which is available through GitHub, can now be used with the Configuration API.

- All servers have an updated web Administrative Console, which includes the following changes:
 - New layouts for operational statistics, processing time, queues, monitors, and installed extensions.
 - Alert and alarm displays that summarize the data in `cn=alerts` and `cn=alarms`, based on the configured gauges, as well as filtering and searching for them.
 - A new LDAP Schema Editor for importing schema files, validating, and creating and editing object classes and attribute types. The editor also supports the viewing of the attribute syntaxes, inheritance, and indexes that exist for each attribute, and the dependencies between object classes and attributes.
- The new Administrative Console can be deployed to independent application servers instead of being co-hosted by the servers. This approach simplifies deployment models and increases the separation between the data and application layers.
- To assist with situations in which a large number of changes might decrease the amount of available disk space, or might increase memory usage or the time required to start the server, alerting and gauge features have been added to the Recent Changes Database.
- Servers can now trigger events whenever log files are rotated. This change includes copy on rotate and summarize on rotate listeners, as well as Server SDK support for creating custom log file rotation listeners.
- Root user accounts can now be created, changed, and removed across the topology by using the `dsconfig` tool or the Administrative Console.

Known Issues and Workarounds

The following issues are known in the current version of PingDataSync Server:

- When deploying the Administrative Console in Tomcat 8 and accessing the Administrative Console application by using Tomcat's Web Application Manager, some browsers, including Safari and Firefox, generate a path URL that encodes the dash in `ubid-console`. This issue results in a path such as `http://localhost:8888/ubid%2Dconsole/`, which causes session-management errors.

Workaround: Copy and paste the generated link into a browser, and replace the encoded dash with a dash (-) character.

- The `PermSize` and `MaxPermSize` JVM properties are no longer supported in JDK 8, and can be ignored.

Workaround: To remove these properties, modify the `config/java.properties` file and run `bin/dsjavaproperties` while the server is offline.

- The `dsconfig` tool and the Administrative Console enable the creation and management of new Root DN users in this release. However, the ability to change the password of a currently logged-on administrator is limited.

Workaround: To change the administrator's password, use the `ldappasswordmodify` command, and provide the current and new password.

Resolved Issues

The following issues have been resolved with this release of PingDataSync Server:

Ticket ID	Description
DS-979	Added the ability to search for configuration objects and their properties by name with the <code>dsconfig</code> tool.

Ticket ID	Description
DS-4235	<p>Added support for the following log file rotation listeners, which allow for custom processing whenever a log file is rotated out of service so that a server can no longer write to it:</p> <ul style="list-style-type: none">▪ A <i>copy listener</i> copies the rotated log file to an alternate location, optionally compressing it in the process.▪ A <i>summarize listener</i> invokes the summarize-access-log tool on the rotated log file. <p>The Server SDK also includes an API for creating custom log file rotation listeners.</p>
DS-7505, DS-13571, DS-13860	<p>Updated the default file permissions for new installations on UNIX-based systems. By default, the files and directories that are included in the <code>.zip</code> file are accessible only to the user who extracted the file's contents. Newly created files and directories are also assigned permissions that can be accessed only by the account that is used to run the server. Existing configuration options for setting file permissions, such as the <code>log-file-permissions</code> and <code>db-directory-permissions</code> properties, continue to behave as before. The new <code>config/server.umask</code> file controls the default permissions for all other newly created files and directories.</p>

Ticket ID	Description
DS-9407, DS-15183, DS-15220	<p>Updated the initial server configuration to improve security and usability. These changes apply only to new installations and are not applied when an existing installation is updated. The following changes are included:</p> <ul style="list-style-type: none"> ▪ Updated the default password policy to use a default password-storage scheme that uses a salted 256-bit SHA-2 digest rather than a salted SHA-1 digest. ▪ Updated the root password policy to use a default password-storage scheme of PBKDF2 rather than salted 512-bit SHA-2. ▪ Updated the secure password policy to use a default password-storage scheme of PBKDF2 rather than a CRYPT variant that uses multiple rounds of 256-bit SHA-2. ▪ Updated the Password Policy Import plugin so that it attempts to use the default password policy when selecting a password storage schemes to use for entries that do not explicitly specify a password policy. The plugin also falls back to a salted 256-bit SHA-2 scheme instead of a salted SHA-1 scheme. ▪ Many of the weaker password-storage schemes have been disabled by default, including the following schemes: <ul style="list-style-type: none"> ▪ Base64 ▪ Clear ▪ Unsalted MD5 ▪ Salted MD5 ▪ 3DES ▪ RC4 ▪ Unsalted SHA-1 ▪ The default password policy has been updated to use a password generator that generates strong yet memorable passphrases rather than shorter and less-memorable strings of randomly selected characters. ▪ Many server loggers have been updated to include the following log elements by default: <ul style="list-style-type: none"> ▪ Instance name ▪ Requester DN ▪ Requester IP address ▪ Request controls ▪ The exact match identity mapper has been updated to inspect the mail attribute in addition to the uid attribute. When targeting a user with an authentication ID value, as when using SASL authentication or the proxied authorization v2 request control, an email address can now be specified as an alternative to a user ID. ▪ The UNBOUNDID-TOTP SASL mechanism handler has been updated to prevent TOTP password reuse by default. ▪ Added new request criteria that enable the identification of requests that target the root

Ticket ID	Description
DS-10312	Added the server's process ID to the output of the status tool.
DS-10464	Added a new <code>rotate-log</code> tool to request the rotation of one or more log files.
DS-10466, DS-10765, DS-14479, DS-15318, DS-16154	Addressed issues associated with <code>config-diff</code> . In some situations, for example, <code>config-diff</code> could not generate commands in an order that respected all dependencies. This issue is now fixed. Most expected warnings are excluded by default, but can be included in the output by using the <code>--includeAllWarnings</code> option. Additionally, the <code>--sourceBindPasswordFile</code> and <code>--targetBindPasswordFile</code> options are now applied in conjunction with the <code>--targetConfigGroup</code> and <code>--sourceConfigGroup</code> options.
DS-10946	Added a <code>--dry-run</code> option to <code>dsconfig</code> , which can be used in batch mode to validate the configuration changes in a batch file without applying them.
DS-12191	Added support for setting the request header size in the Jetty HTTP configuration server properties.
DS-13401	Improved the <code>collect-support-data</code> tool to include information that <code>systemd</code> provides on platforms that support it.
DS-13700	<p>Updated command-line tools based on the LDAP SDK tool APIs to add the following features:</p> <ul style="list-style-type: none"> ▪ Tools can use a properties file to obtain default values for arguments that are not available on the command line. If it exists, the server's <code>config/tools.properties</code> file is used by default. Command-line arguments can be used to specify an alternate properties file or to indicate that no properties file is used. ▪ Tools can be launched in an interactive mode, in which the user is prompted for arguments that establish and authenticate a connection, and for any other required arguments. The user can then use an interactive menu to specify values for any remaining arguments.
DS-13823	The <code>collect-support-data</code> tool now captures Kerberos configuration and logging information.
DS-14213	Added the ability to create local constants in LDIF template files by using the new local keyword.
DS-14298	To apply Sync maps programmatically, a new API, <code>applyMaps()</code> , is available for PingDataSync Server plugins.
DS-14430	Updated the Apache commons collections library to address the security vulnerability that CVE 2015-4852 describes.

Ticket ID	Description
DS-14548	Added a monitor entry for each Server SDK extension.
DS-14606	The resync tool now supports sync pipes that use Notification mode.
DS-14694	Added a --prettyPrint option to the config-diff tool to make the output more human-readable.
DS-14704	Updated the restore command so that it can no longer be used to restore a backup of the configuration backend. The command now points the administrator toward safer ways for reverting configuration changes, including using the config-diff command.
DS-14749	Updated the server's support for the Twilio Messaging Service so that it uses the newer Messages API, instead of the earlier SMS API, when sending SMS messages. The earlier API has been deprecated, and Twilio now imposes a 120-character limit for messages sent through that API. The Messages API allows the server to take advantage of the full 160 characters per SMS message.
DS-14765	Updated the Active Directory PingDataSync Source so that it correctly handles the range options on attributes that are returned with the DirSync control.
DS-14807	Tools that prepare a server for access by another server, such as prepare-external-server , now validate base DN entries before modifications are performed on the prepared server.
DS-14857	Fixed an issue with the dsjavaproperties tool, in which java properties for PermSize and MaxPermSize could be added when using JDK 8, which no longer supports these options.
DS-14878	To prevent the possible retention of data in memory, memory utilization has been improved when processing entries with large attributes.
DS-14923	Updated the bcrypt , crypt , PBKDF2 , and sCrypt password-storage schemes so that they can be used to create new instances.
DS-14979	Fixed a case in which changes to attribute syntax configurations did not apply to undefined attributes, which rely on default attribute types.
DS-15015	Server SDK extensions are now built with a Java source version of 1.7 by default.
DS-15087	Fixed an issue in which destination attributes with hard-coded values were excluded inappropriately during a resync, when the --excludeSourceAttr option was used.

Ticket ID	Description
DS-15088	The former suite of Administrative Console applications, each of which was tied to a particular product (for example the <code>dsconsole.war</code> for PingDirectory Server) are no longer available, and have been superseded by a new version of the Administrative Console that can manage any server product. You can choose to access the Administrative Console by hosting it within a server or by deploying it in an external servlet container. For the former option, enable an HTTP Connection Handler and add the Administrative Console Web Application Extension to the handler. For the latter option, download and extract the <code>management-console-[version].zip</code> file, and install the <code>ubid-console.war</code> file according to your container's instructions.
DS-15108	Replaced the <code>scramble-ldif</code> tool with a more powerful <code>transform-ldif</code> tool with support for several additional transformation types. The new <code>transform-ldif</code> tool is backward-compatible with the former <code>scramble-ldif</code> tool, and the <code>scramble-ldif</code> shell script and batch file are still included with the server to ensure compatibility with scripts that depend on that tool.
DS-15175	The Configuration API now returns unquoted, native Javascript values for integer, real number, and Boolean properties. Duration and size property values, such as 1 w or 100 G, continue to be represented as JavaScript string types.
DS-15178	Improved the error messages and examples for <code>create-rc-script</code> and <code>create-systemd-script</code> by explicitly suggesting the use of <code>sudo</code> so that the scripts can modify protected files.
DS-15187	Literal curly brackets (<code>{ }</code>) can now be included in value patterns and conditional value patterns of constructed attribute mappings by doubling them. Literal <code>{</code> and <code>}</code> are specified by <code>{{{</code> and <code>}}}</code> , respectively.
DS-15221	Changed interactive setup default value for HTTPS enablement.
DS-15337	Improved the error messages for <code>create-rc-script</code> and <code>create-systemd-script</code> when the directory in which the script will be created does not exist.
DS-15361, DS-15363, DS-15434	Updated interactive setup to display default values. Also improved the overall layout and appearance.
DS-15400	Addressed an issue in which <code>dsconfig</code> incorrectly permitted the deletion of certain configuration objects.

Ticket ID	Description
DS-15412	Improved the error messages that the manage-extensions tool generates when attempting to install invalid extensions.
DS-15417	Updated the global ACIs that ship with the server to use a separate ACI for each control or extended request to allow by default, rather than grouping all desired controls together in one ACI and all desired extended requests together in a second ACI. This change is reflected only in new installations, and not when updating an existing deployment.
DS-15422	Root DN User configuration entries can now be managed fully through the configuration management interfaces, such as dsconfig and the Administrative Console.
DS-15437	Provided a graphical tool, watch-entry , that is intended to demonstrate replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, the background of modified attributes temporarily becomes red. Attributes can also be directly modified.
DS-15466	Added logging information when initializing web application and servlet extensions in case an extension causes conflicts or delays.
DS-15513	PingDataSync Server now uses the max-connection-age configuration property to limit the age of LDAP connections to external servers.
DS-15521	Updated setup to encode the root password with the PBKDF2 password-storage scheme instead of SHA512.
DS-15522	To prevent Java JVM pauses, the updater tool now increases the PermSize and MaxPermSize parameters to the recommended values.
DS-15571	To accommodate the Administrative Console, increased the minimum memory requirements for the server process from 256MB to 384MB.
DS-15592	Fixed an error that could occur during upgrade when a missing custom schema prevented the configuration from loading.
DS-15621	Updated the Groovy Scripting Language version to 2.4.6.
DS-15622	Fixed an issue that prevented the deletion of disabled debug loggers.
DS-15670	The prepare-endpoint-server CLI that is included with PingDataSync Server correctly sets permissions when the Synchronization user already exists.

Ticket ID	Description
DS-15753	The Data Services Markup Language (DSML) client and gateway components have been discontinued and are no longer available.
DS-16224	Updated the <code>sanitize-log</code> tool to add support for JSON-formatted access and error log files.
DS-16728	Sensitive attribute values can now be redacted in the <code>sync</code> and <code>sync-failed-ops</code> log files. By default, the values of encoded passwords are redacted. The redaction can be configured with the <code>log-redaction-regex</code> property in the global Sync configuration.

Overview of the Server

The PingDirectory Server is a high performance, extensible directory and PingData Platform, written completely in Java™. The Directory Server centralizes consumer and user identity management information, subscriber data management, application configurations, and user credentials into a network, enterprise, or virtualized database environment. It provides seamless data management over a distributed system based on a standardized solution that meets the constant performance demands for today's markets. The Directory Server simplifies administration, reduces costs, and secures information in systems that scale for very large numbers of users.

This chapter provides an overview of the Directory Server's features and components.

Server Features

The PingDirectory Server is a powerful, 100% Java, production-proven PingData Platform solution for mission-critical and large-scale applications. The Directory Server provides an extensive feature-rich set of tools that can meet the production needs of your system.

- **Full LDAP Version 3 Implementation.** The Directory Server fully supports the Lightweight Directory Access Protocol version 3 (LDAP v3), which supports the Request For Comments (RFCs) specified in the protocol. The Directory Server provides a feature-rich solution that supports the core LDAPv3 protocol in addition to server-specific controls and extended operations.
- **High Availability.** The Directory Server supports N-way multi-master replication that eliminates single points of failure and ensures high availability for a networked topology. The Directory Server allows data to be stored across multiple machines and disk partitions for fast replication. The Directory Server also supports replication in entry-balancing proxy server deployments.
- **Administration Tools.** The Directory Server provides a full set of command-line tools, an Administrative Console, and a Java-based setup tool to configure, monitor, and manage any part of the server. The Directory Server has a task-based subsystem that provides automated scheduling of basic functions, such as backups, restores, imports, exports, restarts, and shutdowns. The set of utilities also includes a troubleshooting support tool that aggregates system metrics into a zip file, which administrators can send to your authorized support provider for analysis.
- **Self-Service Account Manager Application.** The Self Service Account Manager project, hosted at <https://github.com/pingidentity/ssam>, is a customizable web application allowing users to perform their own account registration, profile updates, and password changes. The project is for testing and development purposes, and is not a supported application.
- **Delegated Admin Application.** A Javascript-based web application can be installed for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives (CSR) initiating a password reset and unlock; an employee in HR updating an address stored within another employee profile; or an application administrator updating identity attributes or group membership to allow application SSO access.
- **Security Mechanisms.** The Directory Server provides extensive security mechanisms to protect data and prevent unauthorized access. Access control list (ACL) instructions are available down to the attribute value level and can be stored within each entry. The Directory Server allows connections over Secure Sockets Layer (SSL) through an encrypted communication tunnel. Clients can also use the StartTLS extended operation over standard, non-encrypted ports. Other security features include a privilege subsystem for fine-grained granting of rights, a password policy subsystem that allows configurable password validators and storage schemes, and SASL authentication mechanisms to secure data integrity, such as PLAIN, ANONYMOUS, EXTERNAL, CRAM-MD5, Digest-MD5, and GSSAPI. The Directory Server also supports various providers and mappers for certificate-based authentication in addition to the ability to encrypt specific entries or sensitive attributes. See the *PingDirectory Server Security Guide* for details.
- **Monitoring and Notifications.** The Directory Server supports monitoring entries using the PingDataMetrics Server, JConsole, Simple Network Management Protocol (SNMP), or using the Administrative Console. Administrators can track the response times for LDAP operations using a monitoring histogram as well as record performance statistics down to sub-second granularity. The Directory Server also supports configurable notifications, auditing, and logging subsystems with filtered logging capabilities.
- **Powerful LDAP SDK.** The Directory Server is based on a feature-rich LDAP SDK for Java, designed by Ping Identity. The LDAP SDK is a Java API standard that overcomes the many limitations of the Java Naming and Directory Interface (JNDI) model. For example, JNDI does not address the use of LDAP controls and extended operations. The LDAP SDK for Java provides support for controls and extended operations to leverage Ping Identity's extensible architecture for their applications.

For more information on the LDAP SDK for Java, to go <http://www.LDAP.com>.

- **SCIM Extension.** The Directory Server provides a System for Cross-domain Identity Management (SCIM) servlet extension to facilitate moving users to, from, and between cloud-based Software-as-a-Service (SaaS) applications in a secure and fast manner.
- **Server SDK.** Ping Identity also provides the Server SDK, which is a library of Java packages, classes, and build tools to help in-house or third-party developers create client extensions for the PingDirectory Server, PingDirectoryProxy Server, and Data Sync Server. The servers were designed with a highly extensible and scalable architecture with multiple plugin points for your customization needs. The Server SDK provides APIs to alter the behavior of each server's components without affecting its code base.

Administration Framework

The Directory Server provides an administration and configuration framework capable of managing stand-alone servers, server groups, and highly-available deployments that include multiple redundant server instances. Administrators can configure changes locally or remotely on a single server or on all servers in a server group. Each server configuration is stored as a flat file (LDIF) that can be accessed under the `cn=config` branch of the Directory Information Tree (DIT). Administrators can tune the configuration and perform maintenance functions over LDAP using a suite of command-line tools, or an Administrative Console (for configuration and monitoring). The Directory Server also provides plugins to extend the functionality of its components.

Server Tools Location

Ping Identity distributes the Directory Server, Administrative Console, and LDAP SDK for Java in zip format. After unzipping the file, you can access the `setup` utility in the server root directory, located at `PingDirectory`. The Directory Server stores a full set of command-line tools for maintaining your system in the `PingDirectory/bin` directory for UNIX® or Linux® machines and the `PingDirectory\bat` directory for Microsoft® Windows® machines.

Prior to installing the directory server, read Chapter 2 *Preparing Your Environment*, which presents important information on setting up your machines. Chapter 3 *Installing the Directory Server* presents procedures to install a server instance using the `setup` utility. This utility can be run in one of the two available installation modes: interactive command-line, and non-interactive command-line. Chapter 4 *Configuring the Directory Server* provides procedures to modify the configuration of a server instance or a group of servers using the command-line tools and the Administrative Console.

Preparing Your Environment

The PingDirectory Server offers a highly portable and scalable architecture that runs on multiple platforms and operating systems. The Directory Server is specifically optimized for those operating systems used in environments that process a very large number of entries.

This chapter presents some procedures to set up your server machines for optimal processing efficiency.

Before You Begin

The Directory Server requires certain software packages for the proper operation of the server. For optimized performance, the PingDirectory Server requires Java for 64-bit architectures. To view the minimum required Java version, access your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

It is also highly recommended that a Network Time Protocol (NTP) system be in place so that multi-server environments are synchronized and timestamps are accurate.

System requirements

PingDirectory Server has qualified the configurations in this section and has certified that they are compatible with the product. Differences in operating system versions, service packs, and other platform variations are supported until the platform or other required software is suspected of causing an issue.

Platforms

- Windows Server 2019
- Windows Server 2016
- Red Hat Enterprise Linux ES 8.1
- Red Hat Enterprise Linux ES 7.7
- CentOS 8.1
- CentOS 7.7
- SUSE Linux Enterprise 15 SP1
- SUSE Linux Enterprise 12 SP5
- Ubuntu 18.04 LTS
- Ubuntu 16.04 LTS
- Amazon Linux 2

Note: This product has been tested with the default configurations of all operating system components. If your organization has customized implementations or has installed third-party plugins, the deployment of this product might be affected.

Docker

Version: Docker 19.03.5

Host operating system: Ubuntu 18.04 LTS

Base image operating system: Ubuntu 18.04 LTS

Base image operating system: Alpine Linux 3.11

View the Directory Server Docker Image on DockerHub (<https://hub.docker.com/r/pingidentity/pingdirectory>). Visit the PingIdentity DevOps documentation (<https://pingidentity-devops.gitbook.io/devops/>) for more information. Note that only the Directory Server software is licensed under Ping Identity's end user license agreement, and any other software components contained within the image are licensed solely under the terms of the applicable open source/third-party license.

Note: Ping Identity accepts no responsibility for the performance of any specific virtualization software and in no way guarantees the performance or interoperability of any virtualization software with its products.

Java Runtime Environment

- Oracle JDK 8 64-bit
- Oracle JDK 11 LTS 64-bit
- OpenJDK 8 64-bit
- OpenJDK 11
- Corretto 8
- Corretto 11

Note:

The [Ping Identity Java Support Policy](#) applies to your Java Runtime Environment.

Installing Java

For optimized performance, the PingDirectory Server requires Java for 64-bit architectures. You can view the minimum required Java version on your Customer Support Center portal or contact your authorized support provider for the latest software versions supported.

Even if your system already has Java installed, you may want to create a separate Java installation for use by the PingDirectory Server to ensure that updates to the system-wide Java installation do not inadvertently impact the Directory Server. This setup requires that the JDK, rather than the JRE, for the 64-bit version, be downloaded.

To Install Java (Oracle/Sun)

Steps

1. Open a browser and navigate to the Oracle download site.
2. Download the latest version Java JDK. Click the JDK Download button corresponding to the latest Java update.
3. On the Java JDK page, click the Accept Licence Agreement button, then download the version based on your operating system.

Preparing the Operating System (Linux)

The PingDirectory Server has been extensively tested on multiple operating systems. We have found that several operating system optimizations lead to improved performance. These optimizations include increasing the file descriptor limit on Linux systems, setting file system flushes, editing OS-level environment variables, downloading some useful monitoring tools for Redhat Linux systems, and configuring for Huge Page support.

Configuring the File Descriptor Limits

The PingDirectory Server allows for an unlimited number of connections by default, but is restricted by the file descriptor limit on the operating system. If needed, increase the file descriptor limit on the operating system.

If the operating system relies on `systemd`, refer to the Linux operating system documentation for instructions on setting the file descriptor limit.

To Set the File Descriptor Limit (Linux)

About this task

The Directory Server allows for an unlimited number of connections by default but is restricted by the file descriptor limit on the operating system. Many Linux distributions have a default file descriptor limit of

1024 per process, which may be too low for the server if it needs to handle a large number of concurrent connections.

Once the operating system limit is set, the number of file descriptors that the server will use can be configured by either using a `NUM_FILE_DESCRIPTOR` environment variable, or by creating a `config/num-file-descriptors` file with a single line such as, `NUM_FILE_DESCRIPTOR=12345`. If these are not set, the default of 65535 is used. This is strictly optional if wanting to ensure that the server shuts down safely prior to reaching the file descriptor limit.

Steps

1. Display the current `fs.file-max` limit of the system.

```
sysctl fs.file-max
```

The `fs.file-max` limit is the maximum server-wide file limit you can set without tuning the kernel parameters in the `proc` file system.

2. Edit the `/etc/sysctl.conf` file. If there is a line that sets the value of the `fs.file-max` property, make sure that its value is set to at least 1.5 times the per-process limit. If there is no line that sets a value for this property, add the following to the end of the file (100000 is just an example here; specify a value of at least 1.5 times the per-process limit):

```
fs.file-max = 100000
```

3. Display the current hard limit of the system.

```
ulimit -aH
```

The `open files (-n)` value is the maximum number of open files per process limit.

Verify that its value is set to at least 65535.

4. Edit the `/etc/security/limits.conf` file. If the file has lines that set the soft and hard limits for the number of file descriptors, make sure the values are set to 65535. If the lines are not present, add the following lines to the end of the file (before “#End of file”), making certain to insert a tab between the columns.

```
* soft nofile 65535
* hard nofile 65535
```

Note:

The number of open file descriptors is limited by the physical memory available to the host. You can determine this limit with the following command.

```
cat /proc/sys/fs/file-max
```

If the `file-max` value is significantly higher than the 65535 limit, consider increasing the file descriptor limit to between 10% and 15% of the system-wide file descriptor limit. For example, if the `file-max` value is 810752, you could set the file descriptor limit to 100000. If the `file-max` value is lower than 65535, the host is likely not sized appropriately.

5. Reboot your system, and then use the `ulimit` command to verify that the file descriptor limit is set to 65535.

```
# ulimit -n
```

Results

Note: For RedHat 7 or later, modify the `20-nproc.conf` file to set both the open files and max user processes limits:

```
/etc/security/limits.d/20-nproc.conf

Add or edit the following lines if they do not already exist:

*          soft    nproc    65536
*          soft    nofile   65536
*          hard    nproc    65536
*          hard    nofile   65536
root      soft    nproc    unlimited
```

File System Tuning

Newer ext4 systems use delayed allocation to improve performance. This delays block allocation until it writes data to disk. Delayed allocation improves performance and reduces fragmentation by using the actual file size to improve block allocation. This feature may cause a risk of data loss in cases where a system loses power before all of the data has been written to disk. This may occur if a program is replacing the contents of a file without forcing a write to the disk with `fsync`. Make sure the default `auto_da_alloc` option is enabled on ext4 file systems.

Administrators can tune ext3 and ext4 file systems by setting the file system flushes and noatime to improve server performance. The following changes can be made in the `/etc/fstab` file.

To Set the File System Flushes

About this task

With the out-of-the-box settings on Linux systems running the ext3 file system, the data is only flushed to disk every five seconds. If the Directory Server is running on a Linux system using the ext3 file system, consider editing the mount options for that file system to include the following:

```
commit=1
```

This variable changes the flush frequency from five seconds to one second.

You should also set the flush frequency to the `/etc/fstab` file. Doing the change via the mount command alone will not survive across reboots.

To Set noatime on ext3 and ext4 Systems

About this task

If you are using an ext3 or ext4 file system, set `noatime` to improve performance by turning off any `atime` updates during read accesses. Additionally, set the flush frequency to the `/etc/fstab` file. Performing the change through the `mount` command alone does not survive across reboots.

Steps

- Run the following command on an ext3 system.

```
# mount -t ext3 -o noatime /dev/fs1
```

- Run the following command on an ext4 system.

```
# mount -t ext4 -o noatime /dev/fs1
```

Setting the Maximum User Processes

On some Linux distributions (Redhat Enterprise Linux Server/CentOS 6.0 or later), the default maximum number of user processes is set to 1024, which is considerably lower than the same parameter on older distributions (e.g., RHEL/CentOS 5.x). The default value of 1024 leads to some JVM memory errors when running multiple servers on a machine due to each Linux thread being counted as a user process.

At startup, the Directory Server and its tools automatically attempt to raise the maximum user processes limit to 16,383 if the value reported by `ulimit` is less than that. If, for any reason, the server is unable to automatically set the maximum processes limit to 16,383, an error message will be displayed. It is recommended that the limit be set explicitly in `/etc/security/limits.conf`. For example:

```
* soft nproc 65535
* hard nproc 65535
```

The (*) can be replaced with the name of the user under which the software will run. These settings can also be manually configured by setting the `NUM_USER_PROCESSES` environment variable to 16383 or by setting the same variable in a file named `config/num-user-processes`.

About Editing OS-Level Environment Variables

Certain environment variables can impact the Directory Server in unexpected ways. This is particularly true for environment variables that are used by the underlying operating system to control how it uses non-default libraries.

For this reason, the Directory Server explicitly overrides the values of key environment variables like `PATH`, `LD_LIBRARY_PATH`, and `LD_PRELOAD` to ensure that something set in the environments that are used to start the server does not inadvertently impact its behavior.

If there is a legitimate need to edit any of these environment variables, the values of those variables should be set by manually editing the `set_environment_vars` function of the `lib/_script-util.sh` script. You will need to stop (`bin/stop-server`) and re-start (`bin/start-server`) the server for the change to take effect.

Install `sysstat` and `pstack` (Red Hat)

For Red Hat® Linux systems, you should install a couple of packages, `sysstat` and `pstack`, that are disabled by default, but are useful for troubleshooting purposes in the event that a problem occurs. The troubleshooting tool `collect-support-data` uses the `iostat`, `mpstat`, and `pstack` utilities to collect monitoring, performance statistics, and stack trace information on the server's processes. For Red Hat systems, make sure that these packages are installed, for example:

```
$ sudo yum install sysstat gdb dstat -y
```

Install `dstat` (SUSE Linux)

The `dstat` utility is used by the `collect-support-data` tool and can be obtained from the OpenSUSE project website. The following example shows how to install the `dstat` utility on SuSE Enterprise Linux 11 SP2:

1. Login as Root.
2. Add the appropriate repository using the `zypper` tool.
3. Install the `dstat` utility.

```
$ zypper install dstat
```

Disable File System Swapping

About this task

It is recommended that any performance tuning services like `tuned` be disabled. As root, change the current value in the operating system and by adding a line `vm.swappiness = 0` to `/etc/sysctl.conf` to ensure that the correct setting is applied when the system restarts.

If performance tuning is required, `vm.swappiness` can be set by cloning the existing performance profile then adding `vm.swappiness = 0` to the new profile's `tuned.conf` file. This file is located at `/usr/lib/tuned/profile-name/tuned.conf`. The updated profile is then selected by running `tuned-adm profile customized_profile`.

Omit `vm.overcommit_memory`

Administrators should be aware that an improperly configured value for the `vm.overcommit_memory` property in the `/etc/sysctl.conf` file can cause the `setup` or `start-server` tool to fail.

For Linux systems, the `vm.overcommit_memory` property sets the kernel policy for memory allocations. The default value of 0 indicates that the kernel determines the amount of free memory to grant a `malloc` call from an application. If the property is set to a value other than zero, it could lead the operating system to grab too much memory, depriving memory for the `setup` or `start-server` tool.

We recommend omitting the property in the `/etc/sysctl.conf` file to ensure that enough memory is available for these tools.

Managing System Entropy

Entropy is used to calculate random data that is used by the system in cryptographic operations. Some environments with low entropy may have intermittent performance issues with SSL-based communication. This is more typical on virtual machines, but can occur in physical instances as well. Monitor the `kernel.random.entropy_avail` in `sysctl` value for best results.

Set File System Event Monitoring (`inotify`)

An event monitoring tool such as `inotify` can be configured for notifying processes about file system events, including file creation, deletion, and updates. The Linux system puts a limit on the number of `inotify` watches a user can receive. To increase the limit, edit `etc/sysctl.conf` to add a line:

```
fs.inotify.max_user_watches = 524288
```

Run the command:

```
$ sudo sysctl -w fs.inotify.max_user_watches=524288
```

Tune IO Scheduler

Using the correct IO scheduler can increase performance and reduce the possibility of database timeouts when the system is under extreme write load. For file systems running on an SSD, or in a virtualized environment, the `noop` scheduler is recommended. For all other systems, the `deadline` scheduler is recommended. To determine which scheduler is configured on your system, run this command:

```
$ cat /sys/block/<block-device>/queue/scheduler
```

For example:

```
$ cat /sys/block/sda/queue/scheduler
```

Changing the scheduler on a running system can be done with the following command:

```
$ echo 'deadline' > /sys/block/sda/queue/scheduler
```

The change will take effect after the system is restarted. The procedure for configuring a scheduler to use at startup depends on the version of Linux. See the Linux documentation for your specific version for the correct way to configure this setting.

Running as a Non-Root User (Linux)

To run as a non-root user but still allow connections on a privileged port, two options are available:

- **Use a Load-Balancer or Directory Proxy Server.** In many environments, the server can be run on a non-privileged port but can be hidden by a hardware load-balancer or LDAP Directory Proxy Server.
- **Use `netfilter`.** The `netfilter` mechanism, exposed through the `iptables` command, can be used to automatically redirect any requests from a privileged port to the unprivileged port on which the server is listening.

Enabling the Server to Listen on Privileged Ports (Linux)

Linux systems have a mechanism called capabilities that is used to grant specific commands the ability to do things that are normally only allowed for a root account. It may be convenient to enable the server to listen on privileged ports while running as a non-root user.

The `setcap` command is used to assign capabilities to an application. The `cap_net_bind_service` capability enables a service to bind a socket to privileged ports (port numbers less than 1024). If Java is installed in `/ds/java` (and the Java command to run the server is `/ds/java/bin/java`), the Java binary can be granted the `cap_net_bind_service` capability with the following command:

```
$ sudo setcap cap_net_bind_service=+eip /ds/java/bin/java
```

The java binary needs an additional shared library (`libjli.so`) as part of the Java installation. More strict limitations are imposed on where the operating system will look for shared libraries to load for commands that have capabilities assigned. So it is also necessary to tell the operating system where to look for this library. This can be done by creating the file `/etc/ld.so.conf.d/libjli.conf` with the path to the directory that contains the `libjli.so` file. For example, if the Java installation is in `/ds/java`, the contents of that file should be:

```
/ds/java/lib/amd64/jli
```

Run the following command for the change to take effect:

```
$ sudo ldconfig -v
```

Installing the Server

After you have prepared your hardware and software system based on the instructions in Chapter 2, you can begin the setup process using of the PingDirectory Server's easy-to-use installation modes.

This chapter presents the various installation options and procedures available to the administrator.

Getting the Installation Packages

To begin the installation process, obtain the latest ZIP release bundle from Ping Identity and unpack it in a folder of your choice. The release bundle contains the Directory Server code, tools, and package documentation.

To Unpack the Build Distribution

Steps

1. Download the latest zip distribution of the Directory Server software.
2. Unzip the compressed zip archive file in a directory of your choice.

```
$ unzip PingDirectory-<version>.zip
```

You can now set up the Directory Server.

About the Layout of the Directory Server Folders

Once you have unzipped the Directory Server distribution file, you will see the following folders and command-line utilities, shown in the table below.

Layout of the Directory Server Folders

Directories/Files/Tools	Description
License.txt	Licensing agreement for the Directory Server.
README	README file that describes the steps to set up and start the Directory Server.
bak	Stores the physical backup files used with the backup command-line tool.
bat	Stores Windows-based command-line tools for the Directory Server.
bin	Stores UNIX/Linux-based command-line tools for the Directory Server.
classes	Stores any external classes for server extensions.
collector	Used by the server to make monitored statistics available to the PingDataMetrics Server.
config	Stores the configuration files for the backends (admin, config) as well as the directories for messages, schema, tools, and updates.
db	Stores the Oracle Berkeley Java Edition database files for the Directory Server.
docs	Provides the product documentation.
import-tmp	Stores temporary imported items.
ldif	Stores any LDIF files that you may have created or imported.
legal-notice	Stores any legal notices for dependent software used with the Directory Server.
lib	Stores any scripts, jar, and library files needed for the server and its extensions.
locks	Stores any lock files in the backends.
logs	Stores log files for the Directory Server.
metrics	Stores the metrics that can be gathered for this server and surfaced in the PingDataMetrics Server.
resource	Stores the MIB files for SNMP and can include ldif files, make-ldif templates, schema files, dsconfig batch files, and other items for configuring or managing the server.
revert-update	The revert-update tool for UNIX/Linux systems.
revert-update.bat	The revert-update tool for Windows systems.

Directories/Files/Tools	Description
setup	The setup tool for UNIX/Linux systems.
setup.bat	The setup tool for Windows systems.
scim-data-tmp	Used to create temporary files containing SCIM request data.
uninstall	The uninstall tool for UNIX/Linux systems.
uninstall.bat	The uninstall tool for Windows systems.
update	The update tool for UNIX/Linux systems.
update.bat	The update tool for Windows systems.
Velocity	Stores any customized Velocity templates and other artifacts (CSS, Javascript, images), or Velocity applications hosted by the server.

make-ldif Template Format

The make-ldif template demonstrates the use of all supported tags.

Note: This file should not be imported into a directory since it contains elements that are not defined in the schema.

```
# Copyright 2012-2020 Ping Identity Corporation
# All Rights Reserved.
#
# This file provides a make-ldif template whose primary purpose is to
# demonstrate the use of all variations of all supported tags. It is not
# intended to result in an LDIF file that should be imported into a
# directory,
# since it includes elements that aren't defined in the schema.
# Nevertheless,
# this file may be useful to individuals looking to create their own
# make-ldif templates or to customize an existing template.

# Any global replacement tokens defined at the top of the template file will
# be replaced with their corresponding value later in the template anywhere
# the token name appears in square brackets.
define basedn=dc=example,dc=com

# A branch is a special kind of entry with a fixed, non-dynamically
# generated
# DN (although the DN may be based partially or entirely on a global
# replacement token). Some kinds of tags may be used in branch definitions
# (as
# indicated below through the "allowed-in-branch" attribute. Also, the
# "subordinateTemplate" element specifies the type and number of entries to
# create immediately below each branch.
branch: [basedn]

# The template definitions come after the branch definitions, and define
# entries that will be dynamically generated, including their DNs. Entries
# generated from a template may be either created directly below a branch,
# or
# they may be created below other template-generated entries (i.e., a
# template
# may include a "subordinateTemplate" element indicating that one or more
# entries of a different type should appear below each of the initial
# template
# entries. In this template file, each template below will demonstrate the
# use of exactly one tag, and exactly one variation of that tag (so tags
# with
# multiple variations may be illustrated through multiple templates).

template: attribute-value-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name
syntax: open-curly-brace attribute-name close-curly-brace
example: {cn}
allowed-in-branch: true

```

description: This tag will be replaced with the first value of the indicated attribute. The specified attribute must have already been assigned at least one value earlier in the template.

```
template: attribute-value-tag-with-name-and-max-length
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: attribute value tag with name and max length
syntax: open-curly-brace attribute-name colon max-length close-curly-brace
example: {cn:5}
allowed-in-branch: true
description: This tag will be replaced with at most the specified number
of characters from the beginning of the first value of the indicated
attribute. The specified attribute must have already been assigned at
least one value earlier in the template.
```

```
template: dn-tag-full
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with full dn
syntax: less-than "dn" greater-than
example: <dn>
allowed-in-branch: true
description: This tag will be replaced with the full DN of the entry
currently being generated. All RDN attributes must be assigned values
earlier in the template.
```

```
template: dn-tag-partial
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: dn tag with partial dn
syntax: less-than "dn" colon num-components greater-than
example: <dn:1>
allowed-in-branch: true
description: This tag will be replaced with at most the specified number of
components from the entry currently being generated, as counted from left
to right (e.g., a value of 1 will cause only the RDN to be used, a value
of 2 will cause both the current entry's RDN and the parent entry's RDN to
be used, etc.). All RDN attributes must be assigned values earlier in the
template.
```

```
template: escaped-characters
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: An example of escaping special characters
syntax: backslash-character character-to-escape
example: \{ "this" : "is JSON" \}
allowed-in-branch: true
description: The following characters need to be escaped with a backslash in
order to be taken literally by make-ldif: \{ \} \< \> \[ \]
```

```
template: file-tag-path
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path
syntax: less-than "file" colon file-path greater-than
example: <file:cities>
allowed-in-branch: true
```

description: This tag will be replaced with a randomly-selected line from the specified file. The file may be specified using a full path, but if no path information is provided, then it will be assumed to be in the config/MakeLDIF directory below the server root.

```
template: file-tag-path-sequential
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: file tag with path and sequential
syntax: less-than "file" colon file-path colon "sequential" greater-than
example: <file:cities:sequential>
allowed-in-branch: true
description: Each subsequent use of this tag will be replaced with the next line from the specified file. Once all lines of the file have been used, then subsequent uses will start over from the beginning of the file.
```

```
template: first-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: first tag
syntax: less-than "first" greater-than
example: <first>
allowed-in-branch: false
description: This tag will be replaced with a first name value (taken from the first.names file). The algorithm that the make-ldif tool uses guarantees that the combination of the first and last name values will always be unique, no matter how many entries are generated (although it may need to append a number to the last name value in LDIF files with extremely large numbers of values).
```

```
template: guid-tag
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: GUID tag
syntax: less-than "guid" greater-than
example: <guid>
allowed-in-branch: true
description: This tag will be replaced with a randomly-generated globally-unique identifier (GUID), also known as a universally-unique identifier (UUID).
```

```
template: ifabsent-tag-with-name
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name greater-than
example: <ifabsent:cn>This value will only appear if the resulting entry doesn't have a cn attribute.
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will always be replaced with the empty string. However, it may cause any in which this tag is used to be completely suppressed from the resulting entry if the specified attribute already exists in the generated entry. This is primarily useful for attributes whose inclusion in generated entries is not guaranteed (e.g., randomly determined via the presence tag).
```

```
template: ifabsent-tag-with-name-and-value
rdnAttr: cn
objectClass: top
objectClass: make-ldif-example
```

```

cn: ifabsent tag with name
syntax: less-than "ifabsent" colon attribute-name colon attribute-value
greater-than
example: <ifabsent:cn:value>This value will only appear if the resulting
  entry doesn't have a cn attribute with a value of "value".
allowed-in-branch: true
description: This tag is not intended to generate replacement text, and will
  always be replaced with the empty string. However, it may cause any in
  which this tag is used to be completely suppressed from the resulting entry
  if the specified attribute value already exists in the generated entry.
  This is primarily useful for attributes whose inclusion in generated
  entries is not guaranteed (e.g., randomly determined via the presence tag).

objectClass: make-ldif-example
cn: underscore-parentdn tag
syntax: less-than "_parentdn" greater-than
example: <_parentdn>
allowed-in-branch: false
description: This tag will be replaced with the full DN of the entry
  immediately superior to the entry being generated, except with commas
  replaced with underscores.

```

About the Server Installation Modes

One of the strengths of the PingDirectory Server is the ease with which you can install a server instance using the **setup** tool. The **setup** tool allows you to quickly install and configure a stand-alone Directory Server instance.

To install a server instance, run the **setup** tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode prompts for information during the installation process. To run the installation in this mode, use the **setup --cli** command.

- **Non-Interactive Command-Line Mode.** Non-interactive command-line mode is designed for setup scripts to automate installations or for command-line usage. To run the installation in this mode, `setup` must be run with the `--no-prompt` option as well as the other arguments required to define the appropriate initial configuration.

All installation and configuration steps should be performed while logged on to the system as the user or role under which the Directory Server will run.

Before You Begin

After you have unzipped the Directory Server ZIP file, you may want to carry out the following functions depending on your deployment requirements:

- **Custom Schema Elements.** If your deployment uses custom schema elements in a custom schema file (for example, `98-schema.ldif`), you may do one of the following:
 - Copy your custom schema file to the `config/schema` directory before running `setup`.
 - Copy your custom schema file to the `config/schema` directory after `setup` and re-start the server. If replication is enabled, the restart will result in the schema replicating to other servers in the replication topology.
 - Use the **Schema Editor** after `setup`. If replication is enabled, schema definitions added through the **Schema Editor** will replicate to all servers in the replication topology without the need for a server restart.
- **Certificates.** If you are setting up a new machine instance, copy your keystore and truststore files to the `<server-root>/config` directory prior to running `setup`. The keystore and truststore passwords can be placed, in clear text, in corresponding `keystore.pin` and `truststore.pin` files in `<server-root>/config`.
- **Encryption Passphrase.** Encryption for directory data, backups, LDIF exports, and log files can be enabled during `setup` by providing or generating an encryption key with a passphrase.
- **Locations.** Location names are used to define a grouping of PingDirectory Server products based on physical proximity. For example, a location is most often associated with a single datacenter location. During the installation, assign a location to each server for optimal inter-server behavior. The location assigned to a server within Global Configuration can be referenced by components within the server as well as processes external to the server to satisfy "local" versus "remote" decisions used in replication, load balancing, and failover.
- **Validate ACIs.** Many directory servers allow for less restrictive application of its access control instructions (ACIs), so that they accept invalid ACIs. For example, if a Sun/Oracle server encounters an access control rule that it cannot parse, then it will simply ignore it without any warning, and the server may not offer the intended access protection. Rather than unexpectedly exposing sensitive data, PingDirectory Server rejects any ACIs that it cannot interpret, which ensures data access is properly limited as intended, but it can cause problems when migrating data with existing access control rules to a PingDirectory Server. If you are migrating from a Sun/Oracle deployment to a PingDirectory Server, PingDirectory Server provides a `validate-acis` tool in the `bin` directory (UNIX or Linux systems) or `bat` directory (Windows systems) that identifies any ACI syntax problems before migrating data. For more information, see [Validating ACIs Before Migrating Data](#).

Important:

Each Server Deployment Requires an Execution of Setup - Duplicating a Server-root is not Supported. The installation of the server does not write or require any data outside of the server-root directory. After executing `setup`, copying the server-root to another location or system, in order to *duplicate* the installation, is not a supported method of deployment. The server-root can be moved to another host or disk location if a host or file system change is needed.

Ping license keys

License keys are required to install, update, and renew all Ping products.

How to obtain a license

To obtain a license key, contact your account representative or use the [Ping Identity licensing portal](#).

When do you need a license

A license is required for setting up a new single server instance and can be used site-wide for all servers in an environment. Additionally, you must obtain a new license when updating a server to a new major version, such as when upgrading from 7.3 to 8.0. When cloning a server instance with a valid license, you do not need a new license.

Note:

The update process displays a prompt for a new license.

How to specify a license

- Specify a license at setup

You have these options:

- Use the `--licenseKeyFile <path-to-license>` option with `setup`.
- Copy the license file to the server root directory and then run the `setup` tool. The tool discovers the license file.
- Specify a license after setup

Use the Administrative Console or `dsconfig` (in the Topology section, select License).

Note: Placing the new license file in the server root directory does not work in this case.

How to view the license status

To view the details of a license, including its expiration, you have these options:

- The server's `status` tool
- The Administrative Console's **Status** page (On the **Monitors** tab, search for License.)

License expiration

The server provides a notification as the expiration date approaches.

Before a license expires, obtain a new one and install it by using `dsconfig` or the Administrative Console.

Note:

An expiring license causes alerts and alarms but does not affect the functionality of the product.

Setting Up the Directory Server in Interactive Mode

The `setup` tool also provides an interactive text-based command-line interface to set up a Directory Server instance.

To Install the Directory Server in Interactive Mode

Steps

1. Unzip the distribution ZIP file, review [Before You Begin](#), and then go to the server root directory. Use the `setup` utility with the `--cli` option to install the server in interactive mode.

```
$ ./setup
```

If the `JAVA_HOME` environment variable is set to an older version of Java, explicitly specify the path to the Java JDK installation during the setup process. Either set the `JAVA_HOME` environment variable with the Java JDK path or execute the `setup` command in a modified Java environment using the `env` command.

```
$ env JAVA_HOME=/ds/java ./setup
```

2. Read the Ping Identity End-User License Agreement, and type `yes` to continue.
3. Enter the fully qualified host name or IP address of the local host, or press **Enter** to accept the default.
4. Enter the root user DN, or press **Enter** to accept the default (`cn=Directory Manager`).
5. Enter and confirm the root user password.
6. Press **Enter** to enable the Ping Identity services (Configuration, Consent, Delegated Admin, Documentation, and Directory REST API) and Administrative Console over HTTPS. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.
7. Enter the port on which the Directory Server will accept connections from HTTPS clients, or press **Enter** to accept the default.
8. Enter the port on which the Directory Server will accept connections from LDAP clients, or press **Enter** to accept the default.
9. The next two options enable using LDAPS or StartTLS. Type `no` to use a standard LDAP connection, or accept the default (`yes`) to enable both. Enabling LDAPS configures the LDAPS Connection Handler to allow SSL over its client connections. Enabling StartTLS configures the LDAP Connection Handler to allow StartTLS.
10. Select the certificate option for this server:
 - Generate a self-signed certificate for testing purposes only.
 - To use an existing certificate using a Java Keystore, enter the keystore path and keystore PIN.
 - To use an existing certificate using use a PKCS#12 keystore, enter the keystore path and the keystore PIN.
 - To use the PKCS#11 token, enter only the keystore PIN.
11. Choose the desired encryption for the directory data, backups, and log files from the choices provided:
 - Encrypt data with a key generated from an interactively provided passphrase. Using a passphrase (obtained interactively or read from a file) is the recommended approach for new deployments, and you should use the same encryption passphrase when setting up each server in the topology.
 - Encrypt data with a key generated from a passphrase read from a file.
 - Encrypt data with a randomly generated key. This option is primarily intended for testing purposes, especially when only testing with a single instance, or if you intend to import the resulting encryption settings definition into other instances in the topology.
 - Encrypt data with an imported encryption settings definition. This option is recommended if you are adding a new instance to an existing topology that has older server instances with data encryption enabled.
 - Do not encrypt server data.
12. Type the base DN for the data, or accept the default base DN of `dc=example,dc=com`.

13. Choose an option to generate and import sample data. Type the desired number of entries, or press `Enter` to accept the default number (10000). This option is used for quick evaluation of the Directory Server.
See [Initializing Data onto the Server](#) if you want to use other options to initialize the server.
14. Choose the option to tune the amount of memory that will be consumed by the Directory Server and its tools.
15. Press `Enter` to prime or preload the database cache at startup prior to accepting client connections.
Priming the cache can increase the startup time for the Directory Server but provides optimum performance once startup has completed. This option is best used for strict throughput or response time performance requirements, or if other replicas in a replication topology can accept traffic while this Directory Server instance is starting. Priming the cache also helps determine the recommended JVM option, `CMSInitiatingOccupancyFraction`, when a Java garbage collection pause occurs. See [JVM Garbage Collection Using CMS](#).
16. Enter a location name for this server.
17. Enter a unique instance name for this server. Once set, the name cannot be changed.
18. Press `Enter` to accept the default (yes) to start the Directory Server after the configuration has completed. To configure additional settings or import data, type `no` to keep the server in shutdown mode.
19. Choose an option to continue server set up.
20. On the **Setup Summary** page, confirm the configuration. Press `Enter` to accept the default (set up with the parameters given), enter the option to repeat the installation process, or enter the option to cancel the setup completely.

Installing the Directory Server in Non-Interactive Mode

You can run the `setup` command in non-interactive mode to automate the installation process using a script or to run the command directly from the command line. Non-interactive mode is useful when setting up production or QA servers with specific configuration requirements.

The non-interactive command-line mode requires that all mandatory options be present for each command call. If there are missing or incorrect arguments, the `setup` tool fails and aborts the process. You must also use a `--no-prompt` option to suppress interactive output, except for errors, when running in non-interactive mode. Additionally, you must also use the `--acceptLicense` option and specify the port using the `--ldapPort` or `--ldapsPort` option. If neither option is specified, an error message is displayed. To view the license, run `bin/review-license` command.

To automatically tune the JVM to use maximum memory, use the `--aggressiveJVMTuning` and `--maxHeapSize {memory}` options. To preload the database at startup, use the `--primeDB` option.

To configure a deployment using a truststore, see [Installing the Directory Server in Non-Interactive Mode with a Truststore](#).

To see a description of the available command-line options for the `setup` tool, use `setup --help`.

To Install the Directory Server in Non-Interactive Mode

About this task

The following procedure shows how to install a Directory Server in a production or QA environment with no security enabled.

Steps

- Unzip the distribution ZIP file, review “Before You Begin”, and then use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode from the `<server-root>` directory. The following command uses the default root user DN (`cn=Directory Manager`) with the specified `--`

`rootUserPassword` option. You must include the `--acceptLicense` option or the setup will generate an error message.

```
$ ./setup --cli --no-prompt --rootUserPassword "password" \
  --baseDN "dc=example,dc=com" --acceptLicense --ldapPort 389
```

To Install the Directory Server in Non-Interactive Mode with a Truststore

About this task

You can set up the Directory Server using an existing truststore for secure communication. This section assumes that you have an existing keystore and truststore with trusted certificates.

Steps

- Unzip the distribution ZIP file, review [Before You Begin](#), and then, from the server root directory, use `setup` with the `--cli` and `--no-prompt` options for non-interactive mode. The following example enables security using both SSL and StartTLS. It also specifies a JKS keystore and truststore that define the server certificate and trusted CA. The `userRoot` database contents will remain empty and the base DN entry will not be created.

```
$ ./setup --cli --no-prompt --rootUserPassword "password" \
  --baseDN "dc=example,dc=com" --ldapPort 389 --enableStartTLS \
  --ldapsPort 636 --useJavaKeystore config/keystore.jks \
  --keyStorePasswordFile config/keystore.pin \
  --certNickName server-cert --useJavaTrustStore config/truststore.jks \
  --acceptLicense
```

The password to the private key with the keystore is expected to be the same as the password to the keystore. If this is not the case, the private key password can be defined with the Administrative Console or the `dsconfig` tool by editing the Trust Manager Provider standard configuration object.

Installing a Lightweight Server

Users who want to demo or test a lightweight version of the Directory Server on a memory-restricted machine can do so by removing all unused or unneeded configuration objects. All configuration entries, whether enabled or not, take up some amount of memory to hold the definition and listeners that will be notified of changes to those objects.

The configuration framework will not allow you to remove objects that are referenced, and in some cases if you have one configuration object referencing another but really do not need it, then you will first need to remove the reference to it. If you try to remove a configuration object that is referenced, both `dsconfig` and the Administrative Console should prevent you from removing it and will tell you what still references it.

Depending on your test configuration, some example configuration changes that can be made are as follows:

- Reduce the number of worker threads.** Each thread has a stack associated with it, and that consumes memory. If you're running a bare-bones server, then you probably do not have enough load to require a lot of worker threads.

```
$ bin/dsconfig set-work-queue-prop \
  --set num-worker-threads:8 \
  --set num-administrative-session-worker-threads:4 \
  --set max-work-queue-capacity:100
```

- **Reduce the percentage of JVM memory used for the JE database cache.** When you have a memory-constrained environment, you want to ensure that as much of the memory that is there is available for use during processing and not tied up caching database contents.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:5
```

- **Disable the Dictionary Password Validator.** The Dictionary Password Validator takes a lot of memory to hold its dictionary. Disabling it will free up some memory. You can delete the other password validators if not needed, such as Attribute Value, Character Set, Length-based, Repeated Characters, Similarity-based, or Unique Characters Password Validator.

```
$ bin/dsconfig delete-password-validator --validator-name Dictionary
```

- **Remove non-essential schema files.** Although not recommended for production deployments, some candidates that you can remove are the following: 03-rfc2713.ldif, 03-rfc2714.ldif, 03-rfc2739.ldif, 03-rfc2926.ldif, 03-rfc2985.ldif, 03-rfc3712.ldif, 03-uddiv3.ldif.

There are other items that can be removed, depending on your desired configuration. Contact your authorized support provider for assistance.

Running the Status Tool

The Directory Server provides a **status** tool that outputs the current state of the server as well as other information, such as server version, JE Environment statistics, Operation Processing Times, Work Queue, and Administrative Alerts. The **status** tool is located in the `bin` directory (UNIX, Linux) or the `bat` directory (Windows).

To Run the Status Tool

Steps

- Run the **status** command on the command line. The following command displays the current Directory Server status and limits the number of viewable alerts in the last 48 hours. It provides the current state of each connection handler, data sources, JE environment statistics, processing times by operation type and current state of the work queue.

```
$ bin/status --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret

    --- Server Status ---
Server Run Status:   Started 28/Mar/2012:10:47:17.000 -0500
Operational Status: Available
Open Connections:   13
Max Connections:    13
Total Connections:  50

    --- Server Details ---

successfully
Info     : 28/Mar/2012 10:47:14 -0500 : The Directory Server is starting
Info     : 28/Mar/2012 10:44:22 -0500 : The Directory Server has started
successfully
Info     : 28/Mar/2012 10:44:18 -0500 : The Directory Server is starting

Shown are alerts of type [Info,Warning,Error,Fatal] from the past 48 hours
Use the
--maxAlerts and/or --severity options to filter this list

```

Note: By default, the `status` command displays the alerts generated in the last 48 hours. You can limit the number of alerts by using the `--maxAlerts` option.

Where To Go From Here

After you have set up your Directory Server instance, you can configure any specific server settings, import your user database, or run initial performance tests to optimize your server's throughput.

- **Log into the Administrative Console.** Become familiar with configuration options through the Administrative Console interface. The URL is based on the host name and HTTPS port specified during installation, such as `https://hostname.com:443/console`.
- **Apply Server Configurations.** Apply your server configuration changes individually or using a `dsconfig` batch file. The batch file defines the Directory Server configuration tool, `dsconfig`,

commands necessary to configure your server instance. For more information on using batch files, see [Using dsconfig in Batch Mode](#).

If you are migrating from a Sun Java System 5.x, 6.x, 7.x directory server, you can use the `bin/migrate-sun-ds-config` command to migrate your configuration settings to this newly installed server instance.

- **Import Data.** Import user data using the `import-ldif` tool. The import serves as an initial test of the schema settings.

```
$ bin/import-ldif --backendID userRoot --ldifFile ../user-data.ldif
```

- **Install and Configure the Delegated Admin Application.** A Javascript-based web application can be installed for business users to manage identities stored in the Directory Server. The application provides delegated administration of identities for help desk or customer service representatives (CSR) initiating a password reset and unlock; an employee in HR updating an address stored within another employee profile; or an application administrator updating identity attributes or group membership to allow application SSO access.
- **Run Performance Tests.** The Directory Server provides two tools for functional performance testing using in-house LDAP clients that accesses the server directly: `searchrate` (tests search performance) and `modrate` (tests modification performance):

```
$ bin/searchrate --baseDN "dc=example,dc=com" --scope sub \
--filter "(uid=user.[0-1999])" --attribute givenName --attribute sn \
--attribute mail --numThreads 10
```

```
$ bin/modrate --entryDN "uid=user.[0-1999],ou=People,dc=example,dc=com" \
--attribute description --valueLength 12 --numThreads 10
```

Working with Multiple Backends

You can create multiple local database backends, each containing one or more different base DN.

There should be at most one replicating domain on each local database backend. The replication domain should not span multiple local database backends. The typical entry-balancing configuration involves two local database backends: one backend to serve the global domain data that resides above the entry-balancing point and a backend that is defined with the entry-balancing point as the base DN, such as `ou=people,dc=example,dc=com`.

With multiple local database backends configured, the data existing with each backend can be managed independently. In addition, separate index settings are applied to each local database backend.

When creating multiple database backends, consider the following:

- No two backends may have the same base DN.
- If any base DN for a given backend is subordinate to a base DN on another backend, then all base DN on that backend must be subordinate to the base DN of the other backend.
- The total of all `db-cache-percent` values should be no more than 65-70% in most cases and should never be configured to exceed 100%.

Importing Data

After installation, the database, such as `userRoot`, will need to have data imported. For a server to be added to a replicating set, the database will be imported as part of the `dsreplication initialize` operation, which is performed after `dsreplication enable`. A server that will not be added to a replicating set, or the first server of a future replicating set, should have data imported with the `bin/import-ldif` tool. See Chapter 8, Importing and Exporting Data, for more information about the `bin/import-ldif` tool.

Generating Sample Data

About this task

The PingDirectory Server provides LDIF templates that can be used to generate sample entries to initialize your server. You can generate the sample data with the `make-ldif` utility together with template files that come bundled with the ZIP build, or you can use templates files that you create yourself. The templates create sequential entries that are convenient for testing the PingDirectory Server with a range of dataset sizes. The Directory Server templates are located in the `config/MakeLDIF`.

To randomize the data, the `make-ldif` command has a `--randomSeed` option that can be used to seed the random number generator. If this option is used with the same seed value, the template will always generate exactly the same LDIF file.

The sample data templates generate a dataset with basic access control privileges that grants anonymous read access to anyone, grants users the ability to modify their own accounts, and grants the Admin account full privileges. The templates also include the `uid=admin` and `ou=People` entries necessary for a complete dataset. You can bypass the `make-ldif` command entirely and use the `--templateFile` option with the `import-ldif` tool.

Steps

- Use the `make-ldif` command to generate sample data. The command generates 10,000 sample entries and writes them to an output file, `data.ldif`. The random seed generator is set to 0.

```
$ bin/make-ldif --templateFile config/MakeLDIF/example-10k.template \  
--ldifFile /path/to/data.ldif --randomSeed 0
```

To Import Data on the Directory Server Using Offline Import

Steps

1. Create an LDIF file that contains entries, or locate an existing file.

The `import-ldif` tool requires an LDIF file, which conforms to standard LDIF syntax without change records. This means the `changeType` attribute is not allowed in the input LDIF. For information on adding entries to the , see [Managing Entries](#).

2. Stop the Directory Server.

3. Use the offline `import-ldif` to import data from an LDIF file to the Directory Server. For assistance with the list of options, run `import-ldif --help`.

In the following example, the data is imported from the `data.ldif` file to the `userRoot` backend. If any entry is rejected due to a schema violation, then the entry and the reason for the rejection is written to the `rejects.ldif` file. Skipped entries, written to `skipped.ldif`, occur if an entry cannot be placed under a branch node in the DIT or if exclusion filtering is used (`--excludeBranch`, `--excludeAttribute`, or `--excludeFilter`). The `--overwrite` option instructs `import-ldif` to overwrite existing skipped and rejected files. The `--overwriteExistingEntries` option indicates that any existing data in the backend should be overwritten. Finally, the `--stripTrailingSpaces` option strips trailing spaces on attributes that would otherwise result in a LDIF parsing error.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif --  
rejectFile  
rejects.ldif --skipFile skipped.ldif --overwrite --  
overwriteExistingEntries --stripTrailingSpaces
```

4. Re-start the Directory Server.

Running the Server

To start the Directory Server, run the `bin/start-server` command on UNIX or Linux systems (an analogous command is in the `bat` folder on Microsoft Windows systems). The `bin/start-server` command starts the

Directory Server as a background process when no options are specified. To run the Directory Server as a foreground process, use the `bin/start-server` command with the `--nodetach` option.

To Start the Directory Server

Steps

Use `bin/start-server` to start the server.

```
$ bin/start-server
```

To Run the Server as a Foreground Process

Steps

1. Enter `bin/start-server` with the `--nodetach` option to launch the Directory Server as a foreground process.

```
$ bin/start-server --nodetach
```

2. You can stop the Directory Server by pressing **CTRL+C** in the terminal window where the server is running or by running the `bin/stop-server` command from another window.

To Start the Server at Boot Time

By default, the PingDirectory Server does not start automatically when the system is booted. Instead, you must manually start it with the `bin/start-server` command. To configure the Directory Server to start automatically when the system boots, use the `create-systemd-script` utility to create a script, or create the script manually.

Steps

1. Create the service unit configuration file in a temporary location where "ds" is the user the PingDirectory will run as.

```
$ bin/create-systemd-script \
  --outputFile /tmp/ping-directory.service \
  --userName ds
```

2. As a root user, copy the `ping-directory.service` configuration file into the `/etc/systemd/system` directory.
3. Reload `systemd` to read the new configuration file.

```
$ systemctl daemon-reload
```

4. To start the PingDirectory, use the `start` command.

```
$ systemctl start ping-directory.service
```

5. To configure the PingDirectory to start automatically when the system boots, use the `enable` command.

```
$ systemctl enable ping-directory.service
```

6. Log out as root.

If on an RC system, this task is done by creating the startup script with `bin/create-rc-script` and moving it to the `/etc/init.d` directory. Create symlinks to it from the `/etc/rc3.d` directory (starting with an "S" to ensure that the server is started) and `/etc/rc0.d` directory (starting with a "K" to ensure that the server is stopped).

Logging into the Administrative Console

After the server is installed, access the Administrative Console, `https://hostname:HTTPport/console/login`, to verify the configuration and manage the server. To log into the Administrative Console, use the initial root user DN specified during setup (by default `cn=Directory Manager`).

The `dsconfig` command or the Administrative Console can be used to create additional root DN users in `cn=Root DNs`, `cn=config`. These new users require the fully qualified DN as the login name, such as `cn=new-admin,cn=Root DNs,cn=config`. To use a simple user name (with out the `cn=` prefix) for logging into the Administrative Console, the root DN user must have the `alternate-bind-dn` attribute configured with an alternate name, such as "admin."

By default the link to the Administrative Console is `https://hostname:HTTPport/console/login`.

If the Administrative Console needs to run in an external container, such as Tomcat, a separate package (`/server-root/resource/admin-console.zip`) can be installed according to that container's documentation.

Note: The session timeout for the console is 24 hours by default. When this duration is exceeded, all inactive users are logged off automatically.

To set a different timeout value, configure the `server.sessionTimeout` application parameter, which specifies the timeout duration in seconds. You can set the value as an init parameter either in the console or on the command line, as shown below.

- Console

Select **Web Application Extensions# Console** and then use the **Init Parameter** field.

- Command line

The following example uses a value of 1800 seconds (30 minutes).

```
dsconfig set-web-application-extension-prop --no-prompt \
--extension-name Console \
--add init-parameter:server.sessionTimeout=1800
```

For the change to take effect, restart the HTTP(S) Connection Handler or the server itself.

Stopping the Directory Server

The Directory Server provides a simple shutdown script, `bin/stop-server`, to stop the server. You can run it manually from the command line or within a script.

If the Directory Server has been configured to use a large amount of memory, then it can take several seconds for the operating system to fully release the memory and make it available again. If you try to start the server too quickly after shutting it down, then the server can fail because the system does not yet have enough free memory. On UNIX systems, run the `vmstat` command and watch the values in the "free" column increase until all memory held by the Directory Server is released back to the system.

You can also set a configuration option that specifies the maximum shutdown time a process may take.

To Stop the Server

Steps

- Use the `bin/stop-server` tool to shut down the server.

```
$ bin/stop-server
```

To Schedule a Server Shutdown

Steps

- Use the `bin/stop-server` tool with the `--stopTime YYYYMMDDhhmmss` option to schedule a server shutdown.

The Directory Server schedules the shutdown and sends a notification to the `server.out` log file. The following example sets up a shutdown task that is scheduled to be processed on June 6, 2012 at 8:45 A.M. CDT. The server uses the UTC time format if the provided timestamp includes a trailing "Z", for example, 20120606134500Z. The command also uses the `--stopReason` option that writes the reason for the shut down to the logs.

```
$ bin/stop-server --stopTime 20120606134500Z --port 1389 \
  --bindDN "uid=admin,dc=example,dc=com" --bindPassword secret \
  --stopReason "Scheduled offline maintenance"
```

To Restart the Server

About this task

Re-start the Directory Server using the `bin/stop-server` command with the `--restart` or `-R` option. Running the command is equivalent to shutting down the server, exiting the JVM session, and then starting up again.

Steps

- Go to the server root directory, and run the `bin/stop-server` command with the `-R` or `--restart` options.

```
$ bin/stop-server --restart
```

Run the Server as a Microsoft Windows Service

The server can run as a Windows service on Windows Server 2012 R2 and Windows Server 2016. This enables log out of a machine without the server being stopped.

To Register the Server as a Windows Service

About this task

Perform the following steps to register the server as a service:

Steps

- Stop the server with `bin/stop-server`. A server cannot be registered while it is running.
- Register the server as a service. From a Windows command prompt, run `bat/register-windows-service.bat`.
- After a server is registered, start the server from the Windows Services Control Panel or with the `bat/start-server.bat` command.

Command-line arguments for the `start-server.bat` and `stop-server.bat` scripts are not supported while the server is registered to run as a Windows service. Using a task to stop the server is also not supported.

To Run Multiple Service Instances

About this task

Only one instance of a particular service can run at one time. Services are distinguished by the `wrapper.name` property in the `<server-root>/config/wrapper-product.conf` file. To

run additional service instances, change the `wrapper.name` property on each additional instance. Descriptions of the services can also be added or changed in the `wrapper-product.conf` file.

To Deregister and Uninstall Services

About this task

While a server is registered as a service, it cannot run as a non-service process or be uninstalled. Use the `bat/deregister-windows-service.bat` file to remove the service from the Windows registry. The server can then be uninstalled with the `uninstall.bat` script.

Log Files for Services

About this task

The log files are stored in `<server-root>/logs`, and file names begin with `windows-service-wrapper`. They are configured to rotate each time the wrapper starts or due to file size. Only the last three log files are retained. These configurations can be changed in the `<server-root>/config/wrapper.conf` file.

Uninstalling the Server

The Directory Server provides an `uninstall` command-line utility for quick and easy removal of the code base.

To uninstall a server instance, run the `setup` tool in one of the following modes: interactive command-line, or non-interactive command-line mode.

- **Interactive Command-Line Mode.** Interactive command-line mode is a text-based interface that prompts the user for input. You can start the command using the `bin/uninstall` command with the `--cli` option. The utility prompts you for input if more data is required.
- **Non-Interactive Command-Line Mode.** Non-interactive mode suppresses progress information from being written to standard output during processing, except for fatal errors. This mode is convenient for scripting and is invoked using the `bin/uninstall` command with the `--no-prompt` option.

Note: For stand-alone installations with a single Directory Server instance, you can also manually remove the Directory Server by stopping the server and recursively deleting the directory and subdirectories. For example:

```
$ rm -rf /ds/PingDirectory
```

To Uninstall the Server in Interactive Mode

About this task

Interactive mode uses a text-based, command-line interface to help you remove your instance. If `uninstall` cannot remove all of the Directory Server files, the `uninstall` tool generates a message with a list of the files and directories that must be manually deleted. The `uninstall` command must be run as either the root user or the same user (or role) that installed the Directory Server.

Steps

1. From the server root directory, run the `uninstall` command.

```
$ ./uninstall --cli
```

2. Select the components to be removed. If you want to remove all components, press **Enter** to accept the default (remove all). Enter the option to specify the specific components that you want to remove.

```
Do you want to remove all components or select the components to remove?

1) Remove all components
2) Select the components to be removed

q) quit
Enter choice [1]:
```

3. For each type of server component, press **Enter** to remove them or type `no` to keep it.

```
Remove Server Libraries and Administrative Tools? (yes / no) [yes]:
Remove Database Contents? (yes / no) [yes]:
Remove Log Files? (yes / no) [yes]:
Remove Configuration and Schema Files? (yes / no) [yes]:
Remove Backup Files Contained in bak Directory? (yes / no) [yes]:
Remove LDIF Export Files Contained in ldif Directory? (yes / no) [yes]:
```

4. If the Directory Server is part of a replication topology, type `yes` to provide your authentication credentials (Global Administrator ID and password). If you are uninstalling a stand-alone server, continue to step 7.
5. Type the Global Administrator ID and password to remove the references to this server in other replicated servers. Then, type or verify the host name or IP address for the server that you are uninstalling.
6. Next, select how you want to trust the server certificate if you have set up SSL or StartTLS. For this example, press **Enter** to accept the default.

```
How do you want to trust the server certificate for the Directory Server
on server.example.com:389?

1) Automatically trust
2) Use a trust store
3) Manually validate

Enter choice [3]:
```

7. If your Directory Server is running, the server is shutdown before continuing the uninstall process. The uninstall processes the removal requests and completes. View the logs for any remaining files. Manually remove any remaining files or directories, if listed.

To Uninstall the Server in Non-Interactive Mode

The `uninstall` utility provides a non-interactive method to enter the command with the `--no-prompt` option. Another useful argument is the `--forceOnError` option that continues the uninstall process when an error is encountered. If an option is incorrectly entered or if a required option is omitted and the `--forceOnError` option is not used, the command will fail and abort.

Steps

1. From the server root directory, run `uninstall` tool with the `--remove-all` option to remove all of the Directory Server's libraries. The `--quiet` option suppresses output information and is optional. The following command assumes that the Directory Server is stand-alone and not part of a replication topology.

```
$ ./uninstall --cli --remove-all --no-prompt --quiet --forceOnError
```

2. If any files or directories remain, manually remove them.

To Uninstall Selected Components in Non-Interactive Mode

Steps

From the server root directory, run `uninstall` with the `--backup-files` option to remove the Directory Server's backup files. Use the `--help` or `-H` option to view the other options available to remove specific components.

```
$ ./uninstall --cli --backup-files --no-prompt --quiet --forceOnError
```

Upgrading the Server

Ping Identity issues software release builds periodically with new features, enhancements, and fixes for improved server performance. Administrators can use the Directory Server's update utility to upgrade the current server code version.

This chapter presents some update scenarios and their implications that you should consider when upgrading your server code.

Upgrade Overview and Considerations

The upgrade process involves downloading and unzipping a new version of the Directory Server ZIP file on the server to be updated, and running the `update` utility with the `--serverRoot` or `-R` option value from the new root server pointing to the installation to be upgraded.

Consider the following when upgrading replicating servers:

- Upgrade affects only the server being upgraded. The process does not alter the configuration of other servers.
- The `update` tool will verify that the version of Java that is installed meets the new server requirements. To simplify the process, install the version of Java that is supported by the new server before running the tool.
- To be safe, backup the user data (`userRoot`) before an upgrade. Restoring from a backup could be necessary if all other servers in the replication topology have been upgraded and a database or encoding change in the new server version prevents the database from being used with the older server version. The `update` and `revert-update` utilities will issue a warning when this is the case.
- Temporarily raise the replication purge delay for all servers in the topology to cover the expected downtime for maintenance. This will result in a temporary increase in disk usage for the `replicationChanges` database stored in `<server-root>/changelogDb`.
- Replication does not need to be disabled on a server before an upgrade.
- Make sure upgraded servers are working as expected before upgrading the last server in the topology
- Enable new features after all replicating servers are upgraded.

Tip:

For additional considerations, see the [Planning your upgrade guide](#).

Update servers in a topology

 **Note:** This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version, and is not applicable to any updates to server version 8.x or later.

An update to the current PingDirectory Server release includes significant changes as well as the introduction of a topology registry, which stores information that was stored previously in the admin backend, such as server instances, instance and secret keys, server groups, and administrator user accounts. For the admin backend to be migrated, the **update** tool must be provided LDAP authentication options to the peer servers of the server being updated.

The LDAP connection security option requested (either plain, TLS, StartTLS, or SASL) must be configured on every server in the topology. The LDAP credentials must be present on every server in the topology, and must have permissions to read from the admin backend and the config backend of every server in the topology. For example, a root DN user with the **inherit-default-privileges** set to true (such as the **cn=Directory Manager** user) that exists on every server can be used.

- Changes to clustered configurations are not allowed in mixed-version clusters. This applies to configuration in the **cn=Cluster, cn=config** subtree and only applies to servers with matching cluster names. Consider this when updating multiple servers in a cluster.
- To make clustered configuration changes in a mixed-version cluster, choose one of the following options:
 - Update each server to the same version.
 - Temporarily split up the cluster by changing the **cluster-name** property on the server instance configuration objects.
- After you have updated all the servers to the same version, you can again make clustered configuration changes and those changes will mirror across the topology.

After enabling or fixing the configuration of the LDAP connection handler(s) to support the desired connection security mechanism on each server, run the following **dsframework** command on the server being updated so that its admin backend has the most up-to-date information:

```
$ bin/dsframework set-server-properties \
  --serverID serverID \
  --set ldapport:port \
  --set ldapsport:port \
  --set startTLSEnabled:true
```

The **update** tool will verify that the following conditions are satisfied on every server in the topology before allowing the update:

- When the first server is being updated, all other servers in the topology must be online. When updating additional servers, all topology information will be obtained from one of the servers that has already been updated. The **update** tool will connect to the peer servers of the server being updated to obtain the necessary information to populate the topology registry. The provided LDAP credentials must have read permissions to the config and admin backends of the peer servers.
- The instance name is set on every server, and is unique across all servers in the topology. The instance name is a server's identifier in the topology. After all servers in the topology have been updated, each server will be uniquely identified by its instance name. Once set, the name cannot be changed. If needed, the following command can be used to set the instance name of a server prior to the update:

```
$ bin/dsconfig set-global-configuration-prop \
  --set instance-name:uniqueName
```

- The cluster-wide configuration is synchronized on all servers in the topology. Older versions have some topology configuration under **cn=cluster, cn=config** (JSON attribute and field constraints). These items did not support mirrored cluster-wide configuration data. An update should avoid custom configuration changes on a server being overwritten with the configuration on the mirrored subtree master. To synchronize the cluster-wide configuration data across all servers in the topology, run the **config-diff** tool on each pair of servers to determine the differences, and use **dsconfig** to update each instance using the **config-diff** output. For example:

```
$ bin/config-diff --sourceHost hostName \
```

```
--sourcePort port \
--sourceBindDN bindDN \
--sourceBindPassword password \
--targetHost hostName \
--targetPort port \
--targetBindDN bindDN \
--targetBindPassword password
```

If any of these conditions are not satisfied, the **update** tool will list all of the errors encountered for each server, and provide instructions on how to fix them.

Restoring a mixed topology to a clean state

About this task

Note: This information is only applicable when updating from a server version that uses the admin backend to a server version that uses the topology registry. This is only the case when updating from a server version earlier than 7.x to a 7.x version, and is not applicable to any updates to server version 8.x or later.

If you are upgrading a Directory Server version prior to 7.3 to version 7.3 or later and at least one server was previously removed from the topology, you may receive an error message similar to one of the following:

```
[09/Dec/2019:18:37:56.927 -0700] instanceName="[INSTANCE_NAME]" \
  threadID=438 category=REPLICATION severity=NOTICE msgID=118947975
msg="The \
  replication total backlog count is 163364"
```

Or:

```
[09/Dec/2019:17:15:10.108 -0700] category=REPLICATION \
  severity=SEVERE_ERROR msgID=14942295 msg="While clearing the database 997
\
  o=mycompany, the following error happened: (JE 7.5.12) Attempted to
remove \
  non-existent database 997 o=mycompany DatabaseNotFoundException: (JE
7.5.12) \
  Attempted to remove non-existent database 997 o=pingone (DbTree.java:922
\
  DbTree.java:1183 DbTree.java:1235 Environment.java:1001

  (7.3.0.4-20191127203417.000Z-83a75e2a) "
```

Perform the following steps to restore a mixed-version 6.2 - 7.x topology with replication problems to a clean state with all servers at the same level and with replication functioning normally:

Steps

1. Run **bin/export-ldif** on the primary server to export a safe copy of the data.
2. Start the downlevel primary server and stop the upgraded replica server.

3. Run `bin/remove-defunct-server` on the upgraded replica server and do the following at the command prompts:
 - Select the replica server itself.
 - Supply the credentials for the primary server when prompted.
 - Select **[c]** to continue.
 - Enter the path to the local `changelogDB` when prompted
4. Leave the upgraded replica server stopped and stop the downlevel primary server.
5. Run `bin/dsreplication` on the primary server and do the following:
 - Select **2) Manage the topology (add and remove servers)**.
 - Select **4) Cleanup Server**.
 - Select **[c] to continue**.
 - Enter the path to the local `changelogDB` when prompted.
6. Start the downlevel primary server and the upgraded replica server.
7. Run `bin/status` on both servers and verify **Replication: disabled** under **Data Sources**.
8. **IMPORTANT:** Upgrade the replica server to version 7.3.0.5 or later (which contains fixes for issues 00668265 and DS-40955).
9. Upgrade the primary server to the same level as the replica server.
10. Re-enable replication between primary and replica server using the `bin/dsreplication` tool.
11. Re-initialize the replica server data from the primary server.
12. Run `bin/status` on both servers to verify that replication is enabled under **Data Sources** and that both servers show the same number of entries.

To Upgrade the Directory Server

About this task

Perform an upgrade with the following steps.

Steps

1. Download and unzip the new version of the Directory Server in a location outside the existing server's installation. For these steps, assume the existing server installation is in `/prod/PingDirectory` and the new server version is unzipped into `/home/stage/PingDirectory`.
2. Run the `update` tool provided with the new server package to update the existing Directory Server. The update tool may prompt for confirmation on server configuration changes if it detects customization.

```
$ /home/staging/PingDirectory/update --serverRoot /prod/PingDirectory
```

Revert an update

After PingDirectory Server has been updated, you can revert to the last version (one level back) using the `revert-update` tool. The `revert-update` tool accesses a log of file actions taken by the updater to put the file system back to its prior state. If you have run multiple updates, you can run the `revert-update` tool multiple times to revert to each prior update sequentially. You can only revert back one level. For example, if you have run the update twice since first installing the PingDirectory Server, you can run the `revert-update` command to revert to its previous state, then run the `revert-update` command again to return to its original state.

Reverting from version 7.x to a version prior to 7.0

Reverting from version 7.0 or later to a pre-7.0 version can be done using the `revert-update` command with some extra steps. This is also the case when updating or reverting from a pre-6.2.0.2 version to

6.2.0.2 or later. These steps are listed when the **update** and **revert-update** tool are run as well. You may need to perform one or more of the following tasks, depending on your installation and configuration:

- When updating or reverting from 6.2.0.2 or later to a pre-6.2.0.2 version, indexes may need to be rebuilt. Older versions of the server use an incompatible format for Local DB Composite Indexes. To update a server with composite indexes in the previous format, delete these indexes and re-run the update. After the update is complete, recreate the indexes and use the **rebuild-index** tool to rebuild the indexes. The command for recreating an index will be in the "Undo" portion of the **logs/config-audit.log** file. If you wish to later revert to an older version, delete and recreate those composite indexes again after the revert has completed.
- When updating to 7.x for the first time, instance names will need to be set for each server in the topology if they were not previously set. This is done with the following **dsconfig** command:

```
$ bin/dsconfig --bindDN "cn=Directory Manager" \
  --bindPassword secret \
  --no-prompt set-global-configuration-prop \
  --set instance-name:<name>
```

- Topology information such as server instances, instance and secret keys, server groups, and administrator users have moved to the topology portion of the configuration from the **admin** backend. As long as new servers are not added to the topology after this update, the **revert-update** command can be used to return to the previous version. However, if new servers are added, then the restored **admin** backend of this server will not contain information about the new servers, and the local server will not be able to communicate with any other servers in the topology. New servers should not be added to the topology if reverting this update is a possibility.
- If new servers were added to the topology after the update, the new servers must be temporarily removed from the topology until all servers have been reverted to the previous version.
- When a server is reverted to a pre-7.x version, any servers in the topology using the topology portion of the configuration (rather than the **admin** backend) will need to know that the reverted server was downgraded to the **admin** backend. This is done by running the following **dsconfig** command on one of the servers that has not been reverted:

```
$ bin/dsconfig set-server-instance-prop \
  --instance-name <Reverted server instance name> \
  --set server-version:<Version to which server is reverted>
```

- If the topology does not have a master server when this command is run, it will not succeed. In this case, one of the remaining updated servers in the topology must be made master with the following command. This will enable the chosen instance to run the first command successfully.

```
$ bin/dsconfig set-global-configuration-prop \
  --set force-as-master-for-mirrored-data:true
```

- The 7.x server version includes database changes that are not compatible with previous server versions (6.x or older). If you wish to later revert to an older version, the data must be exported to LDIF before performing the reversion. Re-import the data after the revert process has completed. In addition, the **changelogDb/** and **db/changelog/** directories in the reverted server root must be deleted after the revert has completed.

When starting up the server for the first time after a revert has been run, and the necessary extra steps have been completed, the server will display warnings about "offline configuration changes," but they are not critical and will not appear on subsequent start ups.

Revert to the most recent server version

Steps

Use **revert-update** in the server root directory to revert back to the most recent version of the server.

```
$ PingDirectory-old/revert-update
```

Tuning the Server

The PingDirectory Server's installation process automatically determines the optimal Java Virtual Machine (JVM) settings based on calculations of the machine running setup. While the majority of the default configuration and JVM settings are suitable for most deployments, it is not uncommon in high performance environments to make slight adjustments to the Directory Server's JVM settings as well as performance and resource-related configuration changes with the `dsconfig` tool.

This chapter provides guidance for tuning the Directory Server and its tools for both optimum performance with regard to throughput and disk space usage. This chapter presents the following topics:

About Minimizing Disk Access

Most critical to directory server performance is minimizing disk access. Defining a JVM heap size that can contain the entire contents of the database cache in memory is essential to minimizing read operations from disk and achieving optimal performance. It is also important to understand that the database on-disk is comprised of transaction log files, which are only appended to. After an initial database import, the size on-disk will grow by a factor of at least 25% as inactive records accumulate within the transaction logs. Therefore, during normal operation, the on-disk size of the database transaction logs do not represent the memory needed to cache the database.

Another consideration is to minimize the size of the database based on the known characteristics of your data. Minimizing the size of the database not only reduces hard disk requirements but also reduces the memory requirements for the database cache. The Directory Server has the capability to automatically compact common parent DNs, which is an example of optimizing the database size based on known characteristics of the data.

Another consideration is to consider the write load on your server and its affect on the database. While write operations will always require an associated write to disk, an environment that sustains a high load of write operations may consider tuning the background database cleaner to minimize the size of the database on disk.

Memory Allocation and Database Cache

The Directory Server's optimal performance is dependent on the proper allocation of memory to the JVM heap, the number of processor cores in the system, and the correct combination of JVM options for optimized garbage collection. The `setup` tool for the Directory Server automatically assigns the JVM options and determines the memory allocation based on the total amount of memory on the system. However, in most production deployments, additional tuning may be required to meet the performance objectives for your system.

Most often, directory server performance tuning can be accomplished by adjusting a few settings. Tuning these settings, which include both JVM and configuration options, require an understanding of the JVM heap structure as well as the expected database usage. This section describes the basic components of the Directory Server footprint and logic behind the automated tuning of the `setup` tool.

Directory Server Process Memory

The Directory Server is comprised mostly of a JVM heap and a marginal amount of memory allocated by the JVM's execution of native code. While we frequently refer to the JVM Heap as the maximum memory consumed by the Directory Server, the actual process size will be slightly larger than the `Xmx` value due to accumulation of small chunks of native code that Java requires for things, such as SSL sockets.

MY TITLE JDK Heap Structure

Within the JVM Heap, the principal memory components are the New and Old Generations. The New Generation is a smaller area of memory where all data is initially allocated and is cleaned of garbage often. Any data that stays "alive" long enough will be promoted to the Old Generation for the longer term. The Old Generation is where the database cache will eventually reside. The Old Generation size is computed from the leftover heap after defining the `MaxHeapSize` and New Generation sizes; therefore, it is not explicitly stated in the JVM options. A typical set of Generation definitions for the JVM is as follows, where `mx` and `ms` values represent the heap size:

```
-Xmx16g -Xms16g -XX:MaxNewSize=2g -XX-NewSize=2g
```

Note: The `mx` and `ms` values should always be the same, and the `MaxNewSize/NewSize` values should be the same. This will help avoid negative changes in performance.

The `MaxNewSize/NewSize` values should never need to exceed 2g. The `setup` and `dsjavaproperties` tools set `MaxNewSize/NewSize` values based on the results of extensive performance testing, and should not need to be changed.

A Method for Determining Heap and Database Cache Size

The most straightforward approach to defining the proper memory allocation of the directory server components is to use the Directory Server `setup` command on hardware that represents the target production platform, especially with regard to process and memory, and the largest heap size that the `setup` tool will allow. After running `setup`, any schema and production database settings should be defined in preparation for the database import using the `import-ldif` tool.

Note: At the moment after an `import-ldif`, the database is at its most optimized state on disk with no inactive records. Over time, the on-disk representation of the database will grow as much as 25-50% as inactive records accumulate before being removed by the server's cleaner thread.

After the database is imported, the server should be started and a configuration change made to the backend. In this scenario, set the `prime-method` to "preload" on the userRoot backend configuration. Once the change is made, re-start the Directory Server and watch for a successful preload message at the end of startup. If preloading did not complete, the server should be stopped. The `start-server.java-args` entry in the `config/java.properties` file should be edited to use larger values for `-Xmx` and `-Xms` arguments. Then run the `bin/dsjavaproperties` command and restart the server. If preloading completed successfully, the database cache utilization percentage will be of interest. The `status` command will display something like the following:

```
--- JE Environment ---
ID      : Cache Full : Cache   : On-Disk : Alert
-----:-----:-----:-----:-----
userRoot : 30%          : 1.1 gb : 868.6mb : None
```

Looking at the above output and knowing that the database is fully loaded into cache, the 30% utilization is comfortable cushion for future database growth. In general, it is best to leave at least 10-20% cache headroom available.

During this scenario, it was clear from the `start-server` output that the database primed completely and our interpretation of the `status` output was sound. To see the state of the database cache with more detail, perform an `ldapsearch` on the backend monitor.

In addition to the user configured backends, there may be backends for replication and changelog. The heap is shared among all backends. The amount allocated to each backed is calculated according to the procedure in the next section.

Automatic DB Cache Percentages

The setup process automatically tunes the percentage of the `db-cache-percent` property for the `userRoot` backend based on the maximum configured JVM heap size. This is only done for the `userRoot` backend during setup. Other backends created by the user are allocated 10%. The allocation can be changed if needed. When setting up the server, perform the following steps:

- Install the server with necessary memory. The server will autotune the size of the cache.
- Set the autotuned cache size to the limit for the combined cache sizes of all of the backends.
- Divide the server cache based on the expected size of the data in each backend.

Automatic Memory Allocation

If the Memory Tuning feature is enabled during setup, the `setup` algorithm determines the maximum JVM heap size based on the total amount of available system memory. If Memory Tuning is not selected, the server allocates a maximum JVM heap of 384 MB. The Directory Server also allows you to specify the maximum heap size during the setup process. You can enable Memory Tuning during the setup process by selecting the feature during the interactive command-line mode, adding the `--jvmTuningParameter` option using the `setup` tool in non-interactive command-line mode, or regenerating the java properties file with `bin/dsjavaproperties` and the `--jvmTuningParameter` options (seen in [JVM Properties for Server and Command-Line Tools](#) page 75).

If Memory Tuning is selected, the server can allocate the maximum JVM heap depending on the total system memory. The following table displays the automatically allocated maximum JVM heap memory based on available system memory.

Allocated Max JVM Memory if Tuning is Enabled

Available Memory	Allocated JVM Memory
16 GB or more using a 64-bit JVM	The maximum JVM heap size will be set to 70% of total system memory. If the maximum JVM heap size is less than or equal to 128GB of memory (which should be the case for systems with up to 160 GB of memory), then the initial heap size will be set to equal the maximum heap size.
6 GB#16 GB using a 64-bit JVM	total system memory - 4 GB
4 GB–6 GB using a 64-bit JVM	2 GB
2 GB–4 GB	512 MB
1 GB–2 GB	384 MB

Automatic Memory Allocation for the Command-Line Tools

At setup, the Directory Server automatically allocates memory to each command-line utility based upon the maximum JVM heap size. The server sets each command-line utility in the `config/java.properties` with `-Xmx/Xms` values depending on the expected memory needs of the tools. Because some tools can be invoked as a server task while the server is online, there are two definitions of the tool in the `config/java.properties` file: one with `.online` and one with `.offline` added to the name. The online invocations of the tools typically require minimal memory as the task is performed within the Directory

Server's JVM. The offline invocations of the tools, for example, `import-ldif.offline` and `rebuild-index.offline`, can require the same amount of memory that is needed by the Directory Server.

Beyond the offline tool invocations, some tools, such as `ldap-diff` and `verify-index`, may need more than the minimal memory if large databases are involved. The table below lists the tools that are expected to have more than the minimal memory needs along with the rules for defining the default heap size.

Default Memory Allocation to the Command-Line Tools

Command-Line Tools	Allocated JVM Memory
<code>start-server</code> , <code>import-ldif (offline)</code> , <code>rebuild-index (offline)</code>	MaxHeapSize
<code>backup (offline)</code> , <code>dbtest export-ldif (offline)</code> , <code>ldap-diff</code> , <code>restore (offline)</code> , <code>scramble-ldif</code> , <code>summarize-access-log</code> , <code>verify-index</code>	If Max System Memory is: <ul style="list-style-type: none"> ▪ Greater than or equal to 16 GB: set Heap to 3 GB ▪ Greater than or equal to 8 GB: set Heap to 1 GB ▪ Greater than or equal to 4 GB: set Heap to 512 MB ▪ Under 4 GB: set Heap to 256 MB

Database Preloading

Key to Directory Server performance is the ability to maintain the database contents in the database cache within the JVM memory. With a properly sized database cache, a priming method of "preload" directs the server to load the database contents into memory at server startup before accepting the first client connection. The time needed to preload the database is proportional to the database size. To avoid priming, the server can be started with the `start-server --skipPrime` command. If the priming method is `none` or the `--skipPrime` option is specified at startup, the database cache will slowly build as entries are accessed. This could take several days to reach optimal performance.

The "preload" priming method is suitable for nearly all Directory Server deployments. If the size of the database precludes storing the whole database in memory, there are priming alternatives for optimizing server performance. This type of deployment is considered disk-bound since the disk is accessed when processing most operations. See the section Disk-Bound Deployments for more information. The remaining priming options are applicable to these environments.

The Directory Server database `prime-method` property configures how the caches get primed, what gets primed (data, internal nodes, system indexes) and where it gets primed (database cache, file system cache, or both). The `prime-method` property is a multi-valued option that enables preloading the internal nodes into the database cache before the server starts, and then primes the values in the background by cursoring across the database. For more details, see the PingDirectory Server Configuration Reference.

The following is a summary of the priming methods:

- **Preload All Data.** Prime the contents of the backend into the database cache.
- **Preload Internal Nodes Only.** Prime only internal database structure information into the database cache, but do not prime any actual data. (This corresponds to the `cache-keys-only` cache-mode.)
- **Cursor Across Indexes.** Use the `cursor-across-indexes` property to iterate through backend contents. This is similar to (and may be slower than) using the preload mechanism, but it enables priming to happen in the background after the server has started. This is used when shorter start up times are desired, and the slower performance of an uncached database is acceptable until the database is primed.

Configuring Database Preloading

Use the `dsconfig` tool to set the database priming method. If multiple prime methods are used, the order in which they are specified in the configuration is the order in which they will be performed. Changing the preloading option requires re-starting the Directory Server. The following procedure shows how to configure database preloading.

To Configure Database Preloading

Steps

1. Set the prime method to "preload" to load the database contents from disk into memory when the server starts up. This eliminates the need for the server to gradually prime the database cache using client traffic, and ensures that the server has optimal performance when it starts to receive client connections.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set prime-method:preload
```

2. Re-start the Directory Server to apply the changes using **bin/stop-server** and then, **bin/start-server**.

To Configure Multiple Preloading Methods

Steps

1. To achieve the benefits of preloading without delaying server startup, **prime-method** can be set to **preload-internal-nodes-only**, which caches all of the keys within the database but not the values. The database values themselves can be cached in the background once the server has been started with the **cursor-across-indexes** option.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --add prime-method:preload-internal-nodes-only \
  --add prime-method:cursor-across-indexes \
  --set background-prime:true
```

2. Re-start the Directory Server to apply the changes using **bin/stop-server** and then, **bin/start-server**.

To Configure System Index Preloading

Steps

1. Some environments have many indexes configured, though only a few are used for performance-sensitive traffic. In this case, server start up time can be reduced by only preloading the necessary indexes into the database at startup.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload \
  --set prime-all-indexes:false \
  --set system-index-to-prime:dn2id \
  --set system-index-to-prime:id2entry
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name mail \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name uid \
  --set prime-index:true
```

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name entryUUID \
  --set prime-index:true
```

2. Restart the Directory Server to apply the changes using **bin/stop-server** and then, **bin/start-server**.

Databases on Storage Area Networks, Network-Attached Storage, or running in Virtualized Environments

There are several considerations when using network-based storage or storage abstracted by virtualization that are not issues when databases are stored on local disks. A data durability problem occurs when remote storage or the virtualization environment experiences service interruptions, ranging from connectivity loss to total failure from power loss. Data corruption can occur when the storage layer accepts data for writing that is not made durable before a crash occurs. In these cases, a database property can be set that reduces the likelihood of data loss and data corruption. The database property `database-on-virtualized-or-network-storage` can be set on a per-backend environment basis to request all database writes to be written durably to the underlying storage.

There is a performance penalty when enabling this property, and in most cases, is not recommended except where network storage is unreliable. For network file systems, the benefits of faster recovery and less likelihood of data loss from unplanned events may outweigh the penalty. The exact overhead of enabling `database-on-virtualized-or-network-storage` depends on the characteristics of the database, the host file system, storage array configuration, and network and virtualization input and output parameters. The write overhead penalty might be substantial for SAN environments. Incremental and full backup strategies should be used instead if performance is unacceptable.

To enable `database-on-virtualized-or-network-storage` for each applicable backend, use the following command as an example, which references the configuration for the userRoot backend:

```
$ bin/dsconfig set-global-configuration-prop \
  --set database-on-virtualized-or-network-storage:true
```

This should be set to `false` if the database is on a local disk.

Database Cleaner

Production environments that have a high volume of write operations may require cleaner thread tuning to control the on-disk database size as log files with inactive nodes wait to be cleaned and deleted. The Directory Server stores its Oracle® Berkeley DB Java Edition (JE) database files on-disk in the `db` directory. Each JE database log file is labelled `nnnnnnnn.jdb`, where `nnnnnnnn` is an 8-digit hexadecimal number that starts at `00000000` and is increased by `1` for each file written to disk. JE only appends data to the end of each file and does not overwrite any existing data. JE uses one or more cleaner threads that run in the background to compact the number of JE database (`db`) files.

The cleaner threads begin by scanning the records in each `db` file, starting with the file that contains the smallest number of active records. Next, the cleaner threads append any active records to the most recent database file. If a record is no longer active due to modifications or deletions, the cleaner threads leave it untouched. After the `db` file no longer has active records, the cleaner threads can either delete the file or rename the discarded file. Note that because of this approach to cleaning, the database size on-disk can temporarily increase when cleaning is being performed and files are waiting to be removed.

The Local DB Backend configuration object has two properties that control database cleaning: `db-cleaner-min-utilization` and `db-num-cleaner-threads`. The `db-cleaner-min-utilization` property determines, by percentage, when to begin cleaning out inactive records from the database files. By default, the property is set to `75`, which indicates that database cleaning ensures that at least `75%` of the total log file space is devoted to live data. Note that this property only affects the on-disk representation of the database and not the in-memory database cache—only live data is ever cached in memory.

The `db-num-cleaner-threads` property determines how many threads are configured for `db` cleaning. The default single cleaner thread is normally sufficient. However, environments with a high volume of write traffic may need to increase this value to ensure that database cleaning can keep up.

If the number of database files grow beyond your expected guidelines or if the Directory Server is experiencing an increased number of update requests, you can increase the number of cleaner threads using the `dsconfig` tool (select **Backend# select advanced properties# db-num-cleaner-threads**).

Compacting Common Parent DNs

The PingDirectory Server compacts entry DNs by tokenizing common parent DNs. Tokenizing the common parent DNs allows you to increase space usage efficiency when encoding entries for storage. The Directory Server automatically defines tokens for base DNs for the backend (for example, `dc=example,dc=com`). You can also define additional common base DNs that you want to tokenize. For example, use the following configuration to tokenize two branches, `ou=people,dc=example,dc=com` and `ou=customers,dc=example,dc=com`:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --add "compact-common-parent-dn:ou=people,dc=example,dc=com" \
  --add "compact-common-parent-dn:ou=customers,dc=example,dc=com"
```

Import Thread Count

For most systems, the default setting of 16 threads is sufficient and provides good import performance. On some systems, increasing the import thread count may lead to improved import performance, while selecting a value that is too large can actually cause import performance to degrade. If minimizing LDAP import time is crucial to your deployment, you must determine the optimal number of import threads for your system, which is dependent on both the underlying system and the dataset being imported.

You can use the `dsconfig` command to set the number of import threads as follows:

```
$ bin/dsconfig set-backend-prop --backend-name userRoot --set import-thread:24
```

JVM Properties for Server and Command-Line Tools

The Directory Server and tools refer to the `config/java.properties` file for JVM options that include important memory settings. The `java.properties` file sets the default Java arguments for the Directory Server and each command-line utility including the default `JAVA_HOME` path.

The `java.properties` is generated at server setup time and defines memory-related JVM settings based on the user-provided value for max heap size if aggressive memory tuning option was selected at setup. Most of the JVM options specified for both server and tools do not need customization after setup. The exception is the `-Xmx/Xms` options, which specify the maximum and initial JVM heap size. See the section on [Memory Allocation and Database Cache](#) for advice on tailoring the `-Xmx/Xms` values.

Other than altering the heap size of the server process (`start-server`) or command-line tools, the most common change required to `java.properties` is when it is desired to update the JVM version. A single edit will apply the new JVM to all server and tool use.

Applying Changes Using `dsjavaproperties`

To apply the changes to the `config/java.properties` file, edit the file manually, and then run the `bin/dsjavaproperties` utility. The `dsjavaproperties` tool uses the information contained in the `config/java.properties` file to generate a `lib/set-java-home` script (or `lib\set-java-home.bat` on Microsoft Windows systems), which is used by the Directory Server and all of its supporting tools to identify the Java environment and its JVM settings. During the process, `dsjavaproperties` calculates an MD5 digest of the contents of the `config/java.properties` file and stores the digest in the generated `set-java-home` script.

The `dsjavaproperties` utility also performs some minimal validation whenever the property references a valid Java installation by verifying that `$(java-home)/bin/java` exists and is executable.

If you make any changes to the `config/java.properties` file but forget to run `bin/dsjavaproperties`, the Directory Server compares the MD5 digest with the version stored in `set-java-home` and sends a message to standard error if the digests differ:

```
WARNING -- File /ds/PingDirectory
          /config/java.properties has been edited without
running dsjavaproperties to apply the changes
```

To Update the Java Version in the Properties File

About this task

To change the version of java that is used by the server and tools, it is necessary to edit the `config/java.properties` file and apply the change by invoking `bin/dsjavaproperties` with no command line options. Also, the server must be restarted for the change to take affect.

Inside `config/java.properties`, alter the value of `default.java-home` to point to the java correct JRE. Any time the `config/java.properties` file is updated, the `bin/dsjavaproperties` tool must be run to apply the new configuration.

```
$ bin/dsjavaproperties
```

To Regenerate the Java Properties File

About this task

The `dsjavaproperties` command provides a `--initialize` option that allows you to regenerate the Java Properties file specifically if you set up the Directory Server using standard memory usage but opt for aggressive memory tuning after setup. Rather than reconfigure the Java Properties file by re-running `setup` or manually editing the `java.properties` file, you can regenerate the properties file for aggressive memory tuning. Any existing file will be renamed with a ".old" suffix.

Steps

- Run the `dsjavaproperties` command to regenerate the java properties file for aggressive memory tuning:

```
$ bin/dsjavaproperties --initialize --jvmTuningParameter AGGRESSIVE
```

JVM Garbage Collection Using CMS

To ensure reliable server performance with Java, the Directory Server depends on Java's Concurrent Mark and Sweep process (CMS) for background garbage collection. There are several garbage collection options, with CMS being the ideal choice for consistent system availability. The CMS collector runs as one or more background threads, for the most part, within the JVM, freeing up space in JVM Heap from an area called the Old Generation. One of the criteria used by CMS to determine when to start background garbage collection is a parameter called `CMSInitiatingOccupancyFraction`. This percentage value, which applies to the Old Generation, is a recommendation for the JVM to initiate CMS when data occupancy in Old Generation reaches the threshold.

To understand this CMS property, it is important to know how large the Old Generation is and how much data in the Old Generation is expected to be occupied by the database cache. Ideally, the database cache takes less than 70% of the space available in the Old Generation, and the `CMSInitiatingOccupancyFraction` value of 80 leaves plenty of headroom to prevent the JVM from running out of space in Old Generation due to an inability for CMS to keep up. Because CMS takes processing resources away from the Directory Server, it is not recommended to set the `CMSInitiatingOccupancyFraction` at or below the expected database cache size, which would result in the constant running of CMS in the background. See the section on Memory Footprint and Database Cache for a description of determining Old Generation size.

When the CMS collection process cannot keep pace with memory demands in the Old Generation, the JVM will resort to pausing all application processing to allow a full garbage collection. This event, referred to as a *stop-the-world* pause, does not break existing TCP connections or alter the execution of the Directory Server requests. The goal in tuning CMS is to prevent the occurrence of these pauses. When one does occur, the Directory Server will generate an alert, after the pause, and record the pause time in the error log.

Because determining an ideal `CMSInitiatingOccupancyFraction` can be difficult, the approach we have taken is to warn if the Directory Server detects a garbage collection pause by generating a recommended value for the occupancy threshold based on the current amount of memory being consumed by the backend caches. Unfortunately, it is not possible for an administrator to determine the ideal occupancy threshold value in advance. Therefore, to warn of any impending garbage collection pauses, the Directory Server calculates a recommended value for the `CMSInitiatingOccupancyFraction` property and exposes it in the JVM Memory Usage monitor entry in the following attribute:

```
recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

Also, when you start the server, you will see an administrative alert indicating the current state of the `CMSInitiatingOccupancyFraction` and its recommended value.

```
$ bin/start-server [20/April/2012:10:35:25 -0500] category=CORE
severity=NOTICE msgID=458886
msg="PingDirectory Server
      8.1.0.0 (build 20120418135933Z, R6226) starting up"

... (more output) ...

[20/April/2012:10:35:53 -0500] category=UBID_EXTENSIONS severity=NOTICE
msgID=1880555580 msg="Memory-intensive Directory Server
components are configured to consume 71750382 bytes of memory:
['userRoot local DB backend' currently consumes 26991632 bytes and
can grow to a maximum of 64323584 bytes, 'changelog cn=changelog backend'
currently consumes 232204 bytes and can grow to a maximum of 2426798 bytes,
'Replication Changelog Database' currently consumes 376661 bytes and can
grow to a maximum of 5000000 bytes]. The configured value of
CMSInitiatingOccupancyFraction is 36 which is less than the minimum
recommended value (43) for the server's current configuration. Having
this value too low can cause the Concurrent Mark and Sweep garbage
collector to run too often, which can cause a degradation of throughput
and response time. Consider increasing the CMSInitiatingOccupancyFraction
value to at least the minimum value, preferably setting it to the
recommended value of 43 by editing the config/java.properties file,
running dsjavaproperties, and restarting the Directory Server.
If the server later detects that this setting actually leads to a
performance degradation, a separate warning message will be logged.
If this server has not yet been fully loaded with data, then you
can disregard this message"

[20/April/2012:10:35:53 -0500] category=CORE severity=NOTICE msgID=458887
msg="The Directory Server has started successfully"
```

The Directory Server only makes a recommendation if all of the backends are preloaded and the `CMSInitiatingOccupancyFraction` JVM property is explicitly set, which is done automatically. For example, if you installed the Directory Server and specified that the database be preloaded (or "primed") at startup, then the Directory Server can make a good recommendation for the Directory Server when a pause occurs. If the backend database cache is not full and has not been preloaded, then the recommended value may be an inaccurately low value.

Note: The generated value for the Directory Server property could change over time with each Directory Server build, Java release, or changes in data set. If the current value is fairly close to the recommended value, then there is no need to change the property unless the server experiences a JVM pause.

If the Directory Server experiences a JVM garbage collection pause, you can retrieve the recommended value from the server, reset the Directory Server property, run `dsjavaproperties`, and restart the server.

To Determine the CMSInitiatingOccupancyFraction

Steps

1. If you set the Preload Database at startup option during the installation, then skip to step 3. If you are not sure, retrieve the `prime-method` property for the backend as follows:

```
$ bin/dsconfig get-backend-prop --backend-name userRoot \
  --property prime-method
```

2. If the `prime-method` property was not configured, use `bin/dsconfig` to set the property to `PRELOAD`, and then, restart the Directory Server to preload the database cache.

```
$ bin/dsconfig set-backend-prop --backend-name userRoot \
  --set prime-method:preload
```

```
$ bin/stop-server
$ bin/start-server
```

3. At startup, you will see an administrative message if the current `CMSInitiatingOccupancyFraction` property is below the recommended value. You can get the recommended value from this message and change it in the `config/java.properties` file in step 5.
4. If you were unable to see the recommended `CMSInitiatingOccupancyFraction` property at startup presented in the previous step, first you must pre-tune the value of the `CMSInitiatingOccupancyFraction` property to ensure that all of the data is imported into the server and preloading is enabled in the backend. Next, retrieve the recommended `CMSInitiatingOccupancyFraction` value by issuing the following search. If the `recommended-cms-initiating-occupancy-fraction-for-current-data-set` is not present, then make sure that the server has been restarted since enabling preload for the backend(s).

```
$ bin/ldapsearch --baseDN "cn=monitor" \
  "(objectclass=ds-memory-usage-monitor-entry)" \
  cms-initiating-occupancy-fraction \
  recommended-cms-initiating-occupancy-fraction-for-current-data-set
```

```
dn: cn=JVM Memory Usage,cn=monitor
cms-initiating-occupancy-fraction:80
recommended-cms-initiating-occupancy-fraction-for-current-data-set:55
```

5. Open the `config/java.properties` file using a text editor, manually edit the `CMSInitiatingOccupancyFraction` or any other property to its recommended value in the `start-server.java-args` property, and then, save the file when finished. (The following arguments are recommended for a Sun 5440 server. Contact your authorized support provider for specific assistance.):

```
start-server.java-args=-d64 -server -Xmx20g -Xms20g -XX:MaxNewSize=1g
-XX:NewSize=1g -XX:ParallelGCThreads=16 -XX:+UseConcMarkSweepGC
-XX:+CMSConcurrentMTEnabled -XX:+CMSParallelRemarkEnabled
-XX:+CMSParallelSurvivorRemarkEnabled -XX:ParallelCMSThreads=8
-XX:CMSMaxAbortablePrecleanTime=3600000
-XX:+CMSScavengeBeforeRemark -XX:RefDiscoveryPolicy=1
-XX:CMSInitiatingOccupancyFraction=55 -XX:+UseParNewGC
-XX:+UseBiasedLocking -XX:+UseLargePages
-XX:+HeapDumpOnOutOfMemoryError
```

The `-XX:ParallelGCThreads` should be limited to 16 (default) or to 8 for smaller systems. Also, the `-XX:ParallelCMSThreads` should be limited to 8.

6. Run the `bin/dsjavaproperties` command to apply the changes.

```
$ bin/dsjavaproperties
```

7. Restart the Directory Server.

Tuning For Disk-Bound Deployments

For best performance, configure the Directory Server to fully cache the DIT in the backend database cache. Directory Server configuration assumes this scenario. For databases too large to fit in memory, other options are available:

- Configure the server for a disk-bound data set (when the database is stored on an SSD, this configuration yields server performance that is comparable to a fully-cached scenario).
- Use uncached attributes and/or entries as described in the following section.
- Use a Directory Proxy Server in an entry-balancing deployment, which allows all data to be cached in a partitioned environment.

To Tune for Disk-Bound Deployments

About this task

To configure the server for a disk-bound configuration, follow these steps:

Steps

1. When installing the server, choose the "aggressive" option for JVM memory configuration and to preload the data when the server starts.
2. Set the `default-cache-mode` of the `userRoot` backend to `cache-keys-only`.
3. Set operating system `vm.swappiness` to 0 to protect the Directory Server JVM process from an overly aggressive file system cache.
4. When the data set is imported with the above settings, verify in the `import-ldif` output that the cached portions of the data set fit comfortably within the database cache.

Uncached Attributes and Entries

Although achieving optimal Directory Server performance requires that the entire data set be fully cached, there may be deployments in which fully caching the data set is not possible due to hardware or financial constraints, or in which acceptable performance can be achieved by only caching a portion of the data. The Directory Server already provides support for controlling caching on a per-database basis (e.g., to cache only certain indexes and/or system databases), but these features may not provide sufficient control over how memory is used, particularly with regard to which entries are included in the cache, and they do not provide any degree of control over caching only a portion of attributes.

To better address the needs of environments that require partial caching, the Directory Server provides two new options: the ability to exclude certain *entries* from the cache, and the ability to exclude certain *attributes* from the cache. The Directory Server uses an `uncached-id2entry` database container, which is similar to the `id2entry` database that maps an entry's unique identifier and its encoded representation. The `uncached-id2entry` database contains either complete and/or partial representations of entries that are intended to receive less memory for caching. For example, if an entry has a particularly large attribute and the system has hardware constraints on memory, then you can configure the system to not cache this particular attribute or entry. This functionality is only available for the local DB backend, which uses the Berkeley DB Java Edition database.

The `uncached-id2entry` database can be included in the set of databases to prime, but if priming is to be performed, it will only include internal nodes and not leaf nodes. For example, the internal nodes of the `uncached-id2entry` database will be included in the preload if the `prime-all-indexes` option is set to "true," or if the `system-index-to-prime-internal-nodes-only` option has a value of "uncached-id2entry".

Backup/Restore. There are no special considerations for backup and restore with regard to uncached entries and attributes. Backup will successfully save your database contents including uncached entries and attributes. Because of the way the server deals with changes to uncached entry and uncached attribute configuration, there is no problem with restoring a backup that was taken with a different

uncached entry configuration than is currently in place for the server. Any entries encoded in a manner that is inconsistent with the current uncached entry or uncached attribute configuration will be properly re-encoded whenever they are updated, or whenever the re-encode entries task is invoked.

Replication. Replication does not propagate information about which portions of entries may have been cached or uncached, nor does it require that different replicas have the same uncached attribute or uncached entry configuration.

LDIF Import/Export. When LDIF content is imported into the server, the uncached attribute and uncached entry configuration is used to determine on a per-entry basis whether some or all of the content for that entry should be written into the `uncached-id2entry` database. The determination is based on the current configuration and is completely independent of and unaware of the configuration that may have been in place when the LDIF data was initially exported. Neither the LDIF import nor export tools provide any options that specifically target only cached or only uncached content, but these tools do provide the ability to include or exclude entries using search filters, or to include or exclude specific attributes.

Server Access Log. Server access log messages may include `uncachedDataAccessed=true` in the result message for any operation in which it was necessary to access uncached data in the course of processing the associated request. For add, delete, modify, or modify DN result messages, `uncachedDataAccessed=true` indicates that at least a portion of the new or updated entry was written into the `uncached-id2entry` database, or that at least a portion of the updated entry was formerly contained in the `uncached-id2entry` database. For compare result messages, it indicates that at least a portion of the target entry was contained in the `uncached-id2entry` database and that data from the uncached portion of the entry was required to evaluate the assertion. For search result messages, it indicates that one or more of the entries evaluated as potential matches contained uncached data, and that data from the uncached portion of at least one entry was needed in determining what data should be returned to the client.

Uncached Entry/Attribute Properties. The Directory Server provides three new advanced properties on the Local DB Backend to control the caching mode for the `uncached-id2entry` database:

- **uncached-id2entry-cache-mode.** Specifies the cache mode that is used when accessing the records in the `uncached-id2entry` database. If the system has enough memory available to fully cache the internal nodes for this database, then `cache-keys-only` is recommended, otherwise it is better to select `no-caching` to minimize the amount of memory required for interacting with the `uncached-id2entry` database. For more information, see the *PingDirectory Server Configuration Reference*.
- **uncached-attribute-criteria.** Specifies the criteria used to identify attributes that are written into the `uncached-id2entry` database, rather than the `id2entry` database. This property is only used for entries in which the associated `uncached-entry-criteria` does not indicate that the entire entry should be uncached. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all attributes are written into the `id2entry` database.
- **uncached-entry-criteria.** Specifies the criteria used to identify entries that are written into the `uncached-id2entry` database, rather than the `id2entry` database. The property applies to all entry writes, including add, soft delete, modify, and modify DN operations, as well as LDIF import and re-encode processing. Any changes to the property take effect immediately for writes occurring after the change is made. If no value is specified, then all entries are written into the `id2entry` database.

To Configure Uncached Attributes and Entries

About this task

The following procedure assumes that the `uncached-id2entry-cache-mode` property is set to the default value, `cache-keys-only`. For more information on the `uncached-id2entry` cache modes, see the *PingDirectory Server Configuration Reference*.

Steps

1. Run `dsconfig` to uncache entries that match the criteria. Here, the filter will uncache all entries that have its location set to "austin" (i.e., `l=austin`).

```
$ bin/dsconfig create-uncached-entry-criteria \
  --criteria-name "Fully Uncached l=austin" --type filter-based \
  --set enabled:true --set "filter:(l=austin)"
```

2. Run `dsconfig` to uncache attributes that match the criteria (`attribute-type: jpegPhoto`). The `--type simple` option indicates that the simple uncached attribute criteria be used to specify the `attribute-type` that should be uncached, which in this example is `jpegPhoto`. For those entries that are fully stored in the `uncached-id2entry` database container, the uncached attribute will be ignored.

```
$ bin/dsconfig create-uncached-attribute-criteria \
  --criteria-name "Uncached jpegPhoto" --type simple \
  --set enabled:true --set attribute-type:jpegPhoto
```

3. Set the uncached properties for the `userRoot` backend.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set "uncached-entry-criteria:Fully Uncached l=austin" \
  --set "uncached-attribute-criteria:Uncached jpegPhoto"
```

4. Run the `re-encode-entries` tool to initiate a task that causes a local DB `userRoot` backend to re-encode all or a specified subset of the entries that it contains. The tool does not alter the entries themselves but provides a useful mechanism for applying significant changes to the way that entries are stored in the backend. The following command initiates a task that re-encodes all fully-cached entries in the `userRoot` backend, rate-limited to no more than 100 entries per second.

```
$ bin/re-encode-entries --hostname directory.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --skipFullyUncachedEntries \
  --skipPartiallyUncachedEntries --ratePerSecond 100
```

Configuring the Server

The out-of-the-box, initial configuration settings for the PingDirectory Server provide an excellent starting point for most general-purpose Directory Server applications. However, additional tuning might be necessary to meet the performance, hardware, operating system, and memory requirements for your production environment.

The Directory Server stores its configuration settings in an LDIF file, `config/config.ldif`. Rather than editing the file directly, the Directory Server provides command-line and an Administrative Console to configure the server. The Directory Server also includes tools to create server groups, so that configuration changes can be applied to multiple servers at one time.

This chapter presents the following topics:

About the Configuration Tools

The PingDirectory Server configuration can be accessed and modified in the following ways:

- **Using the Administrative Console**. The PingDirectory Server provides an Administrative Console for graphical server management and monitoring. The console provides equivalent functionality as the `dsconfig` command for viewing or editing configurations. All configuration changes using this tool are recorded in `logs/config-audit.log`, which also has the equivalent reversion commands should you need to back out of a configuration.
- **Using the dsconfig Command-Line Tool**. The `dsconfig` tool is a text-based menu-driven interface to the underlying configuration. The tool runs the configuration using three operational modes:

interactive command-line mode, non-interactive command-line mode, and batch mode. All configuration changes made using this tool are recorded in `logs/config-audit.log`.

About dsconfig Configuration Tool

The `dsconfig` tool is the text-based management tool used to configure the underlying Directory Server configuration. The tool has three operational modes: interactive mode, non-interactive mode, and batch mode.

The `dsconfig` tool also offers an offline mode using the `--offline` option, in which the server does not have to be running to interact with the configuration. In most cases, the configuration should be accessed with the server running in order for the server to give the user feedback about the validity of the configuration.

Using dsconfig in Interactive Command-Line Mode

In interactive mode, the `dsconfig` tool offers a filtering mechanism that only displays the most common configuration elements. The user can specify that more expert level objects and configuration properties be shown using the menu system.

Running `dsconfig` in interactive command-line mode provides a user-friendly, menu-driven interface for accessing and configuring the PingDirectory Server. To start `dsconfig` in interactive command-line mode, simply invoke the `dsconfig` script without any arguments. You will be prompted for connection and authentication information to the Directory Server, and then a menu will be displayed of the available operation types.

In some cases, a default value will be provided in square brackets. For example, `[389]` indicates that the default value for that field is port 389. You can press **Enter** to accept the default. To skip the connection and authentication prompts, provide this information using the command-line options of `dsconfig`.

To Configure the Server Using dsconfig Interactive Mode

Steps

1. Launch the `dsconfig` tool in interactive command-line mode.

```
$ bin/dsconfig
```

2. Next, enter the LDAP connection parameters. Enter the Directory Server host name or IP address, or press **Enter** to accept the default.
3. Enter the number corresponding to the type of LDAP connection (1 for LDAP, 2 for SSL, 3 for StartTLS) that you are using on the Directory Server, or press **Enter** to accept the default (1).
4. Next, type the LDAP listener port number, or accept the default port. The default port is the port number of the server local to the tool.
5. Enter the user bind DN (default, `cn=Directory Manager`) and the bind DN password.
6. On the **Directory Server Configuration Console** main menu, type a number corresponding to the configuration that you want to change. Note that the number can change between releases or within the same release, depending on the options selected (for example, in cases where more expert level objects and and properties are displayed).

In this example, select the number for Backend. Then, set the `db-cache-percent` to 40%. The optimal cache percentage depends on your system performance objectives and must be tuned as determined through analysis. In many cases, the default value chosen by the `setup` utility is sufficient.

7. On the **Backend management** menu, enter the number corresponding to view and edit an existing backend.
8. Select the backend to work with. In this example, using the basic object menu, only one backend that can be viewed in the directory, `userRoot`. Press **Enter** to accept the default.

9. From the **Local DB Backend** properties menu, type the number corresponding to the `db-cache-percent` property.
10. Enter the option to change the value, and then type the value for the `db-cache-percent` property. In this example, type 40 for "40 %".
11. Review the changes, and then type `f` to apply them.

Before you apply the change, the `dsconfig` interactive command-line mode provides an option to view the equivalent non-interactive command based on your menu selections. This is useful in building `dsconfig` script files for configuring servers in non-interactive or batch mode. If you want to view the equivalent `dsconfig` non-interactive command, type `d`. For more information, see [Getting the Equivalent dsconfig Non-Interactive Mode Command](#).
12. In the **Backend management** menu, type `q` to quit the `dsconfig` tool.

To View dsconfig Advanced Properties

About this task

For most configuration settings, some properties are more likely to be modified than others. The `dsconfig` interactive mode provides an option that hides or shows additional advanced properties that administrators might want to configure.

Steps

1. Repeat steps 1–9 in the previous section using `dsconfig` in Interactive Command-Line Mode.
2. From the **Local DB Backend properties** menu, type `a` to display the advanced properties, which toggles any hidden properties.

Using dsconfig Interactive Mode: Viewing Object Menus

Because some configuration objects are more likely to be modified than others, the PingDirectory Server provides four different object menus that hide or expose configuration objects to the user. The purpose of object levels is to simply present only those properties that an administrator will likely use. The Object type is a convenience feature designed to unclutter menu readability.

The following object menus are available:

- **Basic.** Only includes the components that are expected to be configured most frequently.
- **Standard.** Includes all components in the Basic menu plus other components that might occasionally need to be altered in many environments.
- **Advanced.** Includes all components in the Basic and Standard menus plus other components that might require configuration under special circumstances or that might be potentially harmful if configured incorrectly.
- **Expert.** Includes all components in the Basic, Standard, and Advanced menus plus other components that should almost never require configuration or that could seriously impact the functionality of the server if not properly configured.

To Change the dsconfig Object Menu

Steps

1. Repeat steps 1–6 in the section using `dsconfig` in To Install the Directory Server in Interactive Mode.
2. On the **PingDirectory Server configuration** main menu, type `o` (letter "o") to change the object level. By default, Basic objects are displayed.
3. Enter a number corresponding to a object level of your choice: 1 for Basic, 2 for Standard, 3 for Advanced, 4 for Expert.
4. View the menu at the new object level. Additional configuration options for the Directory Server components are displayed.

Using dsconfig Interactive: Viewing Administrative Alerts

The `dsconfig` tool and the Administrative Console provide a useful feature that displays notifications for certain operations that require further administrator action to complete the process. If you change a certain backend configuration property, the admin action will appear in two places during a `dsconfig` interactive session: when configuring the property and before you apply the change. For example, if you change the `db-directory` property on the `userRoot` backend (that is, specify the path to the file system path that holds the Oracle Berkeley DB Java Edition backend files), you will see an admin action reminder during one of the steps (shown below).

The admin action alert will also appear as a final confirmation step. The alert allows you to continue and apply the change or back out of the configuration if the resulting action cannot be conducted at the present time. For example, after you type "f" to apply the `db-directory` property change, the admin alert message appears:

```
Enter choice [b]: f
One or more configuration property changes require administrative action or
confirmation/notification.

Those properties include:

* db-directory: Modification requires that the Directory Server be stopped,
the database directory manually relocated, and then the Directory Server
restarted. While the Directory Server is stopped, the directory and files
pertaining to this backend in the old database directory must be manually
moved or copied to the new location.

Continue? Choose 'no' to return to the previous step (yes / no) [yes]:
```

Currently, only a small set of properties display an admin action alert appear in `dsconfig` interactive mode and the Administrative Console. For more information on the properties, see the *PingDirectory Server Configuration Reference*.

Using dsconfig in Non-Interactive Mode

The `dsconfig` non-interactive command-line mode provides a simple way to make arbitrary changes to the Directory Server by invoking it from the command line. To use administrative scripts to automate configuration changes, run the `dsconfig` command in non-interactive mode, which is convenient scripting applications. Note, however, that if you plan to make changes to multiple configuration objects at the same time, then the batch mode might be more appropriate.

You can use the `dsconfig` tool to update a single configuration object using command-line arguments to provide all of the necessary information. The general format for the non-interactive command line is:

```
$ bin/dsconfig --no-prompt {globalArgs} {subcommand} {subcommandArgs}
```

The `--no-prompt` argument indicates that you want to use non-interactive mode. The `{sub-command}` is used to indicate which general action to perform. The `{globalArgs}` argument provides a set of arguments that specify how to connect and authenticate to the Directory Server. Global arguments can be standard LDAP connection parameters or SASL connection parameters depending on your setup. For example, using standard LDAP connections, you can invoke the `dsconfig` tool as follows:

```
$ bin/dsconfig --no-prompt list-backends \
--hostname server.example.com \
--port 389 \
--bindDN uid=admin,dc=example,dc=com \
--bindPassword password
```

If your system uses SASL GSSAPI (Kerberos), you can invoke `dsconfig` as follows:

```
$ bin/dsconfig --no-prompt list-backends \
```

```
--saslOption mech=GSSAPI \  
--saslOption authid=admin@example.com \  
--saslOption ticketcache=/tmp/krb5cc_1313 \  
--saslOption useticketcache=true
```

The `{subcommandArgs}` argument contains a set of arguments specific to the particular subcommand that you wish to invoke. To always display the advanced properties, use the `--advanced` command-line option.

Note: Global arguments can appear anywhere on the command line (including before the subcommand, and after or intermingled with subcommand-specific arguments). The subcommand-specific arguments can appear anywhere after the subcommand.

To Configure the Server Using dsconfig Non-Interactive Mode

Steps

- Use the `dsconfig` command in non-interactive mode to change the amount of memory used for caching database contents and to specify common parent DNs that should be compacted in the underlying database.

```
$ bin/dsconfig set-backend-prop \  
--backend-name userRoot \  
--set db-cache-percent:40 \  
--add "compact-common-parent-dn:ou=accts,dc=example,dc=com" \  
--add "compact-common-parent-dn:ou=subs,dc=example,dc=com"
```

To View a List of dsconfig Properties

Steps

- Use the `dsconfig` command with the `list-properties` option to view the list of all `dsconfig` properties. Remember to add the LDAP connection parameters.

```
$ bin/dsconfig list-properties
```

- Use the `dsconfig` command with the `list-properties` option and the `--complexity <menu level>` to view objects at and below the menu object level. You can also add the `--includeDescription` argument that includes a synopsis and description of each property in the output. Remember to add the LDAP connection parameters.

```
$ bin/dsconfig list-properties --complexity advanced --includeDescription
```

- If the server is offline, you can run the command with the `--offline` option. You do not need to enter the LDAP connection parameters.

```
$ bin/dsconfig list-properties --offline --complexity advanced --  
includeDescription
```

You can also view the `<server-root>/docs/config-properties.txt` that contains the property information provided with the server.

Getting the Equivalent dsconfig Non-Interactive Mode Command

While the `dsconfig` non-interactive command-line mode is convenient for scripting and automating processes, obtaining the correct arguments and properties for each configuration change can be quite time consuming.

To facilitate easy and quick configuration, you can use an option to display the equivalent non-interactive command using `dsconfig` interactive mode. The command displays the equivalent `dsconfig` command

to recreate the configuration in a scripted configuration or to more quickly enter any pending changes on the command line for another server instance.

Note: There are two other ways to get the equivalent `dsconfig` command. One way is by looking at the `logs/config-audit.log`. It might be more convenient to set the Directory Server up the way you want and then get the `dsconfig` arguments from the log. Another way is by configuring an option using the Administrative Console. The console shows the equivalent `dsconfig` command prior to applying the change.

To Get the Equivalent `dsconfig` Non-Interactive Mode Command

Steps

1. Using `dsconfig` in interactive mode, make changes to a configuration but do not apply the changes (that is, do not enter "f").
2. Enter `d` to view the equivalent non-interactive command.
3. View the equivalent command (seen below), and then press **Enter** to continue. For example, based on an example in the previous section, changes made to the `db-cache-percent` returns the following:

```
Command line to apply pending changes to this Local DB Backend:
dsconfig set-backend-prop --backend-name userRoot --set db-cache-percent:40
```

The command does not contain the LDAP connection parameters required for the tool to connect to the host since it is presumed that the command would be used to connect to a different remote host.

Using `dsconfig` Batch Mode

The PingDirectoryProxy Server provides a `dsconfig` batching mechanism that reads multiple `dsconfig` invocations from a file and executes them sequentially. The batch file provides advantages over standard scripting by minimizing LDAP connections and JVM invocations that normally occur with each `dsconfig` call. Batch mode is the best method to use with setup scripts when moving from a development environment to test environment, or from a test environment to a production environment. The `--no-prompt` option is required with `dsconfig` in batch mode.

If a `dsconfig` command has a missing or incorrect argument, the command will fail and abort the batch process without applying any changes to the Directory Proxy Server. The `dsconfig` command supports a `--batch-continue-on-error` option which instructs `dsconfig` to apply all changes and skip any errors.

You can view the `logs/config-audit.log` file to review the configuration changes made to the Directory Proxy Server and use them in the batch file. The batch file can have blank lines for spacing and lines starting with a pound sign (`#`) for comments. The batch file also supports a `"\"` line continuation character for long commands that require multiple lines.

The Directory Proxy Server also provides a `docs/sun-ds-compatibility.dsconfig` file for migrations from Sun/Oracle to PingDirectoryProxy Server machines.

To Configure the Directory Server in `dsconfig` Batch Mode

Steps

1. Create a text file that lists each `dsconfig` command with the complete set of properties that you want to apply to the Directory Server. The items in this file should be in the same format as those accepted by the `dsconfig` command. The batch file can have blank lines for spacing and lines starting with

a pound sign (#) for comments. The batch file also supports a "\ " line continuation character for long commands that require multiple lines.

```
# This dsconfig operation creates the exAccountNumber global attribute
index.
dsconfig create-global-attribute-index
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--index-name exAccountNumber --set prime-index:true

# Here we create the entry-count placement algorithm with the
# default behavior of adding entries to the smallest backend
# dataset first.

dsconfig create-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name example_com_entry_count
--type entry-counter
--set enabled:true
--set "poll-interval:1 m"

# Note that once the entry-count placement algorithm is created
# and enabled, we can delete the round-robin algorithm.
# Since an entry-balancing proxy must always have a placement
# algorithm, we add a second algorithm and then delete the
# original round-robin algorithm created during the setup
# procedure.

dsconfig delete-placement-algorithm
--processor-name ou_people_dc_example_dc_com-eb-req-processor
--algorithm-name round-robin
```

2. Use `dsconfig` with the `--batch-file` option to read and execute the commands.

Syncing Passwords to PingOne

A direct attribute mapping from `userPassword` in PingDirectory Server to `password` in PingOne is used for syncing passwords from PingDirectory Server to PingOne. PingDataSync Server can synchronize passwords that have been encrypted by PingDirectory Server or a hashed version of the password, which is determined by how an administrator chooses to store the passwords on PingDirectory Server.

```
dsconfig create-attribute-mapping \
--map-name PingDirectory_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:userPassword
```

For syncing passwords from a generic RDBMS, a direct attribute mapping still needs to be used, though the `from-attribute` should be whatever attribute is used to store the password in the RDBMS. In the following example, `dbPassword` is used for the password on the RDBMS. Passwords in the RDBMS cannot be encrypted and should be hashed with a scheme that PingDirectory Server recognizes.

```
dsconfig create-attribute-mapping \
--map-name Generic_RDBMS_to_PingOne_User_Map \
--mapping-name password \
--type direct \
--set from-attribute:dbPassword
```

PingDataSync Server cannot synchronize passwords between PingOne systems, as PingDataSync Server cannot retrieve the password from PingOne.

Using PingDirectory Server or PingDirectoryProxy Server with PingFederate OAuth Tokens

About this task

After a PingFederate server has been set up so OAuth 2 tokens can be obtained from the server, some configuration is still needed so that these tokens to be used with SCIM 2 operations on PingDirectory Server or PingDirectoryProxy Server. This section explains how to set up an access token validator, which is the configuration object that handles this task.

The following information is needed:

- The runtime engine service port of the PingFederate server (generally 9031)
- The client id of an OAuth 2 client configured on the PingFederate server
- The client secret of the previously-mentioned OAuth 2 client
- The IP address of the PingFederate server

Steps

1. In order to create the access token validator, the PingFederate server needs to be registered. This can be done with the following command. Note that the hostname verification method is set to allow-all and the Blind Trust manager provider is used for the sake of simplicity; these settings should not be used for production environments.

```
dsconfig create-external-server \
  --server-name PingFederateInstance \
  --type http \
  --set base-url:https://<PingFed IP address>:<PingFed port> \
  --set hostname-verification-method:allow-all \
  --set "trust-manager-provider:Blind Trust"
```

2. Create the access token validator using the following command. Note that the client-id and client-secret values should be taken from the PingFederate OAuth 2 client that will be used with the PingDirectory Server or PingDirectoryProxy Server.

```
dsconfig create-access-token-validator \
  --validator-name PingFederateValidator \
  --type ping-federate \
  --set enabled:true \
  --set authorization-server:PingFederateInstance \
  --set client-id:<client-id> \
  --set client-secret:<client-secret>
```

3. Add the access token validator to the SCIM 2 HTTP Servlet configuration with the following command:

```
dsconfig set-http-servlet-extension-prop \
  --extension-name SCIM2 \
  --set access-token-validator:PingFederateValidator
```

4. This setup can be tested using the ServiceProviderConfig endpoint, which does not require any scopes to access, just a valid bearer token. A GET request to `/scim/v2/ServiceProviderConfig` should return a response similar to the following:

```
{
  "schemas": [
    "urn:ietf:params:scim:schemas:core:2.0:ServiceProviderConfig"
  ],
  "patch": {
    "supported": true
  },
}
```

```

    "bulk": {
      "supported": false,
      "maxOperations": 0,
      "maxPayloadSize": 0
    },
    "filter": {
      "supported": true,
      "maxResults": 0
    },
    "changePassword": {
      "supported": true
    },
    "sort": {
      "supported": false
    },
    "etag": {
      "supported": false
    },
    "authenticationSchemes": [
      {
        "name": "OAuth 2.0 Bearer Token",
        "description": "The OAuth 2.0 Bearer Token Authentication
        scheme. OAuth enables clients to access protected resources by obtaining
        an access token, which is defined in RFC 6750 as \"a string representing
        an access authorization issued to the client\", rather than using the
        resource owner's credentials directly.",
        "specUri": "http://tools.ietf.org/html/rfc6750",
        "type": "oauthbearertoken",
        "primary": true
      }
    ],
    "meta": {
      "resourceType": "ServiceProviderConfig",
      "location": "https://localhost:8443/scim/v2/ServiceProviderConfig"
    }
  }
}

```

About Recurring Tasks and Task Chains

For regular maintenance items that need to be done on the PingDirectory Server, you can create recurring tasks and task chains with the `dsconfig create-recurring-task` command. These tasks can perform regular backups, LDIF exports, enter and exit lockdown mode, or other static operations. Because this process is owned by the server, tasks do not require special privileges or credentials, and they can be run when the server is offline.

You create tasks and then add them to a recurring task chain for scheduling. The task chain ensures that invocations of a task or set of tasks run in a specified order and do not overlap.

A recurring task includes:

- The task-specific object classes to include in the task entry.
- The task-specific attributes to include in the task entry, if any.
- Whether to alert on task start, success, and/or failure.
- Any addresses to email on task start, success, and/or failure.
- Whether to cancel an instance of the task if it is dependent upon another task, and that task does not complete successfully.

After you create a task, add one or more tasks to and schedule them with a task chain using the `dsconfig create-recurring-task-chain` command.

A recurring task chain includes:

- An ordered list of the tasks to invoke.

- The months, days, times, and time zones in which each task can be scheduled to start.
- The behavior to exhibit if any of the tasks are interrupted by a server shutdown.
- The behavior to exhibit if the server is offline when the start time occurs.

Note:

Changing the schedule for an existing recurring task chain only takes effect the next time that an instance of the chain needs to be scheduled. It does not affect any existing instances of the chain that are already scheduled. That existing instance still runs at the originally scheduled time; when that run is complete, the server schedules the next iteration according to the then-current schedule logic.

Also, you cannot simply cancel the existing instance to get the next instance to run ten minutes earlier. When you cancel an iteration of a recurring task chain, the server automatically schedules the next instance for the earliest time that matches the scheduling criteria that is later than the one that was just canceled. It will never schedule a new instance for earlier than or the same time as one that you manually canceled.

LDIF Export as a Recurring Task

For new installations, LDIF exports occur by default every day at 1:05 a.m. (in the JVM's default time zone, which is generally the time zone configured for the underlying system). At this time, the server will export the contents of each non-administrative backend to a file in the server root "ldif" directory. The LDIF exports are compressed and encrypted, if the global configuration is set to encrypt LDIF exports by default (which is enabled if encryption is configured during setup). The LDIF exports are rate limited to ten megabytes per second to minimize the impact on server performance, and exports are retained for seven days.

The recurring task chain is created in instances that are updated to this release, but is not enabled by default. LDIF export can export multiple backends in the same recurring task. The `backend-id` property can include multiple backends, or an `exclude-backend-id` property can exclude one or more backends. These optional properties are mutually exclusive, so only one can be provided.

- If the `backend-id` property has one or more values, only the backends with those IDs will be exported.
- If the `exclude-backend-id` property has one or more values, all public backends (all backends containing user-supplied data) except those listed will be exported.
- If neither the `backend-id` property nor the `exclude-backend-id` property supply values, all public backends will be exported.

Lockdown Mode as a Recurring Task

Recurring tasks can be created to place the server in lockdown mode and take the server out of lockdown mode. These tasks are useful for scheduling other tasks while the server is mostly idle and not accepting connections from clients.

While in lockdown mode, the server will report itself as unavailable, and will also reject requests from any user that doesn't have the `lockdown-mode` privilege. The recommended flow for a recurring task chain that uses lockdown mode would be:

1. Enter lockdown mode task.
2. Delay task that waits for the work queue to report that the server is idle.
3. Desired tasks to perform while the server is in lockdown mode.
4. Leave lockdown mode task.

The enter and leave lockdown mode tasks each have one optional property that can be used to supply a description for why that the server is being placed in this mode.

File Retention Recurring Task

A recurring task can be configured to remove files in a specified directory that match a given pattern, excluding files that match count-based, time-based, or space-based retention criteria. If any files are to be removed, the oldest files will be removed before the most recent file.

If the file name pattern includes a "`${timestamp}`" element, the timestamp is used to identify the file's age. If the file name pattern does not include a timestamp, then the file's age is determined by using the file's creation time if that is available, or the last modified time if the creation time is not available. If a file's age cannot be determined, the file is not removed.

If multiple files have the same age, lexicographic ordering is used to differentiate between them. Lexicographic ordering is applicable only for files with no `retain-file-age` property configured, or for files that are older than that age. If multiple files do not share the same age, but that age is younger than the `retain-file-age` value, then those files are retained.

At least one of the `retain-file-count`, `retain-file-age`, or `retain-aggregate-file-size` properties must be specified.

To Create a Recurring Task and Task Chain

About this task

Use `dsconfig` to create one or more tasks and then add them to a task chain for scheduling.

Steps

1. Create a task. The following creates a backup task.

```
$ bin/dsconfig create-recurring-task \
  --task-name backup-1 \
  --type backup \
  --set 'email-on-failure:admin2@company.com' \
  --set 'email-on-failure:admin@company.com' \
  --set compress:true \
  --set encrypt:true \
  --set "retain-previous-full-backup-age:4 w" \
  --set retain-previous-full-backup-count:10
```

2. Create a task chain to schedule and run recurring tasks.

```
$ bin/dsconfig create-recurring-task-chain \
  --chain-name "backup chain" \
  --set recurring-task:backup-1 \
  --set scheduled-date-selection-type:selected-days-of-the-month \
  --set scheduled-day-of-the-month:last-day-of-the-month \
  --set scheduled-time-of-day:02:00
```

Exec Tasks

Exec tasks allow administrators and external users to execute a specified command on the server once or as recurring tasks. The server has a number of restrictions to safeguard the use of these commands and ensure that they cannot be used by unauthorized individuals. The set of commands that can be executed is also limited. One of these restrictions is that the absolute path to the command to execute must be listed in the `<server-root>/config/exec-command-whitelist.txt` file. Other safeguards and requirements include:

- The global configuration must be updated to allow the exec task. The server does not permit it by default. The following configuration change enables this:

```
$ bin/dsconfig set-global-configuration-prop \
  --add allowed-task:com.unboundid.directory.server.tasks.ExecTask
```

- The user scheduling the task must have the **exec-task** privilege. The server does not grant permission to run this task to any user by default, not even root users. The following configuration changes grant the **exec-task** privilege to a single root user, all root users, or a single non-root user:

```
$ bin/dsconfig set-root-dn-user-prop --user-name "{username}" \
  --add privilege:exec-task
```

```
$ bin/dsconfig set-root-dn-prop \
  --add default-root-privilege-name:exec-task
```

```
dn: {userdn}
changetype: modify
add: ds-privilege-name
ds-privilege-name: exec-task
```

The **schedule-exec-task** tool can be used to create an exec task from the command line. For example, the following command can be used to schedule an exec task to run the **verify-index** tool to check the integrity of the **cn** index in the backend that hosts "**dc=example,dc=com**", assuming that the server is installed in **/ds**:

```
$ bin/schedule-exec-task --hostname directory.example.com \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --promptForBindPassword \
  --waitForCompletion \
  --logCommandOutput \
  /ds/bin/verify-index --baseDN dc=example,dc=com --index cn
```

Topology Configuration

Topology configuration enables grouping servers and mirroring configuration changes automatically. It uses a master/slave architecture for mirroring shared data across the topology. All writes and updates are forwarded to the master, which forwards them to all other servers. Reads can be served by any server in the group. Servers can be added to an existing topology at installation.

 **Note:** To remove a server from the topology, it must be uninstalled with the **uninstall** tool.

Topology Master Requirements and Selection

A topology master server receives any configuration change from other servers in the topology, verifies the change, then makes the change available to all connected servers. The master always sends a digest of its subtree contents on each update. If the node has a different digest than the master, it knows it's not synchronized. The servers will pull the entire subtree from the master if they detect that they are not synchronized. A server may detect it is not synchronized with the master under the following conditions:

- At the end of its periodic polling interval, if a server's subtree digest differs from that of its master, then it knows it's not synchronized.
- If one or more servers have been added to or removed from the topology, the servers will not be synchronized.

The master of the topology is selected by prioritizing servers by minimum supported product version, most available, newest server version, earliest start time, and startup UUID (a smaller UUID is preferred).

After determining a master, the topology data is reviewed from all available servers (every five seconds by default) to determine if any new information makes a server better suited to being the master. If a new server can be the master, it will communicate that to the other servers, if no other server has advertised that it should be the master. This ensures that all servers accept the same master at approximately the

same time (within a few milliseconds of each other). If there is no better master, the initial master maintains the role.

After the best master has been selected for the given interval, the following conditions are confirmed:

- A majority of servers is reachable from that master. (The master server itself is considered while determining this majority.)
- There is only a single master in the entire topology.

If either of these conditions is not met, the topology is without a master and the peer polling frequency is reduced to 100 milliseconds to find a new master as quickly as possible. If there is no master in the topology for more than one minute, a `mirrored-subtree-manager-no-master-found` alarm is raised. If one of the servers in the topology is forced as master with the `force-as-master-for-mirrored-data` option in the Global Configuration object, a `mirrored-subtree-manager-forced-as-master-warning` warning alarm is raised. If multiple servers have been forced as masters, then a `mirrored-subtree-manager-forced-as-master-error` critical alarm will be raised.

Topology Components

When a server is installed, it can be added to an existing topology, which will clone the server's configuration. Topology settings are designed to operate without additional configuration. If required, some settings can be adjusted to fit the needs of the environment.

Server configuration settings

Configuration settings for the topology are configured in the Global Configuration and in the Config File Handler Backend. Though they are topology settings, they are unique to each server and are not mirrored. Settings must be kept the same on all servers.

The Global Configuration object contains a single topology setting, `force-as-master-formirrored-data`. This should be set to true on only one of the servers in the topology, and is used only if a situation occurs where the topology cannot determine a master because a majority of servers is not available. A server with this setting enabled will be assigned the role of master, if no suitable master can be determined.

The Config File Handler Backend defines three topology (`mirrored-subtree`) settings:

- `mirrored-subtree-peer-polling-interval` – Specifies the frequency at which the server polls its topology peers to determine if there are any changes that may warrant a new master selection. A lower value will ensure a faster failover, but it will also cause more traffic among the peers. The default value is five seconds. If no suitable master is found, the polling frequency is adjusted to 100 milliseconds until a new master is selected.
- `mirrored-subtree-entry-update-timeout` – Specifies the maximum length of time to wait for an update operation (add, delete, modify or modify-dn) on an entry to be applied by the master on all of the servers in the topology. The default is 10 seconds. In reality, updates can take up to twice as much time as this timeout value if master selection is in progress at the time the update operation was received.
- `mirrored-subtree-search-timeout` – Specifies the maximum length of time in milliseconds to wait for search operations to complete. The default is 10 seconds.

Topology settings

Topology meta-data is stored under the `cn=topology, cn=config` subtree and cluster data is stored under the `cn=cluster, cn=config` subtree. The only setting that can be changed is the cluster name.

Monitor Data for the Topology

Each server has a monitor that exposes that server's view of the topology in its monitor backend, so that peer servers can periodically read this information to determine if there are changes in the topology. Topology data includes the following:

- The server ID of the current master, if the master is not known.
- The instance name of the current master, or if a master is not set, a description stating why a master is not set.

- A flag indicating if this server thinks that it should be the master.
- A flag indicating if this server is the current master.
- A flag indicating if this server was forced as master.
- The total number of configured peers in the topology group.
- The peers connected to this server.
- The current availability of this server.
- A flag indicating whether or not this server is not synchronized with its master, or another node in the topology if the master is unknown.
- The amount of time in milliseconds where multiple masters were detected by this server.
- The amount of time in milliseconds where no suitable server is found to act as master.
- A SHA-256 digest encoded as a base-64 string for the current subtree contents.

The following metrics are included if this server has processed any operations as master:

- The number of operations processed by this server as master.
- The number of operations processed by this server as master that were successful.
- The number of operations processed by this server as master that failed to validate.
- The number of operations processed by this server as master that failed to apply.
- The average amount of time taken (in milliseconds) by this server to process operations as the master.
- The maximum amount of time taken (in milliseconds) by this server to process an operation as the master.

Servers and Certificates

PingDirectory Server uses the following main types of certificates:

- *Listener certificates* are used to secure communication by way of TLS.
- *Inter-server certificates* are used to authenticate between server instances in a topology.

The following sections describe these certificate types in more detail.

Listener Certificates

When a client initiates TLS negotiation with the server, the server presents a certificate chain to the client, and the certificate at the head of the chain functions as a listener certificate. Because the client decides whether to trust the certificate chain, we recommend that the chain be signed by an issuer whom the client is likely to trust, or that the client can be easily configured to trust.

Although you can create self-signed certificates with long lifespans, a certificate that a certification authority signs is likely to have a relatively short lifespan. Commercial authorities typically issue certificates that are valid for only one or two years, and some authorities use considerably shorter validity windows. For example, the nonprofit Let's Encrypt service, which obtains trusted certificates free of charge as long as you can prove that you control the relevant domains, issues certificates that are valid for up to three months only.

Short certificate lifespans might prove inconvenient for administrators who need to replace them, but they offer some security benefits. In particular, because most clients do not verify whether a certificate has been revoked, a relatively short validity window minimizes the timeframe during which a compromised certificate can be used. If the process for replacing certificates is streamlined or automated, the inconvenience can be kept to a minimum.

Listener certificates are stored in keystores that are referenced by key manager providers, which in turn provide the logic and configuration needed to access the key stores. If a server component like a connection handler requires access to a certificate that it presents to a peer during the TLS-negotiation process, that component must reference the key manager provider that points to the keystore containing the appropriate certificate. If the keystore contains multiple certificates, and if the component that references the keystore includes a property that specifies the certificate's nickname, the certificate with the alias is selected. Otherwise, the server lets the JVM select a certificate, and the one that it chooses might not be well-defined.

The server also provides *trust manager providers*, which determine whether to trust the certificate chains with which it is presented. A trust manager provider can reference a specified truststore file, but other options include the JVM-default truststore, which uses the Java installation's default set of trusted issuers, and the blind trust manager provider, which automatically trusts every certificate chain that is presented to it.

Note: Never use a blind trust manager in a production environment because it leaves the server vulnerable to impersonation and man-in-the-middle attacks. However, a blind trust manager can be convenient in test environments when troubleshooting certain types of problems.

Replacing Listener Certificates

About this task

Certification authorities typically restrict the lifespans of the certificates that they sign. If you use a certification authority to issue listener certificates, you probably need to replace the certificates on a regular basis. This task includes the following steps:

1. Obtain a new certificate chain.
2. Make necessary updates to the key manager provider and the connection handler configurations
3. Update the server instance listener configuration with the new certificate.

Although you can replace certificates manually, the `replace-certificate` tool helps to automate the process. The `replace-certificate` tool is particularly useful because it provides information about multiple listener certificates, at least during the transitional phase that occurs when you install them.

The `replace-certificate` tool offers the following modes of operation:

- Interactive mode – Walks you through the process of obtaining a new certificate and installing it in the server. In addition to the convenience this offers, interactive mode also displays the non-interactive commands that are required to achieve the same result.
- Non-interactive mode – Useful when scripting the process of replacing a certificate.

The `replace-listener-certificate` subcommand handles all of the work that is involved in replacing a listener certificate. Besides the arguments that are required to authenticate to PingDirectory Server, such as `--bindDN` and `--bindPasswordFile`, the `replace-listener-certificate` subcommand also takes arguments that provide the following information:

- Details about the keystore that contains the new certificate.
- Updates that must be made to the key and trust manager providers.
- Whether to signal the HTTP connection handler to reload its certificates after the update is complete.

The following arguments are available:

- `--source-key-store-file {path}` – Path to the JKS or PKCS #12 file that contains the private key entry with the new certificate chain. This argument is required.
- `--source-key-store-password {password}` – Cleartext password that is needed to access the contents of the source keystore.
- `--source-key-store-password-file {path}` – Path to the file that contains the password necessary to access the contents of the source keystore. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database.
- `--source-certificate-alias {alias}` – Password that is required to access the appropriate private key in the source keystore. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the keystore password is used as the private key password.
- `--source-private-key-password-file {path}` – Path to the file that contains the password needed to access the appropriate private key in the source keystore. The file can contain the password in the clear or can be encrypted with a definition from the server's encryption settings database. If neither the `--source-private-key-password` nor the `--source-private-key-password-file` argument is provided, the keystore password is used as the private key password.

- `--key-manager-provider {name}` – Name of the key manager provider that is updated to use the new certificate chain. The value must identify a file-based key manager provider, and it must be enabled. Defaults to JKS if a value is not specified.
- `--trust-manager-provider {name}` – Name of the trust manager provider that is updated with the information required to trust the new certificate chain. The value must identify a file-based trust manager provider, and it must be enabled. If neither this argument nor the `--use-jvm-default-trust-manager-provider` argument is provided, the tool assumes that the name of the trust manager provider is identical to the name of the key manager provider.
- `--use-jvm-default-trust-manager-provider` – Indicates that the server must be configured to use the JVM-default trust manager provider, which trusts certificates signed by issuers in the `cacerts` truststore provided with the JVM, rather than updating an existing trust manager provider.
- `--target-certificate-alias {alias}` – Alias to use for the new certificate in the key manager provider's keystore, as well as for appropriate updates in the trust manager provider's truststore. Defaults to an alias of `server-cert` if a value is not specified.

Note: If the key manager provider's keystore, or the trust manager provider's truststore, already contains an entry with the given alias, the existing entry is renamed.

- `--reload-http-connection-handler-certificates` – Indicates that the tool is requesting that the server cause any HTTPS-based connection handlers to reload their certificates, so that the connection handlers can use the updated certificate.

LDAP connection handlers react to the change immediately, and start presenting the new certificate chain during subsequent TLS negotiations. However, HTTPS connection handlers continue using the former certificate until the connection handler is restarted, or until the connection handler is asked specifically to reload its certificates.

Note: This option might prevent clients with existing TLS sessions that were negotiated with the former certificate from being resumed.

The following example uses Interactive mode to replace the listener certificate chain. The output includes the non-interactive commands that are needed to perform the corresponding operations:

```
$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses for TLS
   communication
2 - Replace the inter-server certificate that the server uses to
   authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
   topology registry
4 - Purge any retired inter-server certificates for this server from the
   topology registry
q - Quit without doing anything

Enter your choice: 1

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

NOTE: 'JKS' is the only key manager provider that is suitable to be
updated with a new listener certificate. Automatically selecting that
```

```
provider
```

Which trust manager provider do you wish to update with information needed to trust the new listener certificate?

- 1 - JKS
- d - Use the JVM-default trust manager provider to trust any certificate signed by an authority in the JVM's default set of trusted issuers

Enter your choice [1]: **1**

How would you like to obtain the new listener certificate?

- 1 - Generate a new self-signed certificate
- 2 - Generate a request for a certificate to be signed by a certification authority
- 3 - Use a certificate in an existing key store
- q - Quit without doing anything

Enter your choice: **2**

Enter the subject DN that you would like to use for the new certificate. The subject DN typically includes some or all of the following components:

- * CN -- The common name for the certificate. This is typically the fully-qualified name (not an IP address) that most clients will use to connect to the server (alternate names and IP addresses may be provided later). We strongly recommend including a CN attribute in the certificate subject
- * OU -- Typically the name of the department or organizational unit that manages the server
- * O -- Typically the name of the company or organization that manages the server
- * L -- Typically the name of the city or locality in which the server is located
- * ST -- Typically the full name (NOT an abbreviation) of the state or province in which the server is located
- * ST -- Typically the two-character ISO 3166 country code for the country in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: **CN=ds1.example.com,O=Example Corp,C=US**

Enter the complete set of resolvable names (not IP addresses) that clients are expected to use to access the server. These names will be included in the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk as a wildcard in the leftmost component that will match any host name in that component. For example, '*.example.com' indicates that the certificate may be used in any server whose fully-qualified name consists of exactly three components, and in which the last two components are 'example.com'

The current set of DNS names to include in the set of subject alternative names is:

- * ds1.example.com

```
* ip6-localhost
* localhost
```

What would you like to do?

- 1 - Use the current set of DNS names
- 2 - Add another DNS name
- 3 - Remove a specific DNS name
- 4 - Clear the current set of DNS names
- 5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: **2**

Enter the new DNS name to include: ds.example.com

The current set of DNS names to include in the set of subject alternative names is:

```
* ds.example.com
* dsl.example.com
* ip6-localhost
* localhost
```

What would you like to do?

- 1 - Use the current set of DNS names
- 2 - Add another DNS name
- 3 - Remove a specific DNS name
- 4 - Clear the current set of DNS names
- 5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: **1**

Enter the complete set of IPv4 and IPv6 addresses that clients are expected to use to access the server. These addresses will be included in the certificate's subject alternative name extension. Wildcards are not allowed

The current set of IP addresses to include in the set of subject alternative names is:

```
* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:feld:811d
```

What would you like to do?

- 1 - Use the current set of IP addresses
- 2 - Add another IP address
- 3 - Remove a specific IP address
- 4 - Clear the current set of IP addresses
- 5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: **1**

Generating a certificate signing request with the following command:

```
manage-certificates \
  generate-certificate-signing-request \

How would you like to import the signed certificate into the key store?

- 1 - I expect to get the signed certificate back right away. Walk me through the process of importing it into the key store
- 2 - I will manually import the signed certificate

Enter your choice [1]: **1**

Enter the path to the file containing the signed certificate (and optionally any necessary issuer certificates): /ca/server-cert.pem

NOTICE: Certificate file '/ca/server-cert.pem' ends with certificate 'CN=dsl.example.com,O=Example Corp,C=US' that was signed by issuer 'CN=Example Intermediate CA,O=Example Corp,C=US', but that issuer certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Intermediate CA,O=Example Corp,C=US' certificate (and optionally its issuer chain): /ca/intermediate-ca-cert.pem

NOTICE: Certificate file '/ca/intermediate-ca-cert.pem' ends with certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' that was signed by issuer 'CN=Example Root CA,O=Example Corp,C=US', but that issuer certificate could not be found in the JVM-default trust store

Enter the path to a file containing the 'CN=Example Root CA,O=Example Corp,C=US' certificate (and optionally its issuer chain): /ca/root-ca-cert.pem

Would you like to request that the server reload any certificates associated with HTTP connection handlers configured with support for HTTPS so that they will start using the new certificate right away? Note that this may prevent clients from resuming TLS sessions created before the reload

- 1 - Yes. Reload the certificates associated with any HTTPS-enabled HTTP connection handlers
- 2 - No. Do not reload the certificates. HTTPS connection handlers will continue to use their current certificates until the server (or at least the connection handler) is restarted, or until the reload-http-connection-handler-certificates tool is run
- q - Quit without doing anything else

Enter your choice [1]: **1**

About to invoke the following command:

```
replace-certificate \
  replace-listener-certificate \
  --bindDN "cn=Directory Manager" \
  --bindPassword '*****REDACTED*****' \
  --key-manager-provider JKS \
  --trust-manager-provider JKS \
  --source-key-store-file /ds/tmp/replace-certificate-temporary-key-
\
  store-281484917294163222.jks \
  --source-key-store-password-file /ds/config/ads-truststore.pin \
  --source-certificate-alias generated-certificate \
  --reload-http-connection-handler-certificates
```

```

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No. Quit without doing anything else

Enter your choice [1]: 1
Successfully replaced the listener certificate

```

As part of its processing steps, the **replace-certificate** tool updates the server instance listener configuration object to include the new listener certificate. Instead of replacing any certificates that may already reside within the configuration object, the **replace-certificate** tool merges them with the new certificate. To remove earlier certificates from the server instance listener configuration, use the **purge-retired-listener-certificates** subcommand, which does not take arguments other than the ones that are required to authenticate to the server.

The following code provides an example:

```

$ bin/replace-certificate
This tool can be used to replace the listener certificate or the
inter-server certificate for this Directory Server server instance

Which action would you like to perform?

1 - Replace a listener certificate that the server uses for TLS
communication
2 - Replace the inter-server certificate that the server uses to
authenticate to other instances in the topology
3 - Purge any retired listener certificates for this server from the
topology registry
4 - Purge any retired inter-server certificates for this server from the
topology registry
q - Quit without doing anything

Enter your choice: 3

Enter the DN of the account to use to authenticate to the server
[cn=Directory Manager]: cn=Directory Manager
Enter the password for that user: {password}

About to invoke the following command:

    replace-certificate \
      purge-retired-listener-certificates \
      --bindDN "cn=Directory Manager" \
      --bindPassword '*****REDACTED*****'

Do you want to invoke this command?

1 - Yes, run this replace-certificate command
2 - No. Quit without doing anything else

Enter your choice [1]: 1

NOTE: Purging one non-active listener certificate from entry
'cn=ldap-listener-mirrored-config,cn=Server Instance

Listeners,cn=ds1,cn=Server Instances,cn=Topology,cn=config'

```

```
Successfully purged one retired listener certificate
```

Inter-Server Certificates

Each server instance in a topology has an inter-server certificate that is generated during the setup process. Because this certificate is not exposed to clients, a trusted issuer does not need to sign it. Instead, the topology registry, which represents a mirrored portion of the configuration with information about every PingDirectory Server instance in the environment, contains the information that each instance needs to trust the inter-server certificates for all other instances.

Inter-server certificates can also be used to protect certain secrets that are shared among servers within the topology, like the secrets that are used to digitally sign log files, backups, and LDIF exports. Inter-server certificates also include the encryption keys that reversible password-storage schemes use.

The inter-server certificate is generated with a long lifespan. Replace it only when you suspect that its private key is compromised.

Replacing the Inter-Server Certificate

About this task

The inter-server certificate is intended for use only between server instances within the same topology. Because it is not exposed to regular clients, the inter-server certificate does not need to be trusted.

During the installation process, the inter-server certificate is generated with a long lifespan, and therefore does not require replacement under normal circumstances. We discourage replacing the inter-server certificate unless you suspect that its private key is compromised.

To replace the inter-server certificate, use the `replace-certificate replace-inter-server-certificate` command, which performs the following steps:

As when replacing a listener certificate

- Acquires the new inter-server certificate from a provided JKS or PKCS #12 keystore.
- Makes the necessary updates to the appropriate server keystore. In the case of the inter-server certificate, the relevant keystore resides in the `config/ads-truststore` file.
- Updates the server instance configuration object to include the new inter-server certificate.

To avoid the need to replace the inter-server certificate on a regular basis, we recommend that you use a self-signed certificate with a long lifespan. Each server instance must possess its own, unique inter-server certificate that satisfies the following conditions:

- Uses an RSA key pair
- Has a minimum key size of 2048 bits

The following types of certificates are not allowed:

- Certificates with an elliptic curve key pair
- Certificates with an RSA key that is smaller than 2048 bits

The `replace-inter-server-certificate` subcommand takes a subset of the arguments that are used with the `replace-listener-certificate` subcommand, including the following arguments:

- `--source-key-store-file {path}--source-key-store-password {password}`
- `--source-key-store-password-file {path}`
- `--source-certificate-alias {alias}`
- `--source-private-key-password {password}`
- `--source-private-key-password-file {path}`

The following example replaces the inter-server certificate in interactive mode, and includes the non-interactive command that achieves the same result:

\$ bin/replace-certificate

This tool can be used to replace the listener certificate or the inter-server certificate for this Directory Server server instance

Which action would you like to perform?

- 1 - Replace a listener certificate that the server uses for TLS communication
- 2 - Replace the inter-server certificate that the server uses to authenticate to other instances in the topology
- 3 - Purge any retired listener certificates for this server from the topology registry
- 4 - Purge any retired inter-server certificates for this server from the topology registry
- q - Quit without doing anything

Enter your choice: **2**

WARNING: The inter-server certificate is used only for the purpose of authenticating this server instance to other servers in the topology, and to encrypt some legacy secrets. It is NOT used to encrypt communication (listener certificates are used for that purpose), and the trust mechanism that we use for authenticating inter-server certificates is stronger when using self-signed certificates than when using certificates signed by a publicly trusted authority

We strongly discourage replacing the inter-server certificate unless you believe that the key has been compromised. Any errors in the process of replacing the certificate could render the server unable to authenticate to other instances in the topology, and may interfere with replication or other forms of inter-server communication, and also the server's ability to perform certain types of encryption and digital signing

Are you sure you want to replace the inter-server certificate?

- 1 - No. Do not replace the inter-server certificate
- 2 - Yes. Proceed with replacing the inter-server certificate

Enter your choice [1]: **2**

Enter the DN of the account to use to authenticate to the server

[cn=Directory Manager]: cn=Directory Manager

Enter the password for that user: **{password}**

How would you like to obtain the new inter-server certificate?

- 1 - Generate a new self-signed certificate
- 2 - Generate a request for a certificate to be signed by a certification authority
- 3 - Use a certificate in an existing key store. Note that each server instance must have a unique inter-server certificate, and we do not recommend using the same certificate as both a listener certificate and an inter-server certificate

q - Quit without doing anything

Enter your choice: **1**

Enter the subject DN that you would like to use for the new certificate. The subject DN typically includes some or all of the following components:

- * CN -- The common name for the certificate. This is typically the fully-qualified name (not an IP address) that most clients will use to connect to the server (alternate names and IP addresses may be provided later). We strongly recommend including a CN attribute in the certificate subject
- * OU -- Typically the name of the department or organizational unit that manages the server
- * O -- Typically the name of the company or organization that manages the server
- * L -- Typically the name of the city or locality in which the server is located
- * ST -- Typically the full name (NOT an abbreviation) of the state or province in which the server is located
- * ST -- Typically the two-character ISO 3166 country code for the country in which the server is located

For example, a subject DN might look like 'CN=ds.example.com,OU=Directory Services,O=Example Corp,L=Austin,ST=Texas,C=US'

Enter the desired subject DN: **CN=ds1,O=Example Corp,C=US**

Enter the complete set of resolvable names (not IP addresses) that clients are expected to use to access the server. These names will be included in the certificate's subject alternative name extension

Specific host names are generally preferable, but you may use an asterisk as a wildcard in the leftmost component that will match any host name in that component. For example, '*.example.com' indicates that the certificate may be used in any server whose fully-qualified name consists of exactly three components, and in which the last two components are 'example.com'

The current set of DNS names to include in the set of subject alternative names is:

- * ds1.example.com
- * ip6-localhost
- * localhost

What would you like to do?

- 1 - Use the current set of DNS names
- 2 - Add another DNS name
- 3 - Remove a specific DNS name
- 4 - Clear the current set of DNS names
- 5 - Do not include any subject alternative DNS names in the certificate

Enter your choice [1]: **1**

Enter the complete set of IPv4 and IPv6 addresses that clients are expected to use to access the server. These addresses will be included in the certificate's subject alternative name extension. Wildcards are not allowed

The current set of IP addresses to include in the set of subject alternative names is:

```
* 0:0:0:0:0:0:0:1
* 10.5.1.133
* 10.5.3.99
* 127.0.0.1
* 127.0.1.1
* 172.30.12.185
* fe80:0:0:0:3957:af69:bd92:6c73
* fe80:0:0:0:ace8:231f:e348:db8d
* fe80:0:0:0:fc94:6eff:fe1d:811d
```

What would you like to do?

- 1 - Use the current set of IP addresses
- 2 - Add another IP address
- 3 - Remove a specific IP address
- 4 - Clear the current set of IP addresses
- 5 - Do not include any subject alternative IP addresses in the certificate

Enter your choice [1]: **1**

Generating a self-signed certificate with the following command:

```
manage-certificates \
generate-self-signed-certificate \
--keystore /ds/tmp/replace-certificate-temporary-key-store- \
12068302381295037387.jks \
--keystore-password-file '*****REDACTED*****' \
--keystore-type JKS \
--alias generated-certificate \
--subject-dn "CN=ds1,O=Example Corp,C=US" \
--validity-start-time 20191111120632 \
--days-valid 7300 \
--key-algorithm RSA \
--key-size-bits 2048 \
--signature-algorithm SHA256withRSA \
--key-usage digitalSignature \
--key-usage keyEncipherment \
--extended-key-usage server-auth \
--extended-key-usage client-auth \
--subject-alternative-name-dns ds1.example.com \
--subject-alternative-name-dns ip6-localhost \
--subject-alternative-name-dns localhost \
--subject-alternative-name-ip-address 0:0:0:0:0:0:0:1 \
--subject-alternative-name-ip-address 10.5.1.133 \
--subject-alternative-name-ip-address 10.5.3.99 \
--subject-alternative-name-ip-address 127.0.0.1 \
--subject-alternative-name-ip-address 127.0.1.1 \
--subject-alternative-name-ip-address 172.30.12.185 \
--subject-alternative-name-ip-address fe80:0:0:0:3957:af69:bd92:6c73 \
--subject-alternative-name-ip-address fe80:0:0:0:ace8:231f:e348:db8d \
--subject-alternative-name-ip-address fe80:0:0:0:fc94:6eff:fe1d:811d
```

Successfully generated the self-signed certificate

About to invoke the following command:

```
replace-certificate \
  replace-inter-server-certificate \
  --bindDN "cn=Directory Manager" \
  --bindPassword '*****REDACTED*****' \
  --source-key-store-file /ds/tmp/replace-certificate-temporary-key-
\
  store-12068302381295037387.jks \
  --source-key-store-password-file /ds/config/ads-truststore.pin \
  --source-certificate-alias generated-certificate
```

Do you want to invoke this command?

- 1 - Yes, run this replace-certificate command
- 2 - No. Quit without doing anything else

Enter your choice [1]: **1**

Successfully replaced the inter-server certificate

The new inter-server certificate is merged with the existing values in the server instance configuration entry. To delete earlier values that are no longer needed, use the **purge-retired-inter-server-certificates** subcommand. The following code provides an example:

```
$ bin/replace-certificate
```

This tool can be used to replace the listener certificate or the inter-server certificate for this Directory Server server instance

Which action would you like to perform?

- 1 - Replace a listener certificate that the server uses for TLS communication
- 2 - Replace the inter-server certificate that the server uses to authenticate to other instances in the topology
- 3 - Purge any retired listener certificates for this server from the topology registry
- 4 - Purge any retired inter-server certificates for this server from the topology registry
- q - Quit without doing anything

Enter your choice: **4**

Enter the DN of the account to use to authenticate to the server

[cn=Directory Manager]: cn=Directory Manager

Enter the password for that user: **{password}**

About to invoke the following command:

```
replace-certificate \
  purge-retired-inter-server-certificates \
  --bindDN "cn=Directory Manager" \
  --bindPassword '*****REDACTED*****'
```

Do you want to invoke this command?

- 1 - Yes, run this replace-certificate command
- 2 - No. Quit without doing anything else

```
Enter your choice [1]: 1
```

```
# Initializing the server's encryption framework...
Successfully purged one retired inter-server certificate from the topology
registry
```

X.509 Certificates

PingDirectory Server supports X.509 certificates, the type that you are most likely to encounter. [RFC 5280](#) describes X.509v3, which provides the current version of the specification.

An X.509v3 certificate includes the following components:

- X.509 encoding version – Enables the differentiation between an X.509v3 certificate and one that conforms to an earlier or future version of the specification.
- Serial number of the certificate – Integer value that uniquely identifies a certificate as issued by a certification authority. Although serial numbers were frequently generated in sequential order in the past, they are now required to be unpredictable with at least 20 bits of entropy.
- Subject DN – Distinguished name for the certificate, which often provides details about the context in which the certificate is to be used. For more information, see XREF to Certificate subject DNs.
- Issuer DN – Distinguished name for the issuer certificate, which is the certificate used to sign the certificate. For a self-signed certificate, this value matches the subject DN.
- Validity window – Indicates the timeframe during which the certificate is considered valid. This component includes the following elements:
 - notBefore – Specifies the earliest time at which the certificate is considered valid.
 - notAfter – Specifies the latest time at which the certificate is considered valid.
- Public key – Public portion of a pair of cryptographically linked keys. For more information, see XREF to Certificate key pairs.
- Signature – Type of cryptographic proof that the certificate truly was sent from the issuer and has remained unaltered. As its name implies, a *self-signed certificate* is signed with its own private key. Otherwise, it is signed with the issuer's private key.

An X.509v3 certificate might also include the following optional components:

- Subject unique ID – Uniquely identifies the certificate. Because this component has been deprecated in favor of the subject key identifier extension, it is generally omitted from X.509v3 certificates.
- Issuer unique ID – Subject unique ID of the issuer certificate, if available. This component has been deprecated in favor of the authority key identifier extension.
- Set of extensions – Provides additional context for the certificate and the manner in which it is used. For more information, see XREF to Certificate extensions.

Certificate Subject DNs

A certificate's subject distinguished name (DN) provides information about the manner in which the certificate is to be used. Like an LDAP DN, a certificate's subject DN consists of a comma-delimited series of attribute-value pairs. Unlike an LDAP DN, however, the attribute names in a certificate subject DN are typically written all in uppercase characters. (Attribute names in an LDAP DN are typically written in lowercase or CamelCase characters.)

A certificate's subject DN is also referred to as its *subject*. The following attributes commonly appear in a certificate subject:

- **CN** – Common name. For a listener certificate, the **CN** attribute typically identifies the host name that clients use to access the certificate, although the subject alternative name extension provides a more highly recommended mechanism for accomplishing the same task. Most certificate subject DNs include at least the **CN** attribute.
- **E** – Email address.

- `OU` – Name of the organizational unit, such as the relevant department.
- `O` – Name of the organization or company.
- `L` – Name of the locality, such as the appropriate city.
- `ST` – Full name of the state or province.
- `C` – ISO 3166 country code.

A certificate subject includes at least one attribute-value pair, and the `CN` attribute is typically present. Other attributes can be omitted, although the `O` and `C` attributes are also common. For example, a listener certificate for a server with an address of `ldap.example.com`, which is run by the US-based company Example Corp, might have a subject of `CN=ldap.example.com,O=Example Corp,C=US`.

Certificate Key Pairs

Each certificate contains a key pair that consists of two keys that are linked cryptographically. If you encrypt data with one key, the data can be only decrypted with the other key. Although a key pair can be created easily when both keys are generated simultaneously, the process of deriving one key from the other is extremely difficult. (In cryptographic terms, the process is computationally infeasible).

When generating a key pair, one key is designated as the *public key*, and the other key is designated the *private key*. The public key can be made widely available, but the private key must be kept secret and not shared with anyone. As long as the secrecy of the private key is maintained, the key pair can be used to perform the following functions:

- Encryption – If someone wants to send you a secret message without anyone else viewing it, the message can be encrypted with your public key. Because you alone possess the private key, only you can decrypt the message.

Encryption is also referred to as *confidentiality*.

- Digital signatures – If you encrypt data with your private key, it can be decrypted only with your public key. Because your public key can be made widely available, this encryption method does not actually protect the content. However, digital signatures prove that a message came from you because only your private key could have generated it.

Note:

When generating a digital signature, the entire message is generally not encrypted. Instead, only a hash of the message is encrypted, typically by using a digest algorithm like SHA-256.

This approach protects the integrity of a message. A decrypted signature that matches the digest of the original message guarantees that, not only did the message come from you, but it has remained unaltered since you signed it.

The following public key algorithms are used primarily in certificates that facilitate TLS communication:

- RSA – Based on the multiplication of large prime numbers.
- EC – Based on computations that involve special types of elliptical curves.

Although RSA is supported more widely than EC, it is slower and requires larger keys to achieve the same level of security. To support legacy clients, we recommend that you use an RSA certificate and choose a key size of at least 2,048 bits.

If all your clients support EC certificates, we recommend that you use an EC certificate with a key size of at least 256 bits.

Certificate Extensions

Extensions provide additional context for a certificate. The following examples represent some of the more common extension types:

- Subject key identifier – Holds a unique identifier for the certificate, which is generally derived from the certificate's public key.

- Authority key identifier – Holds the subject key identifier for the issuer certificate. This extension type helps to identify the issuer certificate, especially when presented with an incomplete certificate chain.
- Subject alternative name – Holds a list of ways that clients are expected to reference a server when establishing a connection to it.

Note: Clients must take this information into account when deciding whether to trust a server's certificate.

The most common types of values include DNS names, IP addresses, and URIs. DNS names must be fully qualified, but can optionally use an asterisk in the leftmost component to match any single name in that component. For example, `*.example.com` could match `www.example.com` or `ldap.example.com`, but would not match `ldap.east.example.com` or `example.com`.

- Key usage – Provides information about the manner in which the certificate is expected to be used. The following key usages are allowed:
 - `digitalSignature` – Indicates that the certificate can be used for digitally signing data, excluding certificates and CRLs.
 - `nonRepudiation` – Indicates that the certificate can be used to prevent denying the authenticity of a message. `nonRepudiation` is also known as `contentCommitment`.
 - `keyEncipherment` – Indicates that the certificate can be used to protect encryption keys, such as symmetric keys that are derived during TLS key agreement.
 - `dataEncipherment` – Indicates that the certificate can be used for encrypting data directly.
 - `keyAgreement` – Indicates that the certificate's public key can be used for key agreement, such as deriving the symmetric key that protects TLS communication.
 - `keyCertSign` – Indicates that the certificate can act as a certification authority and be used for signing other certificates.
 - `cRLSign` – Indicates that the certificate can be used to sign certificate revocation lists (CRLs).
 - `encipherOnly` – When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for encrypting data during key agreement.
 - `decipherOnly` – When used in conjunction with `keyEncipherment`, indicates that the public key can be used only for decrypting data during key agreement.
- Extended key usage – Acts as an alternative to the key usage extension and provides additional high-level functionality. The following extended key usages are allowed:
 - `serverAuth` – Indicates that the server can present the certificate to the client during TLS negotiation.
 - `clientAuth` – Indicates that the client can present the certificate to the server during TLS negotiation.
 - `codeSigning` – Indicates that the certificate can be used to sign source and compiled code.
 - `emailProtection` – Indicates that the certificate can be used to sign or encrypt email messages.
 - `timeStamping` – Indicates that the certificate can be used to assert the time that an event occurred.
 - `ocspSigning` – Indicates that the certificate can be used to sign an online certificate status protocol (OCSP) response.
- Basic constraints – Indicates whether the certificate can act as a certification authority and, if so, the maximum number of intermediate certificates that can appear beneath it in a certificate chain.

Certificate Chains

A *certificate chain* is an ordered list of one or more certificates. In such a chain, each subsequent certificate is the issuer of the previous certificate. During TLS negotiation, the server presents a certificate chain to the client, which determines whether to trust the chain and continue with the negotiation. The client can also present its own certificate chain to the server.

If a certificate is self-signed, its chain contains only that single certificate. If a certificate is signed by a self-signed certification authority certificate, such as a root CA, the chain contains two certificates: the server

certificate and the CA certificate that follows it. If a single intermediate CA (a CA certificate that is signed by a root CA) is present, the chain contains the server certificate, followed by the intermediate CA, and finally the root CA.

Intermediate certification authorities are useful for security purposes, especially in commercial authorities. If a client trusts a root CA certificate, it is likely to trust anything with that root CA certificate at the base of its chain. Consequently, the root CA certificate must be kept secure.

Note: If the root CA certificate is compromised, any certificate that is directly or indirectly signed by it can no longer be trusted.

With intermediate CA certificates, the root certificate can be kept offline in secure storage and used only when a new intermediate CA certificate must be signed. The intermediate CA certificates can be used to sign end-entity certificates, but must be protected to avoid compromising even one of the certificates. A compromised certificate must be revoked, along with all of the certificates that it signed. In such a scenario, the root CA can be used to sign a new certificate.

Note: The certificate chain that the server presents to the client, or that the client presents to the server, during TLS negotiation does not necessarily need to be the complete chain. If the root CA at the end of the chain is widely trusted, the server can assume that the client already has that root CA in its default set of trusted certificates, and can leave it off the chain with the assumption that the client will retrieve it from its default trust store. While the same assumption could theoretically be true for intermediate CA certificates, only the root CA certificate is commonly omitted. Upon receiving such an incomplete chain, the client looks in its default trust store to determine whether it contains the issuer certificate, which it can identify by using properties like the issuer DN or an authority key identifier extension.

The certificate at the head of a certificate chain, which appears as the first one in the list, is often called the *end-entity certificate*. If this certificate appears at the head of the chain that a server presents during TLS negotiation, it is also referred to as the *server certificate*. If the certificate appears at the head of a chain that a client presents, it is also referred to as a *client certificate*. The certificate at the end of a complete chain must be a root CA certificate. In the case of a self-signed certificate, the chain contains only a single certificate that serves both roles.

Representing Certificates, Private Keys, and Certificate Signing Requests

X.509 is an encoding format that uses the ASN.1 distinguished encoding rules (DER), which exist in binary format. When writing a certificate to a file, either a raw DER format or a plaintext format called *PEM* can be used. PEM encoding consists of a line that contains the text `-----BEGIN CERTIFICATE-----`, followed by a set of lines that contains the base64-encoded representation of the raw DER bytes (typically with no more than 64 characters per line), followed by a line that contains the text `-----END CERTIFICATE-----`.

The X.509 encoding contains a certificate's public key, but not its private key. The PKCS #8 specification in [RFC 5958](#) describes the encoding for private keys. This approach also uses a DER encoding with a PEM variant that uses `-----BEGIN PRIVATE KEY-----` and `-----END PRIVATE KEY-----` rather than `-----BEGIN CERTIFICATE-----` and `-----END CERTIFICATE-----`. RFC 5958 also describes an encrypted representation of the private key, but that format is currently unsupported.

The PKCS #10 specification in [RFC 2986](#) describes the certificate signing request (CSR) format. This format also uses a DER encoding with a PEM variant that uses a header of `-----BEGIN CERTIFICATE REQUEST-----` and a footer of `-----END CERTIFICATE REQUEST-----`.

Note: Some implementations use the alternate, nonstandard forms `-----BEGIN NEW CERTIFICATE REQUEST-----` and `-----END NEW CERTIFICATE REQUEST-----`.

Certificate Trust

When a server presents its certificate chain to a client during TLS negotiation, the client decides whether to trust the certificate chain, and concludes whether it is communicating with a legitimate server instead of an impostor.

If a client is tricked through DNS hijacking into communicating with a rogue application instead of with a legitimate server, the application can steal the client's credentials, or can fool the client into concluding that it has performed an action that, in reality, it has not performed. If a rogue application acts as a broker between the client and the legitimate server, the client might be unable to detect the trickery, and the malicious application might be capable of stealing data or altering the communication. Consequently, we recommend that you avoid "trust all" or "blind trust" options in a production environment.

When determining whether to trust a server certificate chain, a client performs the following steps:

1. Verifies that it has received the complete certificate chain.

If a server presents an incomplete chain, the client must ensure that it can complete the chain with information in an explicitly provided trust store or default trust store. If the client cannot complete the certificate chain, the chain is not trusted.

2. Verifies that each subsequent certificate in the chain is the issuer certificate for, and that its private key was used to sign, the certificate that precedes it.

If a certificate chain contains extraneous certificates, or if a subsequent certificate did not issue the certificate that precedes it, the chain is not trusted.

3. Confirms that it has a reason to trust the certificate at the root of the chain.

This step is generally performed by ensuring that the root CA certificate can be found in either a default trust store or a trust store that is configured for use by the client. If the client has no prior knowledge of the root CA certificate, the chain is not trusted.

4. Verifies that the current time lies within the validity window for each certificate in the chain.

The chain is not trusted under the following conditions:

- When the `notBefore` value of any certificate in the chain is later than the current time.
- When the `notAfter` value of any certificate in the chain is earlier than the current time.

5. Verifies that the server certificate (at the head of the chain) is suitable for the server with which the client thinks it is communicating.

The client must verify that the address used to connect to the server matches one of the following values:

- The CN attribute of the certificate's subject.
- One of the values of any subject alternative name extension.

These steps represent a starting point. If necessary, the client can perform additional types of validation. For example, if a root or intermediate certification authority maintains a certificate revocation list (CRL) or supports the online certificate status protocol (OCSP), the client must verify that none of the certificates in the chain has been revoked. The client can also verify that the CA certificates include the basic constraints extension, and that the server certificate does not contain too many levels. Other checks, like those that use certificate policy extensions, can also be performed.

Keystores and Truststores

A *keystore* is a type of database that holds certificates. The following examples represent the most common forms of keystores:

- File that uses the Java-specific Java KeyStore (JKS) format.
- File that uses the standard PKCS #12 format.
- Collection of files that holds certificates and private keys, typically in PEM or DER format.
- Hardware security module (HSM) that makes the certificate information available through an interface like PKCS #11.

PingDirectory Server supports file-based keystores by using the JKS and PKCS #12 formats, and by using hardware security modules that are accessible through PKCS #11. The server does not currently support a keystore format that consists of individual certificate and private key files. To import these files into a JKS or PKCS #12 keystore, use the `manage-certificates` tool.

A keystore also represents a collection of entries, each of which is identified by a name that an alias calls. Keystores can have the following entry types:

- *Private key entries* contain a certificate chain and a private key. When a server accepts a TLS-based connection, it uses a private key entry to obtain the certificate chain that it presents to the client. The server can also use the private key from the same entry to process its key agreement. Similarly, a client uses a private key entry when presenting its own certificate chain to a server.
- *Trusted certificate entries* contain a single certificate without a private key. As the name implies, a trusted certificate entry is intended primarily for use when determining whether to trust a certificate chain that is presented during TLS negotiation.
- *Secret key entries* contain a secret key only, without an associated certificate. These types of entries are not used for TLS processing. Instead, they hold symmetric encryption keys or other types of secrets.

A password, which is sometimes called a *PIN*, protects the contents of a keystore. In some cases, like with JKS keystores, some content might be accessible without a password, and a password might be required only when trying to access private keys or secret keys. In other cases, like with PKCS #12 keystores, you might need a password for any interaction with the keystore.

Additional passwords can further protect private keys. This approach is often the same as with the keystore password, but the password can be different. This tactic is useful when a single keystore is shared for multiple purposes, for example, and when merely having access to the keystore does not guarantee access to all of the data that it contains.

Note: A *truststore* is another name for a keystore that is intended primarily for use when determining whether to trust a certificate chain that has been presented. Truststores generally contain primarily trusted certificate entries, but that case is not required.

Java runtime environments typically include a default truststore, often `jre/lib/security/cacerts` or `lib/security/cacerts`, that is prepopulated with several widely trusted certification authority certificates. When presented with a certificate that one of these authorities has signed, the default truststore can allow the certificate to be trusted without any additional configuration. When presented with a self-signed certificate, or when presented with a certificate that is signed by an issuer not in the default truststore (such as a private corporate certification authority), a separate truststore is required.

Transport Layer Security

The phrase *transport layer security* (TLS) describes a mechanism for securely communicating between two parties that might have no prior knowledge of each other. TLS is the successor to *secure sockets layer* (SSL), and the two terms are often used interchangeably, even though such usage might not technically be correct.

Note: *SSL* remains the more widely recognized term. The abbreviation *TLS* occasionally generates confusion with the StartTLS extended operation, particularly in LDAP. For more information, see XREF to StartTLS.

TLS provides security in the form of the following main components:

- *Certificate trust* is about reassuring a connection-initiating client that it is communicating with the server to which it intended to connect. To ensure that the server shares the same degree of confidence in the identity and legitimacy of the client, it can ask the client to present its own certificate chain. For more information, see XREF to earlier section about Certificate Trust.

- *Cipher selection* involves choosing the cipher and the key to protect the bulk of the communication. Although a client can use a server certificate's public key to encrypt data before sending it, this approach can lead to the following issues:
 - Unless the client presents its own certificate chain to the server, the server cannot encrypt the data that it sends back to the client.
 - Public key encryption is considerably slower than symmetric encryption, in which the same key is used for both encryption and decryption. Public key encryption is also called *asymmetric encryption* because different keys are used to encrypt and decrypt data.
 - If you rely entirely on the security of a private key to ensure the secrecy of a communication, and if the private key becomes compromised, data that has been encrypted with the private key must also be considered compromised.

Rather than rely solely on public key encryption to protect communication between a client and server, the TLS negotiation process allows a client and server to agree on the type of encryption and the secret key that they will use after completing the negotiation process.

TLS Handshakes

The process of negotiating the TLS is referred to as the *handshake*. Although the exact process depends on the TLS version that is ultimately chosen, the following steps represent the basic components of a TLSv1.2 handshake:

1. The client sends a `hello` message that provides the server with the following information:
 - Highest supported version of the TLS protocol.
 - The cipher suites that the client uses.
 - Set of extensions with additional information, like the address that the client uses to communicate with the server, the signature algorithms and elliptic curves that the client supports, and whether the client supports secure renegotiation.
2. The server returns a `server hello` message that provides the client with the following information:
 - TLS protocol version that the server uses.
 - The cipher suite that the server selects.

The server can also provide its own extensions to the client.
3. The server sends a `certificate` message that provides its certificate chain to the client.
4. The server can optionally send a `server key exchange` message with additional information that the client might need to securely derive the same symmetric encryption key that the server generates.
5. The server can optionally send a `certificate request` message that asks the client to present its own certificate chain to the server.
6. The server sends a `server hello done` message to inform the client that it has completed its `hello` sequence.
7. The client can optionally send a `certificate` message to the server with its own certificate chain.

 **Note:**

The client sends a `certificate` message only when the server initially sends a certificate request. If the client receives such a request, it can refuse to, and probably will not, send a certificate chain.

The server decides whether to require a client certificate chain. In LDAP, the server commonly asks the client to present a certificate, but continues with TLS negotiation even if the client does not present one. This approach supports authentication methods like SASL EXTERNAL, in which a client uses the certificate chain that it presents during TLS negotiation as proof of its identity.

8. The client derives a symmetric key to use for the remainder of the encrypted processing, and sends a `client key exchange` message to the server.

The `client key exchange` message includes the information that the server needs to generate the same key. Only the client and server know the value of the key, even if another entity can observe the communication that passes between the client and the server.

9. If the client presents a certificate chain to the server, it also sends a `certificate verify` message to prove that the private key for the certificate is included at the head of the chain.
10. The client sends a `change cipher spec` message to the server, which informs the server that the client will use the agreed-upon symmetric key to encrypt everything else that it sends to the server.
11. The client sends a `finished` message to the server to indicate that it has completed its portion of the handshake.
12. The server sends a `change cipher spec` message to the client, which informs the client that the server will use the agreed-upon symmetric key to encrypt everything else that it sends to the client.
13. The server sends a `finished` message to the client to indicate that it has completed its portion of the handshake.

TLS version 1.3 uses a different handshake sequence that can require only a single round-trip to exchange the necessary information between the client and the server. (TLS version 1.2 requires two round-trips.) To accomplish this task, TLS version 1.3 tries to guess the type of key agreement that the server wants to use, and sends the relevant information to the server up front instead of waiting to hear from the server.

Because an extra round of communication between the client and server is eliminated, the server finishes its portion of the negotiation before the client. As a result, the server must assume that the client trusts its certificate chain. Because the server might log a successful negotiation only to discover late, through a TLS alert, that the client rejected the certificate, this approach might complicate certain types of troubleshooting.

Key Agreement

Key agreement processing provides a critical component of TLS negotiation. It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

- RSA key exchange – The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.
- Diffie-Hellman (DH) key exchange – The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, we recommend that you use ECHDE over DHE, and either of those options over RSA. The Diffie-Hellman algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. However, the use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

Key Agreement

Key agreement processing provides a critical component of TLS negotiation. It allows the client and server to select the symmetric key that encrypts the remainder of the communication, but does not reveal the key to anyone who can access the communication. Although several key agreement algorithms are available, the following types are the most common:

- RSA key exchange – The client generates random data, uses the server's public key to encrypt it, and provides it to the server, which uses its private key to decrypt it. The client and server alike derive the encryption key from the randomly generated data.
- Diffie-Hellman (DH) key exchange – The client and server agree publicly on a pair of mathematically linked numbers, and each participant chooses its own secret value. Through a special computation, they generate a key that can be discovered only by someone who knows one of the secret values. Although several variants of the Diffie-Hellman algorithm can be used in key exchange, we recommend the ECHDE and DHE versions because they use ephemeral keys with no relation to the server's certificate. Of those two versions, ECDHE is faster and uses smaller keys.

When possible, we recommend that you use ECHDE over DHE, and either of those options over RSA. The Diffie-Hellman algorithms provide a substantial benefit over RSA in the form of forward secrecy. Because RSA key exchange uses the server certificate's public key to encrypt data, the encryption can be broken if the certificate's private key is compromised. This warning applies to previously captured data as well as to communication on new TLS connections. However, the use of ephemeral keys in ECDHE and DHE ensures that, even if the certificate's private key is compromised, the encrypted communication remains indecipherable to anyone but the client and server, although anyone with the private key can still impersonate the legitimate server.

LDAP StartTLS Extended Operation

In most scenarios, a client that uses TLS establishes a connection to a port that is dedicated to its use, like 636 (LDAPS) or 443 (HTTPS). The client then begins the TLS-negotiation process by sending a `client hello` message over the connection. In some scenarios, however, the client establishes a non-secure connection and later converts it to a secure one. In LDAP, this task is accomplished by using the `StartTLS` extended operation.

The `StartTLS` extended operation provides the following advantages over a dedicated LDAPS connection:

- To enable secure as well as insecure communication, only one port needs to be opened through a firewall.
- A client can use *opportunistic encryption*, in which the client performs the following steps:
 - Queries the root DSE to determine whether the server supports StartTLS.
 - Secures the connection, if possible.

Opportunistic encryption is useful in scenarios like following referrals because LDAP URLs do not officially support LDAPS as a scheme.

To make certain that a communication is always secure, we recommend using LDAPS instead of establishing an insecure connection that you secure later with the `StartTLS` extended operation. If you enable support for unencrypted LDAP communication, as `StartTLS` requires, a client might send a password-containing bind request or other sensitive data over an unencrypted connection. A server can be configured to reject unencrypted communication, but it cannot prevent a client from sending an unencrypted request.

 **Note:** Although you can use `StartTLS` to temporarily secure a connection before falling back on an unencrypted LDAP communication, PingDirectory Server does not support this strategy.

About the manage-certificates Tool

PingDirectory Server offers a `manage-certificates` tool that enables interaction with JKS and PKCS #12 key stores. Although it behaves similarly to the `keytool` utility that accompanies most Java distributions, `manage-certificates` is easier to use, provides improved usage information, and offers additional functionality.

Available Subcommands

The `manage-certificates` tool uses the following subcommands to indicate which function to invoke:

- **list-certificates** – Lists the certificates in a keystore.
- **import-certificate** – Imports a certificate into a trusted certificate entry, or imports a certificate chain and private key into a private key entry.
- **export-certificate** – Exports a certificate from a keystore.
- **export-private-key** – Exports a private key from a keystore.
- **generate-self-signed-certificate** – Generates a self-signed certificate.
- **generate-certificate-signing-request** – Generates a certificate-signing request that can be provided to a certification authority.
- **sign-certificate-signing-request** – Signs a certificate-signing request with a specified issuer certificate.
- **check-certificate-usability** – Checks a specified certificate in a keystore to verify whether it is suitable for use as a listener certificate.
- **trust-server-certificate** – Initiates the TLS-negotiation process with a specified server to obtain its certificate chain, so that a truststore can be updated with the necessary information to trust the chain.
- **display-certificate-file** – Displays the contents of a file that contains one or more PEM-encoded or DER-encoded X.509 certificates.
- **display-certificate-signing-request-file** – Displays the contents of a file that contains a PEM-encoded or DER-encoded PKCS #10 certificate-signing request (CSR).
- **change-certificate-alias** – Changes the alias for an entry in a keystore.
- **change-keystore-password** – Changes the password for a keystore.
- **change-private-key-password** – Changes the password that protects the private key for a specified entry in a keystore.

Common Arguments

Most of the **manage-certificates** subcommands require access to a JKS or PKCS #12 keystore. In such instances, use the **--keystore** argument to specify the path to the keystore.

If the keystore already exists, the tool detects automatically whether it is a JKS or PKCS #12 keystore. If the operation creates a new keystore, you can specify the type explicitly by using the **--keystore-type** argument, followed by a value of JKS or PKCS12. If you do not specify the keystore type, a default value of JKS is used.

Some situations require you to provide the password that is needed to access the keystore. For a JKS keystore, you might need to provide a keystore password only for operations that involve creating a keystore or accessing a private key. However, you will likely need to provide the password for all operations that involve a PKCS #12 keystore.

To provide a keystore password, use one of the following arguments:

- **--keystore-password**, followed by the clear-text password for the keystore.
- **--keystore-password-file**, followed by the path to a file that contains the password for the keystore. The file might contain the password in the clear, or it might be encrypted with a definition from the server's encryption-settings database.
- **--prompt-for-keystore-password**. If this argument is provided, the tool prompts you interactively to provide the password.

If a private key is protected with a different password than the keystore itself, specify one of the following arguments to provide the private key password:

- **--private-key-password**, followed by the plaintext password.
- **--private-key-password-file**, followed by the path to a file that contains the clear-text or encrypted password.
- **--prompt-for-private-key-password**, which causes the tool to prompt interactively for the password.

Several operations require you to specify the keystore entry to target. In such scenarios, provide the **--alias** argument, followed by the name of the alias for that entry.

Listing the Certificates in a Keystore

About this task

To list the certificates in a keystore, use the `list-certificates` subcommand. This subcommand requires you to specify the path to the keystore file, and possibly the password that is needed to access the keystore. The following options are also available:

- `--alias {alias}` – Specifies the alias of the certificate to display. If this value is not provided, all certificates are displayed. To list more than one specific certificate, specify this value multiple times.
- `--display-pem-certificate` – Includes a PEM-encoded representation of each certificate as part of the output.
- `--verbose` – Includes details about each certificate.

The following command demonstrates the basic listing of a keystore that contains a single certificate chain:

```
$ bin/manage-certificates list-certificates \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin

Alias: server-cert (Certificate 1 of 2 in a chain)
Subject DN: CN=ds1.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Certification Authority,O=Example Corp,C=US
Validity Start Time: Saturday, November 9, 2019 at 11:26:09 AM CST
                    (8 minutes, 15 seconds ago)
Validity End Time: Sunday, November 8, 2020 at 11:26:09 AM CST
                  (364 days, 23 hours, 51 minutes, 44 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)

Generating Self-Signed Certificates

About this task

Because a *self-signed certificate* claims itself as its own issuer, the process of creating one is straightforward. Although self-signed certificates are convenient for testing environments, clients do not trust them by default. Consequently, we do not recommend using them as listener certificates in production environments.

The **manage-certificates** tool offers a **generate-self-signed-certificate** subcommand that can be used to create a self-signed certificate. In addition to the arguments that provide information about the keystore, certificate alias, and optional private key password, the following arguments are available:

- **--subject-dn {subject}** – Subject DN for the certificate to create. This value is required.

- `--days-valid {number}` – Number of days that the certificate remains valid. Defaults to 365 if no value is specified.
- `--validity-start-time {timestamp}` – Indicates the time at which the certificate begins its validity window. This value is assumed to reflect the local time zone, and must be expressed in the form `YYYYMMDDhhmmss`, where a value of `20190102030405` indicates January 2, 2019, at 3:04:05 AM. Defaults to the current time if no value is specified.
- `--key-algorithm {name}` – Name of the algorithm to use when generating the key pair. For a listener certificate, this value is typically RSA or EC. Defaults to RSA if no value is specified.

 **Note:** This argument cannot be used in conjunction with the `--replace-existing-certificate` argument.

- `--key-size-bits {number}` – Length of the key, in bits, to generate. If the `--key-algorithm` argument is given, then `--key-size-bits {number}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is given, then `--key-size-bits {number}` must not be specified.

Typical key sizes are as follows:

- RSA key – 2048 or 4096 bits. If a default RSA key is used but this argument is not provided, a default key size of 2048 bits is used.
- Elliptic curve key – 256 or 384 bits.
- `--signature-algorithm {name}` – Name of the algorithm to use to sign the certificate. If the `--key-algorithm` argument is used to specify an algorithm other than RSA, then `--signature-algorithm {name}` must also be specified. Conversely, if the `--replace-existing-certificate` argument is used, then `--signature-algorithm {name}` must not be specified.

Typical signature algorithms include `SHA256withRSA` for certificates with RSA keys, and `SHA256withECDSA` for certificates with elliptic curve keys. If a default key algorithm is used but the `--signature-algorithm {name}` argument is not provided, a default value of `SHA256withRSA` is used.

- `--replace-existing-certificate` – Uses the new certificate to replace an existing certificate in the keystore (within the same alias), and reuses the key for that certificate.
- `--inherit-extensions` – Indicates that, when replacing an existing certificate, the new certificate contains the same set of extensions as the existing certificate. If the `--replace-existing-certificate` argument is provided but the `--inherit-extensions` argument is omitted, the new certificate contains only arguments that are provided explicitly.
- `--subject-alternative-name-dns {name}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided DNS name. The given name must be fully qualified, although it can contain an asterisk (*) as a wildcard in the leftmost component. To include multiple DNS names in the subject alternative name extension, specify the `--subject-alternative-name-dns {name}` argument multiple times.
- `--subject-alternative-name-ip-address {address}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided IP address. The given address must be a valid IPv4 or IPv6 address. No wildcards are allowed. To include multiple IP addresses in the subject alternative name extension, specify the `--subject-alternative-name-ip-address {address}` argument multiple times.
- `--subject-alternative-name-email-address {address}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided email address. To include multiple email addresses in the subject alternative name extension, specify the `--subject-alternative-name-email-address {address}` argument multiple times.
- `--subject-alternative-name-uri {uri}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided URI. To include multiple URIs in the subject alternative name extension, specify the `--subject-alternative-name-uri {uri}` argument multiple times.
- `--subject-alternative-name-oid {oid}` – Indicates that the certificate is expected to have a subject alternative name extension with the provided object identifier (OID). The given value must be a valid OID. To include multiple OIDs in the subject alternative name extension, specify the `--subject-alternative-name-oid {oid}` argument multiple times.

- `--basic-constraints-is-ca {value}` – Indicates that the certificate is expected to have a basic constraints extension, with a specified value of true or false, for the flag indicating whether to consider the certificate a certification authority that can be used to sign other certificates.
 - For root and intermediate CA certificates, the `--basic-constraints-is-ca {value}` argument must be present with a value of true.
 - For end-entity certificates, the `--basic-constraints-is-ca {value}` argument can optionally be present with a value of false.
 - For a self-signed certificate, we recommend specifying the `--basic-constraints-is-ca {value}` argument with a value of false to indicate that the certificate is not considered a CA certificate.
- `--basic-constraints-maximum-path-length {number}` – Indicates that the basic constraints extension is expected to include a path length constraint element with the specified value. Use this argument only if `--basic-constraints-is-ca` is provided with a value of true.

A path length constraint value of 0 indicates that the certificate can be used to issue only end-entity certificates. A path length constraint value of 1 indicates that the certificate can be used to sign end-entity certificates or intermediate CA certificates, the latter of which can be used to sign only end-entity certificates. A value greater than 1 indicates the presence of several intermediate CA certificates between it and the end-entity certificate at the head of the chain.

- `--key-usage {value}` – Indicates that the certificate is expected to have a key usage extension with the specified value. The following values are allowed:
 - digital-signature
 - non-repudiation
 - key-encipherment
 - data-encipherment
 - key-agreement
 - key-cert-sign
 - crl-sign
 - encipher-only
 - decipher-only

To include multiple key usages, specify the `--key-usage {value}` argument multiple times.

- `--extended-key-usage {value}`
 - server-auth
 - client-auth
 - code-signing
 - email-protection
 - time-stamping
 - ocsf-signing

To include multiple extended key usages, specify the `--extended-key-usage {value}` argument multiple times.

For example, the following command can be used to generate a self-signed server certificate:

```
bin/manage-certificates generate-self-signed-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
```

```

--subject-alternative-name-dns ds.example.com \
--subject-alternative-name-dns ds1.example.com \
--subject-alternative-name-dns localhost \
--subject-alternative-name-ip-address 1.2.3.4 \
--subject-alternative-name-ip-address 127.0.0.1 \
--subject-alternative-name-ip-address 0:0:0:0:0:0:1 \
--key-usage digital-signature \
--key-usage key-encipherment \
--key-usage key-agreement \
--extended-key-usage server-auth \
--extended-key-usage client-auth

```

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:

Subject DN: CN=ds.example.com,O=Example Corp,C=US

Issuer DN: CN=ds.example.com,O=Example Corp,C=US

Validity Start Time: Monday, January 27, 2020 at 03:40:13 PM CST
(0 seconds ago)

Validity End Time: Tuesday, January 26, 2021 at 03:40:13 PM CST
(364 days, 23 hours, 59 minutes, 59 seconds from now)

Validity State: The certificate is currently within the validity window.

Signature Algorithm: SHA-256 with ECDSA

Public Key Algorithm: EC (secP256r1)

Generating Certificate Signing Requests

About this task

A *certificate signing request* (CSR) contains all of the information that a certification authority requires to issue a certificate. [RFC 2986](#) defines the request format, which is also known as PKCS #10, and includes the following elements:

- Certificate signing request version
- Requested subject DN for the certificate
- Public key for the requested certificate
- Requested set of extensions for the certificate
- Signature that proves the requester has the private key for the given public key

To create a certificate signing request, use the `manage-certificates generate-certificate-signing-request` command, which performs the following steps:

1. Generated a public and private key pair.
2. Stores the key pair in a keystore with a given alias.
3. Outputs the certificate signing request to the terminal.
4. Optionally writes the certificate signing request to a file.

Because a certificate signing request contains many of the same elements as a certificate, the command to generate one takes most of the same arguments as for generating a self-signed certificate. However, the following arguments are unavailable when generating a CSR:

- `--replace-existing-certificate`
- `--days-valid {number}`
- `--validity-start-time {timestamp}`

The following arguments are available when generating a certificate signing request but not when generating a self-signed certificate:

- `--output-file {path}` – Path to a file to which the certificate signing request is written. If this value is not provided, the request is written only to the terminal in PEM form.
- `--output-format {value}` – Format to use when writing the certificate signing request. This value can be PEM or DER, but the DER format is used only in conjunction with the `--output-file` argument. Defaults to PEM if the `--output-format {value}` argument is not provided.
- `--use-existing-key-pair` – Indicates that the certificate signing request uses a key pair that already exists in the keystore with the given alias, rather than generating a new key pair, in which case the specified alias must not already be in use in the keystore.

The following example command creates a certificate signing request:

```
bin/manage-certificates generate-certificate-signing-request \
  --output-file ds1-cert.csr \
  --output-format PEM \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --keystore-type JKS \
  --alias server-cert \
  --subject-dn "CN=ds.example.com,O=Example Corp,C=US" \
  --key-algorithm EC \
  --key-length-bits 256 \
  --signature-algorithm SHA256withECDSA \
  --subject-alternative-name-dns ds.example.com \
  --subject-alternative-name-dns ds1.example.com \
  --subject-alternative-name-dns localhost \
  --subject-alternative-name-ip-address 1.2.3.4 \
  --subject-alternative-name-ip-address 127.0.0.1 \
  --subject-alternative-name-ip-address 0:0:0:0:0:0:1 \
  --key-usage digital-signature \
  --key-usage key-encipherment \
  --key-usage key-agreement \
  --extended-key-usage server-auth \
  --extended-key-usage client-auth
```

```
Successfully created a new JKS keystore.
```

```
Successfully generated the key pair to use for the certificate signing request.
```

```
Successfully wrote the certificate signing request to file '/ds/build/package/PingDirectory/ds1-cert.csr'.
```

If the contents of the resulting certificate signing request file are made available to a certification authority to be signed, the resulting signed certificate can be imported into the keystore. For more information, see XREF.

To print the contents of a certificate signing request file, use the `display-certificate-signing-request-file` subcommand, which supports the following arguments:

- `--certificate-signing-request-file {path}` – Path to the file that contains the certificate signing request to display.
- `--verbose` – Indicates that the command is expected to display verbose information about the request, rather than a basic information set.

The following example demonstrates the basic output from the command:

```
$ bin/manage-certificates display-certificate-signing-request-file \
--certificate-signing-request-file ds1-cert.csr

PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Signature Algorithm: SHA-256 with ECDSA
Public Key Algorithm: EC (secP256r1)
```

The following example demonstrates the verbose output:

```
$ bin/manage-certificates display-certificate-signing-request-file \
--certificate-signing-request-file ds1-cert.csr \
--verbose

Importing Signed and Trusted Certificates

About this task

To import certificates into a keystore, use the `manage-certificates import-certificate` command, which is used to accomplish the following tasks:

- Import a certificate that a certification authority has signed into the keystore in which the key pair was generated. In this scenario, the certificate is imported into a private key entry, and must be imported as a certificate chain rather than an end-entity certificate.
- Import a trusted issuer certificate into a truststore. In this scenario, the certificate is imported into a trusted certificate entry as a single certificate instead of as a chain.
- Import a certificate chain, along with the private key for the end-entity certificate. This approach imports certificates that were generated through another library, like OpenSSL.

In addition to the arguments that provide information about the keystore and the alias into which the certificate or certificate chain is imported, the `manage-certificates import-certificate` command accepts the following arguments:

- `--certificate-file {path}` – Path to the file that contains the certificate to import. The certificate can be in PEM or DER format, and can be a single certificate or a certificate chain. If the certificates in the chain reside in separate files, specify the `--certificate-file {path}` argument multiple times when you import a certificate chain.
- `--private-key-file {path}` – Path to the file containing the private key that corresponds to the certificate at the head of the imported chain. The private key can be in PEM or DER format.
- `--no-prompt` – Indicates that the certificate is to be imported without prompting for confirmation. By default, a summary of the certificate is displayed, and you must confirm that you want to import it.

The following example command imports a signed certificate into the keystore that generates the certificate signing request:

```
$ bin/manage-certificates import-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --certificate-file ds1-cert.pem \
  --certificate-file ca-cert.pem
```

The following certificate chain will be imported into the keystore into alias `'server-cert'`, preserving the existing private key associated with that alias:

```
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST

Do you want to import this certificate chain into the keystore? yes

Successfully imported the certificate chain.

```

If you do not provide the `--no-prompt` argument, the `manage-certificates import-certificate` tool still displays information about the certificates to import. To view additional information about a certificate before you import it, use the `display-certificate-file` subcommand, which supports the following arguments:

- `--certificate-file {path}` – Path to the file that contains the certificate to view.
- `--verbose` – Displays verbose information about the certificate.

The output of the `display-certificate-file` subcommand has the same format and content as the `list-certificates` subcommand.

Exporting Certificates

About this task

Use the `export-certificate` subcommand to export a single certificate or a certificate chain from a keystore to a file in PEM or DER format. The `export-certificate` subcommand supports the normal arguments about the keystore and certificate alias, in addition to the following arguments:

- `--output-file {path}` – Path to the file to which exported certificates are written. If this value is not provided, the certificates are written to standard output rather than a file.
- `--output-format {format}` – Format in which exported certificates are written. The value can be PEM or DER, but the DER format can be used only if the output is written to a file. Defaults to PEM if no value is specified.
- `--export-certificate-chain` – Indicates that a certificate chain, rather than the end-entity certificate only, is to be exported .
- `--separate-file-per-certificate` – Indicates the use of separate output files for each exported certificate, rather than placing all of the certificates in a single file. If this argument is provided and multiple certificates are to be exported, then `.1` is appended to the path for the indicated output file for the first certificate in the chain, `.2` is appended for the second certificate, and so on.

The following example exports a certificate chain:

```

$ bin/manage-certificates export-certificate \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert.pem \
  --output-format PEM \
  --export-certificate-chain \
  --separate-file-per-certificate

Successfully exported the following certificate to '/ds/server-cert.pem.1':
Subject DN: CN=ds.example.com,O=Example Corp,C=US
Issuer DN: CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Sunday, November 10, 2019 at 09:09:23 PM CST

```

```

(3 hours, 26 minutes, 23 seconds ago)
Validity End Time: Monday, November 9, 2020 at 09:09:23 PM CST
(364 days, 20 hours, 33 minutes, 36 seconds from
now)

05:b7:b9:0d:02:e0:38:3e

```

The **export-certificate** subcommand exports only the public portion of a certificate. Its private key is not included. To export the private key, use the **export-private-key** subcommand, which supports the following arguments, in addition to the usual keystore and alias arguments:

- **--output-file {path}** – Path to the file to which the exported private key is written. If this value is not provided, the key is written to standard output rather than a file.
- **--output-format {format}** – Format in which the exported private key is written. The value can be PEM or DER, but the DER format is used only if the output is written to a file. Defaults to PEM if no value is specified.

The following code provides an example:

```

$ bin/manage-certificates export-private-key \
  --keystore config/keystore \
  --keystore-password-file config/keystore.pin \
  --alias server-cert \
  --output-file server-cert-key.pem \
  --output-format PEM

Successfully exported the private key.

```

Using manage-certificates as a Simple Certification Authority

About this task

If your PingDirectory Server instances need to support an arbitrary or unknown set of clients, we recommend that you configure them with certificates from a trusted issuer, such as a commercial authority or the free Let's Encrypt service. If you control every client that will access the servers, however, you might want to create your own internal certification authority so that you have a common issuer for all servers. In such a scenario, the clients need to trust only the certificates that the issuer signs. Commercial and open-source software packages provide full-featured certification authority functionality, but you can also use

the `manage-certificates` tool to create a CA certificate that you can use to sign certificate-signing requests.

Steps

1. Create a certification authority certificate.

A *certification authority certificate* is a self-signed certificate that possesses the following extensions:

- A *key usage extension* that includes at least the `keyCertSign` usage.
- A *basic constraints extension* that identifies the certificate as a CA certificate.

If you do not plan to use an intermediate CA certificate, the basic constraints extension must have a path length constraint of 0. If you plan to use an intermediate CA certificate, the path length constraint must be 1. Because certificates that the CA certificate signs are valid only for as long as all certificates in the chain remain valid, we recommend that you specify a long lifespan for the CA certificate.

The following example creates a new root CA certificate:

```
$ bin/manage-certificates generate-self-signed-certificate \
  --keystore /ca/root-ca-keystore \
  --keystore-password-file /ca/root-ca-keystore.pin \
  --keystore-type JKS \
  --alias root-ca-cert \
  --subject-dn "CN=Example Root CA,O=Example Corp,C=US" \
  --days-valid 7300 \
  --key-algorithm RSA \
  --key-size-bits 4096 \
  --signature-algorithm SHA256withRSA \
  --basic-constraints-is-ca true \
  --basic-constraints-maximum-path-length 1 \
  --key-usage key-cert-sign \
  --key-usage crl-sign

Successfully created a new JKS keystore.

Successfully generated the following self-signed certificate:
Subject DN:  CN=Example Root CA,O=Example Corp,C=US
Issuer DN:   CN=Example Root CA,O=Example Corp,C=US
Validity Start Time: Monday, January 27, 2020 at 03:47:29 PM CST (0
seconds ago)
Validity End Time: Sunday, January 22, 2040 at 03:47:29 PM CST
(7299 days, 23 hours, 59 minutes, 59 seconds from now)
Validity State: The certificate is currently within the validity window.
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)
SHA-1 Fingerprint:
bc:8e:5b:30:52:ec:03:63:b4:9a:aa:1a:45:a0:fc:84:49:dd:e8:64
SHA-256 Fingerprint:

d5:47:06:cd:a2:95:42:61:1f:c7:aa:04:16:1e:c1:70:41:c4:44:48:bf:74:20:5f:1c:
61:e2:aa:40:08:3a:ff
```

2. Export the public portion of the root CA certificate for future reference.

When you import a signed certificates, you can import the public portion of the root CA certificate as a standalone certificate into truststores, as well as into part of a certificate chain.

3. To create an intermediate CA certificate, create a new certificate signing request for it.

The certificate signing request uses essentially the same settings as the root CA. If you anticipate only a single intermediate CA, however, its basic constraints extension must have a path length constraint of

0, rather than 11, to indicate that it is used only to sign end-entity certificates, and that it cannot create subordinate CA certificates by itself.

The following example command creates a certificate signing request:

```
$ bin/manage-certificates generate-certificate-signing-request \
  --keystore /ca/intermediate-ca-keystore \
  --keystore-password-file /ca/intermediate-ca-keystore.pin \
  --keystore-type JKS \
  --alias intermediate-ca-cert \
  --subject-dn "CN=Example Intermediate CA,O=Example Corp,C=US" \
  --key-algorithm RSA \
  --key-size-bits 4096 \
  --signature-algorithm SHA256withRSA \
  --basic-constraints-is-ca true \
  --basic-constraints-maximum-path-length 0 \
  --key-usage key-cert-sign \
  --key-usage crl-sign \
  --output-file /ca/intermediate-ca-cert.csr \
  --output-format PEM
```

```
Successfully created a new JKS keystore.
```

```
Successfully generated the key pair to use for the certificate signing request.
```

```
Successfully wrote the certificate signing request to file '/ca/intermediate-ca-cert.csr'.
```

4. Use the root CA certificate to sign the certificate signing request for the intermediate CA certificate.

To perform this step, use the `sign-certificate-signing-request` subcommand, which takes most of the same arguments as generating a self-signed certificate. The primary differences between the argument sets are as follows:

- The keystore that contains the certificate uses the provided keystore arguments to sign the request. To specify the name of the certificate to use when signing the request, use the `--signing-certificate-alias` argument.
- To specify the path to the file that contains the certificate signing request file to generate, provide a `--request-input-file` argument.
- To specify the path to the file to which the signed certificate is written, provide a `--certificate-output-file` argument. If this argument is omitted, the PEM representation of the certificate is written to standard output.
- To specify the format, PEM or DER, in which the certificate is written to the output file, provide an `--output-format` argument.
- To specify the subject to use for the signed certificate, use the `--subject-dn` argument. To use the subject DN from the certificate signing request, omit this argument.
- To specify the name of the signature algorithm, use the `--signature-algorithm` argument.

 **Note:** Because the requester generated the key, you cannot specify the key algorithm or the key length.

- To indicate that the signed certificate includes every extension that is listed in the certificate signing request, use the `--include-requested-extensions` argument. If this argument is not provided, explicitly specify the set of extensions to include.

The following example command signs the certificate signing request for an intermediate CA certificate:

```
$ bin/manage-certificates sign-certificate-signing-request \
```

```

--keystore /ca/root-ca-keystore \
--keystore-password-file /ca/root-ca-keystore.pin \
--signing-certificate-alias root-ca-cert \
--days-valid 7300 \
--include-requested-extensions \
--request-input-file /ca/intermediate-ca-cert.csr \
--certificate-output-file /ca/intermediate-ca-cert.pem \
--output-format PEM

```

Read the following certificate signing request:

```

PKCS #10 Certificate Signing Request Version: v1
Subject DN: CN=Example Intermediate CA,O=Example Corp,C=US
Signature Algorithm: SHA-256 with RSA
Public Key Algorithm: RSA (4096-bit)

```

Do you really want to sign this request? yes

```

Successfully wrote the signed certificate to file
'/ca/intermediate-ca-cert.pem'.

```

5. After you obtain the intermediate CA certificate, create secure, offline backups of the root CA certificate.
6. Remove the root CA certificate, or at least its private key, from all systems.

Note: Make certain that all end-entity certificates are signed with the intermediate CA certificate, and that the process is identical to the previous example. Restore the root CA certificate only if you need to sign another intermediate CA certificate.

Enabling TLS Support During Setup

About this task

To enable TLS support in the server, we recommend that you complete one of the following tasks during the setup procedure:

- Provide a keystore that contains the certificate to use.
- Make the installer generate a self-signed certificate.

When you use the **setup** tool in Interactive mode, it prompts you for the information that it needs to configure secure communication, as shown in the following example:

```

Do you want to enable the Directory Server services (Available State,
Available or Degraded State, Configuration, Consent, Directory REST API,
Documentation, SCIM2, and Swagger UI) and Administrative Console over
HTTPS? After setup, you can selectively enable or disable individual
services and applications by configuring the HTTPS Connection Handler
(yes / no) [yes]: yes

```

```

On which port should the Directory Server accept connections from HTTPS
clients? [443]: 443

```

```

On which port should the Directory Server accept connections from LDAP
clients? [389]: 389

```

```

Do you want to enable LDAPS? (yes / no) [yes]: yes
On which port should the Directory Server accept connections from LDAPS
clients? [636]: 636

```

```

Do you want to enable StartTLS? (yes / no) [yes]: yes

```

Certificate server options:

- 1) Generate self-signed certificate (recommended for testing purposes only)
- 2) Use an existing certificate located on a Java Keystore (JKS)
- 3) Use an existing certificate located on a PKCS12 keystore
- 4) Use an existing certificate on a PKCS11 token

Enter option [1]: **2**

Java Keystore (JKS) path: **/ca/ds1-keystore**
Keystore PIN: **{password}**

Truststore options:

- 1) Generate a default JKS truststore
- 2) Use an existing JKS truststore
- 3) Use an existing PKCS12 truststore

Enter option [1]: **2**

JKS truststore path: **/ca/truststore**
Truststore password (can be blank): **{password}**

When using **setup** in non-interactive mode, use the following arguments to configure TLS support:

- **--ldapsPort {port}** – Server enables support for LDAPS (LDAP over TLS) on the specified TCP port.
- **--httpsPort {port}** – Server enables support for HTTPS for SCIM, the Directory REST API, and the web-based administration console on the specified TCP port.
- **--enableStartTLS** – LDAP connection handler enables support for the StartTLS extended operation.
- **--generateSelfSignedCertificate** – **setup** generates a self-signed certificate that is presented to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- **--useJavaKeyStore {path}** – Server uses the specified JKS keystore to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- **--usePKCS12KeyStore {path}** – Server uses the specified PKCS #12 keystore to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation.
- **--usePKCS11KeyStore** – Server uses a PKCS #11 keystore, like a hardware security module, to obtain the certificate chain that it presents to clients that use LDAPS, HTTPS, and the StartTLS extended operation. The JVM must already be configured to access the appropriate keystore through PKCS #11.
- **--keyStorePassword {password}** – Password that is needed to interact with the specified JKS, PKCS #12, or PKCS #11 keystore. The **setup** tool assumes that the private key password matches the keystore password.
- **--keyStorePasswordFile {path}** – Path to the file that contains the password needed to interact with the specified JKS, PKCS #12, or PKCS #11 keystore.
- **--certNickname {alias}** – Alias of the private key entry in the specified keystore that contains the certificate chain to present to clients during TLS negotiation. This argument is optional but recommended if the keystore contains multiple certificates.
- **--useJavaTrustStore {path}** – Server uses the specified JKS truststore to determine whether to trust certificate chains that are presented to it during TLS negotiation.
- **--usePKCS12TrustStore {path}** – Server uses the specified PKCS #12 truststore to determine whether to trust certificate chains that are presented to it during TLS negotiation.
- **--trustStorePassword {password}** – Password that is needed to interact with the specified JKS or PKCS #11 truststore.
- **--trustStorePasswordFile {path}** – Path to the file that contains the password needed to interact with the specified JKS or PKCS #11 truststore.

The following example command sets up PingDirectory Server in non-interactive mode with an existing certificate:

```
$ ./setup \
  --no-prompt \
  --acceptLicense \
  --ldapPort 389 \
  --ldapsPort 636 \
  --httpsPort 443 \
  --enableStartTLS \
  --useJavaKeyStore config/keystore \
  --keyStorePasswordFile config/keystore.pin \
  --certNickname server-cert \
  --useJavaTrustStore config/truststore \
  --trustStorePasswordFile config/truststore.pin \
  --baseDN dc=example,dc=com \
  --rootUserDN "cn=Directory Manager" \
  --rootUserPasswordFile root-pw.txt \
  --maxHeapSize 10g \
  --encryptDataWithPassphraseFromFile encryption-settings-password.txt \
  --instanceName ds1 \
  --location Austin \
  --noPropertiesFile
```

```
Ping Identity Directory Server 8.0.0.0
```

```
Initializing ..... Done
Configuring Directory Server ..... Done
Configuring Certificates ..... Done
Starting Directory Server ..... Done
```

```
Access product documentation from docs/index.html
```

Enabling TLS Support after Setup

About this task

If the server has been set up without support for TLS, you can enable TLS support later by completing the following tasks:

1. Obtain a certificate chain.

For more information about obtaining a certificate chain, see [Certificate Chains](#) on page 560. To prepare a JKS or PKCS #12 keystore with an appropriate certificate chain and private key, use the `manage-certificates` tool. We also recommend that you create a truststore that the server can use.

2. Configure the key and trust manager providers. For more information, see [Configuring Key and Trust Manager Providers](#) on page 583.
3. Configure connection handlers. For more information, see [Configuring Connection Handlers](#) on page 584.

Configuring Key and Trust Manager Providers

About this task

After you have a keystore, configure a key manager provider to access it. The server is preconfigured with key manager providers, named `JKS` and `PKCS12`, that can be used with JKS or PKCS #12 keystores,

respectively. As the following example shows, you can update the appropriate key manager provider in most cases to reference the keystore that you plan to use:

```
dsconfig set-key-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set key-store-file:config/keystore \
  --set key-store-pin-file:config/keystore.pin
```

A similar change configures a trust manager provider to reference the appropriate truststore, as the following example shows:

```
dsconfig set-trust-manager-provider-prop \
  --provider-name JKS \
  --set enabled:true \
  --set include-jvm-default-issuers:true \
  --set trust-store-file:config/truststore \
  --set trust-store-pin-file:config/truststore.pin
```

Note: If all clients and servers are expected to use certificates that are signed by issuers and are included in the JVM's default truststore, you can use the `JVM-Default` trust manager provider to accomplish this task.

Configuring Connection Handlers

About this task

After you configure the key and trust manager providers, update the connection handlers to use these. For the LDAP connection handler, which accepts non-secure connections by default, the following command enables StartTLS with a configuration change:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set allow-start-tls:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

If you did not configure secure communication during setup, the LDAPS connection handler is disabled. To configure LDAPS support in this scenario, enable the connection handler and configure most of the same settings. For example, `allow-start-tls` must be set to `false`, and `use-ssl` must be set to `true` as shown below:

```
dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set enabled:true \
  --set key-manager-provider:JKS \
  --set trust-manager-provider:JKS \
  --set ssl-cert-nickname:server-cert \
  --set ssl-client-auth-policy:optional
```

The following example uses a similar configuration change to enable the HTTPS connection handler:

```
dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set enabled:true \
```

```
--set listen-port:443 \  
--set key-manager-provider:JKS \  
--set trust-manager-provider:JKS \  
--set ssl-cert-nickname:server-cert
```

Updating the Topology Registry

About this task

After the server connection handlers are updated to enable TLS, update the *topology registry* to provide information about the new configuration. The topology registry holds information about server instances that are part of the environment, and it helps to facilitate inter-server communication such as replication, mirroring portions of the configuration, and PingDirectory Server's automatic backend server-discovery functionality.

The following types of entries require updating:

- Server instance listener configuration – Provides information that is needed to trust the TLS certificates that instances in the topology present.
- Server instance configuration – Provides information about options for communicating with those instances.

The server instance listener configuration must include the server certificate, which is defined as the certificate at the head of the chain. This version must be the multi-line, PEM-formatted representation of the certificate. You can use `dsconfig` to import the certificate from a file, as the following example shows:

```
bin/dsconfig set-server-instance-listener-prop \  
--instance-name ds1 \  
--listener-name ldap-listener-mirrored-config \  
--set server-ldap-port:636 \  
--set connection-security:ssl \  
--set 'listener-certificate>/ca/ds1-cert.pem'
```

The less-than operator (`>`) in the final line indicates that the value is read from a file rather than provided directly. In addition, you may not need to enclose the property name and path within single straight quotes to prevent the shell from interpreting the less-than symbol as an attempt to redirect input.

Update the server instance configuration object to reflect the new methods that are available for communication with the instance. For example, the `preferred-security` property identifies the mechanism by which other instances in the topology attempt to communicate with the instance. The following code sets the LDAPS and HTTPS ports, indicate that StartTLS support is enabled, and instructs other instances to use SSL (LDAPS) when communicating with the instance:

```
dsconfig set-server-instance-prop \  
--instance-name ds1 \  
--set ldaps-port:636 \  
--set https-port:443 \  
--set preferred-security:ssl \  
--set start-tls-enabled:true
```

Troubleshooting TLS-Related Issues

This section describes strategies for troubleshooting problems that might arise during TLS configuration, including communication and security issues that affect clients as well as PingDirectory Server.

Log Messages

About this task

If you need to troubleshoot TLS-related issues, we recommend that you start by checking the server's access log. If the client can establish a TCP connection to the server, which must occur before TLS negotiation can start, the access log shows a `CONNECT` message with the following information:

- Source and destination address and port for the connection
- Protocol
- Selected client connection policy

If the `CONNECT` does not appear, the client might be unable to communicate with the server. The culprit could be a network problem, a firewall that is blocking attempts to communicate, or something as simple as the client trying to use an incorrect address or port.

If the `CONNECT` message appears in the access log, it typically includes a `conn` element that specifies the connection ID. To view additional log messages for the client connection, use the `search-logs` tool. For example, if the connection ID is `12345`, the following command displays the complete set of associated log messages:

```
$ bin/search-logs --logFile logs/access conn=12345
```

If you are attempting to use LDAPS, one of the following log messages typically appears next:

- `SECURITY-NEGOTIATION` message – Indicates that the client and server successfully completed the negotiation process, and that the issue likely occurred after the TLS session was established. This message also includes details about the negotiation, including the TLS protocol and the selected cipher suite.
- `DISCONNECT` message – Suggests that the issue might involve a failure in the TLS-negotiation process. In such scenarios, the message usually includes a `reason` element that provides additional information about the reason for the disconnect.

If the failure occurred during TLS negotiation, the usefulness of the `DISCONNECT` message depends at least in part on whether the failure occurred on the client or the server. For example, if the server decided to abort the negotiation, the message ideally contains the specific reason. If the problem occurred on the client, the log message likely contains only the general category for the failure.

Note: The TLS protocol does not provide a mechanism for conveying detailed error messages. Instead, it offers only a basic alert mechanism with a fixed set of alert types. For example, if a client does not trust the certificate chain that the server presents to it, the server might receive a generic alert like `certificate_unknown`, even if the client knows the precise reason for rejecting the chain. In such instances, you might need to determine whether the client can provide additional details about the issue.

If the access log does not provide useful information, check the server error log. Although the error log does not normally include information about issues that relate to client communication, it provides helpful information in certain circumstances, like when an internal error within the server interferes with communication attempts.

manage-certificates check-certificate-usability

The `manage-certificates` tool offers a `check-certificate-usability` subcommand that can be used to examine a specified entry in a keystore, and to identify potential issues that might interfere with secure communication. The `check-certificate-usability` tool completes the following tasks:

- Ensures that a specified entry in the keystore includes a private key and a complete certificate chain.
- Checks whether the certificate at the root of the chain is found in the JVM's default set of trusted certificates.
- Ensures that the current time lies within the validity window for all certificates in the chain.

- Validates the signatures for all certificates in the chain.
- Warns if the end-entity certificate is self-signed.
- Warns if the end-entity certificate does not contain an extended key usage extension with the `serverAuth` usage.
- Warns if an the issuer certificates does not have a key usage extension with the `keyCertSign` usage.
- Warns if an issuer certificates does not have a basic constraints extension indicating that it can operate as a certification authority. If the chain violates a path length constraint, the `check-certificate-usability` tool reports an error.
- Ensures that the signature algorithm uses a strong message digest algorithm, like SHA-256. The `check-certificate-usability` tool reports an error for weak digest algorithms like MD5 or SHA-1, and reports a warning for unrecognized digest algorithms.
- Ensures that none of the certificates that use an RSA key pair have a key size less than 2048 bits.

The following example demonstrates the usage for the `manage-certificates check-certificate-usability` command and its output when no problems are identified:

```
$ bin/manage-certificates check-certificate-usability \
--keystore config/keystore \
--keystore-password-file config/keystore.pin \
--alias server-cert

Successfully retrieved the certificate chain for alias 'server-cert':

OK: The certificate chain is complete. Each subsequent certificate is the issuer for the previous certificate in the chain, and the chain ends with a self-signed certificate.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a valid signature.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' will expire at Wednesday, November 11, 2020 at 03:52:44 PM CST (364 days, 23 hours, 54 minutes, 14 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:42 PM CST (7299 days, 23 hours, 54 minutes, 12 seconds from now), which is not in the near future.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' will expire at Monday, November 7, 2039 at 03:52:38 PM CST (7299 days, 23 hours, 54 minutes, 8 seconds from now), which is not in the near future.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' at the head of the chain includes an extended key usage extension, and that extension includes the serverAuth usage.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a basic constraints extension, and the certificate chain satisfies those constraints.

OK: Issuer certificate 'CN=Example Root CA,O=Example Corp,C=US' includes a key usage extension with the keyCertSign usage flag set to true.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' uses a signature algorithm of 'SHA-256 with RSA', which is is considered strong.

OK: Certificate 'CN=dsl.example.com,O=Example Corp,C=US' has a 2048-bit RSA public key, which is considered strong.

```
OK: Certificate 'CN=Example Intermediate CA,O=Example Corp,C=US' has a
4096-bit RSA public key, which is considered strong.
```

```
OK: Certificate 'CN=Example Root CA,O=Example Corp,C=US' has a 4096-bit
RSA public key, which is considered strong.
```

```
No usability errors or warnings were identified while validating the
certificate chain.
```

If any usability issues are identified, they might be responsible for communication problems.

ldapsearch

The `ldapsearch` command-line utility is a simple but powerful tool for issuing searches against an LDAP directory server. It also provides a convenient method for troubleshooting a variety of issues, including problems that are relevant to TLS communication.

The following arguments for TLS-related communication are the most useful:

- `--hostname {address}` – Address of the server to which the connection is established.
- `--port {port}` – TCP port of the server to which the connection is established. The standard port for non-secure LDAP (or LDAP to be secured with StartTLS) is 389, and the standard port for secure LDAPS is 636. However, many deployments use alternate ports, especially non-privileged ports above 1024.
- `--useSSL` – Indicates that the tool establishes an initially insecure LDAP connection, which is secured later with the StartTLS extended operation.
- `--trustStorePath {path}` – Path to the truststore that is used during the course of determining whether to trust the certificate chain that the server presents during TLS negotiation. If neither this argument nor the `--trustAll` argument is provided, the tool prompts you interactively about whether to trust server certificated that are not signed by an issuer in the JVM's default truststore.
- `--trustStoreFormat {format}` – Format for the truststore, which is typically JKS or PKCS12.
- `--trustStorePassword {password}` – Password that is needed to access the contents of the truststore.
- `--trustStorePasswordFile {path}` – Path to the file that contains the password that is needed to access the contents of the truststore.
- `--trustAll` – Indicates that the tool blindly trusts all TLS certificate chains that are presented to it. Although this argument can prove useful for troubleshooting purposes, we do not recommended it for general use.
- `--keyStorePath {path}` – Path to the keystore to use if a client certificate chain is presented to the server. Use this argument only when one of the following conditions is satisfied:
 - The server is configured to require clients to present a certificate.
 - You intend to use the certificate to authenticate through SASL EXTERNAL.
- `--keyStoreFormat {format}` – Format for the keystore, which is typically JKS or PKCS12.
- `--keyStorePassword {password}` – Password that is needed to access the keystore.
- `--keyStorePasswordFile {path}` – Path to the file that contains the password necessary to access the keystore.
- `--certNickname {alias}` – Alias of the private key entry in the keystore to use when obtaining the certificate chain to present to the server.
- `--useSASLExternal` – Indicates that the client authenticates with the EXTERNAL SASL mechanism, which typically identifies the client using the certificate chain that is presented during TLS negotiation.
- `--enableSSLDebugging` – Indicates that the tool is expected to enable the low-level TLS-debugging feature that the JVM provides.

The following command represents the simplest method for testing TLS communication with PingDirectory Server:

```
$ bin/ldapsearch \
  --hostname ds1.example.com \
  --port 636 \
```

```
--useSSL \
--baseDN "" \
--scope base \
"(objectClass=*)"
```

The server presented the following certificate chain:

```
Subject: CN=ds1.example.com,O=Example Corp,C=US

34:34:a1:90:83:8a:d5:12

Do you wish to trust this certificate? Enter 'y' or 'n': y
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: 8d574122-4584-4522-96d9-0cdbc9d2e339
startTime: 20191113061149Z

# Result Code: 0 (success)
# Number of Entries Returned: 1
```

If no trust-related arguments are provided, the tool uses the JVM's default truststore to verify whether to trust the certificate chain, based on the information that it contains. If a trusted authority has signed the server certificate, the negotiation process continues without further interaction.

If the chain cannot be trusted, based on the information in the JVM-default truststore, `ldapsearch` prompts you interactively about whether to trust the certificate. If you accept the chain, the client and server complete the negotiation process, and the client sends the search request to the server. If the search succeeds, the server can communicate over TLS.

To test with a truststore instead of being prompted interactively, use the `--trustStorePath` argument that points to the appropriate truststore. If you are using a JKS truststore, you probably do not need to provide the truststore password. If you are using a PKCS #12 truststore, though, you most likely need to provide the truststore password, as the following example shows:

```
$ bin/ldapsearch \
--hostname ds1.example.com \
--port 636 \
```

```

--useSSL \
--trustStorePath config/truststore.p12 \
--trustStorePasswordFile config/truststore.pin \
--trustStoreFormat PKCS12 \
--baseDN "" \
--scope base \
"(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

To present a client certificate chain to the server – for example, because the server's connection handler is configured with an `ssl-client-auth-policy` value of `required`, or because you plan to use the certificate to authenticate by way of the SASL EXTERNAL mechanism – provide at least the keystore and its corresponding password. You can also specify the alias of the certificate chain to present, which is recommended if your client keystore contains multiple certificates.

The following code provides an example:

```

$ bin/ldapsearch \
--hostname ds1.example.com \
--port 636 \
--useSSL \
--trustStorePath config/truststore.p12 \
--trustStorePasswordFile config/truststore.pin \
--trustStoreFormat PKCS12 \
--keyStorePath client-keystore \
--keyStorePasswordFile client-keystore.pin \
--certNickname client-cert \
--useSASLExternal \
--baseDN "" \
--scope base \
"(objectClass=*)"
dn:
objectClass: top
objectClass: ds-root-dse
startupUUID: c8724159-8c37-45eb-b210-879bfcf74ad6
startTime: 20191113154023Z

# Result Code: 0 (success)
# Number of Entries Returned: 1

```

If you encounter a TLS-related issue that you cannot resolve by examining the `ldapsearch` output or the server logs, use the `--enableSSLDebugging` option to enable the JVM's support for low-level debugging of TLS processing. For more information, see [Low-Level TLS Debugging](#) on page 591.

Low-Level TLS Debugging

If you must resort to low-level debugging options, we recommend that you enable the JVM's support for TLS debugging. Many of the command-line tools that are provided with PingDirectory Server, such as `ldapsearch`, offer an `--enableSSLDebugging` argument that simplifies this process. For other tools, perform the following steps:

1. In the `config/java.properties` file, add the following line to the set of properties for the appropriate tool:

```
-Djavax.net.debug=all
```

2. To make the change take effect, run the `bin/dsjavaproperties` command.

The next time the tool is run, it generates voluminous output detailing the TLS-related processing that the JVM is performing. Potential clues in the output might allow you or the team to identify the issue.

To enable low-level debugging within the server, perform the following steps:

1. In the `config/java.properties` file, add the following line to the `start-server.java-args` property:

```
-Djavax.net.debug=all
```

2. Run `bin/dsjavaproperties`.

3. Restart the server.

Because this approach requires multiple server restarts, it is not highly attractive. However, you might be able to obtain more information without a restart by using the debugging support that is built into the server. To enable this level of support, make the following configuration changes:

```
dsconfig create-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider \
  --set debug-level:verbose

dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:true
```

After you make these changes, the `logs/debug` file captures a substantial amount of information about the TLS-related processing that the server is performing. Although this file does not provide as much detail as the JVM's built-in debugging information, it might help to pinpoint the cause of the problem, and to identify potential solutions. When you no longer require this level of debugging, disable the debug log publisher and remove the debug target, as follows:

```
dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Debug Logger" \
  --set enabled:false

dsconfig delete-debug-target \
  --publisher-name "File-Based Debug Logger" \
  --target-name com.unboundid.directory.server.extensions.TLSConnectionSecurityProvider
```

To troubleshoot TLS communication with a non-Java client that does not offer its own TLS debugging mechanism, and if the server-side debugging support is insufficient, use a network protocol analyzer to capture the communication between the client and the server, and to examine its content. The free open-source [Wireshark utility](#) is an excellent graphical tool that runs on a variety of platforms and provides excellent support for understanding TLS communication. Even if you cannot decipher the encrypted content, you can view at least some of the handshake messages. Unfortunately, more of the handshake is encrypted in TLS version 1.3 than in earlier versions of the protocol. Although this change improves security and privacy, it may interfere with troubleshooting attempts.

Using the Configuration API

PingDirectory Server provides a Configuration API, which may be useful in situations where using LDAP to update the server configuration is not possible. The API is consistent with the System for Cross-domain

Identity Management (SCIM) 2.0 protocol and uses JSON as a text exchange format, so all request headers should allow the `application/json` content type.

The server includes a servlet extension that provides read and write access to the server's configuration over HTTP. The extension is enabled by default for new installations, and can be enabled for existing deployments by simply adding the extension to one of the server's HTTP Connection Handlers, as follows:

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --add http-servlet-extension:Configuration
```

The API is made available on the HTTPS Connection handler's host:port in the `/config` context. Due to the potentially sensitive nature of the server's configuration, the HTTPS Connection Handler should be used for hosting the Configuration extension.

Authentication and Authorization with the Configuration API

Clients must use HTTP Basic authentication to authenticate to the Configuration API. If the user name value is not a DN, then it will be resolved to a DN value using the identity mapper associated with the Configuration servlet. By default, the Configuration API uses an identity mapper that allows an entry's UID value to be used as a user name. To customize this behavior, either customize the default identity mapper, or specify a different identity mapper using the Configuration servlet's `identity-mapper` property. For example:

```
$ bin/dsconfig set-http-servlet-extension-prop \
  --extension-name Configuration \
  --set "identity-mapper:Alternative Identity Mapper"
```

To access configuration information, users must have the appropriate privileges:

- To access the `cn=config` backend, users must have the `bypass-acl` privilege or be allowed access to the configuration using an ACL.
- To read configuration information, users must have the `config-read` privilege.
- To update the configuration, users must have the `config-write` privilege.

Relationship Between the Configuration API and the dsconfig Tool

The Configuration API is designed to mirror the `dsconfig` tool, using the same names for properties and object types. Property names are presented as hyphen case in `dsconfig` and as camel-case attributes in the API. In API requests that specify property names, case is not important. Therefore, `baseDN` is the same as `baseDn`. Object types are represented in hyphen case. API paths mirror what is in `dsconfig`. For example, the `dsconfig list-connection-handlers` command is analogous to the API's `/config/connection-handlers` path. Object types that appear in the schema URNs adhere to a `type:subtype` syntax. For example, a Local DB Backend's schema URN is `urn:unboundid:schemas:configuration:2.0:backend:local-db`. Like the `dsconfig` tool, all configuration updates made through the API are recorded in `logs/config-audit.log`.

The API includes the filter, sort, and pagination query parameters described by the SCIM specification. Specific attributes may be requested using the `attributes` query parameter, whose value must be a comma-delimited list of properties to be returned, for example `attributes=baseDN,description`. Likewise, attributes may be excluded from responses by specifying the `excludedAttributes` parameter.

Operations supported by the API are those typically found in REST APIs:

HTTP Method	Description	Related dsconfig Example
GET	Lists the properties of an object when used with a path representing an object, such as <code>/config/global-configuration</code> or <code>/config/backends/userRoot</code> . Can also list objects when used with a path representing a parent relation, such as <code>/config/backends</code> .	<code>get-backend-prop</code> , <code>list-backends</code> , <code>get-global-configuration-prop</code>
POST	Creates a new instance of an object when used with a relation parent path, such as <code>/config/backends</code> .	<code>create-backend</code>
PUT	Replaces the existing properties of an object. A PUT operation is similar to a PATCH operation, except that the PATCH identifies the difference between an existing target object and a supplied source object. Only those properties in the source object are modified in the target object. The target object is specified using a path, such as <code>/config/backends/userRoot</code> .	<code>set-backend-prop</code> , <code>set-global-configuration-prop</code>
PATCH	Updates the properties of an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<code>set-backend-prop</code> , <code>set-global-configuration-prop</code>
DELETE	Deletes an existing object when used with a path representing an object, such as <code>/config/backends/userRoot</code> .	<code>delete-backend</code>

The OPTIONS method can also be used to determine the operations permitted for a particular path.

Object names, such as `userRoot` in the Description column, must be URL-encoded for use in the path segment of a URL. For example, `%20` must be used in place of spaces, and `%25` is used in place of the percent (%) character. The URL for accessing the HTTP Connection Handler object is:

```
/config/connection-handlers/http%20connection%20handler
```

GET Example

The following is a sample GET request for information about the `userRoot` backend:

```
GET /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
```

The response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",

  }

```

GET List Example

The following is a sample GET request for all local backends:

```

GET /config/backends/
Host: example.com:5033
Accept: application/scim+json

```

The response (which has been shortened):

```

{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 24,
  "Resources": [
    {
      "schemas": [
        "urn:unboundid:schemas:configuration:2.0:backend:ldif"
      ],
      "id": "adminRoot",
      "meta": {
        "resourceType": "LDIF Backend",
        "location": "http://localhost:5033/config/backends/adminRoot"
      },

  },
  ...

```

PATCH Example

Configuration can be modified using the HTTP PATCH method. The PATCH request body is a JSON object formatted according to the SCIM patch request. The Configuration API, supports a subset of possible values for the path attribute, used to indicate the configuration attribute to modify.

The configuration object's attributes can be modified in the following ways. These operations are analogous to the `dsconfig modify-[object]` options.

- An operation to set the single-valued `description` attribute to a new value:

```

{
  "op" : "replace",
  "path" : "description",
  "value" : "A new backend."
}

```

is analogous to:

```

$ dsconfig set-backend-prop
--backend-name userRoot \
--set "description:A new backend"

```

- An operation to add a new value to the multi-valued `jeProperty` attribute:

```

{
  "op" : "add",
  "path" : "jeProperty",
  "value" : "je.env.backgroundReadLimit=0"
}

```

is analogous to:

```

$ dsconfig set-backend-prop --backend-name userRoot \
--add je-property:je.env.backgroundReadLimit=0

```

- An operation to remove a value from a multi-valued property. In this case, path specifies a SCIM filter identifying the value to remove:

```

{
  "op" : "remove",
  "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
}

```

```
}

```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.cleaner.adjustUtilization=false

```

- A second operation to remove a value from a multi-valued property, where the `path` specifies both an attribute to modify, and a SCIM filter whose attribute is value:

```
{
  "op" : "remove",
  "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --remove je-property:je.nodeMaxEntries=32

```

- An option to remove one or more values of a multi-valued attribute. This has the effect of restoring the attribute's value to its default value:

```
{
  "op" : "remove",
  "path" : "id2childrenIndexEntryLimit"
}
```

is analogous to:

```
$ dsconfig set-backend-prop --backend-name userRoot \
  --reset id2childrenIndexEntryLimit

```

The following is the full example request. The API responds with the entire modified configuration object, which may include a SCIM extension attribute `urn:unboundid:schemas:configuration:messages` containing additional instructions:

```
PATCH /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json

{
  "schemas" : [ "urn:ietf:params:scim:api:messages:2.0:PatchOp" ],
  "Operations" : [ {
    "op" : "replace",
    "path" : "description",
    "value" : "A new backend."
  }, {
    "op" : "add",
    "path" : "jeProperty",
    "value" : "je.env.backgroundReadLimit=0"
  }, {
    "op" : "remove",
    "path" : "[jeProperty eq \"je.cleaner.adjustUtilization=false\"]"
  }, {
    "op" : "remove",
    "path" : "jeProperty[value eq \"je.nodeMaxEntries=32\"]"
  }, {
    "op" : "remove",
    "path" : "id2childrenIndexEntryLimit"
  } ]
}
```

Example response:

```

{
  "schemas": [

        of the backend must be exported to LDIF and re-imported to
        allow the new limit to be used for any id2children keys
        that had already hit the previous limit."
    }
  ]
}
}
}

```

Configuration API Paths

The Configuration API is available under the /config path. A full listing of supported sub-paths is available by accessing the base /config/ResourceTypes endpoint:

```

GET /config/ResourceTypes
Host: example.com:5033
Accept: application/scim+json

```

Sample response (abbreviated):

```

{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:ListResponse"
  ],
  "totalResults": 520,
  "Resources": [
    {
      "schemas": [
        "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
      ],
      "id": "dsee-compat-access-control-handler",
      "name": "DSEE Compat Access Control Handler",
      "description": "The DSEE Compat Access Control
        Handler provides an implementation that uses syntax
        compatible with the Sun Java System Directory Server

```

```

    Enterprise Edition access control handler.",
    "endpoint": "/access-control-handler",
    "meta": {
      "resourceType": "ResourceType",
      "location": "http://example.com:5033/config/ResourceTypes/dsee-compat-
access-control-handler"
    }
  },
  {
    "schemas": [
      "urn:ietf:params:scim:schemas:core:2.0:ResourceType"
    ],
    "id": "access-control-handler",
    "name": "Access Control Handler",
    "description": "Access Control Handlers manage the
application-wide access control. The server's access
control handler is defined through an extensible
interface, so that alternate implementations can be created.
Only one access control handler may be active in the server
at any given time.",
    "endpoint": "/access-control-handler",
    "meta": {
      "resourceType": "ResourceType",
      "location": "http://example.com:5033/config/ResourceTypes/access-
control-handler"
    }
  },
  {
    ...

```

The response's `endpoint` elements enumerate all available sub-paths. The path `/config/access-control-handler` in the example can be used to get a list of existing access control handlers, and create new ones. A path containing an object name such as `/config/backends/{backendName}`, where `{backendName}` corresponds to an existing backend (such as `userRoot`) can be used to obtain an object's properties, update the properties, or delete the object.

Some paths reflect hierarchical relationships between objects. For example, properties of a local DB VLV index for the `userRoot` backend are available using a path like `/config/backends/userRoot/local-db-indexes/uid`. Some paths represent singleton objects, which have properties but cannot be deleted nor created. These paths can be differentiated from others by their singular, rather than plural, relation name (for example `global-configuration`).

Sorting and Filtering Objects

The Configuration API supports SCIM parameters for filter, sorting, and pagination. Search operations can specify a SCIM filter used to narrow the number of elements returned. See the SCIM specification for the full set of operations for SCIM filters. Clients can also specify sort parameters, or paging parameters. Include or exclude attributes can be specified in both get and list operations.

GET Parameter	Description
filter	Values can be simple SCIM filters such as <code>id eq "userRoot"</code> or compound filters like <code>meta.resourceType eq "Local DB Backend"</code> and <code>baseDn co "dc=example,dc=com"</code> .
sortBy	Specifies a property value by which to sort.
sortOrder	Specifies either <code>ascending</code> or <code>descending</code> alphabetical order.
startIndex	1-based index of the first result to return.
count	Indicates the number of results per page.

Updating Properties

The Configuration API supports the HTTP PUT method as an alternative to modifying objects with HTTP PATCH. With PUT, the server computes the differences between the object in the request with the current version in the server, and performs modifications where necessary. The server will never remove attributes that are not specified in the request. The API responds with the entire modified object.

Request:

```
PUT /config/backends/userRoot
Host: example.com:5033
Accept: application/scim+json
{
  "description" : "A new description."
}
```

Response:

```
{
  "schemas": [
    "urn:unboundid:schemas:configuration:2.0:backend:local-db"
  ],
  "id": "userRoot",
  "meta": {
    "resourceType": "Local DB Backend",
    "location": "http://example.com:5033/config/backends/userRoot"
  },
  "backendID": "userRoot",
  "backgroundPrime": "false",
  "backupFilePermissions": "700",
  "baseDN": [
    "dc=example,dc=com"
  ],
  "checkpointOnCloseCount": "2",
  "cleanerThreadWaitTime": "120000",
  "compressEntries": "false",
  "continuePrimeAfterCacheFull": "false",

"subtreeDeleteSizeLimit": "100000",
"uncachedId2entryCacheMode": "cache-keys-only",
"writabilityMode": "enabled"
}

```

Administrative Actions

Updating a property may require an administrative action before the change can take effect. If so, the server will return 200 Success, and any actions are returned in the `urn:unboundid:schemas:configuration:messages:2.0` section of the JSON response that represents the entire object that was created or modified.

For example, changing the `jeProperty` of a backend will result in the following:

```

"urn:unboundid:schemas:configuration:messages:2.0": {
  "required-actions": [
    {
      "property": "baseContextPath",
      "type": "componentRestart",
      "synopsis": "In order for this modification to take effect, the
component
must be restarted, either by disabling and re-enabling it,
or
by restarting the server"
    },
    {
      "property": {
        "type": "other",
        "synopsis": "If this limit is increased, then the
contents of the backend must be exported to LDIF
and re-imported to allow the new limit to be used
for any id2children keys that had already hit the

```

```

        previous limit."
    }
  ]
}

```

Updating Servers and Server Groups

Servers can be configured as part of a server group, so that configuration changes that are applied to a single server, are then applied to all servers in a group. When managing a server that is a member of a server group, creating or updating objects using the Configuration API requires the `applyChangeTo` query attribute. The behavior and acceptable values for this parameter are identical to the `dsconfig` parameter of the same name. A value of `single-server` or `server-group` can be specified. For example:

```
http://localhost:8082/config/backends/userRoot?applyChangeTo=single-server
```

Configuration API Responses

Clients of the API should examine the HTTP response code in order to determine the success or failure of a request. The following are response codes and their meanings:

Response Code	Description	Response Body
200 Success	The requested operation succeeded, with the response body being the configuration object that was created or modified. If further actions are required, they are included in the <code>urn:unboundid:schemas:configuration:messages:2.0</code> object.	List of objects, or object properties, administrative actions.
204 No Content	The requested operation succeeded and no further information has been provided, such as in the case of a DELETE operation.	None.
400 Bad Request	The request contents are incorrectly formatted or a request is made for an invalid API version.	Error summary and optional message.
401 Unauthorized	User authentication is required. Some user agents such as browsers may respond by prompting for credentials. If the request had specified credentials in an Authorization header, they are invalid.	None.
403 Forbidden	The requested operation is forbidden either because the user does not have sufficient privileges or some other constraint such as an object is edit-only and cannot be deleted.	None.
404 Not Found	The requested path does not refer to an existing object or object relation.	Error summary and optional message.
409 Conflict	The requested operation could not be performed due to the current state of the configuration. For example, an attempt was made to create an object that already exists, or an attempt was made to delete an object that is referred to by another object.	Error summary and optional message.

Response Code	Description	Response Body
415 Unsupported Media Type	The request is such that the Accept header does not indicate that JSON is an acceptable format for a response.	None.
500 Server Error	The server encountered an unexpected error. Please report server errors to customer support.	Error summary and optional message.

An application that uses the Configuration API should limit dependencies on particular text appearing in error message content. These messages may change, and their presence may depend on server configuration. Use the HTTP return code and the context of the request to create a client error message. The following is an example encoded error message:

```
{
  "schemas": [
    "urn:ietf:params:scim:api:messages:2.0:Error"
  ],
  "status": 404,
  "scimType": null,
  "detail": "The Local DB Index does not exist."
}
```

Working with the Directory REST API

The Directory REST API is the native interface for client access to the PingDirectory Server. The Directory REST API gives developers, who are more comfortable with REST than LDAP, access to arbitrary directory data in a way that ensures directory data remains consistent regardless of whether it is accessed from LDAP or REST. The Directory API is enabled during server setup. After setup, individual services and applications can be enabled or disabled by configuring the HTTPS Connection Handler.

While both the Directory REST API and SCIM provide REST access to directory data, the goals of the two protocols are different. SCIM is useful to generic, external clients that require simple, narrow access to identity data. But because it is a less common standard for identity stores, it may not offer as much functionality or be as easy to use as the Directory REST API.

Rather than trying to manage directory hierarchy or require attribute mapping, the Directory REST API provides direct access to directory data in a way that is dynamic, discoverable, and efficient.

The Directory REST API can be used for the following operations:

HTTP operation	Resource endpoint	Description	Allowed query parameters
DELETE	<code>/directory/v1/{dn}</code>	Delete an entry.	
GET	<code>/directory/v1</code>	Get metadata about the API and server.	
GET	<code>/directory/v1/{dn}</code>	Retrieve a single entry.	<ul style="list-style-type: none"> ▪ <code>expand</code> ▪ <code>includeAttributes</code> ▪ <code>excludeAttributes</code>

HTTP operation	Resource endpoint	Description	Allowed query parameters
GET	<code>/directory/v1/{dn}/subtree</code>	Search an entry's descendants.	<ul style="list-style-type: none"> ▪ filter ▪ searchScope ▪ cursor ▪ limit ▪ includeAttributes ▪ excludeAttributes
GET	<code>/directory/v1/schemas</code>	Retrieve the schemas of all available object classes.	
GET	<code>/directory/v1/schemas/{objectclass}</code>	Retrieve schema for object class.	
GET	<code>/directory/v1/schemas/_operationalAttributes</code>	Retrieve schema for operational attributes.	
GET	<code>/directory/v1/me</code>	Alias for retrieving the current user.	
PATCH	<code>/directory/v1/{dn}</code>	Modify an entry (add or delete values).	expand
POST	<code>/directory/v1</code>	Create a new entry.	expand
PUT	<code>/directory/v1/{dn}</code>	Modify or rename an entry.	expand

The Directory REST API has the following properties, and can be configured with `dsconfig`:

- **basic-auth-enabled**: Specifies whether users can connect to the service with HTTP Basic authentication. If disabled, users will need a Bearer token. If changed, the server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled. Basic auth is enabled by default.
- **identity-mapper**: If HTTP Basic authentication is enabled, the identity mapper referenced by this DN must be used to map the user names provided to user entries. By default, an identity mapper is provided, which maps a fully-qualified DN to an entry. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.
- **access-token-validator**: Specifies the subset of this server's Access Token Validators (by DN), which may be used to validate Bearer authentication tokens. By default, if no validators are specified, then any of the validators on the server may be used. The server must be restarted, or any HTTP Connection Handlers referencing this service disabled and re-enabled for changes to take effect.
- **access-token-scope**: The scope which must be present in Bearer tokens in order to be accepted by this service. If no value is provided, Bearer token authentication is disabled, and only Basic authentication can be used. By default, no value is provided. Changes to this value take effect immediately.
- **audience**: A string or URI audience that must be present in Bearer tokens in order to be accepted by this service. If no value is provided, any audience is acceptable. By default, no value is provided. Changes to this value take effect immediately.
- **max-page-size**: The maximum number of entries to be returned in one page from the search endpoint (actual results returned may be lower due to the limit query parameter on the request and the actual number of available results). The value must be an integer between 1 and 1000. The default value is 100. Changes to this value take effect immediately.

- **schemas-endpoint-objectclass**: The list of object classes that will be returned by the `/schemas/endpoint` in the REST API. By default, no schemas are returned. Changes to this value take effect immediately.

The following example uses **dsconfig** to configure an **objectClass** entity:

```
dsconfig set-http-servlet-extension-props --extension-name "Directory REST
API" \
  --add schemas-endpoint-objectclass:ubidPerson
```

Configuring Server Groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group. After you have set up a server group, you can make an update on one server using **dsconfig**, then you can apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the **dsconfig** non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using **dsconfig** in interactive command-line mode, you will be asked if you want to apply the change to a single server or to all servers in the server group.

About the Server Group Example

You can create an administrative server group using the **dsconfig** tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group as outlined in Replication Configuration.

The following example procedure adds three Directory Server instances into the server group labelled "group-one".

To Create a Server Group

Steps

1. Create a group called "group-one" using **dsconfig**.

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group. If you have set up replication between a set of servers, these server entries will have already been created by the **dsreplication enable** command.

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server1
```

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server2
```

```
$ bin/dsconfig set-server-group-prop \
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

```
$ bin/dsconfig set-global-configuration-prop \
  --set configuration-server-group:group-one
```

4. Test the server group. In this example, enable the log publisher for each directory server in the group, server-group, by using the `--applyChangeTo server-group` option.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:true \
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

6. Repeat step 5 on the second and third directory server instance.
7. Test the server group by disabling the log publisher on the first directory server instance by using the `--applyChangeTo single-server`.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --set enabled:disabled \
  --applyChangeTo single-server
```

8. View the property on the first directory server instance. The first directory server instance should be disabled.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
-----:-----
enabled : false
```

9. View the property on the second directory server instance. Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

Configure the Server Using the Administrative Console

The PingDirectory Server provides a Administrative Console for server configuration and monitoring that has the same functionality as that of the `dsconfig` command. When logging on to the Administrative Console, the console does not persistently store any credentials for authenticating to the Directory Server but uses the credentials provided by the user when logging in. When managing multiple directory server instances, the provided credentials must be valid for each instance.

To Log on to the Administrative Console

About this task

To log on to the console, enter a fully qualified DN (for example, `cn=admin2,cn=Topology Admin Users,cn=Topology,cn=config`). See [Configuring a Global Administrator](#) for instructions.

Steps

1. Start the Directory Server.

```
$ bin/start-server
```

2. Open a browser to `http://server-name:389/console/login`.
3. Enter the root user DN and password, then click **Login**.

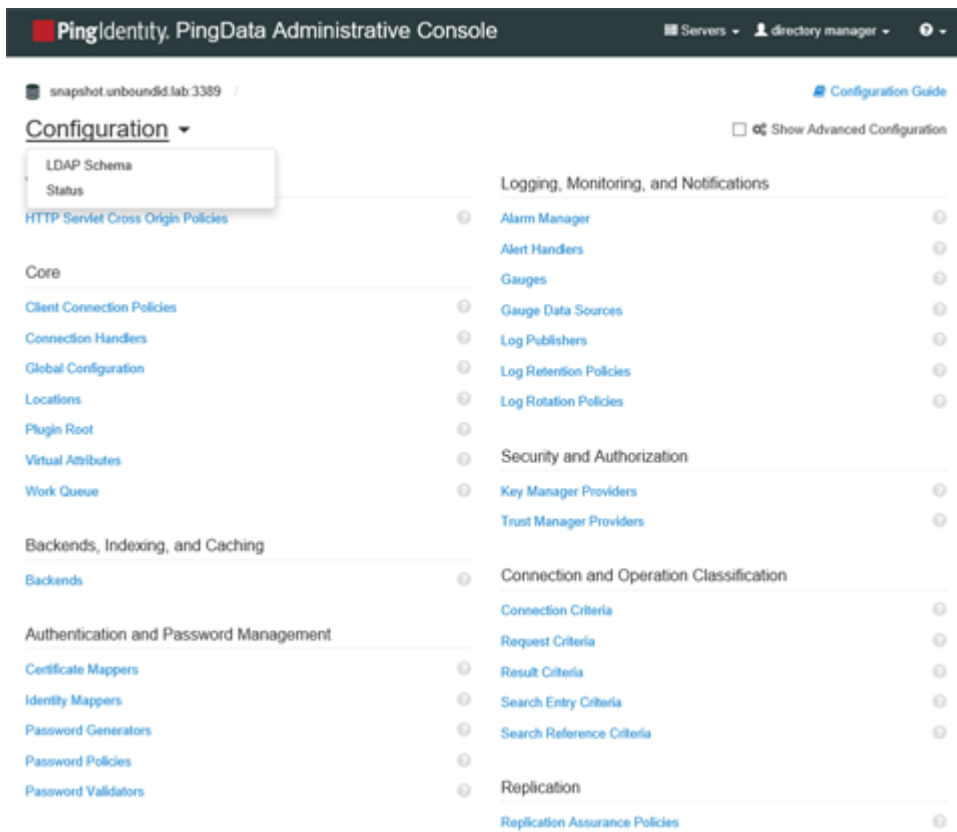

The screenshot shows the PingData Administrative Console login interface. At the top left is the Ping Identity logo. Below it, the title "PingData Administrative Console" is displayed. The login form consists of three input fields: "Server" with the value "ldaps://snapshot.lab:1636", "Username" with the value "directory manager", and "Password" which is masked with dots. A blue "Sign In" button is positioned below the password field. At the bottom left, the copyright notice "© 2015-2016 UnboundID Corp." is visible, and at the bottom right, there is a small help icon.

The console does not persistently store any credentials for accessing the Directory Server. Instead, it uses the credentials provided by the user when logging into the console. When managing multiple directory server instances, the provided credentials must be valid at each instance.

To Configure the Server Using the Console

Steps

1. Log into the Administrative Console. Click **Configuration** to open the **Configuration** menu, and then click **Backends**.

- At the top of the Administrative Console page, click **Show Advanced Properties**. Click **Backends**. For this example, click **userRoot**.

The screenshot shows the 'Edit Local DB Backend' configuration page in the PingIdentity PingData Administrative Console. The page title is 'Edit Local DB Backend' and it includes a sub-header: 'The Local DB Backend uses the Berkeley DB Java Edition to store user-provided data in a local repository.' The configuration is organized into a 'General Configuration' section with the following fields:

- Backend ID**: userRoot
- Description**: (empty text box)
- Enabled**: Enabled
- Base DN**: A list containing 'dc=example,dc=com' with a '+', '-', and 'x' button.
- Writability Mode**: enabled
- Set Degraded Alert When Disabled**: Enabled
- Return Unavailable When Disabled**: Enabled
- Notification Manager**: (empty dropdown menu)
- Is Private Backend**: Enabled

- Change or enter values in the `userRoot` configuration. For this example, change the `DB Cache Percent` value to 40, and then click **Save**.

Generating a Summary of Configuration Components

The Directory Server provides a `config-diff` tool that generates a summary of the configuration in a local or remote directory server instance. The tool is useful when comparing configuration settings on the directory server instance when troubleshooting issues or when verifying configuration settings on newly-added servers to your network. The tool can interact with the local configuration regardless of whether the server is running or not.

Run the `config-diff --help` option to view other available tool options.

To Generate a Summary of Configuration Components

Steps

- Run the `config-diff` tool to generate a summary of the configuration components on the directory server instance. The following command runs a summary on a local online server.

```
$ bin/config-diff
```

- The following example compares the current configuration of the local server to the baseline, pre-installation configuration, ignoring any changes that could be made by the installer, and writes the output to the `configuration-steps.dsconfig` file. This provides a script that can be used to configure a newly installed server identically to the local server:

```
$ bin/config-diff --sourceLocal \
  --sourceBaseline \
  --targetLocal \
  --exclude differs-after-install \
```

```
--outputFile configuration-steps.dsconfig
```

About Root User, Administrator, and Global Administrators

The Directory Server provides three different classes of administrator accounts: root user, administrator, and global administrator. The root user is the LDAP-equivalent of a UNIX super-user account and inherits its privileges from the default root user privilege set (see [Default Root Privileges](#)). The root user "account" is an entry that is stored in the server's configuration under the `cn=Root DNs,cn=config` and bypasses access control evaluation, and can be created manually, or with the `dsconfig` tool. This account has full access to the entire set of data in the Directory Information Tree (DIT) as well as full access to the server configuration and its operations. One important difference between other vendors' servers and the Directory Server's implementation is that the root user's rights are granted through a set of privileges. This allows the Directory Server to have multiple root users on its system if desired; however, the normal practice is to set up administrator user entries. Also, by default, the Root User has no resource limits.

The administrator user can have a full set of root user privileges but often has a subset of these privileges to limit the accessible functions that can be performed. The administrators entries typically have limited access to the entire set of data in the directory information tree (DIT), which is controlled by access control instructions. These entries reside in the backend configuration (for example, `uid=admin,dc=example,dc=com`) and are replicated between servers in a replication topology. In some cases, administrator user accounts may be unavailable when the server enters lockdown mode unless the administrator is given the lock-down mode privilege.

A global administrator is primarily responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology, where configuration changes to one server can be applied to all of the servers at one time. Global Administrator entries are stored in the `cn=Topology Admin Users,cn=Topology,cn=config` backend are always mirrored across servers in a replication topology. These users can be assigned privileges like other admin users but are typically used to manage the data under `cn=Topology,cn=config`.

Managing Root Users Accounts

The PingDirectoryProxy Server provides a default root user, `cn=Directory Manager`, that is stored in the server's configuration file (for example, under `cn=Root DNs,cn=config`). The root user is the LDAP-equivalent of a UNIX super-user account and inherits its read-write privileges from the default root privilege set. Root users can be created and updated with the `dsconfig` tool. Root user entries are stored in the server's configuration. The following is a sample command to create a new root user:

```
bin/dsconfig create-root-dn-user --user-name "Joanne Smith" \
  --set last-name:Smith \
  --set first-name:Joanne \
  --set user-id:jsmith \
  --set 'email-address:jsmith@example.com' \
  --set mobile-telephone-number:8889997777 \
  --set home-telephone-number:5556667777 \
  --set work-telephone-number:4445556666
```

To limit full access to all of the Directory Proxy Server, create separate administrator accounts with limited privileges so that you can identify the administrator responsible for a particular change. Having separate user accounts for each administrator also makes it possible to enable password policy functionality (such as password expiration, password history, and requiring secure authentication) for each administrator.

Default Root Privileges

The PingDirectoryProxy Server contains a privilege subsystem that allows for a more fine-grained control of privilege assignments.

Note: Creating restricted root user accounts requires assigning privileges and necessary access controls for actions on specific data or backends. Access controls are determined by how the directory is configured and the structure of your data. See Chapter 16: Managing Access Controls for more information.

The following set of root privileges are available to each root user DN:

Default Root Privileges

Privilege	Description
audit-data-security	Allows the associated user to execute data security auditing tasks.
backend-backup	Allows the user to perform backend backup operations.
backend-restore	Allows the user to perform backend restore operations.
bypass-acl	Allows the user to bypass access control evaluation.
config-read	Allows the user to read the server configuration.
config-write	Allows the user to update the server configuration.
disconnect-client	Allows the user to terminate arbitrary client connections.
ldif-export	Allows the user to perform LDIF export operations.
ldif-import	Allows the user to perform LDIF import operations.
lockdown-mode	Allows the user to request a server lockdown.
manage-topology	Allows the user to modify topology setting.
metrics-read	Allows the user to read server metrics.
modify-acl	Allows the user to modify access control rules.
password-reset	Allows the user to reset user passwords but not their own. The user must also have privileges granted by access control to write the user password to the target entry.
permit-get-password-policy-state-issues	Allows the user to access password policy state issues.
privilege-change	Allows the user to change the set of privileges for a specific user, or to change the set of privileges automatically assigned to a root user.
server-restart	Allows the user to request a server restart.
server-shutdown	Allows the user to request a server shutdown.
soft-delete-read	Allows the user access to soft-deleted entries.
stream-values	Allows the user to perform a stream values extended operation that obtains all entry DNs and/or all values for one or more attributes for a specified portion of the DIT.
third-party-task	Allows the associated user to invoke tasks created by third-party developers.
unindexed-search	Allows the user to perform an unindexed search in the Oracle Berkeley DB Java Edition backend.
update-schema	Allows the user to update the server schema.

Privilege	Description
use-admin-session	Allows the associated user to use an administrative session to request that operations be processed using a dedicated pool of worker threads.

The Directory Proxy Server provides other privileges that are not assigned to the root user DN by default but can be added using the `ldapmodify` tool (see Modifying Individual Root User Privileges) for more information.

Other Available Privileges

Privilege	Description
bypass-pw-policy	Allows the associated user bypass password policy rules and restrictions.
bypass-read-aci	Allows the associated user to bypass access control checks performed by the server for bind, compare, and search operations. Access control evaluation may still be enforced for other types of operations.
jmx-notify	Allows the associated user to subscribe to receive JMX notifications.
jmx-read	Allows the associated user to perform JMX read operations.
jmx-write	Allows the associated user to perform JMX write operations.
permit-externally-processed-authentication	Allows the associated user accept externally processed authentication.
permit-proxied-mschapv2-details	Allows the associated user to permit MS-CHAP V2 handshake protocol.
proxied-auth	Allows the associated user to accept proxied authorization.

Configuring Administrator Accounts

An administrator account is any account in the user backend that is assigned one or more privileges, or given access to read and write operations beyond that of a normal user entry. The privilege mechanism is the same as that used for Root DN accounts and allows individual privileges to be assigned to an administrator entry.

Typically, administrator user entries are controlled by access control evaluation to limit access to the entire set of data in the Directory Information Tree (DIT). Fine-grained read and write access can be granted using the access control definitions available via the `aci` attribute. Administrator entries reside in the backend configuration (for example, `uid=admin,dc=example,dc=com`) and are replicated between servers in a replication topology.

The following examples show how to configure administrator accounts. The first procedure shows how to set up a single, generic `uid=admin,dc=example,dc=com` account with limited privileges. Note that if you generated sample data at install, you can view an example `uid=admin` entry using `ldapsearch`. The second example shows a more realistic example, where the user is part of the Administrators group. Note that both examples are based on a simple DIT. Actual deployment cases depends on your schema.

To Set Up a Single Administrator Account

Steps

1. Create an LDIF file with an example Administrator entry.

```
dn: uid=admin,dc=example,dc=com
```

```
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
givenName: Admin
uid: admin
cn: Admin User
sn: User
userPassword: password
```

2. Then add the entry using the `ldapmodify` tool.

```
$ bin/ldapmodify --defaultAdd --filename admin.ldif
```

3. Create another LDIF file to add the access control instruction (ACI) to the root suffix, or base DN to give full access to the new administrator. The ACI grants full access to all user attributes, but not to operational attributes. If you want to grant access to operational attributes as well as user attributes, use `(targetattr = "*"|+)` in the access control instruction.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (targetattr = "*")
    (version 3.0; acl "Grant full access for the admin user";
     allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

4. Then add the entry using the `ldapmodify` tool.

```
$ bin/ldapmodify --filename admin.ldif
```

5. Verify the additions using `ldapsearch`. The first command searches for the entry that contains `uid=Admin` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including access control instructions, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=admin)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base
  "(objectclass=*)" "+"
```

6. Add specific privileges to the Admin account. In this example, add the `password-reset` privilege to the admin account from the command line. After typing the privileges, press **CTRL-D** to process the modify operation.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset
```

```
Processing MODIFY request for uid=admin,dc=example,dc=com
MODIFY operation successful for DN uid=admin,dc=example,dc=com
```

7. Assign a password policy for the Admin account. For example, create an "Admin Password Policy", then add the password policy to the account.

```
$ bin/dsconfig create-password-policy \
  --policy-name "Admin Password Policy" \
  --set "description:Password policy for administrators" \
  --set password-attribute:userpassword \
  --set "default-password-storage-scheme:Salted SHA-256" \
  --set password-change-requires-current-password:true \
  --set force-change-on-reset:true \
  --set "max-password-age:25w 5d" \
  --set grace-login-count:3 \
```

```
--no-prompt
```

- Apply the password policy to the account. In this example, the password policy is being added from the command line. The following `ldapmodify` command should be executed with a bind DN that has sufficient rights, such as a Root DN.

```
$ bin/ldapmodify
dn: uid=admin,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config
```

To Change the Administrator Password

About this task

Root users are governed by the Root Password Policy and by default, their passwords never expire. However, if a root user password must be changed, use the `ldappasswordmodify` tool.

Steps

- Open a text editor and create a text file containing the new password. In this example, name the file `rootuser.txt`.

```
$ echo password > rootuser.txt
```

- Use `ldappasswordmodify` to change the root user's password.

```
$ bin/ldappasswordmodify --port 1389 --bindDN "cn=Directory Manager"\
--bindPassword secret --newPasswordFile rootuser.txt
```

- Remove the text file.

```
$ rm rootuser.txt
```

To Set Up an Administrator Group

About this task

The following example shows how to set up a group of administrators that have access rights to the whole Directory Server. The example uses a static group using the `GroupOfUniqueNames` object class.

Steps

- Create an LDIF file with an example Administrator group, and save it as `admin-group.ldif`.

```
dn: ou=Groups,dc=example,dc=com
objectClass: organizationalunit
objectClass: top
ou: Groups

dn: cn=Dir Admins,ou=Groups,dc=example,dc=com
objectClass: groupofuniqueNames
objectClass: top
uniqueMember: uid=user.0, ou=People, dc=example,dc=com
uniqueMember: uid=user.1, ou=People, dc=example,dc=com
cn: Dir Admins
ou: Groups
```

- Then, add the entries using the `ldapmodify` tool.

```
$ bin/ldapmodify --defaultAdd --filename admin-group.ldif
```

3. Create another LDIF file to add the access control instruction (ACI) to the root suffix, or base DN to provide full access to the Directory Server to the new administrator. Save the file as `admin-aci.ldif`.

```
dn: dc=example,dc=com
changetype: modify
add: aci
aci: (target="ldap:///dc=example,dc=com")
    (targetattr != "aci")
    (version 3.0; acl "allow all Admin group";
      allow(all) groupdn = "ldap:///cn=Dir
Admins,ou=Groups,dc=example,dc=com";)
```

4. Then, add the ACI using the `ldapmodify` tool:

```
$ bin/ldapmodify --filename admin-aci.ldif
```

5. Verify the additions using `ldapsearch`. The first command searches for the entry that contains `cn=Dir Admins` and returns it if the search is successful. The second command searches for the base DN and returns only those operational attributes, including access control instructions, associated with the entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(cn=Dir Admins)"
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope base \
  "(objectclass=*)" "+"
```

6. Add specific privileges to each Admin account using an LDIF file, saved as `admin-priv.ldif`. In this example, add the `password-reset` privilege to the `user.0` admin account from the command line. Add the privilege using the `ldapmodify` tool. Repeat the process for the other administrators configured in the Admin group.

```
dn: uid=user.0,ou=People,dc=example,dc=com
changetype: modify
add: ds-privilege-name
ds-privilege-name: password-reset

$ bin/ldapmodify --filename admin-priv.ldif
```

```
Processing MODIFY request for uid=user.0,dc=example,dc=com
MODIFY operation successful for DN uid=user.0,dc=example,dc=com
```

7. Assign a password policy for the Admin account using an LDIF file, saved as `admin-pwd-policy.ldif`. For example, create an "Admin Password Policy", then add the password policy to the account. Apply the password policy to the account using the `ldapmodify` tool.

```
dn: uid=user.0,dc=example,dc=com
changetype: modify
add: ds-pwp-password-policy-dn
ds-pwp-password-policy-dn: cn=Admin Password Policy,cn=Password
Policies,cn=config

$ bin/ldapmodify --filename admin-pwd-policy.ldif
```

Configuring a Global Administrator

A global administrator is created when replication is enabled, and is responsible for managing configuration server groups. A configuration server group is an administration domain that allows you to synchronize configuration changes to one or all of the servers in the group. For example, you can set up a group when configuring a replication topology, where configuration changes to one server can be applied to all of the servers at a time.

Global Administrator(s) are stored in the topology registry. These entries are always mirrored between servers in a topology. Global Administrators can be assigned privileges like other admin users but are

typically used to manage the data under `cn=topology,cn=config` and `cn=config`. You can create new global administrators and remove existing global administrators using the `dsconfig` tool. The global administrator entries are located in the `cn=Topology Admin User, cn=topology,cn=config` branch.

To Create a Global Administrator

Steps

1. Use `dsconfig` to create a new global administrator.

```
$ bin/dsconfig create-topology-admin-user \
  --user-name admin2 \
  --set alternate-bind-dn:cn=admin2 \
  --set password:rootPassword
```

2. To verify the creation of the new administrator, use the `list-topology-admin-users` subcommand with `dsconfig`.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin                : generic
admin2               : generic
```

To Remove a Global Administrator

Steps

1. Use `dsconfig` to delete an existing global administrator.

```
$ bin/dsconfig delete-topology-admin-user --user-name admin2
```

2. To verify the deletion of the global administrator, use the `list-topology-admin-users` option with `dsconfig`.

```
$ bin/dsconfig list-topology-admin-users
Topology Admin User : Type
-----:-----
admin                : generic
```

Configuring Server Groups

The PingDirectory Server provides a mechanism for setting up administrative domains that synchronize configuration changes among servers in a server group. After you have set up a server group, you can make an update on one server using `dsconfig`, then you can apply the change to the other servers in the group using the `--applyChangeTo server-group` option of the `dsconfig` non-interactive command. If you want to apply the change to one server in the group, use the `--applyChangeTo single-server` option. When using `dsconfig` in interactive command-line mode, you will be asked if you want to apply the change to a single server or to all servers in the server group.

About the Server Group Example

You can create an administrative server group using the `dsconfig` tool. The general process is to create a group, add servers to the group, and then set a global configuration property to use the server group. If you are configuring a replication topology, then you must configure the replicas to be in a server group as outlined in Replication Configuration.

The following example procedure adds three Directory Server instances into the server group labelled "group-one".

To Create a Server Group

Steps

1. Create a group called "group-one" using **dsconfig**.

```
$ bin/dsconfig create-server-group --group-name group-one
```

2. Add any directory server to the server group. If you have set up replication between a set of servers, these server entries will have already been created by the **dsreplication enable** command.

```
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server1
```

```
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server2
```

```
$ bin/dsconfig set-server-group-prop \  
  --group-name group-one --add member:server3
```

3. Set a global configuration property for each of the servers that should share changes in this group.

```
$ bin/dsconfig set-global-configuration-prop \  
  --set configuration-server-group:group-one
```

4. Test the server group. In this example, enable the log publisher for each directory server in the group, **server-group**, by using the **--applyChangeTo server-group** option.

```
$ bin/dsconfig set-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --set enabled:true \  
  --applyChangeTo server-group
```

5. View the property on the first directory server instance.

```
$ bin/dsconfig get-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --property enabled
```

```
Property : Value(s)  
-----:-----  
enabled : true
```

6. Repeat step 5 on the second and third directory server instance.
7. Test the server group by disabling the log publisher on the first directory server instance by using the **--applyChangeTo single-server**.

```
$ bin/dsconfig set-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --set enabled:disabled \  
  --applyChangeTo single-server
```

8. View the property on the first directory server instance. The first directory server instance should be disabled.

```
$ bin/dsconfig get-log-publisher-prop \  
  --publisher-name "File-Based Audit Logger" \  
  --property enabled
```

```
Property : Value(s)  
-----:-----  
enabled : false
```

- View the property on the second directory server instance. Repeat this step on the third directory server instance to verify that the property is still enabled on that server.

```
$ bin/dsconfig get-log-publisher-prop \
  --publisher-name "File-Based Audit Logger" \
  --property enabled
```

```
Property : Value(s)
-----:-----
enabled : true
```

Configuring Client Connection Policies

Client connection policies help distinguish what portions of the DIT the client can access. They also enforce restrictions on what clients can do in the server. A client connection policy specifies criteria for membership based on information about the client connection, including client address, protocol, communication security, and authentication state and identity. The client connection policy, however, does not control membership based on the type of request being made.

Every client connection is associated with exactly one client connection policy at any given time, which is assigned to the client when the connection is established. The choice of which client connection policy to use will be reevaluated when the client attempts a bind to change its authentication state or uses the StartTLS extended operation to convert an insecure connection to a secure one. Any changes you make to the client connection policy do not apply to existing connections. The changes only apply to new connections.

Client connections are always unauthenticated when they are first established. If you plan to configure a policy based on authentication, you must define at least one client connection policy with criteria that match unauthenticated connections.

Once a client has been assigned to a policy, you can determine what operations they can perform. For example, your policy might allow only SASL bind operations. Client connection policies are also associated with one or more subtree views, which determine the portions of the DIT a particular client can access. For example, you might configure a policy that prevents users connecting over the extranet from accessing configuration information. The client connection policy is evaluated in addition to access control, so even a root user connecting over the extranet would not have access to the configuration information.

Understanding the Client Connection Policy

Client connection policies are based on two things:

- **Connection criteria.** The connection criteria are used in many areas within the server. They are used by the client connection policies, but they can also be used in other instances when the server needs to perform matching based on connection-level properties, such as filtered logging. A single connection can match multiple connection criteria definitions.
- **Evaluation order index.** If multiple client connection policies are defined in the server, then each of them must have a unique value for the **evaluation-order-index** property. The client connection policies are evaluated in order of ascending evaluation order index. If a client connection does not match the criteria for any defined client connection policy, then that connection will be terminated.

If the connection policy matches a connection, then the connection is assigned to that policy and no further evaluation occurs. If, after evaluating all of the defined client connection policies, no match is found, the connection is terminated.

When a Client Connection Policy is Assigned

A client connection policy can be associated with a client connection at the following times:

- When the connection is initially established. This association occurs exactly once for each client connection.

- After completing processing for a StartTLS operation. This association occurs at most once for a client connection, because StartTLS cannot be used more than once on a particular connection. You also may not stop using StartTLS while keeping the connection active.
- After completing processing for a bind operation. This association occurs zero or more times for a client connection, because the bind request can be processed many times on a given connection.

StartTLS and bind requests will be subject to whatever constraints are defined for the client connection policy that is associated with the client connection at the time that the request is received. Once they have completed, then subsequent operations will be subject to the constraints of the new client connection policy assigned to that client connection. This policy may or may not be the same client connection policy that was associated with the connection before the operation was processed. That is, any policy changes do not apply to existing connections and will be applicable when the client reconnects.

All other types of operations will be subject to whatever constraints are defined for the client connection policy used by the client connection at the time that the request is received. The client connection policy assigned to a connection never changes as a result of processing any operation other than a bind or StartTLS. So, the server will not re-evaluate the client connection policy for the connection in the course of processing an operation. For example, the client connection policy will never be re-evaluated for a search operation.

Restricting the Type of Search Filter Used by Clients

You can restrict the types of search filters that a given client may be allowed to use to prevent the use of potentially expensive filters, like range or substring searches. You can use the `allowed-filter-type` property to provide a list of filter types that may be included in the search requests from clients associated with the client connection policy. This setting will only be used if search is included in the set of allowed operation types. This restriction will only be applied to searches with a scope other than `baseObject`, such as searches with a scope of `singleLevel`, `wholeSubtree`, or `subordinateSubtree`.

The `minimum-substring-length` property can be used to specify the minimum number of non-wildcard characters in a substring filter. Any attempt to use a substring search with an element containing fewer than this number of bytes will be rejected. For example, the server can be configured to reject filters like `"(cn=a*)"` and `"(cn=ab*)"`, but to allow `"(cn=abcde*)"`. This property setting will only be used if search is included in the set of allowed operation types and at least one of `sub-initial`, `sub-any`, or `sub-final` is included in the set of allowed filter types.

There are two primary benefits to enforcing a minimum substring length:

- Allowing very short substrings can require the server to perform more expensive processing. The search requires a lot more server effort to assemble a candidate entry list for short substrings because the server has to examine a lot more index keys.
- Allowing very short substrings makes it easier for a client to put together a series of requests to retrieve all the data from the server (a process known as "trawling"). If a malicious user wants to obtain all the data from the server, then it is easier to issue 26 requests like `"(cn=a*)"`, `"(cn=b*)"`, `"(cn=c*)"`, ..., `"(cn=z*)"` than if the user is required to do something like `"(cn=aaaaa*)"`, `"(cn=aaaab*)"`, `"(cn=aaaac*)"`, ..., `"(cn=zzzzz*)"`.

Setting Resource Limits

Client connection policies can specify resource limits, helping to ensure that no single client monopolizes server resources. You can limit the total number of connections to a server from a particular client or from clients that match specified criteria. You can also limit the duration of the connection.

A client connection policy may only be used to enforce additional restrictions on a client connection. You can never use it to grant a client capabilities that it would not otherwise have.

Any change to any of these new configuration properties will only impact client connections that are assigned to the client connection policy after the change is made. Any connection associated with the client connection policy before the configuration change was made will continue to be subject to the configuration that was in place at the time it was associated with that policy.

Resource Limiting Properties

Property	Description
maximum-concurrent-connections	<p>Specifies the maximum number of client connections that can be associated with that client connection policy at any given time. The default value of zero indicates that no limit will be enforced.</p> <p>If the server already has the maximum number of connections associated with a client connection policy, then any attempt to associate another connection with that policy (e.g., newly-established connections or an existing connection that has done something to change its client connection policy, such as perform a bind or StartTLS operation) will cause that connection to be terminated.</p>
terminate-connection	<p>Specifies that any client connection for which the client connection policy is selected (whether it is a new connection or an existing connection that is assigned to the client connection policy after performing a bind or StartTLS operation) will be immediately terminated.</p> <p>This property can be used to define criteria for connections that you do not want to be allowed to communicate with the Directory Server.</p>
maximum-connection-duration	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established to the Directory Server, regardless of the amount of activity on that connection.</p> <p>A value of "0 seconds" (default) indicates that no limit will be enforced. If a connection associated with the client connection policy has been established for longer than this time, then it will be terminated.</p>
maximum-idle-connection-duration	<p>Specifies the maximum length of time that a connection associated with the client connection policy can remain established with the Directory Server without any requests in progress.</p> <p>A value of "0 seconds" (default) indicates that no additional limit will be enforced on top of whatever idle time limit might already be in effect for an associated connection. If a nonzero value is provided, then the effective idle time limit for any client connection will be the smaller of the <code>maximum-idle-connection-duration</code> from the client connection policy and the idle time limit that would otherwise be in effect for that client.</p> <p>This property can be used to apply a further restriction on top of any value that may be enforced by the <code>idle-time-limit</code> global configuration property (which defines a default idle time limit for client connections) or the <code>ds-rlim-idle-time-limit</code> operational attribute (which may be included in a user entry to override the default idle time limit for that user).</p>
maximum-operation-count-per-connection	<p>Specifies the maximum number of operations that a client associated with the client connection policy will be allowed to request. A value of zero (default) indicates that no limit will be enforced. If a client attempts to request more than this number of operations on the same connection, then that connection will be terminated.</p>

Property	Description
maximum-concurrent-operations-per-connection	<p>Specifies the maximum number of operations that may be active at any time from the same client. This limit is only applicable to clients that use asynchronous operations with multiple outstanding requests at any given time.</p> <p>A value of zero (default) indicates that no limit will be enforced.</p> <p>If a client already has the maximum number of outstanding requests in progress and issues a new request, then that request will be delayed and/or rejected based on the value of the <code>maximum-concurrent-operation-wait-time-before-rejecting</code> property.</p>
maximum-concurrent-operation-wait-time-before-rejecting	<p>Specifies the maximum length of time that a client connection should allow an outstanding operation to complete if the maximum number of concurrent operations for a connection are already in progress when a new request is received on that connection.</p> <p>A value of "0 seconds" (default) indicates that any new requests received while the maximum number of outstanding requests are already in progress for that connection will be immediately rejected.</p> <p>If an outstanding operation completes before this time expires, then the server may be allowed to process that operation. If the time expires, the new request will be rejected.</p>
maximum-ldap-join-size-limit	<p>Specifies the maximum number of entries that can be directly joined with any individual search result entry. A value of zero indicates that no LDAP join size limit is enforced. The limit can be overridden on a per-user basis using the <code>ds-rlim-ldap-join-size-limit</code> operational attribute. The LDAP join size limit is also restricted by the search operation size limit. If a search result entry is joined with more entries than allowed, the join result control will have a "size limit exceeded" (integer value 4) result code.</p>
allowed-request-control	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy will be allowed to use.</p> <p>If any <code>allowed-request-control</code> OIDs are specified, then any request which includes a control not in that set will be rejected. If no <code>allowed-request-control</code> values are specified (default), then any control whose OID is not included in the set of <code>denied-request-control</code> values will be allowed.</p>
denied-request-control	<p>Specifies the OIDs of the request controls that clients associated with the client connection policy will not be allowed to use. If there are any <code>denied-request-control</code> values, then any request containing a control whose OID is included in that set will be rejected.</p> <p>If there are no <code>denied-request-control</code> values (default), then any request control will be allowed if the <code>allowed-request-control</code> property is also empty, or only those controls whose OIDs are included in the set of <code>allowed-request-control</code> values will be allowed if at least one <code>allowed-request-control</code> value is provided.</p>

Property	Description
allowed-filter-type	<p>Specifies the types of components which may be used in filters included in search operations with a non-base scope that are requested by clients associated with the client connection policy. Any non-base scoped search request whose filter contains a component not included in this set will be rejected. The set of possible filter types include:</p> <ul style="list-style-type: none"> ▪ and ▪ or ▪ not ▪ equality ▪ sub-initial ▪ sub-any ▪ sub-final ▪ greater-or-equal ▪ less-or-equal ▪ approximate-match ▪ extensible-match <p>By default, all filter types will be allowed. Also note that no restriction will be placed on the types of filters which may be used in searches with a base scope.</p>
allow-unindexed-searches	<p>Specifies whether clients associated with the client connection policy will be allowed to request searches which cannot be efficiently processed using the configured set of indexes. Note that clients will still be required to have the <code>unindexed-search</code> privilege, so this option will not grant the ability to perform unindexed searches to clients that would not have otherwise had that ability, but it may be used to prevent clients associated with the client connection policy from requesting unindexed searches when they might have otherwise been allowed to do so.</p> <p>By default, this has a value of "true", indicating that any client associated with the client connection policy that has the <code>unindexed-search</code> privilege will be allowed to request unindexed searches.</p>
minimum-substring-length	<p>Specifies the minimum number of bytes, which may be present in any sub-Initial, subAny, or subFinal element of a substring search filter component in a search with a non-baseObject scope. A value of one (which is the default) indicates that no limit will be enforced. This property may be used to prevent clients from issuing overly-vague substring searches that may require the Installing the Directory Server to examine too many entries over the course of processing the request.</p>

Property	Description
maximum-search-size-limit	<p>Specifies the maximum number of entries that may be returned from any single search operation requested by a client associated with this client connection policy. Note that this property only specifies a maximum limit and will never increase any limit that may already be in effect for the client via the <code>size-limit</code> global configuration property or the <code>ds-rlim-size-limit</code> operational attribute.</p> <p>A value of zero (default) indicates that no additional limit will be enforced on top of whatever size limit might already be in effect for an associated connection.</p> <p>If a nonzero value is provided, then the effective maximum size limit for any search operation requested by the client will be the smaller of the size limit from that search request, the <code>maximum-search-size-limit</code> from the client connection policy, and the size limit that would otherwise be in effect for that client.</p>

Defining the Operation Rate

You can configure the maximum operation rate for individual client connections as well as collectively for all connections associated with a client connection policy. If the operation rate limit is exceeded, the Directory Server may either reject the operation or terminate the connection. You can define multiple rate limit values, making it possible to fine tune limits for both a long term average operation rate and short term operation bursts. For example, you can define a limit of one thousand operations per second and one million operations per day, which works out to an average of less than twelve operations per second, but with bursts of up to one thousand operations per second.

Rate limit strings should be specified as a maximum count followed by a slash and a duration. The count portion must contain an integer, and may be followed by a multiplier of k (to indicate that the integer should be interpreted as thousands), m (to indicate that the integer should be interpreted as millions), or g (to indicate that the integer should be interpreted as billions). The duration portion must contain a time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), and may be preceded by an integer to specify a quantity for that unit.

For example, the following are valid rate limit strings:

- 1/s (no more than one operation over a one-second interval)
- 10K/5h (no more than ten thousand operations over a five-hour interval)
- 5m/2d (no more than five million operations over a two-day interval)

You can provide time units in many different formats. For example, a unit of seconds can be signified using s, sec, sect, second, and seconds.

Client Connection Policy Deployment Example

In this example scenario, we assume the following:

- Two external LDAP clients are allowed to bind to the Directory Server.
- Client 1 should be allowed to open only 1 connection to the server.
- Client 2 should be allowed to open up to 5 connections to the server.

Defining the Connection Policies

We need to set a per-client connection policy limit on the number of connections that may be associated with a particular client connection policy. We have to define at least two client connection policies, one for each of the two clients. Each policy must have different connection criteria for selecting the policy with which a given client connection should be associated.

Because the criteria is based on authentication, we must create a third client connection policy that applies to unauthenticated clients, because client connections are always unauthenticated as soon as they are

established and before they have sent a bind request. Plus, clients are not required to send a bind request as their first operation.

Therefore, we define the following three client connection policies:

- **Client 1 Connection Policy**, which only allows client 1, with an evaluation order index of 1.
- **Client 2 Connection Policy**, which only allows client 2, with an evaluation order index of 2.
- **Unauthenticated Connection Policy**, which allows unauthenticated clients, with an evaluation order index of 3.

We define simple connection criteria for the Client 1 Connection Policy and the Client 2 Connection Policy with the following properties:

- The `user-auth-type` must not include none, so that it will only apply to authenticated client connections.
- The `included-user-base-dn` should match the bind DN for the target user. This DN may be full DN for the target user, or it may be the base DN for a branch that contains a number of users that you want treated in the same way.

To create more generic criteria that match more than one user, you could list the DNs of each of the users explicitly in the `included-user-base-dn` property. If there is a group that contains all of the pertinent users, then you could instead use the `[all|any|not-all|not-any]-included-user-group-dn` property to apply to all members of that group. If the entries for all of the users match a particular filter, then you could use the `[all|any|not-all|not-any]-included-user-filter` property to match them.

How the Policy is Evaluated

Whenever a connection is established, the server associates the connection with exactly one client connection policy. The server does this by iterating over all of the defined client connection policies in ascending order of the evaluation order index. Policies with a lower evaluation order index value will be examined before those with a higher evaluation order index value. The first policy that the server finds whose criteria match the client connection will be associated with that connection. If no client connection policy is found with criteria matching the connection, then the connection will be terminated.

So, in our example, when a new connection is established, the server first checks the connection criteria associated with the Client 1 Connection Policy because it has the lowest evaluation order index value. If it finds that the criteria do not match the new connection, the server then checks the connection criteria associated with the Client 2 Connection Policy because it has the second lowest evaluation order index. If these criteria do not match, the server finally checks the connection criteria associated with the Unauthenticated Connection Policy, because it has the third lowest evaluation order index. It finds a match, so the client connection is associated with the Unauthenticated Connection Policy.

After the client performs a bind operation to authenticate to the server, then the client connection policies will be re-evaluated. If client 2 performs the bind, then the Client 1 Connection Policy will not match but the Client 2 Connection Policy will, so the connection will be re-associated with that client connection policy. Whenever a connection is associated with a client connection policy, the server will check to see if the maximum number of client connections have already been associated with that policy. If so, then the newly-associated connection will be terminated.

For example, Client 1 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. Client 1 then sends a bind request. The determination of whether the bind operation is allowed is made based on the constraints defined in the Unauthenticated Connection Policy, because it is the client connection policy already assigned to the client connection. Once the bind has completed, then the server will reevaluate the client connection policy against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to the Client 1 Connection Policy.

Next, Client 2 opens a new connection. Because it is a new connection not yet associated with connection criteria, it is assigned to the Unauthenticated Connection Policy. When Client 2 sends a bind request, the operation is allowed based on the constraints defined in the Unauthenticated Connection Policy. Once the

bind is complete, the client connection is evaluated against the connection criteria associated with Client 1 Connection Policy, because it has the lowest evaluation order index. The associated connection criteria do not match, so the client 2 connection is evaluated against the connection criteria associated with Client 2 Connection Policy, because it has the next lowest evaluation order index. The associated connection criteria match, so processing stops and the client connection is assigned to Client 2 Connection Policy.

Client 1 sends a search request. The Client 1 Connection Policy is used to determine whether the search operation should be allowed, because this is the client connection policy assigned to the client connection for client 1. The connection is not reevaluated, before or after processing the search operation.

To Configure a Client Connection Policy Using the Console

Steps

1. Open the Administrative Console. Provide a user name and password, and then click **Login**.
2. In the **Core Server** section, click **Client Connection Policies**. If you do not see **Client Connection Policies** on the menu, change the Object Types filter to **Standard**.
3. Click **Add New** to add a new policy.
4. Enter a Policy ID. If you want to base your new client connection policy on an existing policy, select it from the **Template** menu.
5. Configure the properties of the client connection policy. To enable the policy, select **Enabled**.
6. Enter the order in which you want the new policy to be evaluated in the **Evaluation Order Index** box, and then click **Continue**. A policy with a lower index is evaluated before a policy with a higher index. The Directory Server uses the first evaluated policy that applies to a client connection.
7. Select the connection criteria that match the client connection for this policy. Click **View and edit** to change the criteria. Click **Select New** to add new criteria. Select the operations allowed for clients that are members of this connection group. Use the **Add and Remove** buttons to make operations available to clients. Specify the extended operations that clients are allowed and denied to use.
8. Enter the type of authorization allowed and the SASL mechanisms that are allowed and denied in response to client requests.
9. Check the **Include Backend Subtree Views** check box if you want to automatically include the subtree views of backends configured in the Directory Server. You can also choose to include and exclude specific base DNs using the appropriate fields.
10. Once you have finished configuring the properties of your client connection policy, click **Confirm then Save** to review the `dsconfig` command equivalent and save your changes. Click **Save Now** to save your changes without first reviewing the `dsconfig` output.

To Configure a Client Connection Policy Using dsconfig

About this task

You can configure a client connection policy using the `dsconfig` tool in interactive mode from the command line. You can access the **Client Connection Policy** menu on the **Standard objects** menu.

Steps

1. Use the `dsconfig` tool to create and configure a client connection policy. Specify the host name, connection method, port number, and bind DN as described in previous procedures.
2. On the Directory Server main menu, change to the **Standard objects** menu by entering `o` and then entering the number for the Standard menu.
3. On the Directory Server main menu, enter the number associated with **Client Connection Policy**.
4. On the **Client Connection Policy management** menu, type the number corresponding to **Create a new connection policy**.
5. Enter `n` to create a new client connection policy from scratch.
6. Next, enter a name for the new client connection policy.

7. On the **Enabled Property** menu, select true to enable the connection policy.
8. On the **Evaluation-Order Property** menu, type a value between 0 and 2147483647 to set the evaluation order for the policy. A client connection policy with a lower evaluation-order will be evaluated before one with a higher number. For this example, type 9999.
9. On the **Client Connection Policy** menu, review the configuration. If you want to make any further modifications, enter the number corresponding to the property. Enter **␣** to finish the creation of the client connection policy.

Any changes that you make to the client connection policy do not apply to existing connections. They will only apply to new connections.

Restricting Server Access Based on Client IP Address

Another common use case is to limit client access to the Directory Server. Two methods are available:

- **Connection Handlers.** You can limit the IP addresses using the LDAP or LDAPS connection handlers. The connection handlers provide an `allowed-client` property and a `denied-client` property. The `allowed-client` property specifies the set of allowable address masks that can establish connections to the handler. The `denied-client` property specifies the set of address masks that are not allowed to establish connections to the handler.
- **Client Connection Policies.** You can take a more fine-grained approach by restricting access by configuring a new Client Connection Policy, then create a new connection criteria and associate it with the connection policy. Connection criteria define sets of criteria for grouping and describing client connections based on a number of properties, including the protocol, client address, connection security, and authentication state for the connection. Each client connection policy may be associated with zero or more Connection Criteria, and server components may use Connection Criteria to indicate which connections should be processed and what kind of processing should be performed (e.g., to select connections and/or operations for filtered logging, or to classify connections for network groups).

To Restrict Server Access Using the Connection Handlers

Steps

- Use `dsconfig` to set the `allowed-client` property for the LDAP connection handler. You should specify the address mask for the range of allowable IP addresses that can establish connections to the Directory Server. You should also specify the loopback address, 127.0.0.1, so that you will still be able to configure the server using the `dsconfig` tool on the local host.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAP Connection Handler" \
  --set "allowed-client:10.6.1.*" \
  --set allowed-client:127.0.0.1
```

To Restrict Server Access Using Client Connection Policies

Steps

1. Create a simple connection criteria. The following example uses the `dsconfig` tool in non-interactive mode. It allows only the Directory Server's IP address and loopback to have access.

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add included-client-address:10.6.1.80 \
  --add included-client-address:127.0.0.1
```

2. Assign the criteria to the client connection policy. After you have run the following command, access is denied to remote IP addresses. The Directory Server does not require a restart.

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy \
  --set connection-criteria:allowed-ip-addr
```

3. Add a remote IP range to the criteria. For this example, add 10.6.1.*. Access from any remote servers is allowed. The Directory Server does not require a restart.

```
$ bin/dsconfig set-connection-criteria-prop \
  --criteria-name allowed-ip-addr \
  --add "included-client-address:10.6.1.*"
```

4. To restore default behavior, you can remove the criteria from the connection policy. The Directory Server does not require a restart. Remember to include the LDAP or LDAPS connection parameters (for example, host name, port, bindDN, bindPassword) with the `dsconfig` command.

```
$ bin/dsconfig set-client-connection-policy-prop \
  --policy-name new-policy --remove connection-criteria:allowed-ip-addr
```

To Automatically Authenticate Clients that Have a Secure Communication Channel

About this task

The Directory Server provides an option to automatically authenticate clients that have a secure communication channel (either SSL or StartTLS) and presented their own certificate. This option is disabled by default, but when enabled, the net effect will be as if the client issued a SASL EXTERNAL bind request on that connection.

This option will be ignored if the client connection is already authenticated (e.g., because it is using StartTLS but the client had already performed a bind before the StartTLS request). If the bind attempt fails, then the connection will remain unauthenticated but usable. If the client subsequently sends a bind request on the connection, then it will be processed as normal and any automatic authentication will be destroyed.

Steps

- Run the following `dsconfig` command.

```
$ bin/dsconfig set-connection-handler-prop \
  --handler-name "LDAPS Connection Handler" \
  --set "auto-authenticate-using-client-certificate:true"
```

Securing the Server with Lockdown Mode

The Directory Server provides tools to enter and leave lockdown mode if the server requires a security lockdown. In lockdown mode, only users with the `lockdown-mode` privilege can perform operations, while those without the privilege are rejected. Root users have this privilege by default; other administrators can be given this privilege. Lockdown mode can also be configured as a recurring task.

The Directory Server can be manually placed into lockdown mode to perform some administrative operation while ensuring that other client requests are not allowed to access any data in the server. In addition, some configuration problems (particularly problems that could lead to inadvertent exposure of sensitive information, like an access control rule that cannot be properly parsed) cause the server to place itself in lockdown mode, so that an administrator can manually correct the problem. Lockdown mode does not persist across restarts. The directory server can be taken out of lockdown mode by using either the `leave-lockdown-mode` tool or by restarting the server. If administrators want to start a server in lockdown mode, they can use the `start-server --lockdownMode` option.

Any client request to the Directory Server in lockdown mode receives an "Unavailable" response.

To Manually Enter Lockdown Mode

Steps

- Use `enter-lockdown-mode` to begin a lockdown mode.

```
$ bin/enter-lockdown-mode
```

To Leave Lockdown Mode

Steps

- Use `leave-lockdown-mode` to end lockdown mode.

```
$ bin/leave-lockdown-mode
```

To Start a Server in Lockdown Mode

Steps

- Use the `--lockdownMode` option with the `start-server` tool to start a server in lockdown mode.

```
$ bin/start-server --lockdownMode
```

Configuring Maximum Shutdown Time

During shutdown, some database checkpointing and cleaning threads may remain active even after the default time period on systems with very large or very busy database backends. If checkpointing or cleaning is aborted prematurely, it could possibly lead to significantly longer startup times for the Directory Server. The Directory Server provides an option for administrators to set the maximum time a shutdown process should take. When a shutdown process is initiated, the server begins stopping all of its internal components and waits up to 5 minutes for all threads to complete before exiting.

Administrators can use the `dsconfig` tool to increase the maximum shutdown time to allow database operations to complete.

To Configure the Maximum Shutdown Time

Steps

- Use the `dsconfig` tool to increase the maximum shutdown time for your system. The following command increases the maximum shutdown time from 5 minutes to 6 minutes. The command allows time values of w (weeks), d (days), h (hours), m (minutes), s (seconds), ms (milliseconds).

```
$ bin/dsconfig set-global-configuration-prop --set "maximum-shutdown-time:6m"
```

Remember to include the LDAP or LDAPS connection parameters (e.g., host name, port, bindDN and bindDN password) with the `dsconfig` command.

The `maximum-shutdown-time` property can also be changed using the `dsconfig` tool in interactive mode. From the main menu, select **Global Configuration**, and then select the option to display advanced properties.

Working with Referrals

A referral is a redirection mechanism that tells client applications that a requested entry or set of entries is not present on the Directory Server but can be accessed on another server. Referrals can be used when entries are located on another server. The Directory Server implements two types of referrals depending on the requirement.

- Referral on Update plugin.** The Directory Server provides a Referral on Update plugin to create any referrals for update requests (add, delete, modify, or modDN operations) on read-only servers. For example, given two replicated directory servers where one server is a master (read-write) and the other, a read-only server, you can configure a referral for any client update requests on the second directory server to point to the master server. If a client application sends an add request, for example, on the second directory server, the directory server responds with a referral that indicates any updates should be made on the master server. All read requests on the read-only server will be processed as normal.

- **Smart Referrals.** The Directory Server supports smart referrals that map an entry or a specific branch of a DIT to an LDAP URL. Any client requests (reads or writes) targeting at or below the branch of the DIT will send a referral to the server designated in the LDAP URL.

Specifying LDAP URLs

Referrals use LDAP URLs to redirect a client application's request to another server. LDAP URLs have a specific format, described in RFC 4516 and require that all special characters be properly escaped and any spaces indicated as "%20". LDAP URLs have the following syntax:

```
ldap[s]://hostname:port/base-dn?attributes?scope?filter
```

where

- *ldap[s]* indicates the type of LDAP connection to the Directory Server. If the Directory Server connects over a standard, non-encrypted connection, then *ldap* is used; if it connects over SSL, then *ldaps* is used. Note that any search request initiated by means of an LDAP URL is anonymous by default, unless an LDAP client provides authentication.
- *hostname* specifies the host name or IP address of the Directory Server.
- *port* specifies the port number of the Directory Server. If no port number is provided, the default LDAP port (389) or LDAPS port (636) is used.
- *base-dn* specifies the distinguished name (DN) of an entry in the DIT. The Directory Server uses the base DN as the starting point entry for its searches. If no base DN is provided, the search begins at the root of the DIT.
- *attributes* specifies those attributes for which the Directory Server should search and return. You can indicate more than one attribute by providing a comma-separated list of attributes. If no attributes are provided, the search returns all attributes.
- *scope* specifies the scope of the search, which could be one of the following: *base* (only search the specified base DN entry), *one* (only search one level below the specified base DN), *sub* (search the base entry and all entries below the specified base DN). If no scope is provided, the server performs a base search.
- *filter* specifies the search filter to apply to entries within the scope of the search. If no filter is provided, the server uses +.

Creating Referrals

You can create a smart referral by adding an entry with the `referral` and `extensibleObject` object classes or adding the object classes to a specific entry. The referral object class designates the entry as a referral object. The `extensibleObject` object class allows you to match the target entry by matching any schema attribute. The following example shows how to set up a smart referral if a portion of a DIT is located on another server.

To Create a Referral

Steps

1. Create an LDIF file with an entry that contains the `referral` and `extensibleObject` object classes.

```
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
objectClass: top
objectClass: referral
objectClass: extensibleObject
ou: Engineering Team1
ref: ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

2. On the first server, add the referral entry using the `ldapmodify` command.

```
$ bin/ldapmodify --defaultAdd --fileName referral-entry.ldif
```

3. Verify the addition by searching for a user.

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com "(uid=user.4)"
```

```
SearchReference(referralURLs={ldap://server2.example.com:6389/
ou=EngineeringTeam1,ou=People,dc=example,dc=com??sub?})
```

To Modify a Referral

Steps

- Use `ldapmodify` with the `manageDSAIT` control to modify the `ref` attribute on the referral entry.

```
$ bin/ldapmodify --control manageDSAIT
dn: ou=EngineeringTeam1,ou=People,dc=example,dc=com
changetype: modify
replace: ref
ref: ldap://server3.example.com/
ou=EngineeringTeam1,ou=People,dc=example,dc=com
```

To Delete a Referral

Steps

- Use `ldapdelete` with the `manageDSAIT` control to delete the referral entry.

```
$ bin/ldapdelete \
--control manageDSAIT "ou=EngineeringTeam1,ou=People,dc=example,dc=com"
```

Configuring a Read-Only Server

The PingDirectory Server provides a means to configure a hub-like, read-only directory server for legacy systems that require it. The read-only directory server participates in replication but cannot respond to any update requests from an external client. You can configure the Directory Server by setting the writability mode to internal-only, which makes the server operate in read-only mode. Read-only mode directory servers can process update operations from internal operations but reject any write requests from external clients. Because the Directory Server cannot accept write requests, you can configure the server to send a referral, which redirects a client's request to a master server. The client must perform the operation again on the server named in the referral.

Note: For Implementers of Third Party Extensions. Many Server SDK extensions use the `InternalConnection` interface to process operations in the server, rather than issuing LDAP requests over the network. If an extension does so in response to an external update request, then any Directory Server using that extension will effectively respond to external update requests, even though the Directory Server is configured to operate in read-only mode, as described above. One possible workaround is to split the extension into two extensions, one for reads and one for writes, then disabling (or not deploying) the write-only extension when configuring a Directory Server in read-only mode.

To Configure a Read-Only Server

Steps

1. Install two replicating directory servers. See [Enabling Replication](#) for various ways to set up your servers.
2. On the second server, use the `dsconfig` command to set the writability mode of the server to internal-only.

```
$ bin/dsconfig set-global-configuration-prop \
```

```
--set writability-mode:internal-only
```

3. On the second server, use the `dsconfig` tool to create a referral that instructs the server to redirect client write requests under `dc=example,dc=com` to `server1.example.com:1389`. The referral itself is defined as a plugin of type `Referral on Update`. This command sets up the server to process read operations but redirects all write operations under `dc=example,dc=com` to another server.

```
$ bin/dsconfig create-plugin --plugin-name "Refer Updates" \
  --type referral-on-update \
  --set enabled:true \
  --set referral-base-url:ldap://server1.example.com:1389/ \
  --set "base-dn:dc=example,dc=com"
```

4. To test the referral, attempt to modify an entry and confirm that the server responds with the result code of 10. The resulting message is available in the server's access log.

```
$ bin/ldapmodify -p 2389 -D "cn=Directory Manager" -w password
dn: uid=user.12,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 408 555 1155
```

```
[06/Aug/2012:15:28:21.468 -0400] MODIFY
RESULT conn=86 op=1 msgID=1 requesterIP="127.0.0.1"
dn="uid=user.12,ou=People,dc=example,dc=com" resultCode=10
referralURLs="ldap://server1.example.com:1389/uid=user.12,
ou=People,dc=example,dc=com" etime=0.223
```

Configuring HTTP Access for the Directory Server

Although most clients communicate with the PingDirectory Server using LDAP, the server also provides support for an HTTP connection handler that uses Java servlets to serve content to clients over HTTP. Ping Identity offers an extension that uses this HTTP connection handler to add support for the System for Cross-domain Identity Management (SCIM) protocol. Third-party developers can also use the Server SDK to write extensions that leverage this HTTP support.

The following sections describe how to configure HTTP servlet extensions and how to configure an HTTP connection handler.

Configuring HTTP Servlet Extensions

To use the HTTP connection handler, you must first configure one or more servlet extensions. Servlet extensions are responsible for obtaining Java servlets (using the Java Servlet 3.0 specification as described in JSR 315) and registering them to be invoked using one or more context paths. If you plan to deploy the SCIM extension, then you should follow the instructions in Chapter 24, "*Managing the SCIM Servlet Extension*." For custom servlet extensions created using the Server SDK, the process varies based on whether you are using a Java-based or Groovy-scripted extension.

Web Application Servlet Extensions

A Web application may be deployed either as a WAR file that has been packaged according to the standard layout and containing a `web.xml` deployment descriptor, or from a directory containing the application's source components arranged in the standard layout.

When deploying a Web application from a directory, you may specify the location of the `web.xml` deployment descriptor if it is not in the standard location. You may also specify the directory used by the server for temporary files. At runtime the web application has access to the server classes.

Java-based Servlet Extensions

For Java-based extensions, first use the Server SDK to create and build the extension bundle as described in the Server SDK documentation. Then, install it using the `manage-extension` tool as follows:

```
$ bin/manage-extension --install/path/to/extension.zip
```

The Java-based extension may then be configured for use in the server using `dsconfig` or the Administrative Console. Create a new Third Party HTTP Servlet Extension, specifying the fully-qualified name for the `HTTPServletExtension` subclass in the `extension-class` property, and providing any appropriate arguments in the `extension-argument` property.

Note: Web Application and Servlet extensions run in a shared embedded web application server environment. Incompatibilities or conflicts may arise from use of different versions of commonly used jars or including frameworks such as loggers, Spring components, JAX-RS implementations or other resources which may require a dedicated Java Virtual Machine (JVM) environment. After introducing a custom extension, check the server error log for an indication that the extension loaded successfully. The error log may also contain debug information if the extension failed to load with an initialization exception or did not complete initialization.

Groovy-Scripted Extensions

For Groovy-scripted extensions, place the necessary Groovy scripts in the appropriate directory (based on the package for those scripts) below the `lib/groovy-scripted-extensions` directory. Then, create a new Groovy Scripted HTTP Servlet Extension, specifying the fully-qualified Groovy class name for the `script-class` property, and providing any appropriate arguments in the `script-argument` property.

Configuring HTTP Operation Loggers

Servlet extensions may write error log messages in the same way as any other kind of server component, but interaction with HTTP clients will not be recorded in the server access log. However, if a servlet extension performs internal operations to interact with data held in the directory server, then those operations may be captured in the access log. To capture information about communication with HTTP clients, you must configure one or more HTTP operations loggers.

By default, the server comes with a single HTTP operation logger implementation, which uses the standard W3C common log format. It records messages in a format like the following:

```
127.0.0.1 - - [01/Jan/2012:00:00:00 -0600] "GET/hello HTTP/1.1" 200 113
```

The log message contains the following elements:

- The IP address of the client that issued the request.
- The RFC 1413 (ident) identity of the client. Because the ident protocol is not typically provided by HTTP clients, the HTTP connection handler never requests this information. This identity will always be represented as a dash to indicate that information is not available.
- The authenticated identity determined for the request by HTTP authentication, or a dash to indicate that the request was not authenticated.
- The time that the request was received.
- The request issued by the client, including the HTTP method, path and optional query string, and the HTTP protocol version used.
- The integer representation of the HTTP status code for the response to the client.
- The number of bytes included in the body of the response to the client.

To configure an HTTP operation logger to use this common log format, create a new instance of a Common Log File HTTP Operation Log Publisher object, specifying the path and name for the active log file to be written and the rotation and retention policies that should be used to manage the log files. In general, properties for Common Log File HTTP Operation Log Publisher objects have the same meaning and use as they do for other kinds of loggers.

You can use the Server SDK to create custom Java-based or Groovy-scripted HTTP operation loggers using the Third Party HTTP Operation Log Publisher and Groovy Scripted HTTP Operation Log Publisher object types.

Example HTTP Log Publishers

When troubleshooting HTTP Connection Handler issues, administrators should first look at the logs to determine any potential problems. The following section shows some `dsconfig` commands and their corresponding log files.

Default Configuration Example. You can configure a default detailed HTTP Log Publisher with default log rotation and retention policies as follows:

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
  --type detailed-http-operation \
  --set enabled:true \
  --set log-file:logs/http-detailed-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy" \
  --set "retention-policy:Size Limit Retention Policy"
```

The corresponding log file provides access information below. The log message contains the following elements:

- The time that the request was received.
- The request ID issued by the client, including the IP address, port, HTTP method, and URL.
- The authorization type, request content type, and status code.
- The response content length.
- The redirect URI.
- The response content type.

The HTTP log file is shown as follows:

```
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300604 from="10.5.1.10:53269"
method="GET" url="https://10.5.1.129:443/Gimel/Users/
uid=user.402914,ou=People,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.145 responseContentLength=1530 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.402914,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:01:19:45 -0600] RESULT requestID=4300605 from="10.5.1.10:53269"
method="PUT" url="https://10.5.1.129:443/Gimel/Users/
uid=user.207585,ou=people,
dc=gimel" authorizationType="Basic" requestContentType="application/json"
statusCode=200 etime=4.872 responseContentLength=1532 redirectURI="https://
x2270-11.example.lab:443/Gimel/Users/uid=user.207585,ou=people,dc=gimel"
responseContentType="application/json"
[23/Feb/2012:11:31:18 -0600] RESULT requestID=4309872 from="10.5.1.10:3
```

Configuration with Request/Response Header Names and Values. The following example adds request/response header names and values, including the "Content-Type" request header, which is normally suppressed by default.

```
$ bin/dsconfig set-log-publisher-prop \
  --publisher-name "HTTP Detailed Access Logger" \
  --set log-request-headers:header-names-and-values \
  --remove suppressed-request-header-name:Content-Type \
  --set log-response-headers:header-names-and-values
```

The following is a log example of a query request by a SCIM Server using the property, `scim-query-rate`. The log message contains the basic log elements shown in the first example plus the following additional information:

- The request header for the host, http method, content type, connection, user agent.
- The response header for the access-control credentials.

```
[23/Oct/2012:11:39:41-0600] RESULT requestID=4665307 from="10.5.0.20:56044"
method="GET" url="https://10.5.1.129:443/Beth/Users?attributes=username,title,
emails,urn:scim:schemas:extension:custom:1.0:descriptions,urn:scim:schemas:
extension:enterprise:1.0:manager,groups,urn:scim:schemas:extension:custom:1.0:
blob&filter=username+eq+%22user.18935%22" requestHeader="Host:
x2270-11.example.
lab:443" requestHeader="Accept: application/json" requestHeader="Content-Type:
application/json" requestHeader="Connection: keep-alive"
requestHeader="User-Agent: Wink Client v1.1.2" authorizationType="Basic"
requestContentType="application/json" statusCode=200 etime=140.384
responseContentLength=11778 responseHeader="Access-Control-Allow-Credentials:
true" responseContentType="application/json"
```

Another log example shows an example user creation event. The client is curl.

```
[23/Oct/2016:11:50:11-0600] RESULT requestID=4802791 from="10.8.1.229:52357"
method="POST" url="https://10.2.1.113:443/Aleph/Users/" requestHeader="Host:
x2270-
11.example.lab" requestHeader="Expect: 100-continue" requestHeader="Accept:
applica-
tion/xml" requestHeader="Content-Type: application/xml" requestHeader="User-
Agent:
curl/7.21.4 (universal-apple-darwin11.0) libcurl/7.21.4 OpenSSL/0.9.8r
zlib/1.2.5"
authorizationType="Basic" requestContentType="application/xml" requestContent-
Length=1773 statusCode=201 etime=11.598 responseContentLength=1472 redirec-
tURI="https://x2270-11.example.lab:443/Aleph/Users/b2cef63c-5e46-11e1-974b-
60334b1a0d7a" responseContentType="application/xml"
```

The final example shows a user deletion request. The client is the Sync Server.

```
[23/Oct/2016:11:38:06-0600] RESULT requestID=4610261 from="10.5.1.114:34558"
method="DELETE" url="https://10.2.1.113:443/Aleph/Users/b8547525-24e0-41ae-
b66b-
0b441800de70" requestHeader="Host: x2270-11.example.lab:443"
requestHeader="Accept:
application/json" requestHeader="Content-Type: application/json"
requestHeader="Con-
nection: keep-alive" requestHeader="User-Agent: DataSync-6.0.0.0 (Build
20121022173845Z, Revision 11281)" authorizationType="Basic"
requestContentType="appli-
cation/json" statusCode=200 etime=10.615 responseContentLength=0
```

Configuring HTTP Connection Handlers

HTTP connection handlers are responsible for managing the communication with HTTP clients and invoking servlets to process requests from those clients. They can also be used to host web applications on the server. Each HTTP connection handler must be configured with one or more HTTP servlet extensions and zero or more HTTP operation log publishers.

If the HTTP Connection Handler cannot be started (for example, if its associated HTTP Servlet Extension fails to initialize), then this will not prevent the entire Directory Server from starting. The Directory Server's **start-server** tool will output any errors to the error log. This allows the Directory Server to continue serving LDAP requests even with a bad servlet extension.

The configuration properties available for use with an HTTP connection handler include:

- **listen-address.** Specifies the address on which the connection handler will listen for requests from clients. If not specified, then requests will be accepted on all addresses bound to the system.

- **listen-port.** Specifies the port on which the connection handler will listen for requests from clients. Required.
- **use-ssl.** Indicates whether the connection handler will use SSL/TLS to secure communications with clients (whether it uses HTTPS rather than HTTP). If SSL is enabled, then `key-manager-provider` and `trust-manager-provider` values must also be specified.
- **http-servlet-extension.** Specifies the set of servlet extensions that will be enabled for use with the connection handler. You can have multiple HTTP connection handlers (listening on different address/port combinations) with identical or different sets of servlet extensions. At least one servlet extension must be configured.
- **http-operation-log-publisher.** Specifies the set of HTTP operation log publishers that should be used with the connection handler. By default, no HTTP operation log publishers will be used.
- **key-manager-provider.** Specifies the key manager provider that will be used to obtain the certificate presented to clients if SSL is enabled.
- **trust-manager-provider.** Specifies the trust manager provider that will be used to determine whether to accept any client certificates presented to the server.
- **num-request-handlers.** Specifies the number of threads that should be used to process requests from HTTP clients. These threads are separate from the worker threads used to process other kinds of requests. The default value of zero means the number of threads will be automatically selected based on the number of CPUs available to the JVM.
- **web-application-extension.** Specifies the Web applications to be hosted by the server.

To Configure an HTTP Connection Handler

About this task

An HTTP connection handler has two dependent configuration objects: one or more HTTP servlet extensions and optionally, an HTTP log publisher. The HTTP servlet extension and log publisher must be configured prior to configuring the HTTP connection handler. The log publisher is optional but in most cases, you want to configure one or more logs to troubleshoot any issues with your HTTP connection.

Steps

1. The first step is to configure your HTTP servlet extensions. The following example uses the `ExampleHTTPServletExtension` in the Server SDK.

```
$ bin/dsconfig create-http-servlet-extension \
  --extension-name "Hello World Servlet" \
  --type third-party \
  --set "extension-
class:com.unboundid.directory.sdk.examples.ExampleHTTPServletExtension" \
  --set "extension-argument:path=/" \
  --set "extension-argument:name=example-servlet"
```

2. Next, configure one or more HTTP log publishers. The following example configures two log publishers: one for common access; the other, detailed access. Both log publishers use the default configuration settings for log rotation and retention.

```
$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Common Access Logger" \
  --type common-log-file-http-operation \
  --set enabled:true \
  --set log-file:logs/http-common-access \
  --set "rotation-policy:24 Hours Time Limit Rotation Policy" \
  --set "rotation-policy:Size Limit Rotation Policy" \
  --set "retention-policy:File Count Retention Policy" \
  --set "retention-policy:Free Disk Space Retention Policy"

$ bin/dsconfig create-log-publisher \
  --publisher-name "HTTP Detailed Access Logger" \
```

```
--type detailed-http-operation \
--set enabled:true \
--set log-file:logs/http-detailed-access \
--set "rotation-policy:24 Hours Time Limit Rotation Policy" \
--set "rotation-policy:Size Limit Rotation Policy" \
--set "retention-policy:File Count Retention Policy" \
--set "retention-policy:Free Disk Space Retention Policy"
```

3. Configure the HTTP connection handler by specifying the HTTP servlet extension and log publishers. Note that some configuration properties can be later updated on the fly while others, like `listen-port`, require that the HTTP Connection Handler be disabled, then re-enabled for the change to take effect.

```
$ bin/dsconfig create-connection-handler \
--handler-name "Hello World HTTP Connection Handler" \
--type http \
--set enabled:true \
--set listen-port:8443 \
--set use-ssl:true \
--set "http-servlet-extension:Hello World Servlet" \
--set "http-operation-log-publisher:HTTP Common Access Logger" \
--set "http-operation-log-publisher:HTTP Detailed Access Logger" \
--set "key-manager-provider:JKS" \
--set "trust-manager-provider:JKS"
```

4. By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to TRUE by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

To Configure an HTTP Connection Handler for Web Applications

About this task

Steps

1. Create the Web application servlet extension.

```
$ bin/dsconfig create-web-application-extension \
--extension-name "Hello Web Application" \
--set "base-context-path:/hello-app" \
--set "document-root-directory:/opt/hello-web-app"
```

2. By default, the HTTP connection handler has an advanced monitor entry property, `keep-stats`, that is set to TRUE by default. You can monitor the connection handler using the `ldapsearch` tool.

```
$ bin/ldapsearch --baseDN "cn=monitor" \
"(objectClass=ds-http-connection-handler-statistics-monitor-entry)"
```

HTTP Correlation IDs

A typical request to a software system is handled by multiple subsystems, many of which may be distinct servers residing on distinct hosts and locations. Tracing the request flow on distributed systems can be challenging, as log messages are scattered across various systems and intermingled with messages for other requests. To make this easier, a correlation ID can be assigned to a request, which is then added to every associated operation as the request flows through the larger system. The correlation ID allows related log messages to be easily located and grouped. The server supports correlation IDs for all HTTP requests received through its HTTP(S) Connection Handler.

When an HTTP request is received, it is automatically assigned a correlation ID. This ID can be used to correlate HTTP responses with messages recorded to the HTTP Detailed Operation log and the trace log. For specific web APIs, the correlation ID may also be passed to the LDAP subsystem. For the SCIM 1,

Delegated Admin, Consent, and Directory REST APIs, the correlation ID will also appear with associated requests in LDAP logs in the `correlationID` key. The correlation ID is also used as the default client request ID value in Intermediate Client Request Controls used by the SCIM 2, Consent, and Directory REST APIs. Values related to the Intermediate Client Request Control appear in the LDAP logs in the `via` key, and are forwarded to downstream LDAP servers when received by the PingDirectoryProxy Server. The correlation ID header is also added to requests forwarded by the PingDataGovernance gateway.

For Server SDK extensions that have access to the current `HttpServletRequest`, the current correlation ID can be retrieved as a string through the `HttpServletRequest`'s `com.pingidentity.pingdata.correlation_id` attribute. For example:

```
(String) request.getAttribute("com.pingidentity.pingdata.correlation_id");
```

Configure HTTP Correlation ID Support

About this task

Correlation ID support is enabled by default for each HTTP Connection Handler.

Steps

- To enable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:true
```

- To disable correlation ID support for the HTTPS Connection Handler:

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set use-correlation-id-header:false
```

Configuring the correlation ID response header

- The server will generate a correlation ID for every HTTP request and send it in the response through the `Correlation-Id` response header. This response header name can be customized. The following example changes the `correlation-id-response-header` property to "X-Request-Id."

```
$ dsconfig set-connection-handler-prop \
  --handler-name "HTTPS Connection Handler" \
  --set correlation-id-response-header:X-Request-Id
```

Accepting an incoming correlation ID from the request

- By default, the server generates a new, unique correlation ID for each HTTP request, and ignores any correlation ID that may be set on the request. This can be changed by designating the names of one or more HTTP request headers that contain an existing correlation ID value. This enables the server to integrate with a larger system consisting of every servers using correlation IDs.

```
$ dsconfig set-connection-handler-prop --handler-name "HTTPS Connection
Handler" \
  --set correlation-id-request-header:X-Request-Id \
  --set correlation-id-request-header:X-Correlation-Id \
  --set correlation-id-request-header:Correlation-Id \
  --set correlation-id-request-header:X-Amzn-Trace-Id
```

HTTP Correlation ID Example Use

In this example, a request to the Directory REST API is made and the correlation ID enables finding HTTP-specific log messages with LDAP-specific log messages. The response to the API call includes a `Correlation-Id` header with the value `a54aee33-c6c6-4467-be25-efd1db7a8b76`.

```
GET /directory/v1/me?includeAttributes=mail HTTP/1.1
```

```

Accept: */*
Accept-Encoding: gzip, deflate
Authorization: Bearer ...
Connection: keep-alive
Host: localhost:1443
User-Agent: HTTPie/0.9.9

HTTP/1.1 200 OK
Content-Length: 266
Content-Type: application/hal+json
Correlation-Id: ee919049-6710-4594-9c66-28b4ada4b127
Date: Fri, 02 Nov 2018 15:16:50 GMT
Request-Id: 369

{
  "_dn": "uid=user.86,ou=People,dc=example,dc=com",
  "_links": {
    "schemas": [
      {
        "href": "https://localhost:1443/directory/v1/schemas/
inetOrgPerson"
      }
    ],
    "self": {
      "href": "https://localhost:1443/directory/v1/
uid=user.86,ou=People,dc=example,dc=com"
    }
  },
  "mail": [
    "user.86@example.com"
  ]
}

```

This correlation ID can be used to search the HTTP trace log for matching log records, as follows:

```

$ grep 'correlationID="ee919049-6710-4594-9c66-28b4ada4b127"'

Domain Name Service (DNS) Caching

If needed, two global configuration properties can be used to control the caching of host name-to-numeric IP address (DNS lookup) results returned from the name resolution services of the underlying operating system. Use the `dsconfig` tool to configure these properties.

- **network-address-cache-ttl** – Sets the Java system property `networkaddress.cache.ttl`, and controls the length of time in seconds that a host name-to-IP address mapping can be cached. The default behavior is to keep resolution results for one hour (3600 seconds). This setting applies to the server and all extensions loaded by the server.
- **network-address-outage-cache-enabled** – Caches host name-to-IP address results in the event of a DNS outage. This is set to true by default, meaning name resolution results are cached. Unexpected service interruptions may occur during planned or unplanned maintenance, network outages or an

infrastructure attack. This cache may allow the server to function during a DNS outage with minimal impact. This cache is not available to server extensions.

To reduce delays due to unnecessary DNS lookups, follow these recommendations:

- Maintain a connection pool in the client app rather than opening new connections for each bind.
- Add appropriate records to DNS, including PTR records.
- Add `options timeout:1` and/or `options single-request` in `/etc/resolv.conf`.
- If IPv6 requests specifically are causing issues, Add `-Djava.net.preferIPv4Stack=true` to the `start-server.java-args` line in PingDirectory Server's `config/java.properties` so that running `bin/dsjavaproperties` and restarting the server will no longer issue IPv6 PTR requests.

IP Address Reverse Name Lookups

PingDirectory Servers perform some numeric IP address-to-host name lookups, including the following:

- Binding to the Directory: Decoding, examining, or evaluating a DNS bind rule
- Logging: Logging information to certain monitors or writing to the error log
- JMX: Creating a server socket
- Key Management: Generating a truststore
- Replication Server: Creating an SSL socket
- Replication Session Management: Obtaining a session or performing a handshake with a replication server
- SASL Authentication: Applying configuration changes
- SMTP Alert Handler: Initializing or sending an alert notification

Address masks configured in Access Control Lists (ACIs), Connection Handlers, Connection Criteria, and Certificate handshake processing may trigger implicit reverse name lookups. For more information about how address masks are configured in the server, review the following information for each server:

- ACI dns: bind rules under *Managing Access Control* (Directory Server and Directory Proxy Server)
- `ds-auth-allowed-address`: *Adding Operational Attributes that Restrict Authentication* (Directory Server)
- Connection Criteria: *Restricting Server Access Based on Client IP Address* (Directory Server and Directory Proxy Server)
- Connection Handlers: restrict server access using Connection Handlers (Configuration Reference Guide for all servers)

Configuring Traffic Through a Load Balancer

If a PingDirectory Server is sitting behind an intermediate HTTP server, such as a load balancer, a reverse proxy, or a cache, then it will log incoming requests as originating with the intermediate HTTP server instead of the client that actually sent the request. If the actual client's IP address must be recorded to the trace log, enable **X-Forwarded-*** handling in both the intermediate HTTP server and PingDirectory Server. For PingDirectory Servers:

- Edit the appropriate Connection Handler object (HTTPS or HTTP), and set `use-forwarded-headers` to `true`.
- When `use-forwarded-headers` is set to `true`, the server will use the client IP address and port information in the **X-Forwarded-*** headers instead of the address and port of the entity that's actually sending the request, the load balancer. This client address information will show up in logs where one would normally expect it to show up, such as in the `from` field of the HTTP REQUEST and HTTP RESPONSE messages.

On the load balancer, configure settings to provide the **X-Forwarded-*** information, such as `X-Forwarded-Host`:. See the product documentation for the device type.

Working with the Referential Integrity plugin

Referential integrity is a plugin mechanism that maintains the DN references between an entry and a group member attribute. For example, if you have a group entry consisting of member attributes specifying the DNs of printers, you can enable the referential integrity plugin to ensure that the group entry is automatically removed if a printer entry is removed from the Directory Server.

The Referential Integrity plugin is disabled by default. When enabled, the plugin performs integrity updates on the specified attributes (for example, member or uniquemember) after a delete, modify DN, or a rename (i.e., subordinate modifyDN) operation is logged to the `logs/ referint` file. If an entry is deleted, the plugin checks the log file and makes the corresponding change to the associated group entry.

Three important points about the Referential Integrity plugin:

- All specified attributes that are configured for Referential Integrity must be indexed.
- On replicated servers, the Referential Integrity plugin configuration is not propagated to other replicas; therefore, you must manually enable the plugin on each replica.
- The plugin settings must also be identical on all machines.
- Subtree delete operations are not allowed if the referential integrity plugin is enabled and configured to operate in synchronous mode. It must be configured to operate in asynchronous mode (by specifying a nonzero update interval) if subtree delete operations will be performed.

To Enable the Referential Integrity plugin

Steps

1. Determine the attributes needed for your system. By default, the `member` and the `uniquemember` attributes are set for the plugin.
2. Run the `dsconfig` tool to enable the Referential Integrity plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
--set enabled:true
```

Working with the Unique Attribute plugin

The Unique Attribute plugin is used to enforce uniqueness constraints on the values of one or more attributes across a portion of the Directory Server. The plugin checks for uniqueness prior to an add, modify, or modify DN request and will instruct the server to reject the request if a constraint violation is found.

The plugin is disabled by default as it can affect performance in heavy write load environments. After the plugin is enabled, it does not check for attribute uniqueness on existing entries, but only on new ADD, MODIFY, or MODDN operations. However, administrators can use the `identify-unique-attribute-conflicts` tool to ensure that no such conflicts exist in the data.

Important: All attributes for which uniqueness should be enforced should be indexed for equality in all backends. The LDAP SDK uniqueness request control can be used for enforcing uniqueness on a per-request basis. See the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control. See the ASN.1 specification to implement support for it in other APIs.

Attribute uniqueness can be enforced in replicated environments in which each replica contains the complete set of data for which to provide uniqueness, regardless of whether clients communicate directly with the server or interact with it through a Directory Proxy Server. In such environments, all servers should have identical uniqueness configurations. Note that it is not possible to *completely* prevent conflicts that arise from simultaneous writes on separate replicas. However, such conflicts will be detected after the changes have been replicated and will trigger administrative alert notifications.

For proxied environments that do not have the complete set of data on all servers (e.g., environments that use entry balancing or that store different portions of the DIT on different servers), you can implement the Global Uniqueness Attribute plugin on the Directory Proxy Server, instead of enabling the attribute uniqueness plugin on the Directory Server. For more information, see the *PingDirectoryProxy Server Administration Guide*.

To Enable the Unique Attribute plugin

Steps

1. Determine which attributes must be unique in your data.
2. Run the `dsconfig` tool to enable the plugin. By default, the plugin type property is set to `postsynchronizationadd`, `postsynchronizationmodify`, `postsynchronizationmodifydn`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn`. If you want to set one plugin type, use the `--set plugin-type:<operation-type>` option. For example, use `--set plugin-type:preoperationadd` with the following command if you only want to check for attribute uniqueness prior to ADD operation.

```
$ bin/dsconfig set-plugin-prop --plugin-name "UID Unique Attribute" \
  --set enabled:true
```

Working with the Purge Expired Data plugin

The Purge Expired Data plugin is used to delete expired entries or attribute values, and cleanup expired PingFederate Persistent Access Grants. When the plugin is enabled, a background thread in the plugin periodically searches for and purges expired data. It is recommended that the Purge Expired Data plugin be enabled on multiple servers in a topology. One server can be configured to delete data, while others can be searching for expired data.

The Purge Expired Data plugin is created and configured with the `dsconfig` tool. Configuration options include the base DN and filter, the items to be purged, how to identify expired data, and the frequency for polling and purging. The search for expired data must be indexed. An alarm is raised if the server purging data falls behind the configured `max-updates-per-second`. Monitoring information is available in the Admin Console, or `cn=monitor`.

To Configure the Purge Expired Data plugin for Expired Entries

About this task

This example deletes all unverified account entries that have not been accessed in the past eight weeks. They could be accounts that potential customers started to create through an application's registration process, but then did not complete. The phone number or email address that was provided during registration was not verified, and should be allowed to be used by another account. The server can track the last access time automatically in the `ds-last-access-time` attribute by enabling the Last Access Time plugin.

Steps

1. If necessary, enable the Last Access Time plugin:

```
$ bin/dsconfig set-plugin-prop \
  --plugin-name "Last Access Time" \
  --set enabled:true
```

2. The Purge Expired Data plugin requires the date attribute that is used to determine expiration to be indexed for ordering. An index on that attribute must be created:

```
$ bin/dsconfig create-local-db-index \
  --backend-name userRoot \
```

```
--index-name ds-last-access-time \
--set index-type:ordering
```

3. If there is data present in the directory, rebuild the index:

```
$ bin/rebuild-index \
--baseDN dc=example,dc=com \
--index ds-last-access-time
```

4. Create the plugin that purges account entries `objectclass=account` that are not verified `verified=false` after eight weeks of inactivity:

```
$ bin/dsconfig create-plugin \
--plugin-name "Purge Old Unvalidated Accounts" \
--type purge-expired-data \
--set enabled:true \
--set datetime-attribute:ds-last-access-time \
--set "expiration-offset:8 w" \
--set "filter:(amp(objectClass=account)(verified=false))"
```

To Configure the Purge Expired Data plugin for Expired Attribute Values

About this task

The Purge Expired Data plugin can also be used to delete values of an attribute that have expired. For example, an application may track information about an employee's session, but the session should expire after 24 hours. There may be multiple active sessions tracked across different devices, with session information that looks like this:

```
sessionInfo: { "sessionId" : "E85FAC04E331FFCA55549B10B7C7A4FA",
"ipAddress": "10.0.0.00", "userAgent": "Mozilla/5.0 (iPad; U; CPU OS 3_2
like Mac OS X; en-us)
AppleWebKit/531.21.10 (KHTML, like Gecko) Version/4.0.4 Mobile/7B367
Safari/531.21.10",
"creationTime" : "2018-03-31T13:10:15Z" }
```

In this example, the LDAP attribute is `sessionInfo`, and the JSON field that stores the timestamp is `creationTime`. These are used to configure the Purge Expired Data plugin.

To purge the JSON attribute values after 24 hours, rather than the entire session entry, the plugin can be created with the following steps.

Steps

1. Create an index on the `creationTime` field of the `sessionInfo` attribute:

```
$ bin/dsconfig create-json-attribute-constraints \
--attribute-type sessionInfo \
--set enabled:true
```

```
$ bin/dsconfig create-json-field-constraints \
--attribute-type sessionInfo \
--json-field creationTime \
--set index-values:true \
--set value-type:string
```

2. Create and enable the plugin:

```
$ bin/dsconfig create-plugin \
--plugin-name "Purge Old Session Data Plugin" \
--type purge-expired-data \
--set enabled:true \
--set "custom-datetime-format:yyyy-MM-dd'T'HH:mm:ss'Z'" \
```

```
--set datetime-attribute:sessioninfo \  
--set datetime-format:custom \  
--set datetime-json-field:creationTime \  
--set "expiration-offset:1 d" \  
--set purge-behavior:delete-json-attribute-values
```

Configuring Uniqueness Across Attribute Sets

Attribute uniqueness can be configured across a set of attributes using the `multiple-attribute-behavior` property. The `multiple-attribute-behavior` property can take the following values:

- **unique-within-each-attribute** - If multiple attributes are specified, then uniqueness will be enforced for all values of each attribute, but the same value may appear in different attributes (in the same entry or in different entries). For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-within-each-attribute"` and add:
 - An entry with a `telephoneNumber` value that matches the `telephoneNumber` attribute in the existing entry, then the add request will fail.
 - An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then that too will fail.
 - An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in the existing entry, then the add request will succeed.
- **unique-across-all-attributes-including-in-same-entry** - If multiple attributes are specified, then uniqueness will be enforced across all of those attributes, so that if a value appears in one of those attributes, that value may not be present in any other of the listed attributes in the same entry, nor in any of the listed attributes in other entries. For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`. If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-including-in-same-entry"` and add:
 - An entry with a `telephoneNumber` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then the add request will fail.
 - An entry with a `mobile` value that matches the `mobile` attribute in an existing entry, then that too will fail.
 - An entry with a `mobile` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then that will fail.
 - An entry with a `telephoneNumber` value (e.g., 123-456-7891) that matches the `mobile` attribute in an existing entry, then that too will fail.
 - An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in an existing entry, then the add request will fail.
- **unique-across-all-attributes-except-in-same-entry** - If multiple attributes are specified, then uniqueness will be enforced across all of those attributes, so that if a value appears in one of those attributes, that value may not be present in any of the listed attributes in other entries. However, the same value may appear in multiple attributes in the same entry. For example, assume you have an existing entry that has attributes, `telephoneNumber=123-456-7890` and `mobile=123-456-7891`.

If you set the uniqueness plugin to have `--set "multiple-attribute-behavior:unique-across-all-attributes-except-in-same-entry"` and add:

- An entry with a `telephoneNumber` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then the add request will fail.
- An entry with a `mobile` value that matches the `mobile` attribute in the existing entry, then that too will fail.
- An entry with a `mobile` value (e.g., 123-456-7890) that matches the `telephoneNumber` attribute in an existing entry, then that will fail.
- An entry with a `telephoneNumber` value (e.g., 123-456-7891) that matches the `mobile` attribute in an existing entry, then that will fail.
- An entry with the same `telephoneNumber` and `mobile` attribute values (e.g., 123-456-7893) but differ from the values in an existing entry, then the add request will succeed.

To Enable Uniqueness Across Attribute Sets

Steps

- Use `dsconfig` to configure the UID Unique Attribute plugin to apply across multiple attributes. The `multiple-attribute-behavior` property is set to `"unique-within-each-attribute"`, which indicates that uniqueness will be enforced for all values of each attribute (e.g., `telephoneNumber=123-456-7890` and `mobile=123-456-7891`), but the same value (e.g., either 123-456-7890 or 123-456-7891) may appear in different attributes in the same entry or in different entries.

```
$ dsconfig create-plugin \
  --plug-in "Unique telephoneNumber and mobile" \
  --type "unique-attribute" \
  --set "enabled:true" \
  --set "type:telephoneNumber" \
  --set "type:mobile" \
  --set "multiple-attribute-behavior:unique-within-each-attribute" \
  --no-prompt
```

Working with the Last Access Time plugin

The Last Access Time plugin is used to record the timestamp of the last activity targeting an entry. The plugin updates the `ds-last-access-time` attribute of the entry when it is accessed by an add, bind, compare, modify, modify DN, or search operation.

The plugin can be used with the Directory Server Uncached Attribute Criteria, or any application that needs to determine how recently an entry has been accessed. The plugin also enables defining request criteria to limit the scope of tracking the last access time. The `max-search-result-entries-to-update` property also prevents mass updates of `ds-last-access-time` when searches contain many results, but may not reflect end-user access. Consider the following when using this plugin:

- The plugin should be enabled on all servers that have the same configuration.
- An updated `ds-last-access-time` attribute value is replicated like any other change to an entry.
- The `ds-last-access-time` attribute is not returned from a search, unless included in the attributes list explicitly, or given the "+" specification for operational attributes.
- The `ds-last-access-time` value format is `yyyyMMddHHmmss.SSS'Z'`, which provides millisecond-level accuracy, such as `20131207144135.821Z`.
- The `ds-last-access-time` attribute can be indexed with a local database index. The ordering index type is the most relevant, but may require a higher index entry limit (default is 4000) to accommodate searches for entries that have not been accessed in a long period of time. The ordering index type, with a short time range or high index entry limit, will result in indexed search results for requests such as `(ds-last-access-time>=20131207144135.821Z)`.

i Important: For deployments earlier than version 4.5 that use the Last Access Time plugin, disable the plugin before upgrading, and then re-enable it after the update is complete. If servers are running different versions, the `last-access-time` updates might occur with a higher frequency than intended.

Working with the Pass-Through Authentication plugin

The Pass-Through Authentication plugin is used to delegate bind operations to remote LDAP servers by forwarding simple bind requests to an external LDAP server, including Active Directory. The plugin can be configured to attempt a local bind, to set or update a local password, and to bypass local password policies to ensure remote passwords are migrated.

Consider the following points when using the Pass-Through Authentication plugin:

- Enable the plugin on all servers that use the same configuration.
- Remote servers that accept a forwarded bind request might require connection security, such as a secure StartTLS or LDAPS TLS connection.
- Consider the manner in which password changes and resets are handled. Updating a password in PingDirectory Server might result in divergent passwords between the local and remote server. If necessary, use PingDataSync Server to synchronize passwords between servers.
- The plugin updates local passwords only if the forwarded simple bind is successful. Expired passwords on a remote server might return an invalid credentials error and cause the overall bind operation to fail.
- Multiple remote servers can be specified. The `server-access-mode` property determines whether the servers are accessed in `round-robin`, `failover-on-unavailable`, or `failover-on-any-failure` mode. The default server access mode is `round-robin`.
- The `update-local-password` property indicates whether the local password value requires updating to the value used in the bind request, in the event that the local bind fails but the forwarded bind succeeds. To update passwords, a local entry must previously exist.
- The `allow-lax-pass-through-authentication-passwords` property indicates whether updates to the local password value accept passwords that do not meet local password policy requirements.
- The `connection-criteria` property specifies a set of connection criteria that must match the client associated with the local bind request for the bind to be forwarded to the remote server.
- The `request-criteria` property specifies a set of request criteria that must match the local bind request or a local target entry for the bind to be forwarded to the remote server.
- The `dn-map` property specifies one or more DN mappings that can be used to transform bind DN's before attempting to forward the bind to remote servers.
- The `search-base-dn` property is used when searching for a remote user entry by using a filter constructed from the pattern that the `search-filter-pattern` property defines. A DN map and search filter pattern cannot both be configured. If neither a DN map nor a search filter pattern is defined, user entries are expected to have the same DN in the local server and the remote servers.

Pass-Through Authentication plugin for the PingOne for Customers Service

Although PingDataSync Server supports bidirectional synchronization between PingDirectory Server and the PingOne for Customers service, it can propagate password changes from the PingOne for Customers service into PingDirectory Server only when using the Pass-Through Authentication plugin for PingOne for Customers Service.

This plugin features a mandatory `try-local-bind` configuration property that enables one of the following modes of operation:

- When `try-local-bind` is `true`, the plugin attempts to authenticate locally first. It sends a request to the PingOne for Customers service only if the local bind attempt fails.
- When `try-local-bind` is `false`, the plugin attempts to authenticate with the PingOne for Customers service first.

The following table identifies and describes the configuration properties associated with the Pass-Through Authentication plugin for PingOne for Customers Service.

Property	Description	Required	Default
<code>api-url</code>	URL that PingDirectory Server uses when communicating with the PingOne for Customers service.	Yes	NA
<code>auth-url</code>	URL that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	NA
<code>oauth-client-id</code>	OAuth client ID that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	NA
<code>oauth-client-secret</code>	OAuth client secret that PingDirectory Server uses to authenticate to the PingOne for Customers service.	Yes	NA
<code>environment-id</code>	Identifier for the PingOne for Customers environment that contains the users for whom pass-through authentication is attempted.	Yes	NA
<code>included-local-entry-base-dn</code>	Set of base DN's for local user entries for whom pass-through authentication might be attempted. If this value is set, only users who exist below a specified base DN allow their authentication attempts to be passed through to the PingOne for Customers service.	No	All public naming contexts (if not set)
<code>connection-criteria</code>	Reference to a connection criteria object that can be used to identify the bind requests to pass through to the PingOne for Customers service, based on the server's knowledge of the client (predominantly expected to be the address, protocol, and security level). If this property is defined, only client connections that match the criteria are included. If this property is not defined, all clients are included.	No	NA
<code>request-criteria</code>	Reference to a request criteria object that can be used to identify the bind requests to pass through to the PingOne for Customers service, based on the contents of the request. If this property is defined, only bind requests that match the criteria are included. If this property is not defined, all bind requests are included.	No	NA
<code>try-local-bind</code>	Indicates whether PingDirectory Server tries to process the bind locally before forwarding the bind request to the PingOne for Customers service. If this value is set to <code>true</code> and the bind succeeds locally, PingDirectory Server does not make a request to the PingOne for Customers service. If this value is set to <code>false</code> , PingDirectory Server ignores local credentials and attempts to authenticate only to the PingOne for Customers service.	Yes	True

Property	Description	Required	Default
<code>override-local-password</code>	<p>Indicates whether PingDirectory Server attempts to bind to the PingOne for Customers service if the local account has a password.</p> <p>This property is used if <code>try-local-bind</code> is <code>true</code>. If it has a value of <code>false</code>, the plugin attempts to authenticate to the PingOne for Customers service only if the local user account does not have a password.</p> <p>If the local bind attempt fails while this value is set to <code>true</code>, the server tries to authenticate to the PingOne for Customers service even if the local account has a password.</p>	Yes	<code>True</code>
<code>update-local-password</code>	<p>Indicates whether PingDirectory Server attempts to set the password for the local user account, regardless of whether one is already set, if the local authentication attempt fails but the attempt to authenticate with the PingOne for Customers service succeeds.</p> <p>This property is used only if <code>try-local-bind</code> is <code>true</code>.</p> <p>If the on-premise PingDirectory Server is the authoritative source for passwords, set this property to <code>false</code> and configure PingDataSync Server to synchronize password changes from PingDirectory Server into the PingOne for Customers service. If the passwords differ, either the local password or the password for the PingOne for Customers service allows the user to authenticate.</p> <p>If the PingOne for Customers service is the authoritative source for passwords, set this property to <code>true</code>. To ensure that a pass-through attempt to the PingOne for Customers service does not override local changes, make all password changes in the PingOne for Customers service.</p>	Yes	<code>False</code>
<code>allow-lax-pass-through-authentication-passwords</code>	<p>Indicates whether PingDirectory Server bypasses the normal password-validation process when setting the local password from the PingOne for Customers service. This property is used only when both <code>try-local-bind</code> and <code>update-local-password</code> are <code>true</code>.</p> <p>If this value is <code>true</code> when a local bind attempt fails but the authentication attempt with the PingOne for Customers service succeeds, the user's password is updated locally even if a local attempt to change the password to the same value would be rejected because the password is considered too weak.</p> <p>If this value is <code>false</code>, pass-through authentication succeeds if the authentication with PingOne for Customers service succeeds. However, the password for the PingOne for Customers service does not replace the local password.</p>	Yes	<code>True</code>

Property	Description	Required	Default
ignored-password-policy-state-error-condition	<p>Set of zero or more password policy state error conditions that are ignored for pass-through authentication.</p> <p>For a list of values and their descriptions, see the following table.</p>	No	NA
user-mapping-local-attribute	<p>Name of an LDAP attribute that is used to map local user entries to the corresponding PingOne for Customers account.</p> <p>This property must include the same number of values as the user-mapping-remote-json-field property, and the order of their values is correlated. If multiple values are specified, all attributes must be present in the local entry, and the plugin performs an AND search in the PingOne for Customers service to locate the user account with all the values in the corresponding fields.</p> <p>The entryDN attribute can be used to represent the DN of the local entry.</p>	Yes	NA
user-mapping-remote-json-field	<p>The name of a PingOne for Customers field that is used to map local user entries to the corresponding PingOne for Customers account.</p> <p>This property must include the same number and order of values as the user-mapping-local-attribute property.</p>	Yes	NA
additional-user-mapping-scim-filter	<p>SCIM filter that is included in the search and is used to identify the PingOne for Customers account that corresponds to the local user entry.</p> <p>If a value is provided for this property, it is ANDed with the SCIM filter that was created to map the local user entry to a PingOne for Customers account. If a value is not provided for this property, no additional filter is used.</p>	No	NA

The following table identifies the values that can be used with the optional configuration property **ignored-password-policy-state-error-condition**, and describes the scenarios in which a user is still permitted to bind by using pass-through authentication.

Property	Scenario in which a user can still bind by using pass-through authentication
temporarily-locked-due-to-failures	The account is locked temporarily because of too many failed attempts.
permanently-locked-due-to-failures	The account is locked permanently because of too many failed attempts.
locked-due-to-idle-interval	The account is locked because the user has not authenticated recently.

Property	Scenario in which a user can still bind by using pass-through authentication
<code>locked-due-to-maximum-reset-age</code>	The account is locked because an administrator recently reset the password, and the user failed to specify a new password within the allotted time frame.
<code>password-is-expired</code>	The password is expired.

Supporting Unindexed Search Requests

By default, the Directory Server denies all unindexed search requests, except for those issued by the bind DNs that have the unindexed-search privilege. This default behavior keeps the server from tying up worker threads on time-consuming, unindexed searches. However, you can turn off the enforcement of the unindexed-search privilege to allow any client to perform an unindexed search. To do this, set the disabled-privilege global configuration property to unindexed-search as follows:

```
$ bin/dsconfig set-global-configuration-prop \
  --set disabled-privilege:unindexed-search
```

If you choose to allow unindexed searches, you may want to cap the maximum number of concurrent unindexed search requests using the maximum-concurrent-unindexed-searches global configuration property. You configure this property using `dsconfig` as follows:

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

You can limit unindexed search privileges for particular clients using the allow-unindexedsearches property of the Client Connection Policy. For more information about configuring Client Connection Policies, see “Configuring Client Connection Policies”.

Server Performance Issues

The following are the most common reasons that customers encounter performance issues and some suggestions for diagnosing and addressing these issues.

- [Slow Password Storage Schemes](#) on page 652
- [Database Size Versus Memory Capacity](#) on page 653
- [Large Number of Access Control Rules](#) on page 653
- [Large Static Groups](#) on page 653
- [Large Index ID Sets](#) on page 654
- [Missing Indexes](#) on page 655

Slow Password Storage Schemes

Certain password storage schemes are intentionally expensive. These include the following:

- PBKDF2
- bcrypt
- scrypt
- Argon2
- The MD5, SHA-2-256 and SHA-2-512 variants of the crypt scheme

These schemes are designed to consume a significant amount of CPU (and also memory in some cases) to increase the amount of resources an attacker must expend to crack a password if they happen to get access to the password's encoded representation. However, this same cost is also incurred for legitimate operations involving the password, including encoding clear-text passwords during account creation and

password changes, and also when validating passwords during authentication. These schemes can be configured to adjust the amount of resources they consume and should be tuned so that the resource consumption under expected peak load will not exceed the capacity of the topology.

In addition, if you are initially populating the server using an LDIF import that contains clear-text passwords, using one of these schemes can cause the LDIF import to proceed at a small fraction of the rate that could be achieved with a faster storage scheme (such as one that uses a 256-bit or 512-bit salted SHA-2 digest). In such cases, you may wish to import the data using a faster scheme and then change the configuration to make the desired scheme the new default and mark the scheme used for import as deprecated. By doing this, accounts with passwords encoded using the import scheme will automatically be re-encoded with the new scheme the first time that the user successfully authenticates using that password.

Database Size Versus Memory Capacity

Best performance is achieved when the contents of the database can be fully cached in memory. If possible, the amount of memory allocated to PingDirectory Server should be large enough so that all of the data can fit in the database cache. Memory sizing estimates appear at the end of the output when the `import-ldif` tool is run.

If the amount of data that needs to be stored exceeds the available memory capacity of the individual systems on which the server will run, there are several options:

- You can break up the data into segments that are small enough to be fully cached on their own, and use PingDirectory Proxy Server's entry balancing functionality to make them appear as a single logical set.
- You can tune the server so that the most-frequently accessed information can be served from memory while disk access may be required for other data. In disk-bound deployments, backend configuration options such as cache mode, uncached attribute criteria, and uncached entry criteria can be used to help prioritize what data should remain in memory versus what may be retrieved from disk.

Large Number of Access Control Rules

As the number of access control rules increases, so does the potential costs of determining whether a client is allowed to request a given operation and of paring down search result entries based on the data that the client is permitted to access. In addition, the server may need to re-evaluate all access control rules after certain update operations (including modify DN operations) to determine whether these may be affected by the change.

In many cases, deployments with an extremely large number of access control rules (especially those with large numbers of branches in which the same structure may be repeated across each of these branches) may be able to leverage parameterized ACIs to dramatically reduce the number of access control rules that need to be defined and evaluated. In other cases, it may be possible to refactor the access control configuration to achieve the same effect but with far fewer rules.

Large Static Groups

Although PingDirectory Server supports very large static groups (with hundreds of thousands of members or more), these can have a significant impact on performance. It can be expensive in terms of system resources to update the group to add or remove members because each update requires rewriting the entire entry. It can also be expensive to decode the entry when retrieving it from the database (even if it is held in the database cache), and to return the list of members to a client in search results.

If possible, consider replacing large static groups with dynamic groups. Dynamic groups automatically determine their membership based on criteria defined in LDAP URLs. A dynamic group consumes very little memory and disk space and does not need to be altered as entries are created, updated, and removed. And in some cases, it may be possible to use virtual static groups in conjunction with dynamic groups to create entries that behave like static groups for read operations in order to maintain compatibility with applications that only understand static groups but use dynamic groups behind the scenes to determine membership.

If it is not possible to eliminate large static groups, you may wish to enable the static group entry cache. While this will not reduce the performance impact of updating large static groups, it can make it much more efficient to access those groups for read operations.

Large Index ID Sets

Indexes store data that make it possible to quickly retrieve matching entries during a search. Each index record maps an index key to a list of the entry IDs for the entries that match that key. For example, for an equality index for a given attribute, there is a key for each unique value for that attribute, and the values for each key of the IDs of the entries which contain that value. For substring indexes, there may be multiple keys for the same attribute value (one for each unique six-character substring within the value), and the same substring may apply to many different values of the same attribute.

As the size of an ID set increases, so does the potential resource cost of accessing the ID set. For an attribute index, ID sets can be stored in one of two ways, each with their own pros and cons for performance:

- In the regular (non-exploded) case, each index key occurs once, and the value of this key is the entire list of IDs for entries that match the key. The ID set for a non-exploded index key can be retrieved very quickly because only a single database read is required. However, as the size of the ID set grows, the cost of updating it also grows since it is necessary to replace the entire set, which requires larger amounts of disk I/O and may place an increased burden on the database cleaner.
- In the exploded case, the same key may be stored multiple times (one for each entry that matches that key), with each instance of the key associated with a different entry ID. Updating the ID set for an exploded key is always fast because the writes will be very small, but the cost of reading the ID set increases with the number of IDs.

Composite indexes can also be used. These offer many advantages over attribute indexes when they can be used. Some of these advantages, such as the ability to configure a base DN or combinations of attributes, do not really have any effect on performance with regard to large ID sets. However, they also use a hybrid of the exploded and non-exploded approaches to maintaining the ID set in that a large set may be split into multiple pieces, but each piece may have up to 5000 IDs rather than just one. This means that retrieving a large ID set from a composite index may be thousands of times cheaper than retrieving the same ID set from an exploded attribute index, and updating a large ID set in a composite index should be much cheaper in terms of systems resources than updating the same ID set in a non-exploded attribute index since the write will be significantly smaller.

In environments with performance problems related to very large index ID sets, you may consider the following options as a way to help improve performance:

- Consider reducing the index entry limit for that index. The index entry limit specifies the maximum number of IDs that an ID set may have for an index key. If a key matches more entries than this limit, the server will stop maintaining the index for that key and attempts to access it will behave as if it were unindexed, while the index will continue to be maintained for keys matching smaller numbers of entries. If you don't have searches that depend only on those keys, then this is an excellent way of eliminating the cost of maintaining large ID sets. Also note that it doesn't make any sense to set the index entry limit to a value that is a large percentage of the total number of entries in the server; in such cases, there may not be a significant performance difference between indexed and unindexed search performance, but there would not be a need to maintain the associated large ID sets.
- If there are cases in which you need a large index entry limit, then consider increasing the limit only for that index rather than increasing the default limit for all indexes in the backend. The `index-entry-limit` property in the backend applies to all indexes that don't specify their own limit, but each index also offers an `index-entry-limit` property that, if set, will override the index entry limit configured for the backend. As such, if you need a higher index entry limit for a particular index, then it is better to set a higher limit just for that one index than to raise the default limit for all indexes in the backend.
- For attribute indexes with keys matching a large number of entries, consider converting it to a composite index when possible. Composite indexes can completely replace equality and ordering attribute indexes, and they can also support "starts with" substring searches (regardless of whether

they also have “contains” or “ends with” components). Composite indexes can’t currently replace approximate match indexes or substring searches that don’t have a “starts with” component.

- Consider eliminating any unnecessary substring indexes. As previously noted, substring indexes are more likely to have large ID sets than equality, ordering, or approximate match indexes because substring keys are generally smaller and any given substring key may apply to multiple attribute values. It’s also not all that well known that equality attribute indexes (and equality composite indexes) will be used for substring searches with a “starts with” component. As such, a substring index will not be used for substring searches with a “starts with” unless there isn’t an equality index for that attribute. If a substring index is defined for an attribute that isn’t targeted by substring searches, or that is only targeted by substring searches that contain a “starts with” component (regardless of whether it also includes “contains” or “ends with” components), then that substring index is not necessary and can be removed. Access logs can be used to determine the types of searches that clients are performing, and the summarize-access-log and search-logs tools may help with that.
- If a substring index is needed for a given attribute, then you may consider increasing the substring length for that index. By default, the server will create a separate substring key for each unique six-character substring in an attribute value, and there may be cases in which the same six-character substring appears in several different values. If that is the case, and if this causes substring keys to have large ID sets, then increasing the substring length for that index will reduce the number of values that may share the any given key, and therefore may reduce the number of IDs associated with that key.
- As a last resort, you may consider tuning the exploded index threshold for an index (the number of entries that an ID set needs to have for a given key before it will transition from a non-exploded set to an exploded one) based on the expected usage for that index. If search performance is more important than update performance for an attribute with large ID sets, then raising the exploded index threshold will help keep the ID set stored as a monolithic block of IDs. On the other hand, if update performance is more important than search performance, then lowering the exploded index threshold may help.

Missing Indexes

Although maintaining unneeded indexes can have a detrimental effect on performance, it can also be detrimental if a needed index is missing.

The best way to identify expensive searches processed in the server is to examine the access logs for search operations with a high etime (elapsed processing time) value. Once you have identified these search operations, you can weed out any of these operations that do not need to be fast. For example, you may have applications that generate reports by performing inefficient searches (for example, searches to retrieve all entries), and it is probably acceptable for those searches to be slow.

For any remaining searches that should be fast but are not, the best way to understand why the search is expensive is to issue a search with the same base DN, scope, and filter, but requesting only the debugsearchindex attribute. This is a special attribute that causes the server to return debug information about the index processing that is performed in the course of evaluating the search and how long it took to complete each step of the evaluation. From this output, you may be able to see which indexes were used and which could not be used because there was either no applicable index or because the index entry limit had been exceeded for the target key. You may also see expensive accesses to exploded indexes. You may also be able to identify indexes that need to be added, indexes that may benefit from being converted to composite indexes, or indexes for which there may be a legitimate need to increase the index entry limit. Alternatively, you may also be able to determine that there could be a different way to perform the search so that it does not depend on components that are unindexed or that match a very large number of entries.

Sun/Oracle Compatibility

For companies that are migrating from a Sun/Oracle server to the PingDirectory Server, the PingDirectory Server provides a `dsconfig` batch file, `sun-ds-compatibility.dsconfig`, which describes the various components that can be configured to make the server exhibit behavior closer to a Sun/Oracle configuration.

Administrators can use the `sun-ds-compatibility.dsconfig` batch file to apply the Directory Server's configuration with the necessary `dsconfig` commands. Simply uncomment the example commands listed in the file, and then run the `dsconfig` command specifying the batch file. Note that this batch file is not comprehensive and must be used together with the `migrate-sun-ds-config` tool, located in the `bin` folder (or `bat` folder for Windows systems) during the migration process. Both the tool and the batch file overlap in some areas but provide good initial migration support from the Sun/Oracle server to a Ping Identity server.

Another useful tool is the `migrate-ldap-schema` tool in the `bin` folder (or `bat` folder for Windows systems), which migrates schema information from an existing LDAP server onto this instance. All attribute type and object class definitions that are contained in the source LDAP server will be added to the targeted instance or written to a schema file.

To Configure the Directory Server for Sun/Oracle Compatibility

Steps

1. From the Directory Server server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder. You can use a text editor to view the file.
2. Read the file completely.
3. Apply any changes to the file by removing the comment symbol at any `dsconfig` command example, and then applying the `dsconfig` command specifying the batch file.

```
$ bin/dsconfig --no-prompt --bindDN "cn=Directory Manager" \
  --bindPassword "password" --batch-file /path/to/dsconfig/file
```

4. Run the `migrate-ldap-schema` tool to move the schema definitions on the source server to the destination Ping Identity server.

```
$ bin/migrate-ldap-schema
```

5. Next, run the `migrate-sun-ds-config` tool to see what differences exist in the Ping Identity configuration versus the Sun/Oracle configuration. On the PingDirectory Server, run the following command:

```
$ bin/migrate-sun-ds-config
```

6. Test the server instance for further settings that may not have been set with the batch file, the `migrate-ldap-schema` tool, or the `migrate-sun-ds-config` tool.
7. If you notice continued variances in your configuration, contact your authorized support provider.

Configuring Soft Deletes

The PingDirectory Server (version 3.2.4 or later) supports a *soft-delete* feature that preserves a deleted entry's attribute and uniqueness characteristics to allow it to be undeleted or permanently removed at a later date.

This chapter introduces the following topics:

About Soft Deletes

The standard implementation of an LDAP server allows for adding, renaming, modifying, searching, comparing, and deleting one or more entries. The DELETE operation is, by specification, a destructive operation that permanently removes an entry and its attributes in a Directory Information Tree (DIT) but records the changes in access, and optionally, audit and change logs. During the DELETE operation, any associations such as references and group memberships are severed to reflect the entry that is removed. Meta attributes like operational attributes, which may be unique to an entry like `entryUUID`, will be lost or be different if the same entry is re-added to the Directory Server.

There are cases, however, where a company may want to preserve their deleted entries to allow for possible undeletion at a later date. For example, a company may want to retain account and subscriber entries for their users (e.g., customers, employees, or partners) who leave but later rejoin. Artifacts that a user creates such as account histories, web pages, notes, may be tracked and recovered while a user is deleted or when the user returns as an active customer.

To facilitate this use case, the Directory Server supports a feature called *soft deletes*, which preserves a deleted entry's attributes and entry uniqueness characteristics to allow the entry to be undeleted or permanently removed at a later date. A delete request may result in a soft delete either by the client explicitly requesting a soft delete or by the request matching criteria defined in an active soft delete policy. The soft-deleted entries are renamed by prefixing an `entryUUID` operational attribute to the DN and adding an auxiliary object class, `ds-soft-delete-entry`, to the entry, which saves the entry in a hidden state. All active references and group memberships are then removed. Once in this hidden state, soft-deleted entries are inaccessible to clients under normal operating conditions. Only clients with the `soft-delete-read` privilege will be allowed to interact with soft-deleted entries.

To allow soft deletes, the Directory Server's attribute uniqueness function has been relaxed to allow for the co-existence of a soft-deleted entry and an active entry with identical naming attributes, such as `uid`. For example, if a user John Smith was soft deleted but a different John Smith was added to the user accounts system, both entries could reside in the DIT without conflict: one in a soft-deleted state; the other, in an active state. The Directory Server extends this capability further by allowing multiple users with the same DN, who would normally conflict if active, to reside in the soft-deleted state.

Soft-deleted entries can be restored with an Undelete operation. However, the same uniqueness constraints that apply when adding a new user to the Directory Server are enforced when a soft-deleted entry is undeleted. Returning to the previous example, John Smith was soft deleted but a different John Smith with the same `uid` as the original John Smith was added later to the system. If the original John Smith was undeleted from its soft-deleted state, it would result in a conflict with the active John Smith entry. Administrators will need to modify the DN of the soft-deleted entry to avoid such conflicts.

Administrators can permanently remove a soft-deleted entry by performing a regular DELETE operation on it. This operation, called a *hard delete*, permanently removes a soft-deleted entry from the server. Also, note that you can also permanently remove a regular non-soft-deleted entry using a hard delete. This is useful when the server is configured with a soft-delete policy that would otherwise turn a regular delete request into a soft delete.

The Directory Server provides tool arguments that can use the Soft Delete Request Control, a Hard Delete Request Control, and other controls necessary to process these operations. Procedures to show how to use these options are presented later in this section.

For replicated topologies, when a participating directory server soft deletes an entry, it notifies the other replicas in the topology to soft delete the same entry on its respective machine. The changelog backend also records these entries by annotating them using an attribute that indicates its soft-deleted state. Modification and hard deletes of soft-deleted entries are not recorded by default in the changelog but can be enabled in the server. For maximum compatibility, it is highly recommended that all servers in the replication cluster support Soft Deletes and have identical Soft Delete configurations.

General Tips on Soft Deletes

There are some general tips about soft deletes that administrators should be aware of:

- **LDAP SDK and Server SDK.** The LDAP SDK and Server SDK both fully supports soft-deletes.
- **Possible Performance Impact for Searching Regular Entries and Soft-Deleted Entries.** There is little performance difference between retrieving a regular entry and a soft-deleted entry, respectively. However, there may be a performance impact when a search operation has to match criteria (such as `uid=john.smith`) for both active entries and soft-deleted entries. For example, if there is one active `uid=john.smith` entry and two soft-deleted `uid=john.smith` entries, it may take the server a little more time to retrieve and try to match the criteria before it can return the results.

- **Soft Delete for Uncached Attributes and Entries.** The soft delete feature fully supports uncached attributes and uncached entries. See the section on [Uncached Attributes and Entries](#) for more information about the feature.
- **Soft Delete for Leaf Nodes Only.** Soft-deletion of any parent entry is not allowed. Likewise, soft-deleted entries that have soft-deleted sub-entries are not allowed.
- **Attempting to Soft-Delete a Soft-Deleted Entry Fails.** There are two available state options for soft-deletes: administrators can permanently delete a soft-deleted entry or undelete the entry. An administrator cannot soft-delete an already soft-deleted entry, which returns an `UNWILLING_TO_PERFORM` result code.
- **Soft-Deleted Users Have No Privileges.** Soft-deleted users do not have the ability to bind to the Directory Server or have authentication access. They cannot change their passwords and cannot undelete themselves. Also, soft-deleted entries cannot be used as an authorization identity using the proxied authorization or immediate client control. It is important to note that the soft-delete process does not destroy privilege assignment. If a soft-deleted entry is undeleted, the restored entry will retain the same privileges it originally had before being soft deleted. (One possible exception to this are those privileges assigned by virtual attributes that no longer match the newly-undeleted entry; those entries do not retain their original privileges.)
- **Soft-Deleted Entries Not Accessible by Other Means.** Soft-deleted entries may not be accessible from alternate access methods like SCIM.
- **Soft-Deleted Entries Can Be Modified but Not Renamed.** Administrators can search for all soft-deleted entries and the original source entry attributes can be updated as long as the administrators has modify privileges and access to the `soft-delete-read` privilege. Any attempt to rename a soft-deleted entry using a MODIFY DN operation will result in an `UNWILLING_TO_PERFORM` result code.
- **Replication.** Replication will have access to the LDAP operations with Soft Delete controls. These operations are transmitted, processed, and replayed as high-level requests, which are re-played on remote replicated servers. The replication conflict-resolution mechanism handles soft-deleted entries like any regular entries. For example, if a soft delete is executed independently on two servers then replicated, this results in a replication conflict. For maximum compatibility, it is highly recommended that all servers in a replication cluster support Soft Deletes and have identical Soft Delete configuration.
- **Transactions.** Soft-deletes are supported in transactions. The processing workflow uses the transactions mechanism and maintains the context information necessary to rollback failures to soft delete or undelete.
- **Soft-Deletes Through the Directory Proxy Server .** There is no special configuration steps to configure Soft Deletes on the Directory Proxy Server. The soft-deleted entry is routed directly to the underlying Directory Server. There is one exception: in an entry-balancing deployment, the Directory Proxy Server is responsible for routing the soft-deleted entry to the Directory Server containing the originally soft-deleted item. Also, as with standard entry-balanced deployments, it is not possible to undelete (using MODDN) an entry to a different Directory Server.
- **Export-LDIF.** The default behavior is to include soft-deleted entries as part of the `export-ldif` operation. If soft-deleted entries are to be excluded from export, administrators can use the `--excludeSoftDeleteEntries` option to filter out the entries.
- **Proxied Authorization.** The Soft Delete feature can be used with users who have proxied authorization privileges.
- **Ignored by Data Sync Server Sync Pipes.** For customers using the PingDataSync Server, soft-deleted entries are not synchronized by the server. Modifications or deletes of a soft-deleted entry are ignored by the Data Sync Server, and do not appear in the changelog by default. An actual soft delete operation appears to the changelog as a regular DELETE, and an actual undelete operation appears in the changelog as a regular ADD.
- **Referential Integrity Plugin Does Not Restore Membership.** References to a deleted DN are not restored by the referential integrity plugin upon undeletion of a soft-deleted entry. For example, if you have referential integrity enabled and you soft-delete a DN that is a member of a static group, the referential integrity plugin will remove this DN from the group's list of members. When you undelete the soft-deleted entry, the plugin will not add the entry back to the group.

- **Criteria-Selected or Explicitly-Requested Purging of Soft Deletes.** The Soft Delete Policy configuration supports two new properties, `soft-delete-retention-time` and `soft-delete-retain-number-of-entries` that performs purging of soft deleted entries. See the section on [Configuring Soft-Delete Automatic Purging](#).
- **Assigning Access to Controls to Non-Root Users Administrators.** By default, the root user account (e.g., `cn=Directory Manager`) has access to all of the controls needed to run the Soft Delete operations. For non-root users, you must grant access to these Soft Delete controls using access control rules. An example is shown in step 1 of the section, [To Configure Soft Deletes as a Global Configuration](#). The following Soft Delete Controls are available to non-root users:
 - **Soft Delete Request Control.** Allows the user to perform a soft delete operation. The OID for the control is 1.3.6.1.4.1.30221.2.5.20.
 - **Soft Delete Response Control.** Allows the server to hold the DN of the soft-deleted entry that results from a soft delete request. The OID for the control is 1.3.6.1.4.1.30221.2.5.21.
 - **Hard Delete Request Control.** Allows the user to run a hard delete operation on the entry, regardless if it is a regular or soft-deleted entry. The OID for the control is 1.3.6.1.4.1.30221.2.5.22.
 - **Undelete Request Control.** Allows the user to undelete a soft-deleted entry using an ADD request. The OID for this control is 1.3.6.1.4.1.30221.2.5.23.
 - **Soft-Deleted Entry Access Request Control.** Allows the user to search for any soft-deleted entries. The OID for this control is 1.3.6.1.4.1.30221.2.5.24. Note that a bind DN with the `stream-values` privilege can perform operations that can reveal soft-deleted entries, even if that bind DN does not have permission to use the Soft-Deleted Entry Access Request Control. For example, if a user can successfully run `dump-dns` or `ldap-diff`, then that user can get a list of soft-deleted entry DNs or soft-deleted entry contents via the output of one of those tools.

Configuring Soft Deletes on the Server

Soft deletes are configured on the Directory Server in several ways:

- **Using a Soft-Delete Policy and Global Configuration Property.** You can configure soft deletes by creating a soft-delete policy and a global configuration property. The soft-delete policy enables the feature on the server, while the global configuration property sets the controls used for the soft-delete requests. To enter a soft delete request, the `ldapmodify` or `ldapdelete` command requires the `--useSoftDelete` option. A delete request that does not have the `--useSoftDelete` option is treated as a hard delete, which permanently removes the entry.
- **Using Connection Criteria.** You can configure soft deletes by defining connection criteria within a client connection policy. Any clients that meet the criteria will have their deletes processed as soft deletes.
- **Using Request Criteria.** You can configure soft deletes by defining request criteria within a client connection policy. Any client requests that meet the criteria will have their deletes processed as soft deletes. Note that you can define both connection criteria and request criteria. Both criteria are exclusive and can exist within a soft-delete policy. In this case, the connection criteria is processed first, then the request criteria.

Configuring Soft Deletes as a Global Configuration

You can configure the soft delete feature by creating a soft-delete policy and then setting the configuration property on the server. The presence of the soft-delete policy enables the feature on the server and allows the global configuration property to send the necessary soft-delete requests.

This configuration setting requires that the `--useSoftDelete` option be used together with the `ldapmodify` or `ldapdelete` commands to send the delete using the Soft Delete Request Control. Without the `--useSoftDelete` option, any delete will be processed as a hard delete.

To Configure Soft Deletes as a Global Configuration

Steps

- Configure a soft delete policy using the `dsconfig` command. The soft delete configuration option requires a soft-delete policy, which enables the feature on the server. This is a required step.

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy
```

- Configure the soft delete as a global configuration property using the `dsconfig` command. The command sets up the soft-delete controls necessary to send them as a request. This is a required step.

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

Results

After a successful modification, the server issues a warning that soft deletes are not enabled and that administrative action may be needed to prune older soft-deleted entries if resources are limited.

Configure a User to Use Soft or Hard Delete Controls

About this task

To allow a user to manipulate soft deletes, the user must be able to use the appropriate controls. By default, only the Directory Manager has these controls. The user also needs to have the `soft-delete-read` privilege assigned. ACIs are required to allow this user to:

- Modify target entries.
- Use the soft delete/undelete controls.
- Use the soft deleted entry access control (to modify soft deleted entries).
- Use the hard delete request control to permanently delete an soft-deleted entry.

Steps

- For example, take the `uid=admin,dc=example,dc=com` user that is installed with the sample user data during setup. This user already has an ACI in place giving it access to user entries:

```
(targetattr="*")(version 3.0; aci "Grant full access for the admin user";
allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

- The other ACIs need to be added to the base suffix (or other point in the DIT as required to possibly restrict the scope):

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.20||1.3.6.1.4.1.30221.2.5.21")
(version 3.0; aci "Allow admins to use the Soft Delete Request Control and
Soft Delete Response Control";
allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.22") (version 3.0; aci "Allow admins
to use the Hard Delete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.23") (version 3.0; aci "Allow admins
to use the Undelete
Request Control";allow (read) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

```
(targetcontrol="1.3.6.1.4.1.30221.2.5.24") (version 3.0; aci "Allow admins
to use the Soft-Deleted
Entry Access RequestControl"; allow (read) userdn="ldap:///
uid=admin,dc=example,dc=com";)
```

- Add the **ds-privilege-name** attribute to the user with the value **soft-delete-read**. Once this is complete, the user can soft delete (and undelete) entries.

```
$ ./bin/ldapmodify -s -p 1389 -D uid=admin,dc=example,dc=com -w password
# Successfully connected to localhost:1389.

dn: uid=user.10,ou=people,dc=example,dc=com
changetype: delete

# Deleting entry uid=user.10,ou=people,dc=example,dc=com ...
# Result Code: 0 (success)
# Soft Delete Response Control:
#   OID: 1.3.6.1.4.1.30221.2.5.21
#   Soft-Deleted Entry DN: entryUUID=8dbe8cb4-1aa3-41c5-88ec-
a6280eeff918+uid=user.10,ou=People,dc=example,dc=com
```

Searching for Soft Deletes

Soft-deleted entries are excluded from normal LDAP searches because they represent "deleted" entries. The `ldapsearch` tool has been updated to support these types of searches. If you want the option to search for soft-deleted entries, there are three ways to do so:

- **Base-Level Search on a Soft-Deleted entry by DN.** Use `ldapsearch` and specify the base DN of the specific soft-deleted entry that you are searching for.
- **Filtered Search by `ds-soft-delete-entry` object class.** To search for all soft-deleted entries, use `ldapsearch` with a filter on the `ds-soft-delete-entry` objectclass.
- **Soft-Delete-Entry-Access Control.** You can use the Soft Delete Entry Access Control with the LDAP search to return soft-deleted entries. The `ldapsearch` tool provides a shortcut option, `--includeSoftDeletedEntries`, that sends the control to the server for processing. The control allows for the following search possibilities:
 - Return only soft-deleted entries.
 - Return non-deleted entries along with soft-deleted entries.
 - Return only soft-deleted entries in undeleted form.

To Run a Base-Level Search on a Soft-Deleted Entry

Steps

- Run `ldapsearch` using the base DN of the specified soft-deleted entry.

```
$ bin/ldapsearch \
  --baseDN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com \
  --searchScope base "(objectClass=*)"

# Soft-deleted entry DN:
# entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
objectClass: ds-soft-delete-entry
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.
uid: user.1
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
```

```

employeeNumber: 1

homePhone: +1 332 432 4295
l: Green Bay
mail: user.3@maildomain.net
st: TN

```

To Run a Filtered Search by soft-delete-entry Object Class

Steps

- Run `ldapsearch` to retrieve all soft-deleted entries using the `ds-soft-delete-entry` object class. The following command retrieves all soft-deleted entries on the server

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  "(objectclass=ds-soft-delete-entry)"

```

To Run a Search using the Soft Delete Entry Access Control

The following examples use the `--includeSoftDeleteEntries {with-non-deleted-entries | without-non-deleted-entries | deleted-entries-in-undeleted-form}` option, which uses the Soft Delete Entry Access Control. You could also use the `--control` option with the Soft Delete Entry Access Control symbolic name, `softdeleteentryaccess`, or the `--control` option with the actual Soft Delete Entry Access Control OID, `1.3.6.1.4.1.30221.2.5.24`.

- Return Only Soft-Deleted Entries.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `without-non-deleted-entries` to return only soft-deleted entries.

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries without-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- Return Non-Deleted Entries Along with Soft-Deleted Entries.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `with-non-deleted-entries` to return non-deleted entries along with soft-deleted entries.

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries with-non-deleted-entries \
  --searchScope sub "(objectclass=*)"

```

- Return Only Soft-Deleted Entries in Undeleted Form.** Run `ldapsearch` using the `--includeSoftDeletedEntries` option with the value of `deleted-entries-in-undeleted-form` to return only soft-deleted entries in undeleted form. Some applications require access to all entries in the server, including both active and soft-deleted entries. The following command returns all entries that were soft-deleted but presents it in a form that is similar to a regular entry with the soft-delete DN in comments. This regular entry format does not show the actual soft-deleted DN but displays it in an "undeleted" form even though it is not actually "undeleted". Also, the object class, `ds-soft-delete-entry`, is not displayed:

```

$ bin/ldapsearch --baseDN dc=example,dc=com \
  --includeSoftDeletedEntries deleted-entries-in-undeleted-form \
  --searchScope sub "(ds-soft-delete-from-dn=*)"

# Soft-deleted entry DN:
# entryUUID=2b5511e2-7616-389b-ab0c-025c805ad32c
+uid=user.14,ou=People,dc=exam-

```

```

ple,dc=com

```

Undeleting a Soft-Deleted Entry Using the Same RDN

To undelete a soft-deleted entry, use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. In an LDIF file or from the command line, specify the `dn:<target entry>` attribute, which is the DN that the entry will be undeleted *to* and the `ds-undelete-from-dn` attribute, which is the entry that will be undeleted *from*. An undelete requires the `add changetype` so that the entry can be re-added to the server.

To Undelete a Soft-Deleted Entry Using the Same RDN

Steps

- Use `ldapmodify` with the `--allowUndelete` option and target the specific soft-deleted entry that you want to restore. The `--allowUndelete` option sends the Soft Undelete Request Control to the server. The first DN is the entry to undelete *to* and the `ds-undelete-from-dn` is the soft-delete entry to undelete *from*.

```

$ bin/ldapmodify --allowUndelete
dn: uid=user.1,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

```

Undeleting a Soft-Deleted Entry Using a New RDN

In some cases, the original RDN, `uid=user.1`, may have been allocated to a new user, which is allowed while the entry is in a soft-deleted state. To properly undelete this entry, you need to specify a new RDN value that the entry should be restored with. In this case, specifying the RDN of `uid=user.5` will undelete the original entry but with the new DN in the example below. In addition, the `uid` attribute on the entry will be updated with the new value of `user.5` as well. All other attributes of the users entry including the `entryUUID` will remain unchanged.

To Undelete a Soft-Deleted-Entry Using a New RDN

Steps

1. Use `ldapmodify` to undelete a soft-deleted entry that has an original RDN, `uid=user.1`, to a new RDN, `uid=user.5`. You will need to ensure that the DN that you are undeleting the entry to does not already exist as this will lead to an "entry already exists" error if you specify a DN that already exists in the Directory Server as a normal entry.

```
$ bin/ldapmodify --allowUndelete
dn: uid=user.5,ou=People,dc=example,dc=com
changetype:add
ds-undelete-from-dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

2. View the results using `ldapsearch`. You will notice the RDN and the `uid` attribute has changed.

```
dn: uid=user.5,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Aartjan Aalders$59748 Willow Street$Green Bay, TN 66239
postalCode: 66239
description: This is the description for Aartjan Aalders.
uid: user.5
userPassword: {SSHA}RdBCwQ2kIw57LukRthjrFBS/oFylJARnmTnorA==
employeeNumber: 1
initials: AKA
givenName: Aartjan
pager: +1 197 025 3730
mobile: +1 890 430 9077
cn: Aartjan Aalders
sn: Aalders
telephoneNumber: +1 094 100 7524
street: 59748 Willow Street
homePhone: +1 332 432 4295
l: Green Bay
mail: user.3@maildomain.net
st: TN
entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4
```

Modifying a Soft-Deleted Entry

You can modify a soft-deleted entry as you would a regular entry using the `ldapmodify` tool and remains hidden in its soft-deleted state after the change. The only restriction is that you cannot change the DN or run a MODDN operation on the soft-deleted entry.

To move a soft-deleted entry from one machine to another, use the `move-subtree` command and specify the DN of the soft-deleted entry. For more information, see [To Move an Entry from One Machine to Another](#).

Note: To modify a soft-deleted entry, the user needs the `soft-delete-read` privilege to access the soft-deleted entry.

To Modify a Soft-Deleted Entry

Steps

- Soft-deleted entries can be modified like any regular entry. Use `ldapmodify` and specify the soft-deleted DN.

```
$ bin/ldapmodify
dn: entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
changetype:modify
replace:telephoneNumber
telephoneNumber: +1 390 103 6918
# Processing MODIFY request for entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
# MODIFY operation successful for DN entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Hard Deleting a Soft-Deleted Entry

To permanently remove a soft-deleted entry from the server, you can run `ldapdelete` on the soft-deleted entry for soft-deleted entries. To hard delete a soft-deleted entry, use `ldapdelete` with the `--useHardDelete` option. The Hard Delete Request Control works with soft deletes. It mostly applies when soft delete policies are in place as a means to override soft deletes requests. If soft deletes are configured, running `ldapdelete` with the Hard Delete Request Control (i.e., using the option, `--useHardDelete`) guarantees any entry will be permanently deleted.

To Hard Delete a Soft-Deleted Entry (Global Configuration)

Steps

- Run `ldapdelete` on a soft-deleted entry to permanently remove it from the Directory Server. This example assumes that you configured soft deletes as a global configuration for requests.

```
$ bin/ldapdelete \
  entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com

Processing DELETE request for entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
DELETE operation successful for DN entryUUID=4e9b7847-edcb-3791-b11b-
7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Note:

You cannot soft-delete an already soft-deleted entry. If you use the `--useSoftDelete` with the `ldapdelete` operation on a soft-deleted entry, an error message will be generated.

```
DELETE operation failed.
Result Code: 53 (Unwilling to Perform)
Diagnostic Message: DELETE operation failed.
```

To Hard Delete a Soft-Deleted Entry (Connection or Request Criteria)

Steps

- Run `ldapdelete` with the `--useHardDelete` option on a soft-deleted entry to permanently remove it from the server. This example assumes that you configured soft deletes using a connection or request criteria.

```
$ bin/ldapdelete --useHardDelete \
  entryUUID=4e9b7847-edcb-3791-
  b11b-7505f4a55af4+uid=user.1,ou=People,dc=example,dc=com
```

Disabling Soft Deletes as a Global Configuration

To disable soft deletes on your Directory Server, simply reset the global configuration property and the remove the soft-delete policy. From that point, all deletes will be processed as hard deletes by default. Any use of the soft-deleted options with the LDAP tools results in an error. Any existing soft-deleted entries that are present after the global configuration is disabled will remain in the server as latent entries.

To Disable Soft Deletes as a Global Configuration

Steps

- Run `dsconfig` to reset the global configuration property. Remember to include the LDAP bind parameters for your system.

```
$ bin/dsconfig set-global-configuration-prop --reset soft-delete-policy
```

- Run `dsconfig` to delete the soft delete policy that you created. Remember to include the LDAP bind parameters for your system.

```
$ bin/dsconfig delete-soft-delete-policy --policy-name default-soft-delete-policy
```

Configuring Soft Deletes by Connection Criteria

The Directory Server supports soft deletes where any delete operation is treated as a soft-delete request as long as the LDAP client meets the connection criteria. You can configure soft deletes by defining the connection criteria used in a client connection policy, and then configuring the soft delete connection criteria in the soft-delete policy.

To Enable Soft Deletes by Connection Criteria

Steps

- Configure a soft-delete policy and global configuration as shown in “Configuring Soft Deletes as a Global Configuration”.
- Create a simple connection criteria using `dsconfig` and name it "Internal Applications". The soft delete connection criteria is configured for a member of a Line of Business (LOB) Applications group connecting from the 10.8.1.0 network.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Internal Applications" \
  --type simple \
  --set included-client-address:10.8.1.0/8 \
  --set "all-included-user-group-dn:cn=LOB
  Applications,ou=Groups,dc=example,dc=com"
```

3. In the soft delete policy created in step 1, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-connection-criteria:Internal Applications"
```

To Disable Soft Deletes by Connection Criteria

Steps

- To disable soft deletes by connection criteria, simply reset the `auto-soft-delete-connection-criteria` property on the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-connection-criteria
```

Configuring Soft Deletes by Request Criteria

Soft deletes can be configured using request criteria within a client connection policy. All delete requests that meet the request criteria is treated as a soft delete. The presence of a soft delete by connection criteria is exclusive of the soft delete by request criteria. Both can be present in a soft-delete policy.

To Enable Soft Deletes by Request Criteria

Steps

1. Configure a soft-delete policy and global configuration as shown in “Configuring Soft Deletes as a Global Configuration”.
2. Configure request criteria for soft deletes. The soft delete request criteria is configured for an external delete request from a member of the Internal Applications group matching an entry with object class "inetorgperson" with the request excluding the Soft Delete Request Control and the Hard Delete Request Control.

```
$ bin/dsconfig create-request-criteria \
  --criteria-name "Soft Deletes" \
  --type simple \
  --set "description:Requests for soft delete" \
  --set operation-type:delete \
  --set operation-origin:external-request \
  --set "connection-criteria:Internal Applications" \
  --set not-all-included-request-control:1.3.6.1.4.1.30221.2.5.20 \
  --set "all-included-target-entry-filter:(objectClass=inetorgperson)"
```

3. In the soft delete policy created in step 1, set the `auto-soft-delete-connection-criteria` property to the simple criteria created in the previous step.

```
$ bin/dsconfig create-soft-delete-policy \
  --policy-name default-soft-delete-policy \
  --set "auto-soft-delete-request-criteria:Soft Deletes"
```

To Disable Soft Deletes by Request Criteria

Steps

- To disable soft deletes by request criteria, reset the soft-delete policy.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset auto-soft-delete-request-criteria
```

Configuring Soft Delete Automatic Purging

By default, the Directory Server retains soft-deleted entries indefinitely. For companies that want to set up automatic purging of soft-deleted entries, the server provides two properties on the Soft Delete Policy that can be configured for either the maximum retention time for all soft-deleted entries and/or the retained number of soft-deleted entries. These changes take effect without requiring a server restart.

To Configure Soft-Delete Automatic Purging

About this task

You can change either the retention time or the retained number of entries to enable automatic purging. By default, both are set to an indefinite retention time and number of entries. The time unit of milliseconds (ms), seconds (s), minutes (m), hours (h), days (d), or weeks (w), may be preceded by an integer to specify a quantity for that unit, such as "1 d", "52 w", etc. Once you configure the properties, the changes take effect immediately without the need for a server restart.

Note that the server will delete all of the soft-deleted entries according to the policy in effect. If the policy is changed while entries are in the process of being deleted, the new policy takes effect after the in-process batch of entries is deleted and applies to any remaining soft-deleted entries going forward according to the new policy.

Steps

1. Retrieve the name of the Soft Delete Policy in effect using the `dsconfig` command. For this example, the Soft Delete Policy is called `default-soft-delete-policy`.

```
$ bin/dsconfig get-global-configuration-prop \
  --property soft-delete-policy
```

2. Do one or both of the following:

- Run `dsconfig` to set the retention time for soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set "soft-delete-retention-time:52 w"
```

- Run `dsconfig` to set the retained number of soft-deleted entries.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --set soft-delete-retain-number-of-entries:1000000
```

3. The Soft Delete Policy must be assigned to the global configuration if it has not been assigned yet.

```
$ bin/dsconfig set-global-configuration-prop \
  --set soft-delete-policy:default-soft-delete-policy
```

To Disable Soft-Delete Automatic Purging

About this task

You can disable Soft-Delete automatic purging using the `dsconfig` command. The change takes effect immediately without the need of a server restart. However, if the server is in the middle of an automatic soft-delete purging, it may continue to purge entries until the next time it evaluates the Soft Delete Policy.

Steps

- Run `dsconfig` to reset the Soft-Delete Policy properties that control automatic purging: `soft-delete-retention-time` and `soft-delete-retain-number-of-entries`.

```
$ bin/dsconfig set-soft-delete-policy-prop \
  --policy-name default-soft-delete-policy \
  --reset soft-delete-retention-time \
  --reset soft-delete-retain-number-of-entries
```

Summary of Soft and Hard Delete Processed

The following table summarizes the resulting actions of a DELETE operation for soft deletes.

If No Automatic Soft Delete Criteria is Configured

Action	Result
Delete	Performs a hard delete on the entry.
Delete with the Soft Delete Request Control	Performs a soft delete on the entry.
Delete of a soft-deleted entry	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Soft Delete Request Control	Not allowed. Generates an <code>UNWILLING_TO_PERFORM</code> error.
Delete with a Hard Delete Request Control	Performs a hard delete on the entry.
Delete of a soft-deleted entry with the Hard Delete Request Control.	Performs a hard delete on the entry.

The following table summarizes the resulting actions of a DELETE operation for soft deletes configured by connection criteria or request criteria.

If Soft Delete Connection or Request Criteria is Configured

Action	Result
Delete not matching criteria	Performs a hard delete on the entry.
Delete matching criteria	Performs a soft delete on the entry.
Delete of a soft-deleted entry not matching criteria	Performs a hard delete on the entry.
Delete of a soft-deleted entry matching criteria	Performs a hard delete on the entry.
Delete not matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.

Action	Result
Delete matching criteria with the Hard Delete Request Control	Performs a hard delete on the entry.
Delete with Soft and Hard Delete Request Controls	Not allowed. Generates an <code>UNWILLING_TO_PERFORM</code> error.

Summary of Soft Delete Controls and Tool Options

The following table shows the OIDs for each soft delete control. The Soft Delete OIDs are defined in the LDAP SDK generated API documentation.

Soft Delete OIDs

OID Type	OID
Soft Delete Request Control	1.3.6.1.4.1.30221.2.5.20
Soft Delete Response Control	1.3.6.1.4.1.30221.2.5.21
Hard Delete Request Control	1.3.6.1.4.1.30221.2.5.22
Soft Undelete Request Control	1.3.6.1.4.1.30221.2.5.23
Soft Delete Entry Access Control	1.3.6.1.4.1.30221.2.5.24

The following table shows the new tool options available for the Soft Delete operations.

Soft Delete Tool Options

Action	Result
<code>ldapdelete / ldapmodify</code>	--useSoftDelete/-s . Process DELETE operations with the Soft Delete Request Control, whereby entries are renamed, and hidden instead of being permanently deleted. The Directory Server must be configured to allow soft deletes. Note that any entries in the LDIF file with the changetype of <code>delete</code> will be processed as a soft-delete request.
<code>ldapdelete</code>	--useHardDelete . Process DELETE operations with the Hard Delete Request Control, which bypasses any soft delete policies and processes the delete request immediately without retaining the entry as a soft-deleted entry. The Directory Server must be configured to allow soft deletes.

Action	Result
ldapsearch	<p>--includeSoftDeletedEntries {with-non-deleted-entries without-non-deleted-entries deleted-entries-in-undeleted-form}. Process search operations with the Soft Delete Entry Access Control. Soft delete search options are as follows:</p> <ul style="list-style-type: none"> ▪ with-non-deleted-entries. Returns all entries matching the search criteria with the results including non-deleted and soft-deleted entries. ▪ without-non-deleted-entries. Returns only soft-deleted entries matching the search criteria. ▪ deleted-entries-in-undeleted-form. Returns only soft-deleted entries matching the search criteria with the results returned in their undeleted entry form. <p>Users must have access to the Soft Delete Entry Access Control to be able to search for soft-deleted entries.</p>
ldapmodify	<p>--allowUndelete. Process ADD operations which include the <code>ds-undelete-from-dn</code> attribute as undelete requests. Undelete requests re-add previously soft-deleted entries back to the server as non-deleted entries by providing the Undelete Request Control with the ADD operation. The Directory Server must be configured to allow soft deletes to process any undelete requests and the client user must have the <code>soft-delete-read</code> privilege.</p>

The following table shows the symbolic names that can be used with the server's LDAP commands using the `--control/-J` option.

Soft Delete OID Symbolic Names using with the `--control/-J` Option

Control	Symbolic Name
Soft Delete Request Control	softdelete
Hard Delete Request Control	harddelete
Soft Undelete Request Control	undelete
Soft Delete Entry Access Control	softdeleteentryaccess

Monitoring Soft Deletes

The Directory Server provides monitoring entries and logs to track all soft delete operations. The access and debug logs do not have any options specific for soft deletes.

New Monitor Entries

Two new monitor entries are present for a backend monitor entry. Administrators will see the following additional monitor entries on `cn=userRoot Backend, cn=monitor`:

- **ds-soft-delete-entry-operations-count**. Displays the number of soft-deletes performed on the backend since server startup.
- **ds-undelete-operations-count**. Displays the number of undeletes performed on the backend since server startup.
- **ds-backend-soft-deleted-entry-count**. Displays the current number of soft-deleted entries in the database.

- **ds-auto-purged-soft-deleted-entry-count.** Displays the current number of soft-deleted entries purged since the backend or server was restarted.

To Monitor Soft Deletes

Steps

- **Run `ldapsearch` on the `cn=userRoot Backend, cn=monitor` branch.** Use a search criteria targeting the `ds-backend-monitor-entry` object class.

```
$ bin/ldapsearch --baseDN "cn=userRoot Backend,cn=monitor" \
  --searchScope sub "(objectclass=ds-backend-monitor-entry)"
```

```
dn: cn=userRoot Backend,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-backend-monitor-entry
objectClass: extensibleObject
cn: userRoot Backend
ds-backend-id: userRoot
ds-backend-base-dn: dc=example,dc=com
ds-backend-is-private: FALSE
ds-backend-entry-count: 200001
ds-backend-soft-deleted-entry-count: 1000
ds-soft-delete-operations-count: 40
ds-undelete-operations-count: 20
ds-auto-purged-soft-deleted-entry-count: 0
ds-base-dn-entry-count: 200001 dc=example,dc=com
ds-backend-writability-mode: enabled
```

Access Logs

The access log records the LDAP operations corresponding to soft delete and undelete for DELETE, SEARCH, MODIFY, and ADD operations with the related soft-deleted values. The access log does not require any configuration for soft delete.

For DELETE (soft-delete) operations, the access log displays:

```
[14/May/2012:09:40:16.942 -0500] DELETE RESULT conn=18 op=1 msgID=2
dn="uid=user.1,ou=People,dc=example,dc=com" resultCode=0 etime=30.367
softDeleteEntryDN="entryUUID=4e9b7847-edcb-3791-b11b-7505f4a55af4+uid=user.1,
ou=People,dc=example,dc=com"
```

For SEARCH operations for soft-deleted entries, the log displays:

```
[14/May/2012:09:40:52.320 -0500] SEARCH RESULT conn=19 op=1 msgID=2
base="dc=example,dc=com" scope=2 filter="(objectclass=ds-soft-delete-entry)"
attrs="ALL" resultCode=0 etime=1.631 entriesReturned=1
```

For MODIFY operations of soft-deleted entries, the log displays:

```
[14/May/2012:09:42:43.679 -0500] MODIFY RESULT conn=20 op=1 msgID=1
dn="entryUUID=4e9b7847-edcb-3791-
b11b-7505f4a55af4+uid=user.1,ou=People,dc=exam-
ple,dc=com" resultCode=0 etime=2.639 changeToSoftDeletedEntry=true
```

For ADD (soft undelete) operations, the log displays:

```
[14/May/2012:09:58:16.728 -0500] ADD RESULT conn=25 op=1 msgID=1
dn="uid=user.0,ou=People,dc=example,dc=com" resultCode=0 etime=22.700
undeleteFromDN="entryUUID=ad55a34a-763f-358f-93f9-da86f9ecd9e4+uid=user.0,
ou=People,dc=example,dc=com"
```

Audit Logs

The audit log captures any MODIFY and DELETE operations of soft-deleted entries. These changes are recorded as fully commented-out audit log entries. The audit log does not require any configuration for soft deletes.

For any soft-deleted entry, the audit log entry displays the `ds-soft-delete-entry-dn` property and its soft-deleted entry DN.

```
# 14/May/2012:10:57:09.054 -0500; conn=30; op=1
# ds-soft-delete-entry-dn: entryUUID=68147342-1f61-3465-8489-
3de58c532130+uid=user.2,ou=People,dc=example,dc=com
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: delete
```

For any MODIFY changes made, the log displays the LDIF, the modifier's name and update time.

```
# 14/May/2012:10:58:33.566 -0500; conn=33; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
  ple,dc=com
# changetype: modify
# replace: homePhone
# homePhone: +1 003 428 0966
#-
# replace: modifiersName
# modifiersName: uid=admin,dc=example,dc=com
#-
# replace: modifyTimestamp
# modifyTimestamp: 20131010020345.546Z
```

For any undelete of a soft-deleted entry, the log displays the `ds-undelete-from-dn` attribute plus the entry unique ID, create time and creator's name.

```
# 14/May/2012:10:59:21.754 -0500; conn=34; op=1
dn: uid=user.2,ou=People,dc=example,dc=com
changetype: add
uid: user.2
ds-undelete-from-dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=Peo-
  ple,dc=example,dc=com
ds-entry-unique-id:: vw1jg801S7GWrTiS3UE5DA==
createTimestamp:: 20131010181148.630Z
creatorsName: uid=admin,dc=example,dc=com
```

For hard (permanent) deletes of a soft-deleted entry, the log displays the soft-deleted entry DN that was removed.

```
# 14/May/2012:11:00:14.055 -0500; conn=36; op=1
# dn:
  entryUUID=68147342-1f61-3465-8489-3de58c532130+uid=user.2,ou=People,dc=exam-
  ple,dc=com
# changetype: delete
```

To Configure the File-Based Audit Log for Soft Deletes

Steps

1. Enable the audit log if it is disabled.

```
$ bin/dsconfig set-log-publisher-prop --publisher-name "File-Based Audit
  Logger" \
--set enabled:true
```

2. View the audit log. The `soft-delete-entry-audit-behavior` property is set to "commented" by default and provides additional information in comments about the soft-deleted entry that was either created or undeleted.

```
# 11/May/2012:15:33:17.552 -0500; conn=13; op=1
# ds-soft-delete-entry-dn:entryUUID=54716bfd-fbc4-3108-ac37-
bf6b1b166e37+uid=user.15,ou=People,dc=example,dc=com
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: delete
```

Change Log

The change log can be configured to capture soft-delete changes to entries, so that external clients, such as PingDataSync Server, can access these changes. The `ds-soft-delete-entry` attribute represents an entry that has been soft-deleted and is part of the source entry passed into the changelog to indicate the entry has been soft-deleted.

Two important points about soft deletes and the changelog are as follows:

- All soft-delete operations appear in the changelog and appear as a regular DELETE operation. When a soft delete occurs, the resulting changelog entry will include a `ds-soft-delete-entry-dn` operational attribute with the value of the soft-deleted entry DN. If you are using PingDataSync Server, it does recognize the `ds-soft-delete-entry-dn` attribute and does not do anything with it.
- The changelog backend's `soft-delete-entry-included-operation` property determines whether or not MODIFY or DELETE operations of soft-deleted entries appear in the changelog. By default, the property is not enabled by default.

To Configure Soft Deletes on the Changelog Backend

Steps

1. Configure soft deletes on the changelog backend.

```
$ bin/dsconfig set-backend-prop \
--backend-name changelog \
--set soft-delete-entry-included-operation:delete \
--set soft-delete-entry-included-operation:modify
```

2. Run a soft-delete operation on an entry.
3. View the changelog for the soft-deleted entry.

```
$ bin/ldapsearch --baseDN cn=changelog \
"(objectclass=*)" "+"
```

```
dn: cn=changelog
subschemaSubentry: cn=schema
entryUUID: 9920f7e9-5a04-392a-82a8-32662d7d3863
ds-entry-checksum: 304022441
dn: changeNumber=1,cn=changelog
targetUniqueId: 94f634df-c90e-39aa-bd4a-9183c29746d0
changeTime: 20120511154141Z
ds-soft-delete-entry-dn: entryUUID=94f634df-c90e-39aa-bd4a-
9183c29746d0+uid=user.9,ou=People,dc=example,dc=com
modifyTimestamp: 20131010020345.546Z
createTimestamp: 20131010181148.630Z
localCSN: 000001373C90085200000000000003
modifiersName: uid=admin,dc=example,dc=com
entry-size-bytes: 298
subschemaSubentry: cn=schema
entryUUID: 459b06c6-89f3-307e-a515-22433eb420b6
createTimestamp: 20120511154141.431Z
modifyTimestamp: 20120511154141.431Z
```

```
ds-entry-checksum: 1157320579
```

Importing and Exporting Data

The PingDirectory Server supports import or export of the database backends in LDAP Data Interchange Format (LDIF). The `bin/import-ldif` and `bin/export-ldif` tools can be used to create or export database backends for online or offline servers. The tools support options that can restrict the input or output to a subset of the entries or a subset of the attributes within entries. The tools also provide features to compress, encrypt or digitally sign the data.

This chapter presents the following topics:

Importing Data

The PingDirectory Server provides initialization mechanisms to import database files. The `import-ldif` command-line tool imports data from an LDAP Data Interchange Format (LDIF) file. The data imported by the `import-ldif` command can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the LDIF file. The command also supports importing data that has been compressed, encrypted or digitally signed or both.

The `import-ldif` utility can be run with the server offline or online. If the server is online, administrators can initiate the import from a local or remote client. The LDIF file that contains the import data must exist on the server system. During an online import, the target database repository, or backend, will be removed from service and data held in that backend will not be available to clients.

The `import-ldif` tool has been modified to help guard against accidental overwriting of existing backend data with the addition of the `--overwriteExistingEntries` option. This option must be present when performing an import into a backend with a branch that already contains entries (although the option is not needed if a branch contains just a single base entry).

Validating an LDIF File

Prior to importing data, you can validate an import file using the Directory Server's `validate-ldif` tool. When run, the tool binds to the Directory Server, locally or remotely, and validates the LDIF file to determine whether it violates the server's schema. Those elements that do not conform to the schema will be rejected and written to standard output. You can specify the path to the output file to which the rejected entries are written and the reasons for their rejection. The `validate-ldif` tool works with regular non-compressed LDIF files or gzip-compressed LDIF files.

To process large files faster, you can also set the number of threads for validation. The tool also provides options to skip specified schema elements if you are only validating certain items, such as attributes only. Use the `--help` option to view the arguments.

To Validate an LDIF File

Steps

- Use the `validate-ldif` tool to validate an LDIF file. Make sure the server is online before running this command.

```
$ bin/validate-ldif --ldifFile /path/to/data.ldif \
  --rejectFile rejectedEntries
```

```
1 of 200 entries (0 percent) were found to be invalid.
1 undefined attributes were encountered.
Undefined attribute departmentname was encountered 1 times.
```

Computing Database Cache Estimate

After successful completion of an import, the `import-ldif` command lists detailed information about the database cache characteristics of the imported data set. The current server configuration is considered along with the capabilities of the underlying hardware to guide decisions for changing JVM size and `database-cache-percent` for the backend.

The `import-ldif` command will complete with a summary of database cache usage characteristics for the imported data set. Additional files are available in the `/logs/tools` directory that describe the database cache characteristics in more detail.

Tracking Skipped and Rejected Entries

During import, entries can be skipped if they do not belong in the specified backend, or if they are part of an excluded base DN or filter. The `--skipFile {path}` argument can be used on the command line to indicate that any entries that are skipped should be written to a specified file. You can add a comment indicating why the entries were skipped.

Similarly, the `--rejectFile {path}` argument can be added to obtain information about which entries were rejected and why. An entry can be rejected if it violates the server's schema constraints, if its parent entry does not exist, if another entry already exists with the same DN, or if it was rejected by a plugin.

Running an Offline Import

You can run the `import-ldif` tool offline to import LDIF data encoded with the UTF-8 character set. This data can come from LDIF files, compressed LDIF files (GZIP format), or from data generated using a MakeLDIF template. You do not need to authenticate as an administrator when performing offline LDIF imports.

To Perform an Offline Import

Steps

- Use the `import-ldif` command to import data from an LDIF file. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --rejectFile /path/to/reject.ldif --skipFile /path/to/skip.ldif
```

To Perform an Offline LDIF Import Using a Compressed File

Steps

- Use the `import-ldif` command to import data from a compressed gzip formatted file. You must also use the `--isCompressed` option to indicate that the input file is compressed. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

```
$ bin/import-ldif --backendID userRoot --isCompressed \
  --ldifFile /path/to/data.gz --rejectFile /path/to/reject.ldif \
  --skipFile /path/to/skip.ldif
```

To Perform an Offline LDIF Import Using a MakeLDIF Template

Steps

- Use the **import-ldif** command to import data from a MakeLDIF template, which is located in the `<server-root>/config/MakeLDIF`. Make sure the Directory Server is offline before running this command. Do not specify any connection arguments when running the command.

The following command uses the standard data template and generates 10,000 sample entries, and then imports the file to the server.

```
$ bin/import-ldif --backendID userRoot \
  --templateFile config/MakeLDIF/example.template
```

Running an Online LDIF Import

Administrators can run LDIF imports while the server is online from another remote server. The online import resembles the offline import, except that you must provide information about how to connect and authenticate to the target server. You can schedule the import of an LDIF file to occur at a particular time using the `--task` and `--start YYYYMMDDhhmmss` options of the **import-ldif** tool.

You can also specify email addresses for users that should be notified whenever the import process completes (regardless of success or failure, or only if the import fails). To set up SMTP notifications, see [Working with the SMTP Account Status Notification Handler](#).

To Perform an Online LDIF Import

Steps

- Use the **import-ldif** tool to import data from an LDIF. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task --hostname server1 --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --backendID userRoot --ldifFile userRoot.ldif
```

To Schedule an Online Import

Steps

- Use the **import-ldif** tool to import data from an LDIF file at a scheduled time. To specify a time in the UTC time zone, include a trailing "Z". Otherwise, the time will be treated as a local time in the time zone configured on the server. Make sure the Directory Server is online before running this command.

```
$ bin/import-ldif --task \
  --hostname server1 \
  --port 389 \
  --bindDN uid=admin,dc=example,dc=com \
  --bindPassword password \
  --backendID userRoot \
  --ldifFile /path/to/data.ldif \
  --start 20111026010000 \
  --completionNotify import-complete@example.com \
  --errorNotify import-failed@example.com
```

```
Import task 2011102617321510 scheduled to start Oct 26, 2011 1:00:00 AM CDT
```

2. Confirm that you successfully scheduled your import task using the `manage-tasks` tool to view a summary of all tasks on the system.

```
$ bin/manage-tasks --summary
```

```
ID           Type      Status
-----
2011102617321510 Import  Waiting on start time
```

3. Use the `manage-tasks` tool to monitor the progress of this task. Use the task ID of the import task. If you cannot find the task ID, use the `--summary` option to view a list of all tasks scheduled on the Directory Server.

```
$ bin/manage-tasks --info 2011102617321510
```

```
Task           Details
-----
ID              2011102617321510
Type            Import
Status          Waiting on start time
Scheduled Start Time  Oct 26, 2011 1:00:00 AM CDT
Actual Start Time
Completion Time
Dependencies Failed  None
Dependency Action   None
Email Upon Completion  admin@example.com
Email Upon Error     admin@example.com

Import         Options
-----
LDIF File      /path/to/data.ldif
Backend ID     userRoot
```

To Cancel a Scheduled Import

Steps

- Use the `manage-tasks` tool to cancel the scheduled task.

```
$ bin/manage-tasks --cancel 2011102417321510
```

Adding Entries to an Existing Directory Server

To add entries to an existing Directory Server while preserving operational attributes, such as `createTimestamp` or `modifiersName`, the Ignore No User Modification control must be attached to the request. The Ignore No User Modification control allows modification of certain attributes that have the No User Modification constraint. Special care should be used with this control.

The Ignore No User Modification is only applied to ADD requests. Using the control to modify an existing entry, resulting in an operational attribute change, will fail.

To Append Entries to an Existing Directory Server

Steps

- Use `ldapmodify` with the Ignore No User Modification control (i.e., the OID is 1.3.6.1.4.1.30221.2.5.5).

```
$ bin/ldapmodify --control 1.3.6.1.4.1.30221.2.5.5 \
--filename change-record.ldif
```

Filtering Data Import

The `import-ldif` command provides a way to either include or exclude specific attributes or entries during an import. The arguments are summarized as follows:

Inclusion and Exclusion Arguments for import-ldif

Argument	Description
<code>--includeBranch</code>	Base DN of a branch to include in the LDIF import (can be specified multiple times)
<code>--excludeBranch</code>	Base DN of a branch to exclude from the LDIF import (can be specified multiple times)
<code>--includeAttribute</code>	Attribute to include in the LDIF import (can be specified multiple times)
<code>--excludeAttribute</code>	Attribute to exclude from the LDIF import (can be specified multiple times)
<code>--includeFilter</code>	Search filter to identify entries to include in the LDIF import (can be specified multiple times)
<code>--excludeFilter</code>	Search filter to identify entries to exclude from the LDIF import (can be specified multiple times)
<code>--excludeOperational</code>	Exclude operational attributes from the LDIF import.
<code>--excludeReplication</code>	Exclude replication attributes from the LDIF import.
<code>--excludeSoftDelete</code>	Exclude soft delete entries from the LDIF import.

Exporting Data

The PingDirectory Server `export-ldif` command-line tool exports data from Directory Server backend to an LDAP Data Interchange Format (LDIF) file. The tool must be run in the non-task based mode, which implies that it works outside of the server JVM process. The `export-ldif` must be run without connection or task arguments while the server is either online or offline. This tool exports a point-in-time snapshot of the backend which is guaranteed to provide a consistent state of the database, in LDIF, which can be reimported with `import-ldif` if necessary.

The data exported by `export-ldif` can include all or a portion of the entries (a subset of the entries or a subset of the attributes within entries or both) contained in the backend. This is accomplished by specifying branches, filters, and attributes to include or exclude. The exported LDIF can be compressed, encrypted or digitally signed.

Note: LDIF exports can be configured as recurring tasks with `dsconfig create-recurring-task`, and then scheduled to run when added to a recurring task chain.

To Perform an Export

Steps

- Use the `export-ldif` command to export data to an LDIF file.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif
```

To Perform an Export from Specific Branches

Steps

- Use the `export-ldif` command to export data to an LDIF file under a specific branch from the `userRoot` backend of the local Directory Server into a compressed file. The command also excludes operational attributes from the exported data and wraps long lines at column 80.

```
$ bin/export-ldif --backendID userRoot --ldifFile userRoot.ldif.gz --
compress \
  --includeBranch ou=people,dc=example,dc=com --excludeOperational \
  --wrapColumn 80
```

Encrypting LDIF Exports and Signing LDIF Files

The Directory Server provides features to encrypt data during an LDIF export using the `export-ldif --encryptLDIF` option and to allow the encrypted LDIF file to be imported onto the same instance or another server in the same replication topology using the `import-ldif` tool. A `--doNotEncrypt` argument can be used to force an LDIF export to be unencrypted, even if automatic encryption is enabled. The `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the LDIF file may be written to disk.

The `export-ldif` tool can be used with the `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` arguments to specify which key to use for encrypting the export. The `import-ldif` tool will automatically detect encryption and compression, and have `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile` options as well.

The Directory Server also provides an additional argument that digitally signs the contents of the LDIF file, which ensures that the content has not been altered since the export. To digitally sign the contents of the exported LDIF file, use the `export-ldif --sign` option. To allow a signed LDIF file to be imported onto the same instance or another server in the same topology, use the `import-ldif --isSigned` option.

Note that there is not much added benefit to both signing and encrypting the same data, since encrypted data cannot be altered without destroying the ability to decrypt it.

To Encrypt an LDIF Export

Steps

- Run `export-ldif` tool with the `--encryptLDIF` option to encrypt the data during an export to an output LDIF file. The following command runs an offline export of the `userRoot` backend, and encrypts the file when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
  --encryptLDIF
```

To Import an Encrypted LDIF File

About this task

An encrypted LDIF file can be imported into the same instance from which it was exported, or into any other server in the same replication topology with that instance. You cannot import an encrypted LDIF file into a server that is not in some way connected to the instance from which it was exported.

Steps

- Run the `import-ldif` tool to import the encrypted LDIF file from the previous example. The command imports the `data.ldif` file, decrypts the contents while overwriting the existing contents to the `userRoot` backend. The tool automatically determines encryption and compression, and it can

automatically identify the correct key for exports that were encrypted with a key obtained from an encryption settings definition or an internal topology key.

```
$ bin/import-ldif --backendID userRoot --ldifFile /path/to/data.ldif \
--overwriteExistingEntries
```

To Sign an Export

Steps

- Run **export-ldif** tool with the **--sign** option to digitally sign the data during an export to an output LDIF file. The following command runs an offline export of the `userRoot` backend, and signs the content when written to an output file called `data.ldif`.

```
$ bin/export-ldif --backendID userRoot \
--ldifFile /path/to/data.ldif --sign
```

To Import a Signed LDIF File

Steps

- Run the **import-ldif** tool to import the signed LDIF file from the previous example. The command imports the `data.ldif` file, checks the signature of the contents while overwriting the existing contents to the `userRoot` backend. The command requires the **--isSigned** option, which instructs the tool that the contents of the LDIF file is signed.

```
$ bin/import-ldif --backendID userRoot \
--ldifFile /path/to/data.ldif \
--overwriteExistingEntries --isSigned
```

Filtering Data Exports

The **export-ldif** command analogous arguments to the **import-ldif** tool to provide a way to either include or exclude specific attributes or entries during an export. The arguments are summarized as follows:

Inclusion and Exclusion Arguments for export-ldif

Argument	Description
--includeBranch	Base DN of a branch to include in the LDIF export (can be specified multiple times)
--excludeBranch	Base DN of a branch to exclude from the LDIF export (can be specified multiple times)
--includeAttribute	Attribute to include in the LDIF export (can be specified multiple times)
--excludeAttribute	Attribute to exclude from the LDIF export (can be specified multiple times)
--includeFilter	Filter to identify entries to include in the LDIF export (can be specified multiple times)
--excludeFilter	Filter to identify entries to exclude from the LDIF export (can be specified multiple times)
--excludeOperational	Exclude operational attributes from the LDIF export.
--excludeReplication	Exclude replication attributes from the LDIF export.
--excludeSoftDelete	Exclude soft delete entries from the LDIF export.

Scrambling Data Files

The Directory Server `transform-ldif` tool provides backward compatibility with the former `scramble-ldif` tool, with additional functionality for configuring input and output files. The `transform-ldif` tool reads data from one or more source LDIF files and writes the transformed data to a single output file.

Using this tool to scramble data, enables obscuring the values of certain attributes so that it is difficult to determine the original values in the source data, while also preserving the characteristics of the associated attribute syntax. This process is repeatable, so that if the same value appears multiple times, it will yield the same scrambled representation each time. Scrambling can be applied to both LDIF entries and LDIF change records.

The process of scrambling data is not the same as encryption. It should only be used to provide simple obfuscation of data. The following are general guidelines for scrambling attributes:

- If the attribute is `userPassword` and its value starts with a scheme name surrounded by curly braces, such as "{SSHA256}XrgyNdl3fid7KYdhd/Ju47KJQ5PYZqlUlyzxQ28f/QXUnNd9fupj9g==", the scheme name will be left unchanged and the rest of the value will be treated like a generic string.
- If the attribute is `authPassword` and its value contains at least two dollar signs, such as "SHA256\$QGbhTDCi1i4=\$8/X7XRGaFCovC5mn7ATPDYIkVoocDD06Zy3lbD4AoO4=", the portion up to the first dollar sign (which represents the name of the encoding scheme) is preserved and the remainder of the value is treated like a generic string.
- If an attribute has a Boolean syntax, the scrambled value will be either **TRUE** or **FALSE**. The determination to use a value of **TRUE** or **FALSE** is random, so scrambling Boolean values is not repeatable. By randomizing the scrambling for Boolean values, the syntax and obfuscation of the original value is preserved.
- If an attribute has a distinguished name syntax (or a related syntax, such as a name and optional UID), scrambling is applied to the values of RDN components for any attributes to be scrambled. For example, if the tool is configured to scramble both the `member` and `uid` attributes, and an entry has a member attribute with a value of "uid=john.doe,ou=People,dc=example,dc=com", that member value will be scrambled in a way that only obscures the "john.doe" portion but leaves the attribute names and all values of non-scrambled attributes intact.
- If an attribute has a generalized time syntax, that value is replaced with a randomized timestamp using the same format (the same number of digits and the same time zone indicator). The randomization will be over a time range that is double the difference between the time the `transform-ldif` tool was launched and the timestamp to be scrambled. For values where that time difference is less than one day, one day will be added to the difference before it is doubled.
- If an attribute has an integer, numeric string, or telephone number syntax, scrambling is only applied to numeric digits while all other characters are left intact. If there are multiple digits, then the first digit will be nonzero.
- If an attribute has an octet string syntax, it is scrambled as follows:
 - Each byte that represents a lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
 - Each byte that represents an uppercase ASCII letter is replaced with a randomly-selected uppercase ASCII letter.
 - Each byte that represents an ASCII digit is replaced with a randomly-selected ASCII digit.
 - Each byte that represents a printable ASCII symbol is replaced with a randomly-selected printable ASCII symbol.
 - Each byte that represents an ASCII control character is replaced with a randomly-selected ASCII letter, digit, or symbol.
 - Each non-ASCII byte will be replaced with a randomly-selected non-ASCII byte.
- If an attribute has a value that represents a valid JSON object, the resulting value will also be a JSON object. All field names will be left intact, and only the values of those fields may be scrambled. If the

`--scrambleJSONField` argument is provided, only the specified fields will have values scrambled. Otherwise, the values of all fields will be scrambled. Field values are scrambled as follows:

- Null values are not scrambled.
- Boolean values are replaced with randomly-selected Boolean values. As with attributes with a Boolean syntax, these values are non-repeatable.
- Number values will have only their digits replaced with randomly-selected digits and all other characters (minus sign, decimal point, exponentiation indicator) are left unchanged.
- String values will be replaced with a randomly-selected generic string.
- Array values have scrambling applied as appropriate for each value in the array. If the array field itself should be scrambled, then all values in the array are scrambled. Otherwise, only JSON objects contained inside the array have scrambling applied to appropriate fields.
- JSON values have scrambling applied as appropriate for their fields.
- If an attribute does not match any of the previous criteria, it is scrambled as follows:
 - Each lowercase ASCII letter is replaced with a randomly-selected lowercase ASCII letter.
 - Each uppercase ASCII letter replaced with a randomly-selected uppercase ASCII letter.
 - Each ASCII digit is replaced with a randomly-selected ASCII digit.
 - All other characters are left unchanged.

The following example reads from an LDIF file named `original.ldif`, scrambles the values of the `telephoneNumber`, `mobile`, and `homeTelephoneNumber` attributes, and writes the results to `scrambled.ldif`:

```
$ bin/transform-ldif --sourceLDIF original.ldif \
  --targetLDIF scrambled.ldif \
  --scrambleAttribute telephoneNumber \
  --scrambleAttribute mobile \
  --scrambleAttribute homeTelephoneNumber \
  --randomSeed 0
```

Backing Up and Restoring Data

The PingDirectory Server provides efficient **backup** and **restore** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler.

This chapter presents the following topics:

Backing Up and Restoring Data

Administrators should have a comprehensive backup strategy and schedule that comprise of daily, weekly, and monthly backups including incremental and full backups of the directory server data, configuration, and backends. Administrators should also have a backup plan for the underlying file system. This dual purpose approach provides excellent coverage in the event that a server database must be restored for any reason.

Note: Backups can be configured as recurring tasks with `dsconfig create-recurring-task`, and then scheduled to run when added to a recurring task chain.

The PingDirectory Server provides efficient **backup** and **restore** command-line tools that support full and incremental backups. The backups can also be scheduled using the UNIX-based cron scheduler or using the Directory Server's Task-based scheduler. The Directory Server can run backups with the server online while processing other requests, so that there is no need to shut down the server or place it in read-only mode prior to starting a backup.

If you back up more than one backend, the **backup** tool creates a subdirectory below a specified backup directory for each backend. If you back up only a single backend, then the backup files will be placed in

the specified directory. A single directory can only contain files from one backend, so that you cannot have backup files from multiple different backends in the same backup directory.

When performing a backup, the server records information about the current state of the server and backend, including the server product name, the server version, the backend ID, the set of base DNs for the backend, and the Java class used to implement the backend logic. For JE backends, the backup descriptor also includes information about the Berkeley DB JE version and information about the attribute and VLV indexes that have been defined.

When restoring a backup, the server compares the descriptor obtained from the backup with the current state of the server and backend. If any problems are identified, the server generates warnings or errors. The administrator can choose to ignore the warnings with the `ignoreCompatibilityWarnings` option to the `restore` tool, whereas errors will always cause the restore to fail. For example, when restoring a *newer* backup into an older version of the server, a warning will be generated. When restoring an *older* backup into a new version of the server, no warning will be generated, but because the `config` and `schema` backends require special handling, the server generates an error if the server versions do not match exactly (major, minor, point, and patch version numbers).

Both the `backup` and `restore` tools provide encryption options `--promptForEncryptionPassphrase`, `--encryptionPassphraseFile`, and `--encryptionSettingsDefinitionID` that can be used to specify which key to use for encrypting the backup. For backups encrypted with an encryption settings definition or an internal topology key, the server will automatically determine the correct key. Or, the `--doNotEncrypt` argument can be used to force a backup to be unencrypted even if automatic encryption is enabled.

If needed, the `--maxMegabytesPerSecond` argument can be used to impose a limit on the rate at which the backup may be written to disk.

Retaining Backups

The backup tool can be used with either the `--retainPreviousFullBackupCount` or `--retainPreviousFullBackupAge` arguments to identify which previous backups should be preserved. Any other backups in that directory will be removed. A new backup will always be preserved. If the new backup is an incremental backup, then any other backups it depends on will also be preserved. However, older backups in the same directory are eligible to be removed.

If the `--retainPreviousFullBackupCount` argument is provided, that number of the most recent previous full backups will be preserved (along with any incremental backups that depend on them). Any other previous full backups (and their dependent incremental backups) can be removed. If the `--retainPreviousFullBackupAge` argument is provided, its value must be a duration represented as an integer followed by a time unit. Any full backups (and their dependent incremental backups) created longer ago than that duration will be eligible to be removed. If both the `--retainPreviousFullBackupCount` and `--retainPreviousFullBackupAge` arguments are provided, then only backups that don't satisfy either condition will be deleted. A value of zero can be specified for the `--retainPreviousFullBackupCount` argument so that only the most recent backup is preserved (along with its dependencies), and all previous backups will be removed.

Note: The `remove-backup` tool also supports the `--retainFullBackupCount` and `--retainFullBackupAge` arguments to delete any backups outside the provided retention criteria.

To List the Available Backups on the System

Steps

- Use the **restore** tool to list the backups in a backup directory.

```
$ bin/restore --listBackups --backupDirectory /mybackups
```

```
[13:26:21] The console logging output is also available in '/ds/PingDirectory/logs/tools/restore.log'
```

```
Backup ID:          20120212191715Z
Backup Date:        12/Feb/2012:13:17:19 -0600
Is Incremental:     false
Is Compressed:      false
Is Encrypted:       false
Has Unsigned Hash:  false
Has Signed Hash:    false
Dependent Upon:     none
Backup ID:          20120212192411Z
Backup Date:        12/Feb/2012:13:24:16 -0600
Is Incremental:     true
Is Compressed:      false
Is Encrypted:       false
Has Unsigned Hash:  false
Has Signed Hash:    false
Dependent Upon:     20120212191715Z
```

To Back Up All Backends

Steps

- Use **backup** to save all of the server's backends. The optional `--compress` option can reduce the amount of space that the backup consumes, but can also significantly increase the time required to perform the backup.

```
$ bin/backup --backUpAll --compress --backupDirectory /path/to/backup
```

To Back Up a Single Backend

Steps

- Go to the server root directory, and use the **backup** tool to save the single backend, `userRoot`.

```
$ bin/backup --backendID userRoot --compress --backupDirectory /path/to/backup
```

To Perform an Offline Restore

Steps

- Use the **restore** command to restore the `userRoot` backend. Only a single backend can be restored at a time. The Directory Server must be shut down before performing an offline restore.

```
$ bin/restore --backupDirectory /path/to/backup/userRoot
```

 **Note:** The server root directory should never be restored from a file system backup or snapshot.

To Assign an ID to a Backup

Steps

- Go to the server root directory, and use the backup tool to save the single backend, userRoot. The following command assigns the backup ID "weekly" to the userRoot backup. The backup file appears under `backups/userRoot` directory as `userRoot-backup-weekly`.

```
$ bin/backup --backupDirectory /path/to/backups/userRoot \
  --backendID userRoot --backupID weekly
```

To Run an Incremental Backup on All Backends

About this task

The Directory Server provides support for incremental backups, which backs up only those items that have changed since the last backup (whether full or incremental) on the system, or since a specified earlier backup. Incremental backups must be placed in the same backup directory as the full backup on which they are based.

Not all backends support incremental backups. If a backend does not support incremental backups, use of the `--incremental` option will have no effect, and a full backup will be taken.

Steps

- The following command runs an incremental backup on all backends based on the most recent backup:

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup
```

To Run an Incremental Backup on a Single Backend

Steps

- Go to the server root directory, and use `backup` to save the single backend, userRoot.

```
$ bin/backup --backendID userRoot --incremental --backupDirectory /path/to/
backup
```

To Run an Incremental Backup based on a Specific Prior Backup

Steps

- You can run an incremental backup based on a specific prior backup that is not the most current version on the system. To get the backup ID, use the `restore --listBackups` command (see below).

```
$ bin/backup --backUpAll --incremental --backupDirectory /path/to/backup \
  --incrementalBaseID backup-ID
```

To Restore an Incremental Backup

About this task

The process for restoring an incremental backup is exactly the same as the process for restoring a full backup for both the online and offline restore types. The `restore tool` will automatically ensure that the full backup and any intermediate incremental backups are restored first before restoring the final incremental backup. The tool will not restore any files in older backups that are no longer present in the final data set.

To Schedule an Online Backup

About this task

You can schedule a backup to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

For online (remote) backups, the backup operation can be conducted while PingDirectory Server is online if you provide information about how to connect and to authenticate to the target Directory Server.

Steps

- You can schedule the backup to occur at a specific time using the Task-based `--start YYYYMMDDhhmmss` option. To specify a time in the UTC time zone format, add a trailing "Z" to the time. Otherwise, the time will be treated as a local time in the time zone configured on the server.

```
$ bin/backup --backUpAll --task --start 20111025010000 \
  --backupDirectory /path/to/backup --completionNotify admin@example.com \
  --errorNotify admin@example.com
```

```
Backup task 2011102500084110 scheduled to start Oct 28, 2011 1:00:00 AM CDT
```

To Schedule an Online Restore

About this task

By providing connection and authentication information (and an optional start time), the restore can be performed via the Tasks subsystem while the server is online. The Tasks subsystem allows you to schedule certain operations, such as `import-ldif`, `backup`, `restore`, `start-server`, and `stop-server`. You can schedule a restore to run as a Task by specifying the timestamp with the `--task` and `--start` options. The option is expressed in "YYYYMMDDhhmmss" format. If the option has a value of "0" then the task is scheduled for immediate execution. You cannot run recurring tasks, so daily operations must be run using cron or through some system that can submit the task.

Steps

- The backend that is being restored will be unavailable while the restore is in progress. To specify a time in the UTC time zone, add a trailing "Z" to the time. Otherwise, the time will be treated as a local time in the configured time zone on the server.

```
$ bin/restore --task --start 20111025010000 \
  --backupDirectory /path/to/backup/userRoot \
  --completionNotify admin@example.com --errorNotify admin@example.com
```

To Encrypt a Backup

Steps

- Go to the server root directory, and use the `backup` tool to backup up the single backend, `userRoot` and encrypt it with the `--encrypt` option.

```
$ bin/backup --encrypt --backendID userRoot --compress --backupDirectory /
path/to/backup
```

To Sign a Hash of the Backup

Steps

- Go to the server root directory, and use the **backup** tool to backup up the single backend, userRoot. Use the **-signHash** option to generate a hash of the backup contents and digitally sign the hash of the backup contents. If you want to generate only a hash of the backup contents, run backup with the **--hash** option.

```
$ bin/backup --signHash --backupDirectory backups/userRoot --backendID
userRoot \
--backupDirectory /path/to/backup
```

To Restore a Backup

Steps

- Go to the server root directory, and use the **restore** tool to restore a backup. The **backup** tool uses a descriptor file to access property information used for the backup, indicating if the backup was compressed, signed and/or encrypted.

```
$ bin/restore --backupDirectory /path/to/backup
```

Moving or Restoring a User Database

Part of any disaster recovery involves the restoration of the user database from one server to another. You should have a well-defined backup plan that takes into account whether or not your data is replicated among a set of servers. The plan is the best insurance against significant downtime or data loss in the event of unrecoverable database issue.

Note: The server root directory should never be restored from a file system backup or snapshot. External backup methods (for example, VM snapshots) are not recommended, especially if data was corrupted during a transaction.

Keep in mind the following general points about database recovery:

- Regular Backup from Local Replicated Directory Server** . Take a backup from a local replicated directory server and restore to the failed server. This will be more recent than any other backup you have.
- Restore the Most Recent Backup**. Restore the most recent backup from a local server. In some cases, this may be preferred over taking a new backup if that would adversely impact performance of the server being backed up although it will take longer for replication to play back changes.
- Contact Support**. If all else fails, contact your authorized support provider and they can work with you (and possibly in cooperation with the Oracle Berkeley DB JE engineers) to try a low-level recovery, including tools that attempt to salvage whatever data they can obtain from the database.

Comparing the Data in Two Directory Servers

The PingDirectory Server provides an **ldap-diff** tool to compare the data on two LDAP servers to determine any differences that they may contain. The differences are identified by first issuing a subtree search on both servers under the base DN using the default search filter (`objectclass=*`) to retrieve the DNs of all entries in each server. When the tool finds an entry that is on both servers, it retrieves the entry from each server and compares all of its attributes. The tool writes any differences it finds to an LDIF file in a format that could be used to modify the content of the source server, so that it matches the content of the target server. Any non-synchronized entries can be compared again for a configurable number of times with an optional pause between each attempt to account for replication delays.

You can control the specific entries to be compared with the `--searchFilter` option. In addition, only a subset of attributes can be compared by listing those attributes as trailing arguments of the command. You can also exclude specific attributes by prepending a `^` character to the attribute. (On Windows operating systems, excluded attributes must be quoted, for example, `"^attrToExclude"`.) The `@objectClassName` notation can be used to compare only attributes that are defined for a given objectclass.

The `ldap-diff` tool can be used on servers actively being modified by checking differing entries multiple times without reporting false positives due to replication delays. By default, it will re-check each entry twice, pausing two seconds between checks. These settings can be configured with the `--numPasses` and `--secondsBetweenPass` options. If the utility cannot make a clean comparison on an entry, it will list any exceptions in comments in the output file.

The Directory Server user specified for performing the searches must be privileged enough to see all of the entries being compared and to issue a long-running, unindexed search. For the Directory Server, the out-of-the-box `cn=Directory Manager` user has these privileges, but you can assign the necessary privileges by setting the following attributes in the user entry:

```
ds-cfg-default-root-privilege-name: unindexed-search
ds-cfg-default-root-privilege-name: bypass-acl
ds-rlim-size-limit: 0
ds-rlim-time-limit: 0
ds-rlim-idle-time-limit: 0
ds-rlim-lookthrough-limit: 0
```

The `ldap-diff` tool tries to make efficient use of memory, but it must store the DNs of all entries in memory. For Directory Servers that contain hundreds of millions of entries, the tool might require a few gigabytes of memory. If the progress of the tool slows dramatically, it might be running low on memory. The memory used by the `ldap-diff` tool can be customized by editing the `ldap-diff.java-args` setting in the `config/java.properties` file and running the `dsjavaproperties` command.

If you do not want to use a subtree search filter, you can use an input file of DNs for the source, target, or both. The format of the file can accept various syntaxes for each DN:

```
dn: cn=this is the first dn
dn: cn=this is the second dn and it is wrapped cn=this is the third dn
# The following DN is base-64 encoded dn::
Y249ZG9uJ3QgeW91IGhhdmUgYmV0dGVyIHROaW5ncyB0byBkbyB0aGFuIHN1ZSB3aGF0IHROaXMgc2F55cw==
# There was a blank line above dn: cn=this is the final entry.
```

CAUTION: Do not manually update the servers when the tool identifies differences between two servers involved in replication. First contact your authorized support provider for explicit confirmation, because manual updates to the servers risk introducing additional replication conflicts.

To Compare Two Directory Servers Using ldap-diff

Steps

1. Use `ldap-diff` to compare the entries in two Directory Server instances. Ignore the `userpassword` attribute due to the one-way password hash used for the password storage scheme.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
"^userpassword"
```

2. Open the output file in a text editor to view any differences. The file is set up so that you can re-apply the changes without any modification to the file contents. The file shows any deletes, modifies, and then adds from the perspective of the source server as the authoritative source.

```
# This file contains the differences between two LDAP servers.
#
# The format of this file is the LDIF changes needed to bring server
# ldap://server1.example.com:1389 in sync with server
# ldap://server2.example.com:2389.
#
# These differences were computed by first issuing an LDAP search at both
# servers under base DN dc=example,dc=com using search filter
# (objectclass=*)
# and search scope SUB to first retrieve the DNs of all entries. And then
# each
# entry was retrieved from each server and attributes: [^userpassword] were
# compared. # # Any entries that were out-of-sync were compared a total of 3
# times
# waiting a minimum of 2 seconds between each attempt to account for
# replication
# delays.
#
# Comparison started at [24/Feb/2010:10:34:20 -0600]
# The following entries were present only on ldap://server2.example.com:2389
# and
# need to be deleted. This entry existed only on ldap://
server1.example.com:1389
# Note: this entry might be incomplete. It only includes attributes:
# [^userpassword]dn: uid=user.200,ou=People,dc=example,dc=com
# objectClass: person
# objectClass: inetOrgPerson
... (more attributes not shown) ...
# st: DC
dn: uid=user.200,ou=people,dc=example,dc=com
changetype: delete

# The following entries were present on both servers but were out of sync.

dn: uid=user.199,ou=people,dc=example,dc=com
changetype: modify
add: mobile
mobile: +1 300 848 9999
-
delete: mobile
mobile: +1 009 471 1808

# The following entries were missing on ldap://server2.example.com:2389 and
# need
# to be added. This entry existed only on ldap://server2.example.com:2389
# Note: this entry might be incomplete. It only includes attributes:

# [^userpassword]
dn: uid=user.13,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
... (more attributes not shown) ...
# Comparison completed at [24/Feb/2010:10:34:25 -0600]
```

To Compare Configuration Entries Using `config-diff`

Steps

- Use `config-diff` to compare Directory Server configurations and produce a `dsconfig` batch file needed to bring the source inline with the target.

The following example compares the current configurations of `server1` and `server2`. The changes necessary to bring `server1`'s configuration inline with `server2` are written to the console. The same credentials are used to connect to both servers.

```
$ bin/config-diff --sourceHost server1 --sourceBindDN "cn=Directory Manager" \
\
--sourceBindPassword password --targetHost server2
```

For more information about runtime options, see the *Command Line Tool Reference* or the `config-diff` tool help.

To Compare Entries Using Source and Target DN Files

Steps

- Use `ldap-diff` to compare the entries in two Directory Server instances. In the following example, the utility uses a single DN input file for the source and target servers, so that no search filter is used. Ignore the `userpassword` attribute due to the password storage scheme that uses a one-way hashing algorithm.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN "dc=example,dc=com" --sourceDNsFile input-file.ldif \
--targetDNsFile input-file.ldif "^userpassword"
```

To Compare Directory Servers for Missing Entries Only Using `ldap-diff`

Steps

- Use `ldap-diff` to compare two Directory Servers and return only those entries that are missing on one of the servers using the `--missingOnly` option, which can significantly reduce the runtime for this utility.

```
$ bin/ldap-diff --outputLDIF difference.ldif \
--sourceHost server1.example.com --sourcePort 1389 \
--sourceBindDN "cn=Directory Manager" --sourceBindPassword secret1 \
--targetHost server2.example.com --targetPort 2389 \
--targetBindDN "cn=Directory Manager" --targetBindPassword secret2 \
--baseDN dc=example,dc=com --searchFilter "(objectclass=*)" \
"^userpassword" \
--missingOnly
```

Revert or Replay Changes

The PingDirectory Server provides support for an audit logger that records information about the changes to data within the server. The data is formatted as LDIF, and it can be replayed with tools such as `ldapmodify` or `parallel-update`. The data also includes information encoded as comments that provide additional context about the changes. By default, the log records the changes as requested by clients, but it can also log the changes in reversible form so that they can be undone.

This audit logger can be useful for the following scenarios:

- If one or more undesirable changes have been made (for example, by a malicious or defective client), it can be used to obtain the necessary changes to revert those operations.
- If a catastrophic loss of all servers in the topology occurs that leaves an audit log available with newer data than any backup or LDIF export (for example, concurrent database corruption across all instances), it can be used to recover changes that may not otherwise be available.
- It can be useful for automating the process of identifying changes made in one topology that can be replayed into another topology (for example, to replay production changes into an isolated server or topology for testing purposes or to attempt to reproduce a problem).
- It can be useful for analytics and reporting purposes.

To assist with these and other uses, the LDAP SDK for Java provides an API for consuming, parsing, and reverting audit log messages. This API can be used for the analytics and reporting. Also available is the **extract-data-recovery-log-changes** tool that can extract audit log changes matching a specified set of criteria so that they can be replayed, either as they were originally processed or in a reversible form that makes it possible to revert those changes.

The Data Recovery Log

The **setup** tool automatically creates an audit logger for data recovery purposes in `logs/data-recovery`. The log is always compressed, and it will be encrypted if data encryption is enabled within the server. The logger has the following properties:

- Log files are written into the `logs/data-recovery` directory so that they are isolated from other log files. The active log file is named `data-recovery.gz.encrypted`, while rotated files are named `data-recovery.{timestamp}.gz.encrypted`.
- The log files are gzip-compressed. If data encryption is enabled, they are encrypted with a key obtained from the server's preferred encryption settings definition.
- Each log file contains no more than 10 MB of data, and is rotated after 24 hours. Keeping the log files small ensures that the entire contents of a log file will easily fit into the **extract-data-recovery-log-changes** tool's memory.
- The server will retain rotated data recovery log files for no more than one week. However, as a safeguard against consuming too much disk space in periods of extremely heavy and prolonged write activity, the server will also retain no more than 1,000 data recovery log files for a maximum of 500 MB of disk space.
- Changes are logged in reversible form and include the authentication and authorization identity of the requester, as well as the IP address. If present, the log message includes details from any intermediate client request control included in the request, which may provide information about the downstream client.

The extract-data-recovery-log-changes Tool

The **extract-data-recovery-log-changes** tool creates an LDIF file (compressed and encrypted by default) with a specified subset of changes from the server's data recovery log. That LDIF file can then be applied to the server using either the `ldapmodify` or `parallel-update`. Before applying the changes, the output file can be decrypted and examined to ensure that the changes it contains look correct. This tool can be useful for disaster recovery.

The **extract-data-recovery-log-changes** tool provides arguments for input and output of the extracted changes, including encryption settings, location, and compression.

The direction of whether changes should be extracted in forward mode or reverse mode is also configured. In forward mode (replay), the audit log messages are traversed from oldest to newest, and extracted changes are presented as they were originally requested. In reverse mode (revert), the audit log messages are traversed from newest to oldest, and extracted changes will be converted to a form that will revert the original changes. Regardless of the direction chosen, additional arguments enable identifying the changes to extract by time, requester address or DN, connection ID, origin,

content type, or alterations. The following is a sample command to revert all changes by user `uid=malicious,ou=People,dc=example,dc=com` between noon and 2 pm on October 15, 2018:

```
$ bin/extract-data-recovery-log-changes \
  --auditLogFile logs/data-recovery/data-
  recovery.201810161234.567.gz.encrypted \
  --outputFile revert-malicious-user-changes.ldif \
  --direction revert \
  --startTime 201810151200.000 \
  --endTime 201810151359.999 \
  --includeAuthorizationDN "uid=malicious,ou=People,dc=example,dc=com"
```

Working with Indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server.

This chapter presents topics related to indexes:

Overview of Indexes

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Indexes are associated with attributes and stored in database index files, which are managed separately for each base DN in the Directory Server. The Directory Server automatically creates index files when you first initialize a base DN or when you use the `dsconfig` tool to create a local DB backend. During modify operations, the Directory Server updates the database index files. If encryption is enabled on the server, indexes will be encrypted.

The PingDirectory Server comes with the following types of indexes:

- **Default system indexes** to ensure that the server operates efficiently. Indexes consist of database files that contain index keys mapping to the list of entry IDs.
- **Default Local DB indexes** that are created for each database suffix. Modify the index to meet your system's requirements using the `dsconfig` tool.
- **Local DB VLV indexes** that allow a client to request the server to send search results using the Virtual List View control.
- **Filtered Indexes** that provide the ability to index an attribute but only for entries that match a specified filter based on an equality index. The filtered index can only be used for searches containing that filter. The filtered index can be maintained independently of the equality index for that attribute and even if a normal equality index is not maintained for that attribute.

General Tips on Indexes

Administrators should keep the following tips in mind when working with indexes:

- **Important Critical Indexes.** The Directory Server has several built-in indexes on the Local DB Backend that are critical to internal server processing and should never be removed.

```
aci, ds-entry-unique-id, objectClass
```

- **Built-in Indexes for Efficient Queries.** The Directory Server has built-in indexes on the Local DB Backend. Internal processing of the server relies on the `aci`, `ds-soft-delete-from-dn`, `ds-soft-delete-timestamp`, `entryUUID`, `member`, `objectClass`, and `uniqueMember` indexes, which must not be removed. The `mail` and `uid` indexes can be removed, but these attributes are referenced from the Password Modify Extended Operation and will cause problems with components such as the Exact Match Identity Mapper. If the `mail` or `uid` indexes are removed, additional configuration

changes may be necessary to ensure that the server starts properly. The `cn`, `givenName`, `mail`, `sn`, and `telephoneNumber` indexes can be safely removed if clients do not query on these attributes. This will reduce the size of the database both on disk and in memory.

- **Online Rebuilds.** Whenever an online index rebuild is in progress, the data in that backend will be available and writable although the index being rebuilt will not be used; therefore, searches which attempt to use that attribute might be unindexed.
- **Index Rebuild Administrative Alert.** The Directory Server generates an administrative alert when the rebuild process begins and ends. It will have a degraded-alert-type of "index-rebuild-in-progress" so that a Directory Proxy Server, such as the Directory Server can avoid using that server while the rebuild is in progress.
- **System Indexes Cannot be Rebuilt.** The contents of the backend must be exported and re-imported in order to rebuild system indexes. See the table below for the list of system indexes.
- **Indexing Certain Attributes.** You should ensure that the following recommendations are used when setting up the indexes.
 - Equality and substring indexes should not be used for attributes that contain binary data.
 - Approximate indexes should be avoided for attributes containing numbers, such as telephone numbers.
- **Unindexed Searches.** Unindexed attributes result in longer search times as the database itself has to be searched instead of the database index file. Only users with the `unindexed-search` privilege are allowed to carry out unindexed searches. In general, applications should be prevented from performing unindexed searches, so that searches that are not indexed would be rejected rather than tying up a worker thread. The ways to achieve this include:
 - Make sure that only the absolute minimum set of users have the `unindexed-search` privilege. This privilege can be used without any other restrictions.
 - To allow unindexed searches with some control, the Permit Unindexed Search request control can be used with the `unindexed-search-with-control` privilege. With this privilege, a user will only be permitted to request an unindexed search if the search request includes the Permit Unindexed Search request control. The `unindexed-search` privilege allows a client to request an unindexed search without this control.
 - The Reject Unindexed Search request control can be used to explicitly indicate that a client does not want the server to process an unindexed search request, regardless of privileges. See the LDAP SDK for information about these controls. These capabilities are also available with the `ldapsearch` tool.
 - Make sure that `allow-unindexed-searches` property is set to `false` in all client connection policies, in which unindexed searches should never be necessary. If the client connection policy should allow unindexed searches, set the `allow-unindexed-searches-with-control` property to `true`. If `allow-unindexed-searches` is `false` but, `allow-unindexed-searches-with-control` is `true`, the policy will only permit an unindexed search if the request includes the Permit Unindexed Search request control. See the LDAP SDK and the `ldapsearch` tool for more information.
 - Set a nonzero value for the `maximum-concurrent-unindexed-searches` global configuration property to ensure that if unindexed searches are allowed, only a limited number of them will be active at any given time. Administrators can configure the maximum number of concurrent unindexed searches by setting a property under Global Configuration.

To change the maximum number of concurrent unindexed searches, use the `dsconfig` tool to set a value for the number. A value of "0" (default) represents no limit on the number of concurrent unindexed searches.

```
$ bin/dsconfig set-global-configuration-prop \
  --set maximum-concurrent-unindexed-searches:2
```

- **Index Entry Limit.** The Directory Server specifies an index entry limit property. This property defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (default value is 4000), then you must

rebuild the indexes using the `rebuild-index` tool. If an index entry limit value is set for the local DB backend, it overrides the value set for the overall JE backend index entry limit configuration (i.e., 4000).

To change the default index entry limit, use the `dsconfig` tool as seen in the following example:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name cn --set index-entry-limit:5000
```

- **Rebuild Index vs Full Import.** You can expect a limited amount of database growth due to the existence of old data when running `rebuild-index` versus doing a full import of your database.

Index Types

The PingDirectory Server supports several types of indexes to quickly find entries that match search criteria in LDAP operations. The Directory Server uses an attribute's matching rules to normalize its values and uses those values as index keys to a list of matching entry IDs. Entry IDs are integer values that are used to uniquely identify an entry in the backend by means of a set of database index files (`id2entry`, `dn2id`, `dn2uri`, `id2children`, `id2subtree`).

Matching rules are elements defined in the schema that tell the server how to interact with the particular attribute. For example, the `uid` attribute has an equality matching rule defined in the schema, and thus, has an equality index maintained by the Directory Server. The following table describes the index types:

Directory Server Index Types

Index Type	Description
Approximate	Used to efficiently locate entries that match the approximate search filter. It is used to identify which entries are approximately equal to a given assertion. Approximate indexes can only be applied to attributes that have a corresponding approximate matching rule.
Equality	Used to efficiently locate entries that match the equality search filter. It is used to identify which entries are exactly equal to a given assertion. Equality indexes can only be applied to attributes that have a corresponding equality matching rule. An offshoot of the equality index is the filtered index, which uses a defined search filter for a specific attribute. The filtered index can be maintained independently of the equality index for a specific attribute.
Ordering	Used to efficiently locate entries that match the ordering search filter. It is used to identify which entries have a relative order of values for an attribute. Ordering indexes can only be applied to attributes that have a corresponding ordering matching rule.
Presence	Used to efficiently locate entries that match the presence search filter. It is used to identify which entries have at least one value for a specified attribute. There is only one presence index key per attribute.
Substring	Used to efficiently locate entries that match the substring search filter. It is used to identify which entries contain specific substrings to a given assertion. Substring indexes can only be applied to attributes that have a corresponding substring matching rule.

System Indexes

The PingDirectory Server contains a set of system database index files that ensure that the server operates efficiently. These indexes cannot be modified or deleted.

System Indexes

Index	Description
dn2id	Allows quick retrieval of DNs. The DN database, or <code>dn2id</code> , has one record for each entry. The key is the normalized entry DN and the value is the entry ID.
id2entry	Allows quick retrieval of entries. The <code>id2entry</code> database contains the LDAP entries. The database key is the entry ID and the value is the entry contents.
referral	Allows quick retrieval of referrals. The referral database called <code>dn2uri</code> contains URIs from referral entries. The key is the DN of the referral entry and the value is that of a labeled URI in the <code>ref</code> attribute for that entry.
id2children	Allows quick retrieval of an entry and its children. The <code>id2children</code> database provides a mapping between an entry's unique identifier and the entry unique identifiers of the corresponding entry's children.
id2subtree	Allows quick retrieval of an entry's subtree. The <code>id2subtree</code> database provides a mapping between an entry's unique identifier and its unique identifiers in its subtree.

To View the System Indexes

Steps

Use the `dbtest` command to view the system and user indexes. The index status indicates if it is a trusted index or not. An index is either trusted or untrusted. An untrusted index requires rebuilding.

```
$ bin/dbtest list-index-status --baseDN dc=example,dc=com --backendID userRoot
```

Managing Local DB Indexes

You can modify the local DB indexes to meet your system's requirements using the `dsconfig` tool. If you are using the `dsconfig` tool in interactive command-line mode, you can access the **Local DB Index** menu from the Basic object menu.

To View the List of Local DB Indexes

Steps

- Use `dsconfig` with the `list-local-db-indexes` option to view the default list of indexes.

```
$ bin/dsconfig list-local-db-indexes --backend-name userRoot
```

```
Local DB Index      : Type      : index-type
-----
aci                 : generic   : presence
cn                  : generic   : equality, substring
ds-entry-unique-id : generic   : equality
givenName           : generic   : equality, substring
mail                : generic   : equality
member              : generic   : equality
objectClass         : generic   : equality
sn                  : generic   : equality, substring
telephoneNumber     : generic   : equality
uid                 : generic   : equality
uniqueMember        : generic   : equality
```

To View a Property for All Local DB Indexes

Steps

- Use `dsconfig` with the `--property` option to view a property assigned set for all local DB indexes. Repeat the option for each property that you want to list. In this example, the `prime-index` property specifies if the backend is configured to prime the index at startup.

```
$ bin/dsconfig list-local-db-indexes --property index-entry-limit \
--property prime-index --backend-name userRoot
```

To View the Configuration Parameters for Local DB Index

Steps

- To view the configuration setting of a local DB index, use `dsconfig` with the `get-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. If you want to view the advanced properties, add the `--advanced` option to your command.

```
$ bin/dsconfig get-local-db-index-prop --index-name aci \
--backend-name userRoot
```

To Modify the Configuration of a Local DB Index

About this task

You can easily modify an index using the `dsconfig` tool. Any modification or addition of an index requires the indexes to be rebuilt. In general, an index only needs to be built once after it has been added to the configuration.

If you add an index, then import the data using the `import-ldif` tool, then the index will be automatically rebuilt. If you add an index, then add the data using some other method than `import-ldif`, you must rebuild the index using the `rebuild-index` tool.

Steps

- Use `dsconfig` with the `set-local-db-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `prime-index` property, which loads the index at startup. This command requires the `--advanced` option to access this property.

```
$ bin/dsconfig set-local-db-index-prop --index-name uid \
--backend-name userRoot --set prime-index:true
```

- View the index to verify the change.

```
$ bin/dsconfig get-local-db-index-prop --index-name uid \
--backend-name userRoot
```

- Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in [General Tips on Indexes](#).

```
$ bin/stop-server
```

- Run the `rebuild-index` tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index uid
```

- Restart the Directory Server if shutdown.

```
$ bin/start-server
```

To Create a New Local DB Index

Steps

1. To create a new local DB index, use **dsconfig** with the `--create-local-db-index` option and the `--index-name`, `--backend-name`, and `--set index-type: <value>` options.

```
$ bin/dsconfig create-local-db-index \
  --index-name roomNumber --backend-name userRoot \
  --set index-type:equality
```

2. View the index.

```
$ bin/dsconfig get-local-db-index-prop \
  --index-name roomNumber --backend-name userRoot
```

3. Stop the Directory Server. You can do an index rebuild with the server online; however, keep in mind the tips presented in [General Tips on Indexes](#) on page 148.

```
$ bin/stop-server
```

4. Rebuild the index using the **rebuild-index** tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index roomNumber
```

5. Restart the Directory Server.

```
$ bin/start-server
```

To Delete a Local DB Index

About this task

You can delete an index using the **dsconfig** tool. Check that no plugin applications are using the index before deleting it. When the index is deleted, the corresponding index database will also be deleted. The disk space is reclaimed once the cleaner threads begin.

Steps

- Use **dsconfig** with the `delete-local-db-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-index \
  --index-name roomNumber --backend-name userRoot
```

Working with Composite Indexes

The PingDirectory Server composite index can be generated from multiple pieces of information (a combination of multiple filter components, or a combination of filter components and a base DN). A composite index can also be based on only a single piece of information.

To improve searches over a large number of entries, equality composite indexes can be used to combine a mandatory equality filter pattern with an optional base DN pattern to improve the performance of searches in directories with a very large number of entries, and in particular with a very large number of non-leaf entries. Equality composite indexes offer two advantages over existing equality attribute indexes in these types of deployments.

Base DN Pattern - If a directory environment has many branches, but searches are often done that are within specific individual branches, the base DN pattern can be used to make search processing more efficient. The server will only need to search entries within a target branch.

For example, if the directory contains an `"ou=Customers,dc=example,dc=com"` branch, with a separate branches below that for sets of customers, like `"ou=ACME,ou=Customers,dc=example,dc=com"`, and

"ou=SHOPCO,ou=Customers,dc=example,dc=com", a composite index with a filter pattern of "(sn=*)" and a base DN pattern of "ou=?,ou=Customers,dc=example,dc=com" can be defined. Then a search with a filter of "(sn=Smith)" and a base DN of "ou=ACME,ou=Customers,dc=example,dc=com" can be used to narrow the search to the Smiths in the ACME branch.

Index Pages - If many entries have the same value for a specific attribute, composite indexes can break large ID sets up across multiple pages, unlike the traditional attribute index. Using the previous example, if a search of the directory returns 50,000 Smiths, the results can be served in blocks of 5,000 IDs. An attribute index will return either one Smith record whose value is a block that contains all 50,000 of the matching entry IDs (if the index isn't exploded), or 50,000 Smith records that each have a value of the matching entry ID (when the index is exploded). The non-exploded form is efficient for searching because all of the entry IDs are returned in a single read, but it's expensive for writing because if a Smith must be added or removed, the entire block of 50,000 entry IDs must be rewritten. The exploded form is efficient for writing (adding or removing a Smith involves just that one entry ID), but it's expensive for searching because it takes 50,000 reads to get all entry IDs for all of the Smiths.

Composite indexes break up the block of entry IDs across multiple pages (a page size of up to 5000). If the directory contains 50,000 Smiths, instead of having to choose between one block of 50,000 IDs or 50,000 blocks of one ID, ten blocks of 5,000 IDs are returned. This improves the efficiency of a read or write across many entries.

There is little performance overhead to the paging mechanism. Use an equality composite index for an attribute that has a lot of entries that have the same value (such as givenName or sn), not for an attribute with very few entries with the same value (such as id or mail). For attributes in which all of the values match a small number of entries, it's better to use an equality attribute index.

When configuring a composite index, define the following properties:

Composite Index Properties

Composite Index Properties	Description
index-filter-pattern	Specifies a single-valued filter property used to identify a portion of the index criteria. This can only be specified at the time that the index definition is created and is required.
index-base-dn-pattern	Specifies a single-valued DN property that may indicate that the index should be scoped to a specific subtree or subtree pattern. This can only be specified at the time the index definition is created and is optional.

Working with JSON Indexes

JSON indexing is similar to general attribute indexing. Where an attribute can be indexed several ways and requires a separate database for each index type, there is only a single database for each JSON field that can be used for different JSON filter types. This database primarily behaves like the database for an equality attribute index. Each database entry key is the normalized form for a value for the target JSON field, and the corresponding database entry value is an list of the entry IDs for all entries in which the associated attribute type has a JSON object with that value for the target field. The database is configured with a comparator (based on the data type for the target field) that enables iterating through values in a logical order to facilitate inequality and subInitial searches.

JSON indexes are automatically created when the JSON Field constraint indicates that a JSON field should be indexed. Indexes can be viewed with the following command:

```
$ bin/dbtest list-index-status \
  --backendID userRoot \
  --baseDN dc=example,dc=com
```

The JSON object filter types that can be enhanced through the use of JSON indexes include:

- `equals`. Identifies entries that have a specific value for the target field. This filter type only requires retrieving a single index key. However, depending on the nature of the search filter, the ID list may contain references to entries that don't actually match the filter (such as if the field is a string, and the filter is configured to use case-sensitive matching).
- `equalsAny`. Identifies entries that have any of a specified set of values for the target field. This filter type only requires retrieving the index keys that correspond to the target values in the filter and merging their ID lists.
- `greaterThan/lessThan`. Identifies entries that have at least one value for the target field that is greater or less than (or possibly equal to) a specified value. This index is similar in use to the `containsField` index, except that it only needs to iterate through a subset of the keys. A filter can contain both `greaterThan` and `lessThan` filters to represent a bounded range.
- `substring`. Identifies entries that have a string value for the target field that matches a given `substring`. The index can only be used for substring filters that include a `subInitial` component. In this case, the server iterates through all of the index keys that match the `startsWith` component, and manually compares values against the remainder of the substring assertion.

JSON indexing is available in local database backends backed by Berkeley DB Java Edition. This includes the following:

- Add, delete, modify, and modify DN operations that make changes to JSON objects stored in the server.
- LDIF imports that include JSON objects, including updates to the cache size estimates for the JSON indexes.
- The `rebuild-index` tool and corresponding backend code to make it possible to generate and rebuild indexes for JSON data. It must be possible to build all JSON indexes for all or a specified subset of fields associated with a given attribute type. The `verify-index` tool should also work with JSON indexes to make it possible to check their validity.
- Matching entry count control and `debugsearchindex` return attribute provide information about relevant JSON index usage.
- Support for monitoring index content and usage.

Note: Exploded indexes and the entry balancing global index do not support JSON objects.

Working with Local DB VLV Indexes

Local DB VLV indexes allow a client to request a subset of results from a sorted list that match a specific search base, scope, and filter. The client can navigate through the list by passing a context back to the server with the virtual list view control. The Local DB VLV index can be used only when the client request contains the virtual list view (VLV) control and the client has been authorized with an ACI with a `targetcontrol` of **2.16.840.1.113730.3.4.9**.

Note: A client request, which includes a virtual list view control, can be successfully processed without a matching Local DB VLV index if the search is completely indexed. This is not an efficient means of using VLV, since the server has to retrieve each entry twice.

To View the List of Local DB VLV Indexes

Steps

- Use `dsconfig` with the `list-local-db-indexes` option to view the default list of indexes. In the example, no VLV indexes are defined.

```
$ bin/dsconfig list-local-db-vlv-indexes --backend-name userRoot
```

To Create a New Local DB VLV Index

Steps

1. Use **dsconfig** with the `create-local-db-ylv-index` option and the `--index-name`, `--backend-name`, and `--set index-type:(propertyValue)` options. If you do not set any property values, the default values are assigned.

```
$ bin/dsconfig create-local-db-ylv-index \
  --index-name givenName --backend-name userRoot --set base-
dn:dc=example,dc=com \
  --set scope:whole-subtree --set filter:"(objectclass=*)" \
  --set sort-order:givenName
```

2. Rebuild the index using the **rebuild-index** tool. You must add the "ylv." prefix to the index name to rebuild the VLV index. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index ylv.givenName
```

To Modify a VLV Index's Configuration

Steps

1. Use **dsconfig** with the `set-local-db-ylv-index-prop` option and the `--index-name` and `--backend-name` properties. In this example, update the `base-dn` property.

```
$ bin/dsconfig set-local-db-ylv-index-prop --index-name givenName \
  --backend-name userRoot --set base-dn:ou=People,dc=example,dc=com
```

2. Rebuild the index using the **rebuild-index** tool. You must add the prefix "ylv." to the index name. The following command can be run with the server on or offline with the addition of the `--task` and connection options.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index ylv.givenName
```

To Delete a VLV Index

About this task

You can delete a VLV index using the **dsconfig** tool. Check that the index is not being used in any plugin applications before deleting it.

Steps

1. Use **dsconfig** with the `delete-local-db-ylv-index` option to remove it from the database.

```
$ bin/dsconfig delete-local-db-ylv-index --index-name givenName \
  --backend-name userRoot
```

2. Verify the deletion by trying to view the ylv index.

```
$ bin/dsconfig get-local-db-ylv-index-prop --index-name givenName \
  --backend-name userRoot
```

Working with Filtered Indexes

The PingDirectory Server filtered index is useful when client search requests consisting of a compound `&-filter` with individual components matching a large number of entries, potentially greater than the index entry limit, have an intersection of a relatively small number of entries.

For example, assume a database contains several thousand company profiles and each company profile is represented by many entries. The "(objectClass=company)" filter matches a small set of entries per company, and therefore may exceed the index entry limit since there are many companies. Also assume that the "(companyDomain=example.com)" filter matches many of the entries for the company with domain `example.com` and can also result in an unindexed search. The more narrow filter "(&(objectClass=company)(companyDomain=example.com))" also results in an unindexed search but only matches a small number of entries. The filtered index makes it possible to index this compound filter by defining an equality index on the `companyDomain` attribute with a static filter of "(objectClass=company)" in the `equality-index-filter` property of the index.

Filtered indexing is primarily useful for cases in which clients frequently issue searches with AND filters that meet the following criteria:

- The AND filter itself matches a relatively small number of entries, but each of the individual components may match a very large number of entries.
- The filter has a dynamic component that does change, and that dynamic component always uses the same attribute.
- The filter has a static component that doesn't change.
- The filter must be narrowed to a base DN, for data structures with many branches, or if indexed attribute values appear in a very large number of entries.

The filtered index can be maintained independently from the equality filter for that attribute. Further, the filtered index will be used only for searches containing the equality component with the associated attribute type ANDed with this filter. When configuring a filtered index, be aware of the `equality-index-filter` and `maintain-equality-index-without-filter` properties of the index.

Once configured and built with the `rebuild-index` tool or `import-ldif`, searches with filters based on the above example will be processed with the index:

```
(&(objectClass=company)(companyDomain=example.com))
(&(objectClass=company)(|(companyDomain=example.com)
(companyDomain=example.org)))
(&(companyDomain=example.com)(objectClass=company))
(&(companyDomain=example.com)(&(objectClass=company)))
(&(companyDomain=example.com)(objectClass=company)(something=else))
(&(companyDomain=example.com)(&(objectClass=company)(something=else)))
(|(&(objectClass=company)(companyDomain=example.com))(&(objectClass=company)
(companyDomain=example.org)))
```

When configuring a filtered index, define the following properties:

Filtered Index Properties

Filtered Index Properties	Description
<code>equality-index-filter</code>	Specifies a search filter that may be used in conjunction with an equality component for the associated attribute type. If an equality index filter is defined, then an additional equality index will be maintained for the associated attribute, but only for entries that match the provided filter. Further, the index will be used only for searches containing an equality component with the associated attribute type ANDed with this filter.
<code>maintain-equality-index-without-filter</code>	Specifies whether to maintain a separate equality index for the associated attribute without any filter, in addition to maintaining an index for each equality index filter that is defined. If this is false, then the attribute will not be indexed for equality by itself but only in conjunction with the defined equality index filters.

To Create a Filtered Index

Steps

1. Use the `dsconfig` tool to create a filtered index. The following command creates an equality index on the `companyDomain` attribute and maintains an index for the equality filter defined `"(objectclass=company)"`. After you have created the index, you must rebuild the indexes.

```
$ bin/dsconfig create-local-db-index --backend-name "userRoot" \
  --index-name companyDomain --set maintain-equality-index-without-
  filter:true \
  --set index-type:equality --set equality-index-
  filter:"(objectclass=company)"
```

2. Stop the Directory Server using `bin/stop-server`.
3. Run the `rebuild-index` tool.

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index companyDomain
```

4. Start the Directory Server using `bin/start-server`.

Tuning Indexes

The PingDirectory Server provides several tools to help you optimize your indexes and improve the overall read and write performance for your system. The server now supports an optional expanded index database using an *exploded* format to process high write load operations. To view the current state of the server's indexes and make adjustments to the index databases, the Directory Server automatically generates an Index Summary Statistics Table after each LDIF import or index rebuild. The `dbtest` tool also includes an Index Histogram to determine the key datasize for the indexes. This section provides descriptions of each of these tools.

About the Exploded Index Format

The `index-entry-limit` Backend configuration property specifies the maximum number of entries kept in an index record, before the server stops maintaining that record, begins scanning the whole database, and runs an expensive unindexed search. If any index keys have already reached this limit, indexes must be rebuilt before they can be allowed to use a new limit. If `index-entry-limit` is configured to be larger than 50000, then any keys that match more than 50000 entries will be stored in a separate database in an expanded (or "exploded") format.

All keys whose entry count is less than 50000 continue to be stored in one database in a consolidated format, such that changes to the key require rewriting all the entry IDs matching the key. All keys whose entry count is greater than 50000 and less than the `index-entry-limit` are stored in a separate database in an exploded format, such that changes to the key require writing only to the updated entry ID.

If the `index-entry-limit` is increased to 100000, any key with an entry count less than 50000 continues to be stored in consolidated format. If a key has an entry count greater than 50000, it will be stored in a separate database where each key is stored with its entry ID individually. The consolidated format is very efficient for read operations because the server can retrieve a row of entry IDs at once, while the exploded format is far more efficient for high volumes of write operations since it avoids large on-disk growth.

Monitoring Index Entry Limits

Index keys that have reached their limit require indexes to be rebuilt before they can be allowed to use a new limit. There are several ways to monitor index limits to avoid a potentially costly rebuild. There are cases in which it is acceptable for index keys to exceed the index entry limit. For example, the `objectClass` attribute type should be indexed for equality because the server needs to use it to find all group entries when bringing a backend online, and also because applications frequently need to find entries of a specific type. However, it doesn't make sense for the "top" `objectClass` key to be indexed, because it appears in every entry in the server.

Choose an index entry limit value that is high enough to ensure that all of the right keys are indexed, but keys that occur too frequently are not. The `verify-index` tool `--listKeysNearestIndexEntryLimit` argument lists a specified number of keys that are closest to the limit without having exceeded it. The index entry limit should be larger than the number of entries matching the largest key to remain indexed, with enough overhead to account for future growth. Use this command regularly to determine if the index entry limit needs to be adjusted.

The `verify-index` tool also provides the `--listKeysExceedingIndexEntryLimit` argument to list all keys for which the value has exceeded the index entry limit and the number of entries in which they appear. If there are keys for which the limit has already exceeded but that need to be maintained, adjust the index entry limit to be higher than the number of entries that contain that key (with additional room for future growth) and run the `rebuild-index` tool (or export to LDIF and re-import).

The server provides other ways to determine if index keys have exceeded, or are close to exceeding, the index entry limit. Some of these include:

- When performing an LDIF import, the tool includes an "Index Summary Statistics" section that provides usage information for each index, including the number of keys for which the index entry limit has been exceeded, and also the number of keys for which the number of matching entries falls within a number of predefined buckets (such as 1–4 entries, 5–9 entries, 10–99 entries, and 100–999 entries).
- If, during a search operation, the server accesses one or more index keys whose values have exceeded the index entry limit, the access log message for that operation will include an `indexesWithKeysAccessedExceedingEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to, or tried to write to, at least one index key whose value exceeded the index entry limit.
- If, during a search operation, the server accesses one or more index keys whose values have not yet exceeded the index entry limit but are more than 80 percent to reaching that limit, the access log message for that operation will include an `indexesWithKeysAccessedNearEntryLimit` field containing a comma-delimited list of the appropriate indexes. The same access log field may appear in log messages for add, delete, modify, and modify DN operations in which the server wrote to at least one index key whose value was within 80 percent of the index entry limit.
- If a search operation requests either includes the `debugsearchindex` attribute, or the matching entry count request control with debugging enabled, the debug information will include any indexes accessed that have exceeded the index entry limit, or that are within 80 percent of the configured index entry limit.
- The monitor entry for each configured index includes attributes that provide information about the number of index keys that have been encountered (since the backend was brought online, or since the index entry limit was changed) in a number of different categories. These monitor attributes include:
 - `ds-index-exceeded-entry-limit-count-since-db-open` — The number of index keys for which the number of matching entries has crossed the index entry limit due to a write operation.
 - `ds-index-unique-keys-near-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries is within 80 percent of the index entry limit.
 - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-search-since-db-open` — The number of unique index keys that have been accessed by a search operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.
 - `ds-index-unique-keys-near-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries is within 80 percent of the index entry limit.
 - `ds-index-unique-keys-exceeding-entry-limit-accessed-by-write-since-db-open` — The number of unique index keys that have been accessed by a write operation for which the number of matching entries has exceeded the index entry limit at some point since the index was last built.

About the Index Summary Statistics Table

The Directory Server now automatically generates an Index Summary Statistics Table, which can be used to determine the optimal configuration for your system's indexes. This table is only generated when the `rebuild-index` tool is run in offline mode. The table is generated after any LDIF import or an index rebuild, and is written to system out and to `logs/tools/rebuild-index-summary.txt`. The table lists the current index entry limit (set by the `index-entry-limit` property on the local DB configuration), the number of keys whose entry count exceeds this limit if any, and the maximum entry count for any key in the index. The table then displays a histogram of the number of keys whose entry falls within a range of values. An example of the Index Summary Statistics table is show below for the `sn.equality` and the `sn.substring` indexes.

The following figure shows that there are seven substrings whose entry counts exceed the `index-entry-limit` of 4000. Six of the substrings are in the 10000-99999 range with the maximum entry count being 13419. By deduction, one more substring must be present in the 1000-9999 range that exceeds the `index-entry-limit` of 4000. These substrings could be expensive for search operations.

```

--- Index Summary Statistics ---
Index          : Limit : >Limit : Max   : 1-9   : 10-99  : 100-999 : 1000-9999 : 10000-99999
-----
dc_example_dc_com_sn.equality : 4000 :       : 2     : 100000 :       :       :       :
dc_example_dc_com_sn.substring : 4000 : 7     : 13419 : 150814 : 7109  : 407    : 36     : 6

```

MY TITLE Example of an Index Summary Statistics Table

About the dbtest Index Status Table

The `dbtest` tool has a `list-all --analyze` option that generates the current status of all of the databases on your system, including all index databases. The table shows the type, entry count (i.e., the number of records in the database), index status (TRUSTED to indicate that the indexes are up-to-date, or UNTRUSTED if the index needs rebuilding), the total data size for each key, the average data size for each key and the maximum data size for each key. Note also that any indexes that are in exploded format are listed on this table.

Index Name	Index Type	JE Database Name	Index Status
id2children	Index	dc_example_dc_com_id2children	TRUSTED
id2subtree	Index	dc_example_dc_com_id2subtree	TRUSTED
uid.equality	Index	dc_example_dc_com_uid.equality	TRUSTED
aci.presence	Index	dc_example_dc_com_aci.presence	TRUSTED
ds-soft-delete-timestamp.ordering	Index	dc_example_dc_com_ds-soft-delete-timestamp.ordering	TRUSTED
ds-soft-delete-from-dn.equality	Index	dc_example_dc_com_ds-soft-delete-from-dn.equality	TRUSTED
givenName.equality	Index	dc_example_dc_com_givenName.equality	TRUSTED
givenName.substring	Index	dc_example_dc_com_givenName.substring	TRUSTED
objectClass.equality	Index	dc_example_dc_com_objectClass.equality	TRUSTED
member.equality	Index	dc_example_dc_com_member.equality	TRUSTED
uniqueMember.equality	Index	dc_example_dc_com_uniqueMember.equality	TRUSTED
cn.equality	Index	dc_example_dc_com_cn.equality	TRUSTED
cn.substring	Index	dc_example_dc_com_cn.substring	TRUSTED
sn.equality	Index	dc_example_dc_com_sn.equality	TRUSTED
sn.substring	Index	dc_example_dc_com_sn.substring	TRUSTED
telephoneNumber.equality	Index	dc_example_dc_com_telephoneNumber.equality	TRUSTED
mail.equality	Index	dc_example_dc_com_mail.equality	TRUSTED
ds-entry-unique-id.equality	Index	dc_example_dc_com_ds-entry-unique-id.equality	TRUSTED

MY TITLE dbtest Output Including Index Databases

Configuring the Index Properties

By default, the `index-entry-limit` is set to 4000, which means the server will stop maintaining index values for keys that match more than 4000 entries. This can be changed with the `dsconfig` tool.

To Configure the Index Properties

About this task

Before running the following commands, be aware that you will need to do an index rebuild on the system, which requires a system shutdown, unless the command is run as a task.

Steps

1. Run `dsconfig` and set the `index-entry-limit` to 5000. By default, the value is set to 4000. Remember to include the bind parameters for your system. Once you enter the command, confirm that you want to apply the changes.

```
$ bin/dsconfig set-backend-prop \
  --backend-name userRoot \
  --set index-entry-limit:5000 \
```

One or more configuration property changes require administrative action or confirmation/notification. Those properties include:

- * `index-entry-limit`: If any index keys have already reached this limit, indexes must be rebuilt before they will be allowed to use the new limit. Setting a large limit (greater than 10,000) could have a big impact on write performance and database growth on disk.

Continue? Choose 'no' to return to the previous step (yes / no) [yes]: yes

2. Stop the server.

```
$ bin/stop-server
```

3. Rebuild the index.

```
$ bin/rebuild-index --baseDN dc=example,dc=com \
  --index cn --index givenName --index objectClass \
  --index sn --maxThreads 10
```

4. View the Index Summary Statistics table, which is automatically displayed to system out after running the `rebuild-index` command. You can also access the table at `logs/tools/rebuild-index-summary.txt`. Repeat the last three steps to make more adjustments to your indexes.

```
--- Index Summary Statistics ---
Index          : Limit : >Limit : Max   : 1-9   : 10-99 : 100-999 : 1000-9999 : 10000-99999 : 100000-999999
-----
dc_example_dc_com_cn.equality      : 5000 :      1 : 100001 :      :      :      :      :      :      :
dc_example_dc_com_cn.substring    : 5000 :    9  : 15401  : 131746 : 22372 : 545   : 39   : 3    :      :
dc_example_dc_com_givenName.equality : 5000 :      16 : 3788   : 4817   :      :      :      :      :      :
dc_example_dc_com_givenName.substring : 5000 :    8  : 23809  : 7039   : 12062 : 483   : 42   : 3    :      :
dc_example_dc_com_objectClass.equality : 5000 :    4  : 100003 : 3       :      :      :      :      :      :
dc_example_dc_com_sn.equality      : 5000 :      8 : 13419  :      :      :      :      :      :      :
dc_example_dc_com_sn.substring    : 5000 :    9  : 15401  : 33967  : 7055  : 459   : 39   : 3    :      :
The first three columns of numbers provide (1) "Limit" - the index entry limit (or blank if there is no limit),
(2) ">Limit" - the number of keys whose entry count exceeds the entry limit, and (3) "Max" - the
maximum entry count for any key in the index. The remaining columns provide the number of keys
whose entry count falls in the range indicated in the column heading
```

5. Restart the server.

```
$ bin/start-server
```

Managing Entries

The Directory Server is a fully LDAPv3-compliant server that comes with a comprehensive set of LDAP command-line tools to search, add, modify, and delete entries.

This chapter presents the following topics:

Searching Entries

The Directory Server provides an `ldapsearch` tool to search for entries or attributes within your server. The tool requires the LDAP connection parameters needed to bind to the server, including the

`baseDN` option to specify the starting point of the search within the server, and the search scope. The `searchScope` option determines the depth of the search:

- `base` (search only the entry specified)
- `one` (search only the children of the entry and not the entry itself)
- `sub` (search the entry and its descendents)

The `ldapsearch` tool provides basic functionality as specified by the RFC 2254 but provides additional features that takes advantage of the Directory Server's control mechanisms. For more information, run the `ldapsearch --help` function.

To Search the Root DSE

About this task

The Root DSE is a special entry that resides at the root of the directory information tree (DIT). The entry holds operational information about the server and its supported controls. Specifically, the root DSE entry provides information about the supported LDAPv3 controls, SASL mechanisms, password authentication schemes, supported LDAP protocols, additional features, naming contexts, extended operations, and server information.

Note: The Directory Server provides an option to retrieve the Root DSE's operational attributes and add them to the user attribute map of the generated entry. This feature allows client applications that have difficulty handling operational attributes to access the root DSE using the `show-all-attributes` configuration property. Once this property is set, the associated attribute types are re-created and re-registered as user attributes in the schema (in memory, not on disk). Once you set the property, you can use `ldapsearch` without "+" to view the root DSE.

Use the `dsconfig` tool to set the `show-all-attributes` property to TRUE, as follows:

```
$ bin/dsconfig set-root-dse-backend-prop --set show-all-attributes:true
```

Steps

- Use `ldapsearch` to view the root DSE entry on the Directory Server. Be sure you include the "+" to display the operational attributes in the entry.

```
$ bin/ldapsearch --baseDN "" --searchScope base "(objectclass=*)" "+"
```

To Search All Entries in the Directory Server

Steps

- Use `ldapsearch` to search all entries in the Directory Server. The filter `"(objectclass=*)"` matches all entries. If the `--searchScope` option is not specified, the command defaults to a search scope of `sub`:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
--searchScope sub "(objectclass=*)" "
```

To Search for an Access Control Instruction

Steps

- Use **ldapsearch** to search the `dc=example,dc=com` base DN entry. The filter `"(aci=*)"` matches all `aci` attributes under the base DN, and the `aci` attribute is specified so that only it is returned. The `cn=Directory Manager` bind DN has the privileges to view an ACI.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(aci=*)" aci

dn: dc=example,dc=com
aci: (targetattr!="userPassword")
  (version 3.0; acl "Allow anonymous read access for anyone";
    allow (read,search,compare) userdn="ldap:///anyone";)
aci: (targetattr="*")
  (version 3.0; acl "Allow users to update their own entries";
    allow (write) userdn="ldap:///self";)
aci: (targetattr="*")
  (version 3.0; acl "Grant full access for the admin user";
    allow (all) userdn="ldap:///uid=admin,dc=example,dc=com";)
```

To Search for the Schema

Steps

- Use **ldapsearch** to search the `cn=schema` entry. The base DN is specified as `cn=schema`, and the filter `"(objectclass=*)"` matches all entries. The command uses a special attribute `"+"` to return all operational attributes:

```
$ bin/ldapsearch --baseDN cn=schema \
  --searchScope base "(objectclass=*)" "+"
```

To Search for a Single Entry using Base Scope and Base DN

Steps

- Use **ldapsearch** to search for a single entry by specifying the base scope and DN:

```
$ bin/ldapsearch --baseDN uid=user.14,ou=People,dc=example,dc=com \
  --searchScope base "(objectclass=*)" "
```

To Search for a Single Entry Using the Search Filter

Steps

- Search for a single entry by specifying the `sub` scope and a search filter that describes a single entry:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope sub "(uid=user.14) "
```

To Search for All Immediate Children for Restricted Return Values

Steps

- Search for all immediate children of `ou=People,dc=example,dc=com`. The attributes returned are restricted to `sn` and `givenName`. The special attribute `"+"` returns all operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
  --searchScope one '(objectclass=*)' sn givenName "+"
```

To Search for All Children of an Entry in Sorted Order

Steps

- Search for all children of the `ou=People,dc=example,dc=com` subtree. The resulting entries are sorted by the server in ascending order by `sn` and then in descending order by `givenName`:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
--searchScope sub --sortOrder sn,-givenName '(objectclass=*)'
```

To Limit the Number of Returned Search Entries and Search Time

Steps

- Search for a subset of the entries in the `ou=People,dc=example,dc=com` subtree by specifying a compound filter. No more than 200 entries will be returned and the server will spend no more than 5 seconds processing the request. Returned attributes are restricted to a few operational attributes:

```
$ bin/ldapsearch --baseDN ou=People,dc=example,dc=com \
--searchScope sub --sizeLimit 200 --timeLimit 5 \
"(&(sn<=Doe)(employeeNumber<=1000))" ds-entry-unique-id entryUUID
```

To Get Information about How Indexes are used in a Search Operation

The PingDirectory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the Directory Information Tree (DIT). Information about the can be obtained about the server's use of indexes in the course of processing a search operation. The following are two basic ways to accomplish this.

Issue a search request with the desired base DN, scope, and filter, and request that the server return the special `debugsearchindex` attribute. Users will need to be granted access to the `debugsearchindex` operational attribute and the `cn=debugsearch` portion of the DIT with the following command:

```
$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetattr=\"debugsearchindex\") (target=\"ldap:///
cn=debugsearch\")
(version 3.0; acl \"Allow members of the Index Debugging Users group
to request the debugsearchindex operational attribute \"; allow
(read,search,compare) groupdn=\"ldap:///cn=Index Debugging
Users,ou=Groups,dc=example,dc=com\");"
```

To issue a search request for the server return the special `debugsearchindex` attribute, use the `ldapsearch` command such as:

```
$ bin/ldapsearch --hostname ds.example.com \
--port 389 --bindDN uid=admin,dc=example,dc=com \
--bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub "(&(givenName=John)(sn=Doe))" debugsearchindex
dn: cn=debugsearch
debugsearchindex: 0.040 ms - Beginning index processing for search
request with base DN 'dc=example,dc=com', scope wholeSubtree,
and filter (&(givenName=John)(sn=Doe)).
debugsearchindex: 0.067 ms - Unable to optimize the AND filter
beyond what the client already provided.
debugsearchindex: 0.834 ms - Candidate set obtained for single-key
filter (givenName=John) from index dc example dc com givenName.equality.
Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2, originalFilter=(givenName=John),
remainingFilter=null, matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.030 ms - Final candidate set for filter (givenName=John)
```

```

    obtained from an unexploded index key in
dc_example_dc_com_givenName.equality.
    Since the scope of the search includes the entire entry container, there
is
    no need to attempt to further pare down the results based on the search
scope.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
    matchingEntryCountType=UNEXAMINED_COUNT)
debugsearchindex: 0.020 ms - Short-circuiting index processing for AND filter
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within the
    short-circuit threshold of 5.
debugsearchindex: 0.030 ms - Obtained a candidate set of size 2 for AND
filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even though
there is still more of the filter to evaluate, the current candidate set
is
    within the short-circuit threshold of 5, so no additional index
processing will
    be performed to try to pare down the results based on the remaining
filter or the
    search scope. Candidate set: CandidateSet(isDefined=true,
isExploded=false,
    isResolved=true, size=2, originalFilter=(&(givenName=John)(sn=Doe)),
    remainingFilter=(sn=Doe), matchingEntryCountType=UPPER_BOUND)
debugsearchindex: 0.016 ms - Completed all index processing. Candidate set:
CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
    originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
    matchingEntryCountType=UPPER_BOUND)

```

The second way would be to issue a search request with the desired base DN, scope, and filter, and include the matching entry count request control with the debug option set to `true`. To do this with `ldapsearch`, use a command such as:

```

$ bin/ldapsearch --hostname ds.example.com --port 389 \
--bindDN uid=admin,dc=example,dc=com --bindPassword password \
--baseDN dc=example,dc=com \
--searchScope sub --matchingEntryCountControl examineCount=0:debug
"(&(givenName=John)(sn=Doe))"
Upper Bound on Matching Entry Count: 2
Matching Entry Count Debug Messages:
* naw-desktop:1389 - 0.104 ms - Beginning index processing for search request
with
    base DN 'dc=example,dc=com', scope wholeSubtree, and filter
    (&(givenName=John)(sn=Doe)).
* naw-desktop:1389 - 0.105 ms - Unable to optimize the AND filter beyond what
the client already provided.
* naw-desktop:1389 - 0.614 ms - Candidate set obtained for single-key filter
(givenName=John) from index
    dc_example_dc_com_givenName.equality. Candidate set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true,
    size=2, originalFilter=(givenName=John), remainingFilter=null,
    matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.090 ms - Final candidate set for filter
    (givenName=John) obtained from an unexploded index key in
    dc_example_dc_com_givenName.equality. Since the scope of the search
    includes the entire entry container, there is no need
    to attempt to further pare down the results based on the search scope.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true,

```

```

    size=2, originalFilter=(givenName=John), remainingFilter=null,
    matchingEntryCountType=UNEXAMINED_COUNT)
* naw-desktop:1389 - 0.045 ms - Short-circuiting index processing for AND
filter
    (&(givenName=John)(sn=Doe)) after evaluating single-key component
    (givenName=John) because the current ID set size of 2 is within the short-
circuit threshold of 5.
* naw-desktop:1389 - 0.111 ms - Obtained a candidate set of size 2 for AND
filter
    (&(givenName=John)(sn=Doe)) with remaining filter (sn=Doe). Even though
there is
    still more of the filter to evaluate, the current candidate set is within
the short-circuit threshold of 5, so no additional index processing will
be performed
    to try to pare down the results based on the remaining filter or the
search scope.
    Candidate set: CandidateSet(isDefined=true, isExploded=false,
isResolved=true, size=2,
    originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
    matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - 0.040 ms - Completed all index processing. Candidate
set:
    CandidateSet(isDefined=true, isExploded=false, isResolved=true, size=2,
    originalFilter=(&(givenName=John)(sn=Doe)), remainingFilter=(sn=Doe),
    matchingEntryCountType=UPPER_BOUND)
* naw-desktop:1389 - The search is partially indexed
(candidatesAreInScope=true,
    unindexedFilterPortion=(sn=Doe))
* naw-desktop:1389 - Constructing an UPPER_BOUND response with a count of 2

```

Working with the Matching Entry Count Control

The `ldapsearch` command can be used with the `--matchingEntryCountControl` option to determine the count of entries that match a search filter. Users will need to be granted access to this control by its OID `1.3.6.1.4.1.30221.2.5.36` with the following command:

```

$ bin/dsconfig set-access-control-handler-prop \
--add "global-aci:(targetcontrol=\"1.3.6.1.4.1.30221.2.5.36\")
    (version 3.0; acl \"Allow members of the Index Debugging Users group to
    use the matching entry count request control \"; allow (read)
    groupdn=\"ldap:///cn=Index Debugging Users,ou=Groups,dc=example,dc=com\");"

```

An `examineCount` control can be used for searches that are at least partially indexed, in order to determine whether to return an examined count, an unexamined count, or an upper bound count. The factors that determine what is returned are:

- A search is fully indexed if indexes can be used to identify the entry IDs for all entries that match the filter without ambiguity. Indexes can also be used to make sure that all of those candidates are within the scope of the search.
- A search is partially indexed if indexes can be used to identify the entry IDs for all entries that match the search criteria, but the candidate list may potentially also include entries that either don't match the filter or are outside the scope of the search.
- A search is unindexed if it is not possible to retrieve a candidate list based on either the filter or the search scope.
- An unexamined count is a count of the exact number of entries that match the search criteria, only through the use of index processing.
- An examined count is the same as an unexamined count, except that all of the candidate entries are examined to determine whether they would have been returned to the client. An examined count may be less than an unexamined count if the set of matching entries includes those that would be removed by access control evaluation, or special entries like LDAP sub-entries, replication conflict entries, or soft-deleted entries.

- An upper bound count is the maximum number of entries that match the criteria, but indicates that the server could not determine exactly how many matching entries there were without examining each candidate, which it did not do.
- If a search is fully indexed, the result is an examined count or an unexamined count. If **alwaysExamine** is true and **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If **alwaysExamine** is false, or if the number of candidates exceeds **examineCount**, the result is an unexamined count.
- If a search is partially indexed, the result is either an examined count or an upper bound count. The **alwaysExamine** flag isn't relevant in this case. If **examineCount** is greater than or equal to the number of candidates, the result is an examined count. If not, the result is an upper bound count.
- If a search is unindexed, the result is either an examined count or an unknown count. If **allowUnindexed** is true, the unindexed search is processed, which can be very expensive. Instead of getting the matching entries back, the examined count is returned. If **allowUnindexed** is false, an unknown count is returned. If **allowUnindexed** is true, the requester needs to have the **unindexed-search** privilege to get the exact count.

The following is a sample `ldapsearch` with the `--matchingEntryCountControl` option:

```

$./ldapsearch \
  --bindDN "cn=directory manager" \
  --bindPassword password \
  --baseDN dc=example,dc=com \
  --matchingEntryCountControl
examineCount=100:alwaysExamine:allowUnindexed:debug \
  "(objectclass=*)"

```

Adding Entries

Depending on the number of entries that you want to add to your Directory Server, you can use the `ldapmodify` tool for small additions. The `ldapmodify` tool provides two methods for adding a single entry: using a LDIF file or from the command line. The attributes must conform to your schema and contain the required object classes.

Adding requests with the **ignore-no-user-modification** control enable a client to include attributes that are not normally allowed from external sources. For example, the **userPassword** attribute is a user-modifiable attribute. An add request with the **ignore-no-user-modification** control allows a one-time exception to the password policy, even if the requesting client does not have the **bypass-pw-policy** privilege. This exception enables specifying pre-encoded passwords.

Note: When adding an entry, the server can ensure that the entry's RDN is unique and does not contain any sensitive information by replacing the provided entry's RDN with the server-generated entryUUID value. An LDAP client written with the LDAP SDK for Java can use the **NameWithEntryUUIDRequestControl** to explicitly indicate which add requests should be named in this way, or the `ldapmodify` tool with the `--nameWithEntryUUID` argument. Also, the **auto-name-with-entry-uuid-connection-criteria** and **auto-name-with-entry-uuid-request-criteria** global configuration properties can be used to identify which add requests should be automatically named this way.

The uniqueness request control can also be used with `ldapmodify` for enforcing uniqueness on a per-request basis. Provide at least one of the **uniquenessAttribute** or **uniquenessFilter** arguments with the request. For more information about this control, see the LDAP SDK documentation and the `com.unboundid.ldap.sdk.unboundidds.controls.UniquenessResponseControl` class for using the control.

To Add an Entry Using an LDIF File

Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user.ldif`. For the `userPassword` attribute, enter the cleartext password. The Directory Server encrypts the password and stores its encrypted value in the server. Make sure that the LDIF file has limited read permissions for only authorized administrators.

```
dn: uid=user.2000,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
postalAddress: Toby Hall$73600 Mash Street$Cincinnati, OH 50563 postalCode:
  50563
description: This is the description for Toby Hall.
uid: user.2000
userPassword: wordsmith employeeNumber: 2000
initials: TBH
givenName: Toby
pager: +1 596 232 3321
mobile: +1 039 311 9878
cn: Toby Hall
sn: Hall
telephoneNumber: +1 097 678 9688
street: 73600 Mash Street
homePhone: +1 214 233 8484
l: Cincinnati
mail: user.2000@maildomain.net
st: OH
```

2. Use the `ldapmodify` tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. If the command is successful, you will see generated success messages with the `#` symbol.

```
$ bin/ldapmodify --defaultAdd --filename add-user.ldif
```

```
# Processing ADD request for uid=user.2000,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2000,ou=People,dc=example,dc=com
```

To Add an Entry Using the Changetype LDIF Directive

About this task

RFC 2849 specifies LDIF directives that can be used within your LDIF files. The most commonly used directive is `changetype`, which follows the `dn:` directive and defines the operation on the entry. The main advantage of using this method in an LDIF file is that you can combine adds and modifies in one file.

Steps

1. Open a text editor and create an entry that conforms with your schema. For example, add the following entry in the file and save the file as `add-user2.ldif`. Note the use of the `changetype` directive in the second line.

```
dn: uid=user.2001,ou=People,dc=example,dc=com
changetype: add
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
```

```
postalAddress: Seely Dorm$100 Apple Street$Cincinnati, OH 50563
postalCode: 50563
description: This is the description for Seely Dorm.
uid: user.2001
userPassword: pleasantry
employeeNumber: 2001
initials: SPD
givenName: Seely pager: +1 596 665 3344
mobile: +1 039 686 4949
cn: Seely Dorm
sn: Dorm
telephoneNumber: +1 097 257 7542
street: 100 Apple Street
homePhone: +1 214 521 4883
l: Cincinnati
mail: user.2001@maildomain.net
st: OH
```

2. Use the `ldapmodify` tool to add the entry specified in the LDIF file. You will see a confirmation message of the addition. In this example, you do not need to use the `--defaultAdd` or its shortform `-a` option with the command.

```
$ bin/ldapmodify --filename add-user2.ldif
```

To Add Multiple Entries in a Single File

About this task

You can have multiple entries in your LDIF file by simply separating each DN and its entry with a blank line from the next entry.

Steps

1. Open a text editor and create a couple of entries that conform to your schema. For example, add the following entries in the file and save the file as `add-user3.ldif`. Separate each entry with a blank line.

```
dn: uid=user.2003,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass:
organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...

dn: uid=user.2004,ou=People,dc=example,dc=com
objectClass: top
objectClass: person
objectClass: organizationalPerson
objectClass: inetOrgPerson
...(similar attributes to previous examples)...
```

2. Use the `ldapmodify` tool to add the entries specified in the LDIF file. In this example, we use the short form arguments for the `ldapmodify` tool.

The `-h` option specifies the host name, the `-p` option specifies the LDAP listener port, `-D` specifies the bind DN, `-w` specifies the bind DN password, `-a` specifies that entries that omit a changetype will be treated as add operations, and `-f` specifies the path to the input file. If the operation is successful, you will see commented messages (those beginning with "#") for each addition.

```
$ bin/ldapmodify -h server.example.com -p 389 \
```

```
-D "cn=admin,dc=example,dc=com" -w password -a -f add-user3.ldif

# Processing ADD request for uid=user.2003,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2003,ou=People,dc=example,dc=com
# Processing ADD request for uid=user.2004,ou=People,dc=example,dc=com
# ADD operation successful for DN uid=user.2004,ou=People,dc=example,dc=com
```

Deleting Entries Using `ldapdelete`

You can delete an entry using the `ldapdelete` tool. You should ensure that there are no child entries below the entry as that could create an orphaned entry. Also, make sure that you have properly backed up your system prior to removing any entries.

To Delete an Entry Using `ldapdelete`

Steps

Use `ldapdelete` to delete an entry. The following example deletes the `uid=user.14` entry.

```
$ bin/ldapdelete uid=user.14,ou=People,dc=example,dc=com
```

To Delete Multiple Entries Using an LDIF File

Steps

1. You can generate a file of DNs that you would like to delete from the Directory Server.

The following command searches for all entries in the `ou=Accounting` branch and returns the DNs of the subentries.

```
$ bin/dump-dns -D "cn=admin,dc=example,dc=com" -w password --baseDN \
               "ou=Accounting,ou=People,dc=example,dc=com" --
outputFile /usr/local/entry_dns.txt
```

2. Run the `ldapdelete` command with the file to delete the entries. The command uses the `--continueError` option, which will continue deleting through the whole list even if an error is encountered for a DN entry.

```
$ bin/ldapdelete --filename /usr/local/entry_dns.txt --continueError
```

Deleting Entries Using `ldapmodify`

You can use the LDIF `changetype` directive to delete an entry from the Directory Server using the `ldapmodify` tool. You can only delete leaf entries.

To Delete an Entry Using `ldapmodify`

Steps

- From the command line, use the `ldapmodify` tool with the `changetype:delete` directive. Enter the DN, press **Enter** to go to the next line, then enter the `changetype` directive. Press **Control-D** twice to enter the EOF sequence (UNIX) or **Control-Z** (Windows).

```
$ bin/ldapmodify --hostname server1.example.com -port 389 --bindDN
"uid=admin,dc=example,dc=com" --bindPassword password
dn:uid=user.14,ou=People,dc=example,dc=com
changetype: delete
```

Modifying Entries Using ldapmodify

You can use the `ldapmodify` tool to modify entries from the command line or by using an LDIF file that has the `changetype:modify` directive and value. If you have more than one change, you can separate them using the `-` (dash) symbol.

To Modify an Attribute from the Command Line

Steps

1. Use the `ldapsearch` tool to locate a specific entry.

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the `ldapmodify` command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changed using the `replace` directive. In this example, we change the telephone number of a specific user entry. When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

To Modify Multiple Attributes in an Entry from the Command Line

Steps

1. Use the `ldapsearch` tool to locate a specific entry.

```
$ bin/ldapsearch -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password -b dc=example,dc=com "(uid=user.2004)"
```

2. Use the `ldapmodify` command to change attributes from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be changes using the `add` and `replace` directive.

In this example, we add the `postOfficeBox` attribute, change the mobile and telephone numbers of a specific user entry. The `postOfficeBox` attribute must be present in your schema to allow the addition. The three changes are separated by a dash ("-"). When you are done typing, you can press **CTRL-D** (Unix EOF escape sequence) twice or **CTRL-Z** (Windows) to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postOfficeBox
postOfficeBox: 111
-
replace: mobile
mobile: +1 039 831 3737
-
replace: telephoneNumber
telephoneNumber: +1 097 453 8232
```

To Add an Attribute from the Command Line

Steps

- Use the `ldapmodify` command from the command line. Specify the modification using the `changetype:modify` directive, and then specify which attributes are to be added using the `add` directive. In this example, we add another value for the `cn` attribute, which is multi-valued. When you are done typing, you can press **CTRL-D** (UNIX EOF escape sequence) twice to process the request.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: cn
cn: Sally Tea Tree
```

An error could occur if the attribute is single-valued, if the value already exists, if the value does not meet the proper syntax, or if the value does not meet the entry's objectclass requirements. Also, make sure there are no trailing spaces after the attribute value.

To Add an Attribute Using the Language Subtype

About this task

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

Steps

The Directory Server provides support for attributes using language subtypes. The operation must specifically match the subtype for successful operation. Any non-ASCII characters must be in UTF-8 format.

```
$ bin/ldapmodify -h server.example.com -p 389 -w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
add: postalAddress; lang-ko
postalAddress; lang-ko:Byung-soon Kim$2020-14 Seoul
```

To Add an Attribute Using the Binary Subtype

About this task

The Directory Server provides support for attributes using binary subtypes, which are typically used for certificates or JPEG images that could be stored in an entry. The operation must specifically match the subtype for successful operation. The version directive with a value of "1" must be used for binary subtypes. Typical binary attribute types are `userCertificate` and `jpegPhoto`.

Steps

- Use the `ldapmodify` command to add an attribute with a binary subtype. The attribute points to the file path of the certificate.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
version: 1
dn: uid=user.2004,ou=People,dc=example,dc=com
```

```
changetype: modify
add: userCertificate;binary
userCertificate;binary:<file:///path/to/cert
```

To Delete an Attribute

Steps

Use `ldapmodify` with the LDIF `delete` directive to delete an attribute.

```
$ bin/ldapmodify -h server.example.com -p 389 -D "cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: employeeNumber
```

To Delete One Value from an Attribute with Multiple Values

About this task

You can use the LDIF `delete` directive to delete a specific attribute value from an attribute. For this example, assuming you have multiple values of `cn` in an entry (e.g., `cn: Sally Tree, cn: Sally Tea Tree`).

Steps

- Use `ldapmodify` to delete a specific attribute of a multi-valued pair, then specify the attribute pair that you want to delete. In this example, we keep `cn:Sally Tree` and delete the `cn: Sally Tea Tree`.

```
$ bin/ldapmodify -h server.example.com -p 389 -D
"cn=admin,dc=example,dc=com" \
-w password
dn: uid=user.2004,ou=People,dc=example,dc=com
changetype: modify
delete: cn
cn: Sally Tea Tree
```

To Rename an Entry

About this task

Renaming an entry involves changing the relative distinguished name (RDN) of an entry. You cannot rename a RDN if it has children entries as this violates the LDAP protocol.

Steps

- Use the `ldapmodify` tool to rename an entry. The following command changes `uid=user.14` to `uid=user.2014` and uses the `changetype`, `newrdn`, and `deleteoldrdn` directives.

```
$ bin/ldapmodify
dn: uid=user.14,ou=People,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 1
```

To Move an Entry Within a Directory Server

About this task

You can use `ldapmodify` to move an entry from one base DN to another base DN. Before running the `ldapmodify` command, you must assign access control instructions (ACIs) on the parent entries. The source parent entry must have an ACI that allows export operations: `allow(export)`. The target parent entry must have an ACI that allows import operations: `allow(import)`. For more information on access control instructions, see [Working with Access Control](#).

Steps

- Use the `ldapmodify` command to move an entry from the Contractor branch to the `ou=People` branch.

```
$ bin/ldapmodify
dn: uid=user.14,ou=contractors,dc=example,dc=com
changetype:moddn
newrdn: uid=user.2014
deleteoldrdn: 0
newsuperior: ou=People,dc=example,dc=com
```

To Move an Entry from One Machine to Another

About this task

The Directory Server provides a tool, `move-subtree`, to move a subtree or one entry on one machine to another. The subtree or entry must exist on the source server and must not be present on the target server. The source server must also support the 'real attributes only' request control. The target server must support the Ignore NO-USER-MODIFICATION request control.

Note: The `move-subtree` tool moves a subtree or multiple entries from one machine to another. The tool does not copy the entries. Once the entries are moved, they are no longer present on the source server.

Steps

- Use the `move-subtree` tool to move an entry (e.g., `uid=test.user,ou=People,dc=example,dc=com`) from the source host to the target host.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
  --entryDN uid=test.user,ou=People,dc=example,dc=com
```

To Move Multiple Entries from One Machine to Another

About this task

The `move-subtree` tool provides the ability to move multiple entries listed in a DN file from one machine to another. Empty lines and lines beginning with the octothorpe character (#) will be ignored. Entry DNs may optionally be prefixed with `dn:` , but long DNs cannot be wrapped across multiple lines.

Steps

1. Open a text file, enter a list of DNs, one DN per line, and then save the file. You can also use the `ldapsearch` command with the special character "1.1" to create a file containing a list of DNs that you want to move. The following example searches for all entries that match `(department=Engineering)` and returns only the DNs that match the criteria. The results are re-directed to an output file, `test-dns.ldif`:

```
$ bin/ldapsearch --baseDN dc=example,dc=com \
  --searchScope sub "(department=Engineering)" "1.1" > test-dns.ldif
```

2. Run the `move-subtree` tool with the `--entryDNFile` option to specify the file of DNs that will be moved from one machine to another.

```
$ bin/move-subtree --sourceHost source.example.com --sourcePort 389 \
  --sourceBindDN "uid=admin,dc=example,dc=com" --sourceBindPassword password \
  --targetHost target.example.com --targetPort 389 \
  --targetBindDN "uid=admin,dc=example,dc=com" --targetBindPassword password \
  --entryDNFile /path/to/file/test-dns.ldif
```

3. If an error occurs with one of the DNs in the file, the output message shows the error. The `move-subtree` tool will continue processing the remaining DNs in the file.

```
An error occurred while communicating with the target server: The entry
uid=user.2,ou=People,dc=example,dc=com cannot be added because an entry with
that name
already exists
Entry uid=user.3,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
Entry uid=user.4,ou=People,dc=example,dc=com was successfully moved from
source.example.com:389 to target.example.com:389
```

Working with the Parallel-Update Tool

The PingDirectory Server provides a `parallel-update` tool, which reads change information (add, delete, modify, and modify DN) from an LDIF file and applies the changes in parallel. This tool is a multi-threaded version of the `ldapmodify` tool that is designed to process a large number of changes as quickly as possible.

The `parallel-update` tool provides logic to prevent conflicts resulting from concurrent operations targeting the same entry or concurrent operations involving hierarchically-dependent entries (for example, modifying an entry after it has been added, or adding a child after its parent). The tool also has a retry capability that can help ensure that operations are ultimately successful even when interdependent operations are not present in the correct order in the LDIF file (for example, the change to add a parent entry is provided later in the LDIF file than a change to add a child entry).

After the tool has applied the changes and reaches the end of the LDIF file, it automatically displays the update statistics described in the following table

Parallel-Update Tool Result Statistics

Processing Statistic	Description
Attempts	Number of update attempts
Successes	Number of successful update attempts
Rejects	Number of rejected updates
ToRetry	Number of updates that will be retried

Processing Statistic	Description
AvgOps/S	Average operations per second
RctOps/S	Recent operations per second. Total number of operations from the last interval of change updates.
AvgDurMS	Average duration in milliseconds
RctDurMS	Recent duration in milliseconds. Total duration from the last interval of change updates.

To Run the Parallel-Update Tool

Steps

1. Create an LDIF file with your changes. The third change will generate a rejected entry because its `userPassword` attribute contains an encoded value, which is not allowed.

```
dn:uid=user.2,ou=People,dc=example,dc=com
changetype: delete

dn:uid=user.99,ou=People,dc=example,dc=com
changetype: moddn
newrdn: uid=user.100
deleteoldrdn: 1

dn:uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==

dn:uid=user.100,ou=People,dc=example,dc=com
changetype: modify
replace: st
st: TX
-
replace: employeeNumber
employeeNumber: 100
```

2. Use `parallel-update` to apply the changes in the LDIF file to a target server. In this example, we use ten concurrent threads. The optimal number of threads depends on your underlying system. The `--ldifFile` and `--rejectFile` options are also required.

```
$ bin/parallel-update --hostname 127.0.0.1 \
  --ldifFile changes.ldif --rejectFile reject.ldif --numThreads 10
```

```
Reached the end of the LDIF file
Attempts Successes Rejects ToRetry AvgOps/S RctOps/S AvgDurMS RctDurMS
-----
         4         3         1         0         3         3         26         26
All processing complete Attempted 4 operations in 1 seconds
```

3. View the rejects file for any failed updates.

```
# ResultCode=53, Diagnostic Message=Pre-encoded passwords are not allowed
  for
# the password attribute userPassword
dn: uid=user.101,ou=People,dc=example,dc=com
changetype: add
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
postalAddress: Ziggy Zad$15172 Monroe Street$Salt Lake City, MI 49843
postalCode: 49843
description: This is the description for Ziggy Zad.
uid: user.101
userPassword: {SSHA}IK57iPozIQybmIJMMdRQOpIRudIDn2RcF6bDMg==
```

Working with the Watch-Entry Tool

The PingDirectory Server provides a **watch-entry** tool, which demonstrates replication or synchronization latency by watching an LDAP entry for changes. If the entry changes, the background of modified attributes will temporarily be red. Attributes can also be directly modified with this tool as well.

To Run the Watch-Entry Tool

Steps

- Perform the following to connect to **server.example.com** as **uid=admin,dc=example,dc=com** and watch entry **uid=kate,ou=people,dc=example,dc=com** for changes:

```
$ bin/watch-entry --hostname server.example.com --port 389 \
  --bindDN uid=admin,dc=example,dc=com --bindPassword password \
  --entryDN uid=user,ou=people,dc=example,dc=com
```

Working with LDAP Transactions

The PingDirectory Server provides support for *batched transactions*, which are processed all at once at commit time. Applications developed to perform batched transactions should include as few operations in the transaction as possible. The changes are not actually processed until the commit request is received. Therefore, the client cannot know whether the changes will be successful until commit time. If any of the operations fail, then the entire set of operations fails.

Batched transactions are write operations (add, delete, modify, modify DN, and password modify) that are processed as a single atomic unit when the commit request is received. If an abort request is received or an error occurs during the commit request, the changes are rolled back. The batched transaction mechanism supports the standard LDAP transaction implementation based on RFC 5805. It is not currently possible to process a transaction that requires changes to be processed across multiple servers or multiple Directory Server backends.

Directory servers may limit the set of controls that are available for use in requests that are part of a transaction. RFC 5805 section 4 indicates that the following controls may be used in conjunction with the transaction specification request control: assertion request control, manageDsaIT request control, pre-read request control, and post-read request control. The proxied authorization v1 and v2 controls cannot be included in requests that are part of a transaction, but they can be included in the start transaction request to indicate that all operations within the transaction should be processed with the specified authorization identity.

The PingDirectory Server supports the following additional controls in conjunction with operations included in a transaction: account usable request control, hard delete request control, intermediate client request control, password policy request control, replication repair request control, soft delete request control, soft deleted entry access request control, subtree delete request control, and undelete request control.

To Request a Batched Transaction Using `ldapmodify`

Steps

1. Use the `ldapmodify` tool's `--useTransaction` option. It provides a mechanism for processing multiple operations as part of a single batched transaction. Create a batch text file with the changes that you want to apply as a single atomic unit:

```
dn:uid=user.3,ou=People,dc=example,dc=com
changetype: delete
dn:uid=user.1,ou=People,dc=example,dc=com
changetype: modify
replace: pager
pager: +1 383 288 1090
```

2. Use `ldapmodify` with the `--useTransaction` and `--filename` options to run the batched transaction.

```
$ bin/ldapmodify --useTransaction --filename test.ldif
```

```
#Successfully created a transaction with transaction ID 400
#Processing DELETE request for uid=user.3,ou=People,dc=example,dc=com
#DELETE operation successful for DN uid=user.3,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Processing MODIFY request for uid=user.1,ou=People,dc=example,dc=com
#MODIFY operation successful for DN uid=user.1,ou=People,dc=example,dc=com
#This operation will be processed as part of transaction 400
#Successfully committed transaction 400
```

Working with Virtual Attributes

The PingDirectory Server provides mechanisms to support virtual attributes in an entry. Virtual attributes are abstract, dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend. While most virtual attributes are operational attributes, providing processing-related information that the server requires, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your directory server requirements.

This chapter presents the following topics:

Overview of Virtual Attributes

The PingDirectory Server allows its entries to hold virtual attributes. Virtual attributes are dynamically generated attributes that are invoked through an LDAP operation, such as `ldapsearch`, but are not stored in the Directory Server backend. Most virtual attributes are operational attributes, providing processing-related information that the server requires. However, the virtual attribute subsystem allows you to create user-defined virtual attributes to suit your requirements.

Viewing the List of Default Virtual Attributes

The Directory Server has a default set of virtual attributes that can be viewed using the `dsconfig` tool. Some virtual attributes are enabled by default and are useful for most applications. You can easily enable or disable each virtual attribute using the `dsconfig` tool.

The default set of virtual attributes are described in the table below. You can enable or disable these attributes using the `dsconfig` tool.

Virtual Attributes

Virtual Attributes	Description
ds-entry-checksum	Generates a simple checksum of an entry's contents, which can be used with an LDAP assertion control to ensure that the entry has not been modified since it was last retrieved.
ds-instance-name	Generates the name of the Directory Server instance from which the associated entry was read. This virtual attribute can be useful in load-balancing environments to determine the instance from which an entry was retrieved.
ds-pwp-state-json	Generates an operational attribute whose values is a JSON object with information about a user's current password policy state.
entryDN	Generates an <code>entryDN</code> operational attribute in an entry that holds a normalized copy of the entry's current distinguished name (DN). Clients can use this attribute in search filters.
hasSubordinates	Creates an operational attribute that has a value of TRUE if the entry has subordinate entries.
isDirectMemberOf	Generates an <code>isDirectMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member. <code>isDirectMemberOf</code> includes only static groups in which the user is explicitly named as a member. Compare to <code>isMemberOf</code> .
isMemberOf	Generates an <code>isMemberOf</code> operational attribute that contains the DNs of the groups in which the user is a member. <code>isMemberOf</code> includes all of the following: <ul style="list-style-type: none"> ▪ Static groups in which the user is explicitly named as a member ▪ Dynamic groups in which the user is a member because of the criteria for that group ▪ Static groups in which the user is a member because they are a member of a nested group that is listed as a member of the static group Compare to <code>isDirectMemberOf</code> .
numSubordinates	Generates an operational attribute that returns the number of child entries. While there is no cost if this operational attribute is enabled, there could be a performance cost if it is requested. Note that this operational attribute only returns the number of immediate children of the node.
subschemaSubentry	A special entry that provides information in the form of operational attributes about the schema elements defined in the server. It identifies the location of the schema for that part of the tree. <ul style="list-style-type: none"> ▪ <code>ldapSyntaxes</code> - set of attribute syntaxes ▪ <code>matchingRules</code> - set of matching rules ▪ <code>matchingRuleUse</code> - set of matching rule uses ▪ <code>attributeTypes</code> - set of attribute types ▪ <code>objectClasses</code> - set of object classes ▪ <code>nameForms</code> - set of name forms ▪ <code>dITContentRules</code> - set of DIT content rules ▪ <code>dITStructureRules</code> - set of DIT structure rules

Virtual Attributes	Description
User Defined Virtual Attribute	Generates virtual attributes with user-defined values in entries that match the criteria defined in the plugin's configuration. User-defined virtual attributes are intended to specify a hard-coded value for entries matching a given set of criteria.
Virtual Static Member	Generates a member attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the <code>Virtual Static Member</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.
Virtual Static Uniquemember	Generates a <code>uniqueMember</code> attribute whose values are the DNs of the members of a specified virtual static group. Virtual static groups are best used in client applications with a large number of entries that can only support static groups and obtains all of its membership from a dynamic group. Do not modify the filter in the <code>Virtual Static Uniquemember</code> attribute as it is an advanced property and modifying it can lead to undesirable side effects.

To View the List of Default Virtual Attributes Using `dsconfig` Non-Interactive Mode

Steps

- Use `dsconfig` to view the virtual attributes.

```
$ bin/dsconfig list-virtual-attributes
```

Viewing Virtual Attribute Properties

Each virtual attribute has basic properties that you can view using the `dsconfig` tool. The complete list of properties is described in the *PingDirectory Server Configuration Reference*. Some basic properties are as follows:

- Description.** A description of the virtual attribute.
- Enabled.** Specifies whether the virtual attribute is enabled for use.
- Base-DN.** Specifies the base DNs for the branches containing entries that are eligible to use this virtual attribute. If no values are given, the server generates virtual attributes anywhere in the server.
- Group-DN.** Specifies the DNs of the groups whose members can use this virtual attribute. If no values are given, the group membership is not taken into account when generating the virtual attribute. If one or more group DNs are specified, then only members of those groups are allowed to have the virtual attribute.
- Filter.** Specifies the filters that the server applies to entries to determine if they require virtual attributes. If no values are given, then any entry is eligible to have a virtual attribute value generated.

To View Virtual Attribute Properties

Steps

- Use `dsconfig` to view the properties of a virtual attribute.

```
$ bin/dsconfig get-virtual-attribute-prop --name isMemberOf
```

Enabling a Virtual Attribute

You can enable a virtual attribute using the `dsconfig` tool. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

To Enable a Virtual Attribute using dsconfig Interactive Mode

Steps

1. Use `dsconfig` to enable a virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.

```
bin/dsconfig
```

2. On the Directory Server main menu, type `o` to change the object menu, and then type the number corresponding to **Standard**.
3. On the Directory Server main menu, type the number corresponding to virtual attributes.
4. On the **Virtual Attribute management** menu, type the number to view and edit an existing virtual attribute.
5. From the list of existing virtual attributes on the system, select the virtual attribute to work with. For this example, type the number corresponding to the `numSubordinates` virtual attribute.
6. On the **numSubordinates Virtual Attribute Properties** menu, type the number to enable the virtual attribute. On the **Enabled Property** menu for the `numSubordinates` virtual attribute, type the number to change the value to TRUE.
7. On the **numSubordinates Virtual Attribute Properties** menu, type `f` to apply the changes.
8. Verify that the virtual attribute is enabled. Note that this example assumes you have configured the group entries.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(ou=People)" numSubordinates
```

```
dn: ou=People,dc=example,dc=com
numSubordinates: 1000
```

To Enable a Virtual Attribute Using dsconfig Non-Interactive Mode

Steps

- Use `dsconfig` to enable the `numSubordinates` virtual attribute.

```
$ bin/dsconfig set-virtual-attribute-prop \
  --name numSubordinates --set enabled:true
```

Creating User-Defined Virtual Attributes

User-defined virtual attributes allow you to specify an explicit value to use for the virtual attribute. There are no restrictions on the length of the value for a user-defined virtual attribute. You must only ensure that the new virtual attribute conforms to your schema, otherwise you will see an error message when you configure it.

You can define your virtual attributes using the `dsconfig` tool on the Standard object menu. Only the value property is specific to the user-defined virtual attribute. All the other properties are common across all kinds of virtual attributes, which include the following:

- **enabled** -- Indicates whether the virtual attribute should be used.
- **attribute-type** -- The attribute type for the virtual attribute that will be generated.
- **base-dn, group-dn, filter** -- May be used to select which entries are eligible to contain the virtual attribute.
- **client-connection-policy** -- May be used to configure who can see the virtual values.
- **conflict-behavior** -- Used to indicate how the server should behave if there are one or more real values for the same attribute type in the same entry. The server can either return only the real value(s), only the virtual value(s), or merge both real and virtual values.

- **require-explicit-request-by-name** -- Used to indicate whether the server should only generate values for the virtual attribute if it was included in the list of requested attributes.
- **multiple-virtual-attribute-evaluation-order-index, multiple-virtual-attribute-merge-behavior** -- Used to control the behavior the server should exhibit if multiple virtual attributes may be used to contribute values to the same attribute.

To Create a User-Defined Virtual Attribute in Interactive Mode

About this task

The following example shows how to create a user-defined virtual attribute that assigns an Employee Password Policy to any entry that matches the filter "(employeeType=employee)".

Steps

1. Run **dsconfig** to configure the user-defined virtual attribute. Specify the connection port, bind DN, password, and host information. Then type the LDAP connection parameter for your Directory Server: 1 for LDAP, 2 for SSL, 3 for StartTLS.
2. On the Directory Server main menu, type **o** to change the object menu, and then type the number to select Standard.
3. On the Directory Server main menu, type the number corresponding to virtual attributes.
4. On the **Virtual Attribute management** menu, type the number to create a new virtual attribute.
5. Next, you can use an existing virtual attribute as a template for your new attribute, or you can create a new attribute from scratch. In this example, type **n** to create a new Virtual Attribute from scratch.
6. On the **Virtual Attribute Type** menu, enter a number corresponding to the type of virtual attribute that you want to create. In this example, type the number corresponding to User Defined Virtual Attribute.
7. Next, enter a name for the new virtual attribute. In this example, enter "Employee Password Policy Assignment."
8. On the **Enabled Property** menu, enter the number to set the property to true (enable).
9. On the **Attribute-Type Property** menu, type the `attribute-type` property for the new virtual attribute. You can enter the OID number or attribute name. The `attribute-type` property must conform to your schema. For this example, type "ds-pwp-password-policy-dn".
10. Enter the value for the virtual attribute, and then press Enter or Return to continue. In this example, enter `cn=Employee Password Policy,cn=Password Policies,cn=config`, and then type Enter or Return to continue.
11. On the **User Defined Virtual Attributes** menu, enter a description for the virtual attribute. Though optional, this step is useful if you plan to create a lot of virtual attributes. Enter the option to change the value, and then type a description of the virtual attribute. In this example, enter: Virtual attribute that assigns the Employee Password Policy to all entries that match (employeeType=employee).
12. On the **User Defined Virtual Attribute** menu, type the number corresponding to the filter.
13. On the **Filter Property** menu, enter the option to add one or more filter properties, type the filter, and then press Enter to continue. In this example, type (employeeType=employee). Press the number to use the filter value entered.
14. On the **User Defined Virtual Attribute** menu, type **f** to finish creating the virtual attribute.
15. Verify that the attribute was created successfully. Add the `employeeType=employee` attribute to an entry (e.g., `uid=user.0`) using **ldapmodify**. Add the `employeeType=contractor` attribute to another entry (e.g., `uid=user.1`).
16. Use **ldapsearch** to search for the user with the `employeeType=employee` attribute (e.g., `uid=user.0`). You will notice the `ds-pwp-password-policy-dn` attribute has the assigned password policy as its value.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" \
```

```
ds-password-policy-dn
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ds-pwp-password-policy-dn: cn=Employee Password Policy,cn>Password
Policies,cn=config
```

17. Run `ldapsearch` again using the filter `"(uid=user.1)"`, the `ds-pwp-password-policy-dn` attribute will not be present in the entry, because the entry has the attribute, `employeeType=contractor`.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.1)" \
ds-password-policy-dn
```

```
dn: uid=user.1,ou=People,dc=example,dc=com
```

To Create a User-Defined Virtual Attribute Using `dsconfig` in Non-Interactive Mode

Steps

- You can also use `dsconfig` in non-interactive command-line mode to create a virtual attribute. The following command sets up the Employee Password Policy Assignment virtual attribute introduced in the previous section:

```
$ bin/dsconfig create-virtual-attribute \
--name "Employee Password Policy Assignment" \
--type user-defined \
--set enabled:true \
--set attribute-type:ds-pwp-password-policy-dn \
--set "filter:(employeeType=employee)" \
--set "value:cn=Employee Password Policy,cn>Password Policies,cn=config"
```

Creating Mirror Virtual Attributes

The PingDirectory Server provides a feature to mirror the value of another attribute in the same entry or mirror the value of the same or a different attribute in an entry referenced by the original entry. For example, given a DIT where users have a `manager` attributed with a value of the DN of the employee as follows:

```
dn: uid=apeters,ou=people,dc=example,dc=com
objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
uid: apeters
... (more attributes) ...
```

You can set up a mirror virtual attribute, so that the returned value for the `managerName` virtual attribute can be the `cn` value of the entry referenced by the `manager` attribute as follows:

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)" \
dn: uid=apeters,ou=people,dc=example,dc=com

objectClass: person
objectClass: inetOrgPerson
objectClass: organizationalPerson
objectClass: top
manager:uid=jdoe,ou=people,dc=example,dc=com
managerName: John Doe
uid: apeters
... (more attributes not shown) ...
```

To Create a Mirror Virtual Attribute in Non-Interactive Mode

About this task

You can also use **dsconfig** in non-interactive command-line mode to create a mirror virtual attribute. The following example sets up the `managerName` virtual attribute introduced in the previous section:

Steps

1. Update the schema to define the `managerName` attribute. In a text editor, create a file with the following schema definition for the attribute and save it as `98-myschema.ldif`, for example, in the `<server-root>/config/schema` folder. You can optionally add the attribute to an object class.

```
dn: cn=schema
objectClass: top
objectClass: ldapSubentry
objectClass: subschema attributeTypes: ( 1.3.6.1.4.1.32473.3.1.9.4 NAME
'managerName'
EQUALITY caseIgnoreMatch SUBSTR caseIgnoreSubstringsMatch SYNTAX
1.3.6.1.4.1.1466.115.121.1.44{256}
X-ORIGIN 'Directory Server Example' )
```

2. Restart the Directory Server.

```
$ bin/stop-server --restart
```

3. Use **dsconfig** to create the virtual attribute.

```
$ bin/dsconfig create-virtual-attribute \
--name "managerName" \
--type mirror \
--set "description:managerName from manager cn" \
--set enabled:true \
--set attribute-type:managerName \
--set source-attribute:cn \
--set source-entry-dn-attribute:manager
```

4. Verify the mirror virtual attribute by searching for an entry.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=apeters)"
```

```
dn: uid=apeters,ou=People,dc=example,dc=com
... (attributes) ...
manager: uid=jdoe,ou=People,dc=example,dc=com
managerName: John Doe
```

Editing a Virtual Attribute

You can edit virtual attributes by using the **dsconfig** tool. Ensure that the virtual attribute conforms to your plugin schema. Otherwise, an error message appears when you attempt to edit the virtual attribute. If you are using **dsconfig** in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

To Edit a Virtual Attribute Using dsconfig in Non-Interactive Mode

Steps

- Use **dsconfig** to change a property's value.

```
$ bin/dsconfig set-virtual-attribute-prop --name dept-number \
--set "value:111"
```

Deleting a Virtual Attribute

You can delete virtual attributes using the `dsconfig` tool. If you are using `dsconfig` in interactive command-line mode, you can access the virtual attribute menu on the Standard object menu.

To Delete a Virtual Attribute

Steps

- Use `dsconfig` to delete an existing virtual attribute.

```
$ bin/dsconfig delete-virtual-attribute --name dept-number
```

Working with Composed Attributes.

PingDirectory Server's support for virtual attributes is a useful facility that can dynamically generate values in entries for a wide range of use cases. These are used to generate key operational attributes like `entryDN`, `subschemaSubentry`, `isMemberOf`, `numSubordinates`, `hasSubordinates`, and `ds-entry-checksum`. The values of other attributes in the same or different entries can be mirrored, and values can be constructed from other attributes in the same entry. Items such as password policies and privileges can be dynamically, and it is also possible to create custom virtual attribute providers with the Server SDK using a wide variety of logic.

However, virtual attributes are not an ideal solution for all use cases. This section provides information on composed attributes, which dynamically generate attribute values to complement virtual attributes. Composed attributes are suited for some scenarios that virtual attributes do not support.

Virtual Attribute Limitations

Performance Limitations

There may be performance limitations associated with generating virtual attributes. Although the performance impact of actually generating the values is limited by only computing these values if they are to be returned to the client, there can still be a noticeable impact on performance. In addition, virtual attributes may be included or excluded based on a range of criteria and the evaluation of this criteria (for example, based on group membership) may impact performance..

Indexing Limitations

Virtual attributes do not mix well with indexing. You cannot index the values of a virtual attribute since these values can change from one invocation to the next.

Some virtual attributes do implement support for an index-like functionality in that they offer logic that may be able to quickly identify entries that have specified virtual attribute values. These include the following:

- When mirroring values from another attribute in the same entry, and when that source attribute type is indexed, the mirror virtual attribute provider can use an internal search to identify matching entries.
- The `entryDN` virtual attribute provider can retrieve the entry with the specified DN.
- The `isMemberOf` virtual attribute provider can use the server's group manager to identify the members of a targeted group.

However, this is not an option for all types of virtual attributes. For example, it is not available for user-defined virtual attributes that have a static value, for constructed virtual attributes whose values are composed from multiple other attributes in the same entry, for mirror virtual attributes whose values come from other entries, or for any custom virtual attribute types implemented using the Server SDK.

In addition, there is not a good solution for the case where you want to have a mix of real and virtual values for the same attribute type (whether in the same entry or in different entries). If you define an index for that

attribute type, it will only include entries with real values; entries with virtual values will be overlooked. On the other hand, if there is no index but the virtual attribute provider does support some search functionality, only entries with virtual values will be matched and entries with only real values will be excluded.

Unexpected Behavior for Write Operations

Another significant issue with virtual attributes is that they can result in unexpected behaviors when targeted by write operations. These behaviors include the following:

- Attempting to delete a virtual value will fail with a “no such attribute” result.
- If the virtual attribute provider is configured with a conflict-behavior of real-overrides-virtual, then attempting to add a value to an entry that only has virtual values will cause the virtual values to disappear.
- If the virtual attribute provider is configured with a conflict-behavior of real-overrides-virtual, then attempting to remove all real values of an entry will cause the virtual values to appear.
- If the virtual attribute provider is configured with a conflict-behavior of virtual-overrides-real, then attempting to add new values or replace the set of existing values will yield a success result, but the operation will have no visible effect on the entry.
- If the virtual attribute provider is configured with a conflict-behavior of merge-real-and-virtual, then attempting to replace the set of values for an entry will yield a success result, but only the real values will have been replaced, and the virtual values will remain.

There is currently no method to prevent attempts to write to attributes with virtual values. The NO-USER-MODIFICATION constraint in attribute type definitions is honored, but this constraint can only be applied to operational attribute types; this is not an acceptable limitation in many cases. Access control restrictions could work for many clients, but will not have any effect for requesters with the bypass-acl privilege.

Overview of Composed Attributes

Composed attributes are generated when an entry is written. This includes entries that are created by add operations and LDIF imports; these may also be created, updated, or removed when processing modify and modify DN operations. The server may optionally permit or reject attempts to alter the generated values.

Composed values are based solely on a combination of static text and the contents of the entry in which the value is to be generated. It is not possible to construct values using content from other entries in the server, as the necessary content may not be available at the time the value is to be generated (for example, if the referenced entry does not yet exist), and it would also be difficult to ensure that the value is kept up to date whenever the referenced entry changes or is removed. Values are generated using the same logic that is available for constructed virtual attributes, as well as for constructed attribute mapping functionality in the Synchronization Server.

The composed attribute functionality is implemented using a plugin. The plugin is invoked during the pre-operation phases for add, modify, and modify DN operations, and it also operates during LDIF import.

The server also provides an administrative task that can be used to iterate through all entries in a backend and generate values as necessary. This is useful when a new composed attribute plugin instance is created after the backend has already been populated and you do not wish to export the data to LDIF and re-import.

The server does not provide any first-class extensibility mechanisms for composed attributes. Unlike virtual attributes, which can be created through the Server SDK, composed attribute support is intentionally limited to what can be provided by the server. You can implement your own plugins to generate your own data if necessary.

Composed Attribute Plugin Configuration Properties

The composed attribute plugin provides the following configuration properties:

- **plugin-type** - The plugin type values for which the server will be registered. This is a mandatory multi-valued property with a default that includes all of the `ldifimport`, `preoperationadd`, `preoperationmodify`, and `preoperationmodifydn` values. It is recommended in general that you do not override this default set, but this may be useful in some rare corner cases. The available options include:
 - `ldifimport` - Indicates that values should be generated for the target attribute in any appropriate entries created during LDIF import processing.
 - `preoperationadd` - Indicates that values should be generated for the target attribute in any appropriate entries created by add operations.
 - `preoperationmodify` - Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify operations.
 - `preoperationmodifydn` - Indicates that values should be generated or altered for the target attribute in any appropriate entries updated by modify DN operations.
- **attribute-type** - The name or OID of the attribute type for which values are to be generated. This attribute type must be defined in the schema. This is a mandatory, single-valued property with no default. If multiple composed attribute types are desired, then a separate instance of the plugin should be configured for each. However, if multiple values should be composed for the same attribute type from different sets of source attributes, then a single instance of the plugin is recommended with multiple value patterns.
- **value-pattern** - The value pattern that specifies the logic that should be used when constructing values. This pattern must be compatible with the format expected by the `com.unboundid.directory.server.sync.mapping.ConstructedValue` class. This is a mandatory, multi-valued property in which the order of the values will be preserved. If this is configured with multiple values, then the behavior the plugin should exhibit will be controlled by the `multiple-value-pattern-behavior` property. Note that a value pattern will only be used for an entry if that entry contains all of the attributes referenced in the value pattern. Also note that virtual attributes are not considered when generating values.
- **multiple-value-pattern-behavior** - The behavior that the server should exhibit if multiple `value-pattern` values are configured. This will be a single-valued property with a default value of `use-first-non-rejected-value-pattern-with-non-empty-values-but-may-reject`.

 **Note:** The primary reason that a rejection may occur is as a result of multivalued source attributes, but it could also occur if an unexpected error occurs while trying to generate values.

The available options include:

- `use-first-non-rejected-value-pattern-with-non-empty-values-but-may-reject` - Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result. If all value patterns yield empty results (for example, if the entry is missing at least one source attribute for each of the value patterns), then no composed value will be generated. If no value pattern yields a non-empty result but at least one is rejected, then the operation will fail, or the entry will be rejected if performing an LDIF import.
- `use-first-non-rejected-value-pattern-with-non-empty-values-and-never-reject` - Indicates that the server should only use values generated from the first value pattern that is not rejected and yields a non-empty result. If none of the value patterns yield non-empty results (regardless of whether any of them is rejected), then no composed value will be generated.
- `use-first-rejection-or-first-value-pattern-with-non-empty-values` - Indicates that the server should only use values generated from the first value pattern that yields non-empty results, but if a rejection is encountered before a non-empty result is obtained, then the operation (or LDIF entry) will be rejected. If none of the value patterns is not rejected and yields a non-empty result, then no composed value will be generated.
- `use-all-non-rejected-value-patterns-with-non-empty-values-but-may-reject` - Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry. As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns will be used. If none of the value patterns yielded non-empty results but none were rejected, then no composed value will be generated. If none of the value patterns

yielded non-empty results and at least one was rejected, then the operation will fail or the LDIF entry will be rejected.

- `use-all-non-rejected-value-patterns-with-non-empty-values-and-never-reject` - Indicates that the server should use all values generated by all of the value patterns that were not rejected for the entry. As long as at least one value pattern generated a non-empty result, then the entire set of values generated by all value patterns will be used. If none of the value patterns yielded non-empty results (regardless of whether any of them was rejected), then no composed value will be generated.
- `use-first-rejection-or-all-value-patterns-with-non-empty-values` - Indicates that the server should use all of the values generated by all of the value patterns as long as none of them is rejected. If any value pattern is rejected, then the operation will fail or the LDIF entry will be rejected. If none of the value patterns is rejected but none of them generates any values, then no composed values will be generated.
- `multi-valued-attribute-behavior` - The behavior that the server should exhibit if any of the attributes used in the value pattern have multiple values. Note that at most one source attribute may have multiple values; if multiple source attributes have multiple values, and if this property is configured to try to use all of them, then the attempt to generate composed values for the entry may fail. This will be a single-value property with a default value of `use-all-values-if-possible-but-reject-if-not`. Available options include:
 - `use-first-value` - Indicates that the server should only use the first value for each source attribute referenced in the value pattern. With this value, entries should never be rejected for having multivalued attributes.
 - `reject-entries-with-any-multivalued-source-attribute` - Indicates that the server should reject any entry that has more than one value for any of the source attributes.
 - `use-all-values-if-possible-but-reject-if-not` - Indicates that the server should use all values for the source attributes, as long as at most one of them has multiple values. If multiple source attributes have multiple values, the entry will be rejected.
 - `use-all-values-if-possible-but-only-first-value-if-not` - Indicates that the server should use all values for the source attributes, as long as at most one of them has multiple values. If multiple source attributes have multiple values, then only the first value from each source attribute will be used so that the entry will not be rejected.
- `target-attribute-exists-during-initial-population-behavior` - The behavior that the server should exhibit for add operations and LDIF imports for entries that already contain one or more values for the target attribute. This will be a single-valued property with a default of `preserve-existing-values`. The available options include:
 - `preserve-existing-values` - Indicates that the server should preserve existing values in entries that are added or imported, and should only construct values for entries that do not already contain the target attribute.
 - `overwrite-existing-values` - Indicates that the server should only use generated values for the target attribute and that any values provided during an add or LDIF import will be discarded.
 - `merge-existing-and-composed-values` - Indicates that the server should preserve any existing values for the target attribute, but should also construct any additional values.

 **Note:** This option may only be used if the target attribute type allows multiple values.

- `reject-existing-values-in-add-but-preserve-in-ldif-import` - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but that it should preserve any existing values when performing an LDIF import. Note that the server will not reject entries that already contain the target attribute when performing an LDIF import since this would interfere with

the ability to export data to LDIF from a server that contains composed values and then re-import the LDIF file.

- `reject-existing-values-in-add-but-overwrite-in-ldif-import` - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but that it should replace any existing values in an LDIF import with the values which would be composed for that entry.
- `reject-existing-values-in-add-but-merge-in-ldif-import` - Indicates that the server should reject any add operation that attempts to provide any values for the target attribute, but should preserve any existing values when performing an LDIF import and add any additional values that should be composed for the entry.
- `update-source-attribute-behavior` - The behavior that the server should exhibit for entries that are updated by modify or modify DN operations that alter values for one of the attributes used in the value pattern. This will be a single-valued property with a default of `replace-composed-values`. The available options include:
 - `replace-composed-values` - Indicates that the server should only update values for the target attribute that match those that would have been generated by the plugin. Values that would not have been generated by the plugin will be preserved.
 - `replace-all-values` - Indicates that the server should always replace the target attribute with new composed values, even if the existing values were not generated by the plugin.
 - `preserve-existing-values` - Indicates that the server should always preserve the existing values for the target attribute, even if they were generated by the plugin.
- `source-attribute-removal-behavior` - The behavior that the server should exhibit when an entry is updated in a manner that removes one or more source attributes needed to compose values for the target attribute. This will be a single-valued property with a default of `preserve-non-composed-values`. The available options include:
 - `preserve-non-composed-values` - Indicates that the server will attempt to remove any values for the target attribute that would have been generated for that entry by the associated value patterns, but that it will preserve any other values that may exist for the target attribute. However, if the target attribute is required by any of the object classes in the entry and if that entry only contains composed values for the target attribute, then the composed values will be preserved to avoid violating the schema.
 - `preserve-all-values` - Indicates that the server will preserve any values that exist for the target attribute, regardless of whether they would have been composed by any of the value patterns.
 - `remove-all-values-but-preserve-all-if-required` - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of `preserve-all-values` if the target attribute type is required by any of the entry's object classes.
 - `remove-all-values-but-preserve-non-composed-values-if-required` - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of `preserve-non-composed-values` if the target attribute type is required by any of the entry's object classes.
- `update-target-attribute-behavior` - The behavior that the server should exhibit when a client attempts to alter the target attribute with a modify or modify DN operation. This will be a single-valued property with a default of `always-allow`. The available options include
 - `always-allow` - Indicates that the server will always permit clients to alter the value of the target attribute, regardless of whether these values were generated.
 - `allow-only-for-non-composed-values` - Indicates that the server will only permit clients to alter values for the target attribute that were not generated by the plugin. Attempts to alter composed values will be rejected.
 - `never-allow` - Indicates that the server should reject any attempt to alter the target attribute, regardless of the values it may have.
- `include-base-dn` - A base DN that may be used to restrict the set of entries for which values will be composed. The include/exclude criteria configuration options are described in more detail below.

- `exclude-base-dn` - A base DN that may be used to restrict the set of entries for which values will be composed. The `include/exclude` criteria configuration options are described in more detail below.
- `include-filter` - A search filter that may be used to restrict the set of entries for which values will be composed. The `include/exclude` criteria configuration options are described in more detail below.
- `exclude-filter` - A search filter that may be used to restrict the set of entries for which values will be composed. The `include/exclude` criteria configuration options are described in more detail below.
- `updated-entry-newly-matches-criteria-behavior` - The behavior that the server should exhibit if an entry that previously did not satisfy either the base DN or filter criteria, but is updated so that it does match any configured base DN or filter criteria. This will be a single-valued property with a default value of `preserve-existing-values-and-compose-new-values`. The available options include:
 - `preserve-existing-values-without-composing-new-values` - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and no additional composed values will be added. If the entry did not contain the target attribute, then no composed values will be generated for the entry.
 - `preserve-existing-values-or-compose-new-values` - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and no additional composed values will be added. However, if the entry did not contain the target attribute, then composed values will be generated for the entry.
 - `preserve-existing-values-and-compose-new-values` - Indicates that if the entry already had one or more values for the target attribute, those values will be preserved and any additional values that would be composed for that entry will also be added. If the entry did not contain the target attribute, then composed values will be generated for the entry.
 - `compose-new-values-without-preserving-existing-values` - Indicates that if the entry already had one or more composed values for the target attribute, then those values will be removed and replaced with the composed values that would be generated for it. If the entry did not contain the target attribute, then composed values will be generated for it. If no composed values would be generated for the entry (for example, if it was missing at least one source attribute for each value pattern), then the entry will not include the target attribute, regardless of whether it contained existing values for the attribute.
- `updated-entry-no-longer-matches-criteria-behavior` - The behavior that the server should exhibit if an entry previously satisfied the configured base DN and filter criteria but has been updated so that it no longer matches that criteria. This will be a single-valued property with a default of `preserve-all-values`. The available options include:
 - `preserve-all-values` - Indicates that the server will preserve any values that exist for the target attribute, regardless of whether they would have been composed by any of the value patterns.
 - `preserve-non-composed-values` - Indicates that the server will attempt to remove any values for the target attribute that would have been generated for that entry by the associated value patterns, but will preserve any other values that may exist for the target attribute. However, if the target attribute is required by any of the object classes in the entry, and if that entry only contains composed values for the target attribute, then the composed values will be preserved to avoid violating the schema.
 - `remove-all-values-but-preserve-all-if-required` - Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of `preserve-all-values` if the target attribute type is required by any of the entry's object classes.
 - `remove-all-values-but-preserve-non-composed-values-if-required` —Indicates that the server will attempt to remove all values for the target attribute from the entry, regardless of whether they would have been composed, but that it will fall back to a behavior of `preserve-non-composed-values` if the target attribute type is required by any of the entry's object classes.

By default, attribute values will be composed for every entry in any public backend that contains all of the source attributes used in the appropriate value patterns. If you wish to restrict composed values to a specific set of entries, that can be done with the `include-base-dn`, `exclude-base-dn`, `include-filter`, and `exclude-filter` properties.

If the `include-base-dn` property is provided, then values will only be composed for entries at or below one of those base DN's. If the `exclude-base-dn` property is provided, then values will not be composed for any entries at or below one of those base DN's. If both properties are provided and a given entry resides below both an include and an exclude base DN, then the exclude base DN will take precedence, and values will not be generated for that entry. If neither property is specified, then the naming contexts of all public backends will be used as the default set of include base DN's.

If the `include-filter` property is provided, then values will only be composed for entries that match at least one of those filters. If the `exclude-filter` property is provided, then values will not be composed for any entries that match at least one of those filters. If both properties are provided and a given entry matches both include and exclude filters, then the exclude filter will take precedence, and values will not be generated for that entry. If neither property is specified, then the server will behave as if an include filter of “(&)” had been specified. Note that no virtual attributes will be considered when evaluating this filter, although composed values may be taken into consideration. See [Composed Attribute Dependency Considerations](#) on page 736 for more information about the order in which composed attribute definitions will be evaluated.

Populate Composed Attribute Values Task

When a composed attribute plugin is created in the server, it takes effect immediately and starts creating values for any appropriate add, modify, and modify DN operations. However, existing entries will not automatically be populated with generated values. This can be achieved by exporting the data to LDIF and re-importing it, but this would require temporarily taking each instance out of service since importing into a single instance will have no effect on the data in other instances. The LDIF import option is really only feasible when you are starting from scratch, not when you have existing data. To address this need, a “populate composed attribute values” task is provided. This task iterates through all entries in one or more backends and generates values as appropriate for any entries.

This task provides several number of configuration attributes, including the following:

- `ds-task-populate-composed-attribute-plugin-config` - An optional, multi-valued attribute that can be used to specify the names or DN's of the composed attribute plugin configuration entries for which values should be generated. If this attribute is omitted, then values will be generated for all defined and enabled composed attribute plugin instances.
- `ds-task-populate-composed-attribute-backend-id` - An optional, multi-valued attribute that may be used to specify the backend ID's of the backends in which values should be generated. If this attribute is omitted, then an appropriate set of backends will be determined based on the include and exclude base DN's for the selected plugins.
- `ds-task-populate-composed-attribute-max-rate-per-second` - An optional, single-valued integer attribute that can be used to specify the maximum number of entries to be updated per second. If this attribute is omitted, then no rate limit will be imposed.

The task uses the same logic that the plugin uses for entries imported from LDIF when deciding what values to include in the entry, but it will use internal modify operations to make any necessary updates to the entry. These changes will be replicated to other servers in the topology, so the task only needs to be invoked on a single instance. However, it is recommended running it only after the composed attribute plugins have been configured on all instances in the topology, as this will ensure that no entries (including those added or updated while the task is running) are overlooked.

A `populate-composed-attribute-values` command-line tool that can be used to invoke the task and monitor its progress is provided. Since this processing is not expected to be needed on a regular basis, this is not offered as a recurring task.

Composed Attribute Dependency Considerations

Composed attributes must not have any dependency on virtual attributes. The server will not use virtual attribute values when generating values from a value pattern, and it will also not use virtual attribute values when determining whether an entry matches an include or exclude filter.

There is normally no need to have one composed attribute depend on another. If one composed attribute is constructed from other attributes in the entry, then another composed attribute that needs to use another composed attribute as its source can simply include the value pattern for that first composed attribute as part of its own value pattern. However, this may not be sufficient if the composed values can be overridden by clients.

If there is a reason that one composed attribute needs to depend on another, then it should be sufficient to ensure that the following requirements are satisfied:

- Any composed attribute plugins that have dependencies should be configured so that they will be invoked in the appropriate order. This may be accomplished through the `plugin-order-ldif-import`, `plugin-order-pre-operation-add`, `plugin-order-pre-operation-modify`, and `plugin-order-pre-operation-modify-dn` properties in the plugin root configuration.
- The populate composed attribute values task should be run separately for each of the attributes to be generated. The first run should be to generate values for any composed attributes that are not dependent on any other composed attributes. The second run should generate values for any composed attributes that were created during the first run. If multiple levels of nesting are required, then additional runs of the task will also be required.

Schema Validation Considerations

The server only generates composed attributes for entries in which that attribute is allowed to be present. For user attributes, `tist` means that the target attribute type must be permitted by at least one of the object classes associated with the entry. If an entry does not have any object class that permits the target attribute, then an attempt to generate composed values for the entry will fail with an `objectClassViolation (65)` result. This restriction does not exist for operational attributes.

The server allows composed attributes to satisfy mandatory attribute requirements. That is, if the target attribute is declared as a `MUST` type for any of the entry's object classes, then it must be possible for a client to add an entry that does not include any values for that attribute type as long as the server will compose a value for that attribute.

The server also enforces attribute syntax restrictions for composed attributes. If a composed attribute would violate the syntax for the associated attribute type, then the operation that would result in that composed attribute value is rejected with an `INVALID_ATTRIBUTE_SYNTAX` result. This may be overridden on a per-attribute-type basis using the `permit-syntax-violations-for-attribute` property in the global configuration.

Note: If this option is used to permit values that violate the associated syntax, then matching operations involving malformed values may not behave in a predictable manner,

The server should also enforce the `SINGLE-VALUE` constraint for the target attribute type. If an attribute type is defined with this constraint, it is not possible to configure the composed attribute plugin in a manner that could generate multiple values for that attribute and any operation that would result in multiple values for the target attribute is rejected.

Composed attributes cannot set values for operational attributes that are defined with the `NO-USER-MODIFICATION` constraint.

Replication Considerations

The composed attribute configuration should be identical for all servers in the replication topology. Whenever a composed attribute plugin is configured for one instance, the same definition should be added to all other instances in the topology.

Composed attribute values should only be generated for the server that processes the request from the client. When that operation is replicated to other servers, the composed attribute changes should be included as part of that operation.

Replicated changes involving composed attributes should not be subject to restrictions that would prevent external clients from writing to those values. This includes composed values for operational attribute types with the NO-USER-MODIFICATION constraint as well as for cases in which the plugin forbids clients from modifying values.

Note: The plugin rejects any modify DN operation that alters source attributes in a way that would result in composed attribute changes.

Synchronization Server Considerations

There should not be any issues synchronizing changes involving composed attributes from a PingDirectory Server instance to some other type of endpoint. Changes that create or update composed attributes should be written to the LDAP changelog, just like changes to regular attributes.

Synchronization to a PingDirectory Server configured with one or more composed attribute plugin instances may be more problematic. In particular, it may not be possible to a composed attribute type if the plugin that generates values for that attribute is configured to prohibit external clients from altering values of that attribute.

If the PingDirectory Server is used as a sync destination in an environment in which some attribute values may need to be composed, then it may be desirable to compose those values in the Synchronization Server using a constructed attribute mapping rather than attempting to generate them in the Directory Server with the composed attribute plugin.

Directory Proxy Server Considerations

The use of PingDirectoryProxy Server is not expected to require any special consideration in an environment involving composed attributes. This should be true for both simple and entry-balanced proxy configurations.

Troubleshooting Considerations

For operations that are rejected for reasons related to composed attribute processing (for example, if an add, modify, or modify DN operation is rejected because the composed value would have violated the syntax for the target attribute type, or if an attempt was made to alter a composed attribute value in a way that is not permitted by the plugin), the diagnostic message is returned to the client and included in the access log.

The composed attribute plugin also contains detailed debug logging support. If you encounter unexpected behavior when using the composed attribute plugin, you should enable debugging for the plugin to provide information to help diagnose the problem.

Security Considerations

The primary security consideration for composed attributes is that they may expose the values of other attributes. For example, if the cn attribute is composed from the values of the givenName and sn attributes, then a user with permission to read the cn attribute could determine the values of the givenName and sn attributes even if they do not have permission to read these attributes directly. However, this is not usually a significant concern and you can address this by ensuring that the user's access-control configuration restricts access to source attributes used in a composed attribute value pattern and imposes similar restrictions to the composed attribute.

Limitations of Composed Attributes Relative to Virtual Attributes

Composed attribute support provides an alternative to a specific set of use cases, and these use cases may also be addressed by virtual attribute support. While the composed attribute solution may provide

improvements in performance, searchability, and write behavior, it also has a number of limitations relative to the virtual attribute subsystem. Some of those limitations include:

- When creating a composed attribute plugin in the server, manual action is required to populate composed values in existing entries. When enabling a virtual attribute, the attribute is immediately available to clients.
- When removing a virtual attribute from the server, values that would have been generated for the attribute will no longer be present. When removing or disabling a composed attribute plugin, composed values that had already been generated will remain.
- Virtual attributes can be configured so that the values are only generated under certain conditions (for example, only for certain clients), and so that different values may be generated for different clients. Composed attributes will be the same for all clients (although access controls can be used to restrict which clients have access to them).
- Virtual attributes do not require any additional storage or memory usage. Composed attributes actually exist in the database and therefore require additional disk space and memory for caching.
- The composed attribute plugin can only generate values from a combination of static text and values from other attributes in the same entry. Virtual attributes can use a much wider range of logic when generating values, including custom logic implemented using the Server SDK.

Working with Groups

LDAP groups are special types of entries that represent collections of users. Groups are often used by external clients, for example, to control who has access to a particular application or features. They may also be used internally by the server to control its behavior. For example, groups can be used by the access control, criteria, or virtual attribute subsystems.

The specific ways in which clients create and interact with a particular group depends on the type of group being used. In general, there are three primary ways in which clients attempt to use groups:

- To determine whether a specified user is a member of a particular group.
- To determine the set of groups in which a specified user is a member.
- To determine the set of all users that are members of a particular group.

This chapter provides an overview of Directory Server groups concepts and provides procedures on setting up and querying groups in the Directory Server.

Overview of Groups

The Directory Server provides the following types of groups:

- **Static Groups.** A static group is an entry that contains an explicit list of member or uniquemember attributes, depending on its particular structural object class. Static groups are ideal for relatively small, infrequently changing elements. Once the membership list grows, static groups become more difficult to manage as any change in a member base DN must also be changed in the group. Static groups use one of three structural object classes: `groupOfNames`, `groupOfUniqueNames`, and `groupOfEntries`.

The Directory Server also supports nested groups, in which a parent group entry contains child attributes whose DNs reference another group. Nested groups are a flexible means to organize entries that provide inherited group membership and privileges. To maintain good performance throughout, a group cache is enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups.

- **Dynamic Groups.** A dynamic group has its membership list determined by search criteria using a LDAP URL. Dynamic groups solve the scalability issues encountered for static groups as searches are efficient, constant-time operations. However, if searches range over a very large set of data, performance could be affected.

- **Virtual Static Groups.** A virtual static group is a combination of both static and dynamic groups, in which each member in a group is a virtual attribute that is dynamically generated when invoked. Virtual static groups solve the scalability issues for clients that can only support static groups and are best used when the application targets a search operation for a specific member. Virtual static groups are not good for applications that need to retrieve the entire membership list as the process for constructing the entire membership list can be expensive.

About the `isMemberOf` and `isDirectMemberOf` Virtual Attribute

The existence of both static, nested, dynamic, and virtual static groups can make it unnecessarily complex to work with groups in the server, particularly because the ways you interact with them are so different. And the fact that static groups can use three different structural object classes (not counting the auxiliary class for virtual static groups) does not make things any easier.

To make group operations simpler, the PingDirectory Server provides the ability to generate either an `isMemberOf` and `isDirectMemberOf` virtual attributes in user entries. These attributes dramatically simplify the process for making group-related determinations in a manner that is consistent across all types of groups.

The value of the `isMemberOf` virtual attribute is a list of DNs of all groups (including static, nested, dynamic, and virtual static groups) in which the associated user is a member. The value of the `isDirectMemberOf` virtual attribute is a subset of the values of `isMemberOf`, which represents the groups for which the entry is an explicit or direct member. Both are enabled by default.

Because the `isMemberOf` and `isDirectMemberOf` are operational attributes, only users who specifically have been granted the privilege can see it. The default set of access control rules do not allow any level of access to user data. The only access that is granted is what is included in user-defined access control rules, which is generally given to a `uid=admin` administrator account. It is always a best practice to restrict access to operational and non-operational attributes to the minimal set of users that need to see them. The root bind DN, `cn=Directory Manager`, has the privilege to view operational attributes by default.

To determine whether a user is a member of a specified group using the `isMemberOf` virtual attribute, simply perform a base-level search against the user's entry with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group. The following table illustrates this simple base-level search:

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)</code>
Requested Attributes	<code>1.1</code>

If this search returns an entry, then the user is a member of the specified group. If no entry is returned, then the user is not a member of the given group.

To determine the set of all groups in which a user is a member, simply retrieve the user's entry with a base-level search and include the `isMemberOf` attribute:

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectclass=*)</code>
Requested Attributes	<code>isMemberOf</code>

To determine the set of all members for a specified group, issue a subtree search with an equality filter targeting the `isMemberOf` attribute with a value that is the DN of the target group and requesting the attributes you wish to have for member entries:

Base DN	ou=People,dc=example,dc=com
Scope	sub
Filter	(isMemberOf=cn=Test Group,ou=Groups,dc=example,dc=com)
Requested Attributes	cn, mail

The `isDirectMemberOf` virtual attribute can be used in the examples above in place of `isMemberOf` if you only need to find groups that users are an actual member of. You must use `isMemberOf` for nested group membership.

Note that if this filter targets a dynamic group using an unindexed search, then this may be an expensive operation. However, it will not be any more expensive than retrieving the target group and then issuing a search based on information contained in the member URL.

For static groups, this approach has the added benefit of using a single search to retrieve information from all user entries, whereas it would otherwise be required to retrieve the static group and then perform a separate search for each member's entry.

Using Static Groups

A static group contains an explicit membership list where each member is represented as a DN-valued attribute. There are three types of static groups supported for use in the Directory Server:

- groupOfNames.** A static group that is defined with the `groupOfNames` structural object class and uses the `member` attribute to hold the DNs of its members. RFC 4519 requires that the `member` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `member` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfNames` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
cn: Test Group
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

- groupOfUniqueNames.** A static group that is defined with the `groupOfUniqueNames` structural object class and uses the `uniquemember` attribute to hold the DNs of its members. RFC 4519 requires that the `uniquemember` attribute be required in an entry. However, the Directory Server has relaxed this restriction by making the `uniquemember` attribute optional so that the last member in the group can be removed. The following entry depicts a group defined with the `groupOfUniqueNames` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
cn: Test Group
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
uniquemember: uid=user.3,ou=People,dc=example,dc=com
```

- groupOfEntries.** A static group that is defined with the `groupOfEntries` object class and uses the `member` attribute to hold the DNs of its members. This group specifies that the `member` attribute is optional to ensure that the last member can be removed from the group. Although the draft proposal (draft-findlay-ldap-groupofentries-00.txt) has expired, the Directory Server supports this implementation. The following entry depicts a group defined with the `groupOfEntries` object class:

```
dn: cn=Test Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfEntries
cn: Test Group
```

```
member: uid=user.1,ou=People,dc=example,dc=com
member: uid=user.2,ou=People,dc=example,dc=com
member: uid=user.3,ou=People,dc=example,dc=com
```

Creating Static Groups

You can configure a static group by adding it using an LDIF file. Static groups contain a membership list of explicit DNs specified by the `uniquemember` attribute.

To Create a Static Group

Steps

1. Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniqueNames` object class and `uniquemember` attributes. If you did not have `ou=groups` set up in your server, then you can add it in the same file. When done, save the file as `static-group.ldif`. The following example LDIF file creates two groups, `cn=Development` and `cn=QA`.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups

dn: cn=Development,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Development
ou: groups
uniquemember: uid=user.14,ou=People,dc=example,dc=com
uniquemember: uid=user.91,ou=People,dc=example,dc=com
uniquemember: uid=user.180,ou=People,dc=example,dc=com

dn: cn=QA,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: QA
ou: groups
uniquemember: uid=user.0,ou=People,dc=example,dc=com
uniquemember: uid=user.1,ou=People,dc=example,dc=com
uniquemember: uid=user.2,ou=People,dc=example,dc=com
```

2. Use `ldapmodify` to add the group entries to the server.

```
$ bin/ldapmodify --defaultAdd --filename static-group.ldif
```

3. Verify the configuration by using the virtual attribute `isDirectMemberOf` that checks membership for a non-nested group. By default, the virtual attribute is disabled by default, but you can enable it using `dsconfig`.

```
$ bin/dsconfig set-virtual-attribute-prop --name isDirectMemberOf --set
enabled:true
```

4. Use `ldapsearch` to specifically search the `isDirectMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isDirectMemberOf
```

```
dn: uid=user.14,ou=People,dc=example,dc=com
isDirectMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

5. Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an `aci` attribute in an LDIF file, and save the file as `dev-group-aci.ldif`. Add the file

using the `ldapmodify` tool. You can create a similar ACI for the QA group, which is not shown in this example.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target ="ldap:///ou=People,dc=example,dc=com")
    (targetattr != "cn || sn || uid")
    (targetfilter ="(ou=Development)")
    (version 3.0; acl "Dev Group Permissions";
      allow (write) (groupdn = "ldap:///
cn=Development,ou=groups,dc=example,dc=com");)
```

6. Add the file using the `ldapmodify` tool.

```
$ bin/ldapmodify --filename dev-group-aci.ldif
```

To Add a New Member to a Static Group

Steps

- To add a new member to the group, add a new value for the `uniquemember` attribute that specifies the DN of the user to be added. The following example adds a new `uniquemember`, `user.4`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
add: uniquemember
uniquemember: uid=user.4,ou=People,dc=example,dc=com
```

To Remove a Member from a Static Group

Steps

- To remove a member from a static group, remove that user's DN from the `uniquemember` attribute. The following example removes the DN of `user.1`:

```
dn: cn=QA,ou=Groups,dc=example,dc=com
changetype: modify
delete: uniquemember
uniquemember: uid=user.1,ou=People,dc=example,dc=com
```

Searching Static Groups

The following sections describe how to compose searches to determine if a user is a member of a static group, to determine all the static groups in which a user is a member, and to determine all the members of a static group.

To Determine if a User is a Static Group Member

About this task

To determine whether a user is a member of a specified group, perform a base-level search to retrieve the group entry with an equality filter looking for the membership attribute of a value equal to the DN of the specified user.

For best performance, you will want to include a specific attribute list (just `cn`, or `1.1` request that no attributes be returned) so that the entire member list is not returned. For example, to determine whether the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the `groupOfNames` static group `cn=Test Group,ou=Groups,dc=example,dc=com`, issue a search with the following criteria:

Search Criteria for a Single User's Membership in a Static Group

Base DN	cn=Test Group,ou=Groups,dc=example,dc=com
Scope	base
Filter	(member=uid=john.doe,ou=People,dc=example,dc=com)
Requested Attributes	1.1

If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group. If you do not know the membership attribute for the specified group (it could be either a `member` or `uniqueMember` attribute), then you may want to revise the filter so that it allows either one as follows:

```
( | (member=uid=john.doe,ou=People,dc=example,dc=com)
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) )
```

Steps

- Run a base-level search to retrieve the group entry with an equality filter looking for the membership attribute.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com"
--searchScope base "(member=uid=john.doe,ou=People,dc=example,dc=com) "
"1.1"
```

To Determine the Static Groups to Which a User Belongs

About this task

To determine the set of all static groups in which a user is specified as a member, perform a subtree search based at the top of the DIT. The search filter must be configured to match any type of static group in which the specified user is a member.

For example, the following criteria may be used to determine the set of all static groups in which the user, `uid=john.doe,ou=People,dc=example,dc=com`, is a member:

Search Criteria for Determining All the Static Groups for a User

Base DN	dc=example,dc=com
Scope	sub
Filter	((&(objectClass=groupOfNames) (member=uid=john.doe,ou=People,dc=example,dc=com)) (&(objectClass=groupOfUniqueNames)(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com)) (&(objectClass=groupOfEntries) (member=uid=john.doe,ou=People,dc=example,dc=com))))
Requested Attributes	1.1

Every entry returned from the search represents a static group in which the specified user is a member.

Steps

- Run a sub-level search to retrieve the static groups to which a user belongs.

```
$ bin/ldapsearch --baseDN "dc=example,dc=com" --searchScope sub \
" ( | (&(objectClass=groupOfNames)
```

```
(member=uid=john.doe,ou=People,dc=example,dc=com) \
(&(objectClass=groupOfUniqueNames) \
(uniqueMember=uid=john.doe,ou=People,dc=example,dc=com) \
(&(objectClass=groupOfEntries) \
(member=uid=john.doe,ou=People,dc=example,dc=com))) "1.1"
```

Note: A base level search of the user's entry for `isMemberOf` or `isDirectMemberOf` virtual attributes will give the same results. You can also use the virtual attributes with virtual static groups.

To Determine the Members of a Static Group

About this task

To determine all of the members for a static group, simply retrieve the group entry including the membership attribute. The returned entry will include the DNs of all users that are members of that group. For example, the following criteria may be used to retrieve the list of all members for the group `cn=Test Group,ou=Groups,dc=example,dc=com`:

Search Criteria for All of the Static Group's Members

Base DN	<code>cn=Test Group,ou=Groups,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(objectClass=*)</code>
Requested Attributes	<code>member uniqueMember</code>

If you want to retrieve additional information about the members, such as attributes from member entries, you must issue a separate search for each member to retrieve the user entry and the desired attributes.

Steps

- Run a base-level search to retrieve all of the members in a static group.

```
$ bin/ldapsearch --baseDN "cn=Test Group,ou=Groups,dc=example,dc=com" \
--searchScope base "(objectclass=*)" uniqueMember
```

Note: If you want to retrieve attributes from member entries, it is more efficient to search all users whose `isMemberOf` attribute contains the group DN, returning the attributes desired.

Using Dynamic Groups

Dynamic groups contain a set of criteria used to identify members rather than maintaining an explicit list of group members. If a new user entry is created or if an existing entry is modified so that it matches the membership criteria, then the user will be considered a member of the dynamic group. Similarly, if a member's entry is deleted or if it is modified so that it no longer matches the group criteria, then the user will no longer be considered a member of the dynamic group.

In the Directory Server, dynamic groups include the `groupOfURLs` structural object class and use the `memberurl` attribute to provide an LDAP URL that defines the membership criteria. The base, scope, and filter of the LDAP URL will be used in the process of making the determination, and any other elements present in the URL will be ignored. For example, the following entry defines a dynamic group in which all users below `dc=example,dc=com` with an `employeeType` value of `contractor` will be considered members of the group:

```
dn: cn=Sales Group,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
```

```
cn: Sales Group
memberURL: ldap:///dc=example,dc=com??sub?(employeeType=contractor)
```

Assuming that less than 80,000 entries have the `employeeType` of `contractor`, you need to create the following index definition to evaluate the dynamic group:

```
$ bin/dsconfig create-local-db-index --backend-name userRoot \
  --index-name employeeType --set index-entry-limit:80000 \
  --set index-type:equality
```

Creating Dynamic Groups

You can configure a dynamic group in the same manner as static groups using an LDIF file. Dynamic groups contain a membership list of attributes determined by search filter using an LDAP URL. You must use the `groupOfURLs` object class and the `memberURL` attribute.

To Create a Dynamic Group

Steps

1. Assume that `uid=user.15` is not part of any group. Use `ldapsearch` to verify that `uid=user.15` is not part of any group. In a later step, we will add the user to the dynamic group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
"(uid=user.15)" ou
```

```
dn: uid=user.15,ou=People,dc=example,dc=com
```

2. Assume for this example that `uid=user.0` has an `ou=Engineering` attribute indicating that he or she is a member of the Engineering department.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub "(uid=user.0)"
ou isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
ou: Engineering
```

3. Open a text editor, and then create a dynamic group entry in LDIF. The LDIF defines the dynamic group to include all users who have the `ou=Engineering` attribute. When done, save the file as `add-dynamic-group.ldif`.

```
dn: cn=eng-staff,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfURLs
ou: groups
cn: eng-staff
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(ou=Engineering)
```

4. Use `ldapmodify` to add the group entry to the server.

```
$ bin/ldapmodify --defaultAdd --filename add-dynamic-group.ldif
```

5. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.0` is a member of the `cn=Engineering` group or any other group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.0)" isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

6. If your data is relatively small (under 1 million entries), you can search for all users in the group that meet the search criteria (`ou=Engineering`). For very large databases, it is not practical to run a database-wide search for all users as there can be a performance hit on the Directory Server. The

following command returns the DNs of entries that are part of the `cn=eng-staff` dynamic group and sorts them in ascending order by the `sn` attribute.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --sortOrder sn \
  "(isMemberOf=cn=eng-staff,ou=groups,dc=example,dc=com)" dn
```

7. Add `uid=user.15` to the `eng-staff` group by adding an `ou=Engineering` attribute to the entry. This step highlights an advantage of dynamic groups: you can make a change in an entry without explicitly adding the DN to the group as you would with static groups. The entry will be automatically added to the `eng-staff` dynamic group.

```
$ bin/ldapmodify
dn: uid=user.15,ou=People,dc=example,dc=com
changetype: modify
add: ou
ou: Engineering
```

8. Use `ldapsearch` to check if the user is part of the `cn=eng-staff` dynamic group.

```
$ bin/ldapsearch --baseDN dc=example,dc=com --searchScope sub
  "(uid=user.15)" isMemberOf
```

```
dn: uid=user.15,ou=People,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

Searching Dynamic Groups

The following sections describe how to compose searches to determine if a user is a member of a dynamic group, to determine all the dynamic groups in which a user is a member, and to determine all the members of a dynamic group.

To Determine if a User is a Dynamic Group Member

About this task

To determine whether a user is a member of a specific dynamic group, you must verify that the user's entry is both within the scope of the member URL and that it matches the filter contained in that URL. You can verify that a user's entry is within the scope of the URL using simple client-side only processing. Evaluating the filter against the entry on the client side can be more complicated. While possible, particularly in clients that are able to perform schema-aware evaluation, a simple alternative is to perform a base-level search to retrieve the user's entry with the filter contained in the member URL.

For example, to determine whether the user `uid=john.doe,ou=People,dc=example,dc=com` is a member of the dynamic group with the above member URL, issue a search with the following criteria:

Search Criteria for a Single User's Membership in a Dynamic Group

Base DN	<code>uid=john.doe,ou=People,dc=example,dc=com</code>
Scope	<code>base</code>
Filter	<code>(ou=Engineering)</code>
Requested Attributes	<code>1.1</code>

Note that the search requires the user DN to be under the search base defined in the `memberurl` attribute for the user to be a member. If the search returns an entry, then the user is a member of the specified group. If the search does not return any entries, then the user is not a member of the group.

To Determine the Dynamic Groups to Which a User Belongs

About this task

To determine the set of all dynamic groups in which a user is a member, first perform a search to find all dynamic group entries defined in the server. You can do this using a subtree search with a filter of "(objectClass=groupOfURLs)".

You should retrieve the `memberURL` attribute so that you can use the logic described in the previous section to determine whether the specified user is a member of each of those groups. For example, to find the set of all dynamic groups defined in the `dc=example,dc=com` tree, issue a search with the following criteria:

Search Criteria for Determining All of the Dynamic Groups for a User

Base DN	dc=example,dc=com
Scope	sub
Filter	(objectClass=groupOfURLs)
Requested Attributes	memberURL

Each entry returned will be a dynamic group definition. You can use the base, scope, and filter of its `memberURL` attribute to determine whether the user is a member of that dynamic group.

To Determine the Members of a Dynamic Group

About this task

To determine all members of a dynamic group, issue a search using the base, scope, and filter of the member URL. The set of requested attributes should reflect the attributes desired from the member user entries, or "1.1" if no attributes are needed.

For example, to retrieve the `cn` and `mail` attributes from the group described above, use the following search:

Search Criteria for Determining the Members of a Dynamic Group

Base DN	dc=example,dc=com
Scope	sub
Filter	(employeeType=contractor)
Requested Attributes	cn, mail

 **CAUTION:** Note that this search may be expensive if the associated filter is not indexed or if the group contains a large number of members.

Using Dynamic Groups for Internal Operations

You can use dynamic groups for internal operations, such as ACI or component evaluation. The Directory Server performs the `memberurl` parsing and internal LDAP search; however, the internal search operation may not be performed with access control rules applied to it.

For example, the following dynamic group represents an organization's employees within the same department:

```
dn: cn=department 202,ou=groups,dc=example,dc=com
objectClass: top
```

```
objectClass: groupOfURLs
cn: department 202
owner: uid=user.1,ou=people,dc=example,dc=com
owner: uid=user.2,ou=people,dc=example,dc=com
memberURL: ldap:///ou=People,dc=example,dc=com??sub?
(&(employeeType=employee)(departmentNumber=202))
description: Group of employees in department 202
```

The above group could be referenced from within the ACI at the `dc=example,dc=com` entry. For example:

```
dn:dc=example,dc=com
aci: (targetattr="employeeType")
  (version 3.0; acl "Grant write access to employeeType" ;
    allow (all) groupdn="ldap:///cn=department
    202,ou=groups,dc=example,dc=com";)
```

Any user matching the filter can bind to the server with their entry and modify the `employeeType` attribute within any entry under `dc=example,dc=com`.

Using Virtual Static Groups

Static groups can be easier to interact with than dynamic groups, but large static groups can be expensive to manage and require a large amount of memory to hold in the internal group cache. The Directory Server provides a third type of group that makes it possible to get the efficiency and ease of management of a dynamic group while allowing clients to interact with it as a static group. A *virtual static group* is a type of group that references another group and provides access to the members of that group as if it was a static group.

To create a virtual static group, create an entry that has a structural object class of either `groupOfNames` or `groupOfUniqueNames` and an auxiliary class of `ds-virtual-static-group`. It should also include a `ds-target-group-dn` attribute, whose value is the group from which the virtual static group should obtain its members. For example, the following will create a virtual static group that exposes the members of the `cn=Sales Group,ou=Groups,dc=example,dc=com` dynamic group as if it were a static group:

```
dn: cn=Virtual Static Sales Group,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfNames
objectClass: ds-virtual-static-group
cn: Virtual Static Sales Group
ds-target-group-dn: cn=Sales Group,ou=Groups,dc=example,dc=com
```

Note that you must also enable a virtual attribute that allows the `member` attribute to be generated based on membership for the target group. A configuration object for this virtual attribute does exist in the server configuration, but is disabled by default. To enable it, issue the following change:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
  --set enabled:true
```

If you want to use virtual static groups with the `groupOfUniqueNames` object class, then you will also need to enable the `Virtual Static uniqueMember` virtual attribute in the same way.

Creating Virtual Static Groups

If your application only supports static groups but has scalability issues, then using a virtual static group could be a possible solution. A virtual static group uses a virtual attribute that is dynamically generated when called after which the operations that determine group membership are passed to another group, such as a dynamic group. You must use the `ds-virtual-static-group` object class and the `ds-target-group-dn` virtual attribute.

Virtual static groups are best used when determining if a single user is a member of a group. It is not a good solution if an application accesses the full list of group members due to the performance expense at

constructing the list. If you have a small database and an application that requires that the full membership list be returned, you must also enable the `allow-retrieving-membership` property for the Virtual Static `uniqueMember` virtual attribute using the `dsconfig` tool.

To Create a Virtual Static Group

Steps

1. Open a text editor, and then create a group entry in LDIF. The entry contains the `groupOfUniqueNames` object class, but in place of the `uniqueMember` attribute is the `ds-target-group-dn` virtual attribute, which is part of the `ds-virtual-static-group` auxiliary object class. When done, save the file as `add-virtual-static-group.ldif`.

```
dn: cn=virtualstatic,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
objectclass: ds-virtual-static-group
ou: groups
cn: virtual static
ds-target-group-dn: cn=eng-staff,ou=groups,dc=example,dc=com
```

2. Use `ldapmodify` to add the virtual static group entry to the server.

```
$ bin/ldapmodify -h server1.example.com -p 389 -D
"uid=admin,dc=example,dc=com" \
-w password -a -f add-virtual-static-group.ldif
```

3. Use `dsconfig` to enable the Virtual Static `uniqueMember` attribute, which is disabled by default.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. In the previous section, we set up `uid=user.0` to be part of the `cn=eng-staff` dynamic group. Use `ldapsearch` with the `isMemberOf` virtual attribute to determine if `uid=user.0` is part of the virtual static group.

```
$ bin/ldapsearch -h server1.example.com -p 389 -D "cn=Directory Manager" \
-w secret -b dc=example,dc=com "(uid=user.0) isMemberOf
```

```
dn: uid=user.0,ou=People,dc=example,dc=com
isMemberOf: cn=virtualstatic,ou=groups,dc=example,dc=com
isMemberOf: cn=eng-staff,ou=groups,dc=example,dc=com
```

5. Use `ldapsearch` to determine if `uid=user.0` is a member of the virtual static group. You should see the returned `cn=virtualstatic` entry if successful.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.0,ou=People,dc=example,dc=com))"
```

6. Next, try searching for a user that is not part of the `cn=eng-staff` dynamic group (e.g., `uid=user.20`), nothing will be returned.

```
$ ldapsearch -h localhost -p 1389 -D "cn=Directory Manager" -w password \
-b "cn=virtualStatic,ou=Groups,dc=example,dc=com" \
"(&(objectclass=groupOfUniqueNames) \
(uniqueMember=uid=user.20,ou=People,dc=example,dc=com))"
```

Searching Virtual Static Groups

Because virtual static groups behave like static groups, the process for determining whether a user is a member of a virtual static group is identical to that of a member in a static group. Similarly, the process

for determining all virtual static groups in which a user is a member is basically the same as the process as that of real static groups in which a user is a member. In fact, the query provided in the static groups discussion returns virtual static groups in addition to real static groups, because the structural object class of a virtual static group is the same as the structural object class for a static group.

You can also retrieve a list of all members of a virtual static group in the same way as a real static group: simply retrieve the `member` or `uniqueMember` attribute of the desired group. However, because virtual static groups are backed by dynamic groups and the process for retrieving member information for dynamic groups can be expensive, virtual static groups do not allow retrieving the full set of members by default. The virtual attribute used to expose membership can be updated to allow this with a configuration change such as the following:

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static member" \
  --set allow-retrieving-membership:true
```

Because this can be an expensive operation, we recommend that the option to allow retrieving virtual static group membership be left disabled unless it is required.

Creating Nested Groups

The PingDirectory Server supports nested groups, where the DN of an entry that defines a group is included as a member in the parent entry. For example, the following example shows a nested static group (e.g., `cn=Engineering Group`) that has `uniqueMember` attributes consisting of other groups, such as `cn=Developers Group` and the `cn=QA Group` respectively.

```
dn: cn=Engineering Group,ou=Groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniqueMember: cn=Developers,ou=Groups,dc=example,dc=com
uniqueMember: cn=QA,ou=Groups,dc=example,dc=com
```

Nested group support is enabled by default on the Directory Server. To support nested groups without the performance hit, the Directory Server uses a group cache, which is also enabled by default. The cache supports static group nesting that includes other static, virtual static, and dynamic groups. The Directory Server provides a new monitoring entry for the group cache, `cn=Group Cache,cn=Monitor`.

In practice, nested groups are not commonly used for several reasons. LDAP specifications do not directly address the concept of nested groups, and some servers do not provide any level of support for them. Supporting nested groups in LDAP clients is not trivial, and many directory server-enabled applications that can interact with groups do not provide any support for nesting. If nesting support is not needed in your environment, or if nesting support is only required for clients but is not needed for server-side evaluation (such as for groups used in access control rules, criteria, virtual attributes, or other ways that the server may need to make a membership determination), then this support should be disabled.

To Create Nested Static Groups

Steps

1. The following example shows how to set up a nested static group, which is a static group that contains `uniqueMember` attributes whose values contain other groups (static, virtual static, or dynamic). Open a text editor, and then create a group entry in LDIF. Make sure to include the `groupOfUniqueNames` object class and `uniqueMember` attributes. If you did not have `ou=groups` set up in your server, then you can add it in the same file. When done, save the file as `nested-group.ldif`. Assume that the static groups, `cn=Developers Group` and `cn=QA Group`, have been configured.

```
dn: ou=groups,dc=example,dc=com
objectclass: top
objectclass: organizationalunit
ou: groups
```

```
dn: cn=Engineering Group,ou=groups,dc=example,dc=com
objectclass: top
objectclass: groupOfUniqueNames
cn: Engineering Group
uniquemember: cn=Developers,ou=groups,dc=example,dc=com
uniquemember: cn=QA,ou=groups,dc=example,dc=com
```

2. Use `ldapmodify` to add the group entry.

```
$ bin/ldapmodify --defaultAdd --filename nested-static-group.ldif
```

3. Verify the configuration by using the `isMemberOf` virtual attribute that checks the group membership for an entry. By default, the virtual attribute is enabled. Use `ldapsearch` to specifically search the `isMemberOf` virtual attribute to determine if `uid=user.14` is a member of the `cn=Development` group. In this example, assume that the administrator has the privilege to view operational attributes.

```
$ bin/ldapsearch --baseDN dc=example,dc=com "(uid=user.14)" isMemberOf
```

```
dn: uid=user.14,ou=People,dc=example,dc=com
isMemberOf: cn=Development,ou=groups,dc=example,dc=com
```

4. Typically, you would want to use the group as a target in access control instructions. Open a text editor, create an ACL in LDIF, and save the file as `eng-group-aci.ldif`.

```
dn: ou=People,dc=example,dc=com
changetype: modify
add: aci
aci: (target = "ldap:///ou=People,dc=example,dc=com")
      (targetattr != "cn || sn || uid")
      (targetfilter = "(ou=Engineering Group)")
      (version 3.0; acl "Engineering Group Permissions";
        allow (write) (groupdn = "ldap:///cn=Engineering
        Group,ou=groups,dc=example,dc=com");)
```

5. Add the file using the `ldapmodify` tool.

```
$ bin/ldapmodify --filename eng-group-aci.ldif
```

Note: When nesting dynamic groups, you cannot include other groups as members of a dynamic group. You can only support "nesting" by including the members of another group with a filter in the member URL. For example, if you have two groups `cn=dynamic1` and `cn=dynamic2`, you can nest one group in another by specifying it in the member URL as follows:

```
cn=dynamic1,ou=groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
memberURL: ldap:///dc=example,dc=com??sub?
(isMemberOf=cn=dynamic2,ou=groups,dc=example,dc=com)
```

The members included from the other group using this method are not considered "nested" members and will be returned even when using `isDirectMemberOf` when retrieving the members.

Maintaining Referential Integrity with Static Groups

The Directory Server can automatically update references to an entry whenever that entry is removed or renamed in a process called *referential integrity*. For example, if a user entry is deleted, then referential integrity plugin will remove that user from any static groups in which the user was a member (this is not necessary for dynamic groups, since no explicit membership is maintained). Similarly, if a modify DN operation is performed to move or rename a user entry, then referential integrity updates static groups in which that user is a member with the new user DN.

Referential integrity support is disabled by default, but may be enabled using the `dsconfig` tool as follows:

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" \
  --set enabled:true
```

Other configuration attributes of note for this plugin include:

- **attribute-type.** This attribute specifies the names or OIDs of the attribute types for which referential integrity will be maintained. By default, referential integrity is maintained for the `member` and `uniqueMember` attributes. Any attribute types specified must have a syntax of either distinguished name (OID "1.3.6.1.4.1.1466.115.121.1.12") or name and optional UID (OID "1.3.6.1.4.1.1466.115.121.1.34"). The specified attribute types must also be indexed for equality in all backends for which referential integrity is to be maintained.
- **base-dn.** This attribute specifies the subtrees for which referential integrity will be maintained. If one or more values are provided, then referential integrity processing will only be performed for entries which exist within those portions of the DIT. If no values are provided (which is the default behavior), then entries within all public naming contexts will be included.
- **log-file.** This attribute specifies the path to a log file that may be used to hold information about the DNs of deleted or renamed entries. If the plugin is configured with a nonzero update interval, this log file helps ensure that appropriate referential integrity processing occurs even if the server is restarted.
- **update-interval.** This attribute specifies the maximum length of time that a background thread may sleep between checks of the referential integrity log file to determine whether any referential integrity processing is required. By default, this attribute has a value of "0 seconds", which indicates that all referential integrity processing is to be performed synchronously before a response is returned to the client. A duration greater than 0 seconds indicates that referential integrity processing will be performed in the background and will not delay the response to the client.

In the default configuration, where referential integrity processing is performed synchronously, the throughput and response time of delete and modify DN operations may be adversely impacted because the necessary cleanup work must be completed before the response to the original operation can be returned. Changing the configuration to use a non-zero update interval alleviates this performance impact because referential integrity processing uses a separate background thread and does not significantly delay the response to delete or modify DN operations.

However, performing referential integrity processing in a background thread may introduce a race condition that may adversely impact clients that delete a user and then immediately attempt to re-add it and establish new group memberships. If referential integrity processing has not yet been completed for the delete, then newly-established group memberships may be removed along with those that already existed for the previous user. Similarly, if the newly-created user is to be a member of one or more of the same groups as the previous user, then attempts by the client to re-establish those memberships may fail if referential integrity processing has not yet removed the previous membership. For this reason, we recommend that the default synchronous behavior be maintained unless the performance impact associated with it is unacceptable and clients are not expected to operate in a manner that may be adversely impacted by delayed referential integrity processing.

Note: The internal operations of the referential integrity plugin are not replicated. So, in a replicated topology, you must enable the referential integrity plugin consistently on all servers in the topology to ensure that changes made by the referential integrity plugin are passed along to a replication server.

For more information about administering the referential integrity plugin, see Chapter 6, "Configuring the Directory Server" in the *PingDirectory Server Administration Guide*.

Monitoring the Group Membership Cache

The Directory Server logs information at startup about the memory consumed by the group membership cache. This hard-coded cache contains information about all of the group memberships for internal processing, such as ACIs. The group membership cache is enabled by default.

The information about this cache is logged to the standard output log (`server.out`) and the standard error log. When using groups, you can use the log information to tune the server for best performance. For example, at startup the server logs a message like the following to the `server.out` log:

```
[16/Aug/2011:17:14:39.462 -0500] category=JEB severity=NOTICE msgID=1887895587
msg="The database cache now holds 3419MB of data and is 32 percent full"
```

The error log will contain something like the following:

```
[16/Aug/2011:18:40:39.555 -0500] category=EXTENSIONS severity=NOTICE
msgID=1880555575
msg="'Group cache (174789 static group(s) with 7480151 total memberships and
1000002
unique members, 0 virtual static group(s), 1 dynamic group(s))' currently
consumes
149433592 bytes and can grow to a maximum of 149433592 bytes"
```

Using the Entry Cache to Improve the Performance of Large Static Groups

The PingDirectory Server provides an entry cache implementation, which allows for fine-grained control over the kinds of entries that may be held in the cache. You can define filters to specify the entries included in or excluded from the cache, and you can restrict the cache so that it holds only entries with at least a specified number of values for a given set of attributes.

Under most circumstances, we recommend that the Directory Server be used *without* an entry cache. The Directory Server is designed to efficiently retrieve and decode entries from the database in most cases. The database cache is much more space-efficient than the entry cache, and heavy churn in the entry cache can adversely impact garbage collection behavior.

However, if the Directory Server contains very large static groups, such as those containing thousands or millions of members, and clients need to frequently retrieve or otherwise interact with these groups, then you may want to enable an entry cache that holds only large static groups.

In servers containing large static groups, you can define an entry cache to hold only those large static groups. This entry cache should have an include filter that matches only group entries (for example, "(|(objectclass=groupOfNames)(objectclass=groupOfUniqueNames)(objectclass=groupOfEntries))"). The filter contains a minimum value count so that only groups with a large number of members (such as those with at least 100 `member` or `uniqueMember` values) will be included. The Directory Server provides an entry cache implementation with these settings although it is disabled by default.

To Enable the Entry Cache

Steps

- Run `dsconfig` to enable the entry cache.

```
$ bin/dsconfig set-entry-cache-prop --cache-name "Static Group Entry Cache"
\
--set enabled:true
```

To Create Your Own Entry Cache for Large Groups

Steps

- You can create your own entry cache for large groups using the `dsconfig create-entry-cache` subcommand.

```
# bin/dsconfig create-entry-cache --type fifo \
--set enabled:true \
--set cache-level:10 \
```

```
--set max-entries:175000 \
--set "include-filter:(objectClass=groupOfUniqueNames)" \
--set min-cache-entry-value-count:10000 \
--set min-cache-entry-attribute:uniquemember
```

Monitoring the Entry Cache

You can monitor the memory consumed by your entry cache using the `entry-cache-info` property in the periodic stats logger. You can retrieve the monitor entry over LDAP by issuing a search on `baseDN="cn=monitor" using filter="(objectClass=ds-fifo-entry-cache-monitor-entry) "`. For example, the entry might appear as follows:

```
dn: cn=Static Group Entry Cache Monitor,cn=monitor
objectClass: top
objectClass: ds-monitor-entry
objectClass: ds-fifo-entry-cache-monitor-entry
objectClass: extensibleObject
cn: Static Group Entry Cache Monitor
cacheName: Static Group Entry Cache
entryCacheHits: 6416407
entryCacheTries: 43069073
entryCacheHitRatio: 14
maxEntryCacheSize: 12723879900
currentEntryCacheCount: 1
maxEntryCacheCount: 175000
entriesAddedOrUpdated: 1
evictionsDueToMaxMemory: 0
evictionsDueToMaxEntries: 0
entriesNotAddedAlreadyPresent: 0
entriesNotAddedDueToMaxMemory: 0
entriesNotAddedDueToFilter: 36652665
entriesNotAddedDueToEntrySmallness: 0
lowMemoryOccurrences: 0
percentFullMaxEntries: 0
jvmMemoryMaxPercentThreshold: 75
jvmMemoryCurrentPercentFull: 24
jvmMemoryBelowMaxMemoryPercent: 51
isFull: false
capacityDetails: NOT FULL: The JVM is using 24% of its available memory.
  Entries can be
  added to the cache until the overall JVM memory usage reaches the configured
  limit of
  75%. Cache has 174999 remaining entries before reaching the configured limit
  of 175000.
```

By default, the entry cache memory is set to 75%, with a maximum of 90%.

Tuning the Index Entry Limit for Large Groups

The Directory Server uses indexes to improve database search performance and provide consistent search rates regardless of the number of database objects stored in the DIT. You can specify an index entry limit property, which defines the maximum number of entries that are allowed to match a given index key before it is no longer maintained by the server. If the index keys have reached this limit (which is 4000 by default), then you must rebuild the indexes using the `rebuild-index` tool as follows:

```
$ bin/rebuild-index --baseDN dc=example,dc=com --index objectclass
```

In the majority of Directory Server environments, the default index entry limit value of 4000 entries should be sufficient. However, group-related processing, it may be necessary to increase the index entry limit. For directories containing more than 4000 groups with the same structural object class (i.e., more than 4000 entries, 4000 `groupOfUniqueNames` entries, 4000 `groupOfEntries` entries, or 4000 `groupOfURLs` entries), then you may want to increase the index entry limit for the `objectClass` attribute so that it has a

value larger than the maximum number of group entries of each type. Set `index-entry-limit` property using a command line like the following:

```
$ bin/dsconfig set-local-db-index-prop --backend-name userRoot \
  --index-name objectClass --set index-entry-limit:175000
```

As an alternative, a separate backend may be created to hold these group entries, so that an unindexed search in that backend yields primarily group entries. If you make no changes, then the internal search performed at startup to identify all groups and any user searches looking for groups of a given type may be very expensive.

For directories in which any single user may be a member of more than 4000 static groups of the same type, you may need to increase the index entry limit for the `member` and/or `uniqueMember` attribute to a value larger than the maximum number of groups in which any user is a member. If you do not increase the limit, then searches to retrieve the set of all static groups in which the user is a member may be unindexed and therefore very expensive.

Summary of Commands to Search for Group Membership

The following summary of commands show the fastest way to retrieve direct or indirect member DN's for groups.

- To retrieve direct member (non-nested) DN's of group `"cn=group.1,ou=groups,dc=example,dc=com"`.

```
$ bin/ldapsearch --baseDN "cn=group.1,ou=Groups,dc=example,dc=com"
  "(objectClass=*)" uniqueMember member
```

- To retrieve direct member entries (non-nested) under `"dc=example,dc=com"` of group `"cn=group.1,ou=groups,dc=example,dc=com"`. This is useful when attributes from member entries are used in the filter or being returned.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
  "(isDirectMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

- To retrieve group DN's in which user `"uid=user.2,ou=people,dc=example,dc=com"` is a direct member (non-nested, static groups).

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
  "(objectClass=*)" isDirectMemberOf
```

- To retrieve all member entries under `ou=people,dc=example,dc=com` of group `"cn=group.1,ou=groups,dc=example,dc=com"`.

```
$ bin/ldapsearch --baseDN "ou=people,dc=example,dc=com"
  "(isMemberOf=cn=group.1,ou=Groups,dc=example,dc=com) "
```

- To retrieve the group DN's in which user `"uid=user.2,ou=people,dc=example,dc=com"` is a member.

```
$ bin/ldapsearch --baseDN "uid=user.2,ou=people,dc=example,dc=com"
  "(objectClass=*)" isMemberOf
```

Migrating Sun/Oracle Groups

You can migrate Sun/Oracle static and dynamic groups to PingDirectory Server groups. The following sections outline the procedures for migrating static groups to both Ping Identity static groups and virtual static groups as well as how to migrate dynamic groups. For information about the differences in access control evaluation between Sun/Oracle and the PingDirectory Server, see [Migrating ACLs from Sun/Oracle to PingDirectory Server](#).

Migrating Static Groups

The PingDirectory Server supports static LDAP groups with structural object classes of `groupOfNames`, `groupOfUniqueNames`, or `groupOfEntries`. In general, static groups may be imported without modification.

A FIFO entry cache can be enabled to cache group-to-user mappings, which improves performance when accessing very large entries, though at the expense of greater memory consumption. The PingDirectory Server provides an out-of-the-box FIFO entry cache object for this purpose. This object must be explicitly enabled using `dsconfig` as described in [Using the Entry Cache to Improve the Performance of Large Static Groups](#).

To Migrate Static Groups

Steps

1. Run the `migrate-ldap-schema` tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.
2. Run the `migrate-sun-ds-config` tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the `import-ldif` tool.
5. From the PingDirectory Server root directory, open the `sun-ds-compatibility.dsconfig` file in the `docs` folder using a text editor.
6. Find the **FIFO Entry Cache** section and, after reading the accompanying comments, enable the corresponding `dsconfig` command by removing the comment character ("`#`").

```
$ bin/dsconfig set-entry-cache-prop \
  --cache-name "Static Group Entry Cache" --set enabled:true
```

7. To ensure that references to an entry are updated automatically when the entry is deleted or renamed, enable the Referential Integrity plugin.

```
$ bin/dsconfig set-plugin-prop --plugin-name "Referential Integrity" --set
enabled:true
```

If this Directory Server is part of a replication topology, you should enable the Referential Integrity plugin for each replica.

Migrating Static Groups to Virtual Static Groups

In many cases, electing to use virtual static groups in place of static groups can produce marked performance gains without any need to update client applications. The specifics of a migration to virtual static groups varies depending on the original DIT, but the general approach involves identifying common membership traits for all members of each group and then expressing those traits in the form of an LDAP URL.

In the following example, the common membership trait for all members of the All Users group is the parent DN `ou=People,dc=example,dc=com`. In other cases, a common attribute may need to be used. For example, groups based on the location of its members could use the `l` (location) or `st` (state) attribute.

To Migrate DSEE Static Groups to Virtual Static Groups

About this task

In the following example, consider the common case of an "All Users" group, which contains all entries under the parent DN `"ou=People,dc=example,dc=com"`. When implemented as a virtual static group, this group may have a large membership set without incurring the overhead of a static group.

Steps

1. First, create a dynamic group.

```
dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfURLs
cn: Dynamic All Users
memberURL: ldap:///ou=People,dc=example,dc=com??sub?(objectClass=person)
```

2. Next, create a virtual static group that references the dynamic group.

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
objectClass: top
objectClass: groupOfUniqueNames
objectClass: ds-virtual-static-group
cn: All Users
ds-target-group-dn: cn=Dynamic All Users,ou=Groups,dc=example,dc=com
```

3. Finally, the Virtual Static `uniqueMember` virtual attribute must be enabled to populate the All Users group with `uniqueMember` virtual attributes.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set enabled:true
```

4. Confirm that the virtual static group is correctly configured by checking a user's membership in the group.

```
$ bin/ldapsearch --baseDN "cn=All Users,ou=Groups,dc=example,dc=com" \
--searchScope base "(uniqueMember=uid=user.0,ou=People,dc=example,dc=com)"
1.1
```

```
dn: cn=All Users,ou=Groups,dc=example,dc=com
```

5. The ability to list all members of a virtual static group is disabled by default. You may enable this feature, but only if specifically required by a client application.

```
$ bin/dsconfig set-virtual-attribute-prop --name "Virtual Static
uniqueMember" \
--set allow-retrieving-membership: true
```

Note: The virtual static group may also be implemented using the `groupOfNames` object class instead of `groupOfUniqueNames`. In that case, you must update the Virtual Static member configuration object instead of the Virtual Static `uniqueMember` configuration object.

Migrating Dynamic Groups

The PingDirectory Server supports dynamic groups with the `groupOfURLs` object class. In general, dynamic groups may be imported without modification.

To Migrate Dynamic Groups

Steps

1. Run the `migrate-ldap-schema` tool to enumerate any schema differences between the DSEE deployment and the Ping Identity deployment.
2. Run the `migrate-sun-ds-config` tool to enumerate any configuration differences between the DSEE deployment and the Ping Identity deployment.
3. Import or configure any necessary schema and/or configuration changes recorded by the above tools.
4. Import the existing users and groups using the `import-ldif` tool.

Encrypting Sensitive Data

The Directory Server provides several ways that you can protect sensitive information in the server. If not enabled during server setup, you can enable on-disk encryption for data in backends as well as in the changelog and the replication databases, and you can also protect sensitive attributes by limiting the ways that clients may interact with them.

This chapter presents the following topics:

- [Encrypting and Protecting Sensitive Data](#) on page 759
- [Backing Up and Restoring the Encryption-Settings Definitions](#) on page 764
- [Configuring Sensitive Attributes](#) on page 767
- [Configuring Global Sensitive Attributes](#) on page 769
- [Excluding a Global Sensitive Attribute on a Client Connection Policy](#) on page 770

Encrypting and Protecting Sensitive Data

The Directory Server provides an encryption-settings database that holds encryption and decryption definitions to protect sensitive data. You can enable on-disk encryption for data in backends as well as in the changelog and the replication databases. You can also protect sensitive attributes by limiting the ways that clients may interact with them.

About the Encryption-Settings Database

The encryption-settings database is a repository that the server uses to hold information for encrypting and decrypting data. The database contains any number of *encryption-settings definitions* that specifies information about the cipher transformation and encapsulates the key used for encryption and decryption.

Before data encryption can be enabled, you first need to create an encryption-settings definition. An encryption-settings definition specifies the cipher transformation that should be used to encrypt the data, and encapsulates the encryption key. The `encryption-settings` command-line tool can be used to manage the encryption settings database, including creating, deleting, exporting, and importing encryption-settings definitions, listing the available definitions, and indicating which definition should be used for subsequent encryption operations.

Although the encryption-settings database can have multiple encryption-settings definitions, only one of them can be designated as the *preferred* definition. The preferred encryption-settings definition is the one that will be used for any subsequent encryption operations. Any existing data that has not yet been encrypted remains unencrypted until it is rewritten (e.g., as a result of a modify or modify DN operation, or if the data is exported to LDIF and re-imported). Similarly, if you introduce a new preferred encryption-settings definition, then any existing encrypted data will continue to use the previous definition until it is rewritten. If you do change the preferred encryption-settings definition for the server, then it is important to retain the previous definitions until you are confident that no remaining data uses those older keys.

Supported Encryption Ciphers and Transformations

The set of encryption ciphers that are supported by the Directory Server is limited to those ciphers supported by the JVM in which the server is running. For specific reference information about the algorithms and transformations available in all compliant JVM implementations, see the following:

- [Java Cryptography Architecture Reference Guide](#)
- [Java Cryptography Architecture Standard Algorithm Name Documentation](#)

When configuring encryption, the cipher to be used must be specified using a key length (in bits) and either a cipher algorithm name (e.g., "AES") or a full cipher transformation which explicitly specifies the mode and padding to use for the encryption (e.g., "AES/CBC/ PKCS5Padding"). If only a cipher algorithm is given, then the default mode and padding for that algorithm will be automatically selected.

The following cipher algorithms and key lengths have been tested using the Sun/Oracle JVM:

Cipher Algorithms

Cipher Algorithm	Key Length (bits)
AES	128
Blowfish	128
DES	64
DESede	192
RC4	128

Note: By default, some JVM implementations may come with limited encryption strength, which may restrict the key lengths that can be used. For example, the Sun/Oracle JVM does not allow AES with 192-bit or 256-bit keys unless the unlimited encryption strength policy files are downloaded and installed.

The Directory Server supports four Cipher Stream Providers, which are used to obtain cipher input and output streams to read and write encrypted data.

Cipher Stream Providers

Cipher Stream Providers	Description
Default	Default cipher stream provider using a hard-coded default key.
File-Based	Used to read a specified file in order to obtain a password used to generate cipher streams for reading and writing encrypted data.
Third-Party	Used to provide cipher stream provider implementations created in third-party code using the Server SDK.
Wait-for-Passphrase	Causes the server to wait for an administrator to enter a passphrase that will be used to derive the key for cipher streams. You can supply the passphrase to the server by running <code>encryption-settings supply-passphrase</code> .

Using the `encryption-settings` Tool

The `encryption-settings` tool provides a mechanism for interacting with the server's encryption-settings database. It may be used to list the available definitions, create new definitions, delete existing definitions, and indicate which definition should be the preferred definition. It may also be used to export definitions to a file for backup purposes and to allow them to be imported for use in other Directory Server instances.

To List the Available Encryption Definitions

Steps

- Use the `encryption-settings` tool with the `list` subcommand to display the set of available encryption settings definitions. This subcommand does not take any arguments. For each definition, it will include the unique identifier for the definition, as well as the cipher transformation and key length that will be used for encryption and whether it is the preferred definition.

```
$ bin/encryption-settings list
```

```
Encryption Settings Definition ID: 4D86C7922F71BB57B8B5695D2993059A26B8FC01
Preferred for New Encryption: false
Cipher Transformation: DESede
Key Length (bits): 192
```

```
Encryption Settings Definition ID: F635E109A8549651025D01D9A6A90F7C9017C66D
Preferred for New Encryption: true
Cipher Transformation: AES
Key Length (bits): 128
```

Creating Encryption-Settings Definitions

To create a new encryption-settings definition, use the `create` subcommand. This subcommand takes the following arguments:

- **--cipher-algorithm {algorithm}**. Specifies the base cipher algorithm that should be used. This should just be the name of the algorithm (e.g., "AES", "DES", "DESede", "Blowfish", "RC4", etc.). This argument is required.
- **--cipher-transformation {transformation}**. Specifies the full cipher transformation that should be used, including the cipher mode and padding algorithms (e.g., "AES/CBC/ PKCS5Padding"). This argument is optional, and if it is not provided, then the JVM-default transformation will be used for the specified cipher algorithm.
- **--key-length-bits {length}**. Specifies the length of the encryption key in bits (e.g., 128). This argument is required.
- **--set-preferred**. Indicates that the new encryption-settings definition should be made the preferred definition and therefore should be used for subsequent encryption operations in the server. When creating the first definition in the encryption-settings database, it will automatically be made the preferred definition.

To Create an Encryption-Settings Definition

Steps

- Use the **encryption-settings** tool with the `create` subcommand to specify the definition.

```
$ bin/encryption-settings create --cipher-algorithm AES \
  --key-length-bits 128 --set-preferred
```

```
Successfully created a new encryption settings definition with ID
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Changing the Preferred Encryption-Settings Definition

To change the preferred encryption-settings definition, use the **encryption-settings** tool with the `set-preferred` subcommand. This subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be exported. This argument is required.

To Change the Preferred Encryption-Settings Definition

Steps

- Use the **encryption-settings** tool with the `set-preferred` subcommand to change a definition to a preferred definition.

```
$ bin/encryption-settings set-preferred --id
4D86C7922F71BB57B8B5695D2993059A26B8FC01
```

```
Encryption settings definition 4D86C7922F71BB57B8B5695D2993059A26B8FC01 was
successfully set as the preferred definition for subsequent encryption
operations
```

Deleting an Encryption-Settings Definition

To delete an encryption-settings definition, use the `encryption-settings` tool with the `delete` subcommand. The subcommand takes the following arguments:

- `--id {id}`. Specifies the ID for the encryption-settings definition to be deleted. This argument is required.

Never delete an encryption-settings definition if data in the server is still encrypted using the settings contained in that definition. Any data still encrypted with a definition that has been removed from the database will be inaccessible to the server and will cause errors for any attempt to access it. This includes the replicationChanges and changelog databases, which the `re-encode-entries` tool will not re-encode with the new encryption-settings definition. Therefore, wait for the amount of time defined in the `replication-purge-delay`, of the Replication Server, and `changelog-maximum-age` of the changelog Backend (if enabled) before removing previous encryption-settings definitions. To safely delete a compromised encryption-settings definition, see the [Dealing with a Compromised Encryption Key](#) section.

To stop using a definition for encryption and use a different definition, make sure that the desired definition exists in the encryption-settings database and set it to be the preferred definition. As long as the encryption key has not been compromised, there is no harm in having old encryption-settings definitions available to the server, and it is recommended that they be retained just in case they are referenced by something.

The preferred encryption-settings definition cannot be deleted unless it is the only one left. To delete the currently-preferred definition when one or more other definitions are available, make one of the other definitions preferred as described in the previous section.

To Delete an Encryption-Settings Definition

Steps

- Use the `encryption-settings` command with the `delete` subcommand. Make sure to include the `--id` argument to specify the definition.

```
$ bin/encryption-settings delete --id
F635E109A8549651025D01D9A6A90F7C9017C66D
```

```
Successfully deleted encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D
```

Configuring the Encryption-Settings Database

Because the encryption-settings database contains the encryption keys used to protect server data, the contents of the encryption-settings database is itself encrypted. By default, the server will derive a key to use for this purpose, but it is recommended that you customize the logic used to access the encryption-settings database with a cipher stream provider. The Server SDK provides an API that can be used to create custom cipher stream provider implementations, but the server also comes with one that will obtain the key from a PIN file that you create (see the example procedure below).

To Configure the Encryption-Settings Database

Steps

1. Use `dsconfig` to configure the server so that the encryption-settings database is encrypted with a PIN contained in the file `config/encryption-settings.pin`.

```
$ bin/dsconfig create-cipher-stream-provider \
--provider-name "Encryption Settings PIN File" \
--type file-based \
--set enabled:true \
--set password-file:config/encryption-settings.pin
```

2. Use `dsconfig` to set the global configuration property for the cipher stream provider, which sets the on-disk encryption.

```
$ bin/dsconfig set-global-configuration-prop \
  --set "encryption-settings-cipher-stream-provider:Encryption Settings PIN
  File"
```

3. Use the `encryption-settings` tool to create a new encryption-settings definition. This command automatically generates a new 256-bit encryption key for use with AES encryption, and mark it as the preferred definition for future encryption operations in the server. Note that this command will fail if you do not have the unlimited encryption strength policy installed as described in the previous section (if you do not have that policy installed, then you are restricted to a 128-bit key for AES encryption).

```
$ bin/encryption-settings create \
  --cipher-algorithm AES \
  --key-length-bits 256 \
  --set-preferred
```

4. Obtain a list of the definitions in the encryption-settings database.

```
$ bin/encryption-settings list
```

5. You can export an encryption-settings definition from the database using a command like the following where the encryption-settings ID should be changed as necessary to suit your deployment:

```
$ bin/encryption-settings export \
  --id DA39A3EE5E6B4B0D3255BFEF95601890AFD80709 \
  --output-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin
```

6. If no PIN file is specified, then you will be interactively prompted to provide it. To import an encryption-settings definition into the database on another server.

```
$ bin/encryption-settings import \
  --input-file /tmp/exported-key \
  --pin-file /tmp/exported-key.pin \
  --set-preferred
```

Encrypt Passphrase Files

Using an encrypted passphrase or `tools.properties` file enables you to have credentials available for use by the server and command-line tools, but not stored in the clear. These files should be encrypted with the `encrypt-file` tool, including:

- Certificate keystore and truststore PIN files. When setting up an instance with encryption enabled and at least one of SSL or StartTLS enabled, the installer will automatically encrypt the PIN files for the `config/keystore`, `config/truststore`, and `config/ads-truststore` certificate databases.
- Passphrase files specified by command-line arguments. For example, most LDAP tools offer `--bindPasswordFile`, `--keystorePasswordFile`, and `--truststorePasswordFile` arguments.
- The `config/tools.properties` file, which will automatically be used to obtain a default set of arguments for most command-line tools. Alternately, the `--propertiesFilePath` argument can be used to specify an alternate properties file.

These files should be encrypted with the following considerations:

- If the file is encrypted with a key obtained from the server's encryption settings database, then the server and associated command-line tools should be able to retrieve the appropriate key from the encryption settings database so that the clear-text contents of the file can be accessed without any interaction (although if the cipher stream provider configured to protect the contents of the encryption settings database requires interaction, like the wait for passphrase cipher stream provider, then command-line tools may require interaction to unlock the encryption settings database).
- If the file is encrypted with a passphrase that the user specifies rather than one obtained from the encryption settings database, then the user will be interactively prompted for that passphrase when

running the tool. This option cannot be used for keystore and truststore PIN files that need to be accessed by the server.

To encrypt a file with the server's preferred encryption settings definition, use a command such as:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted
```

To use a key from an encryption settings definition that isn't the default, use the **--encryption-settings-id** argument to specify the ID of the desired encryption settings definition (which can be obtained with **encryption-settings list**), such as:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --encryption-settings-id 4B6899D6716FC3AFFD71F7B447EB135063A0E724
```

To encrypt the file with a passphrase rather than a key from an encryption settings definition, use either the **--prompt-for-passphrase** argument to interactively prompt for the passphrase, or use the **--passphrase-file** argument to specify the path to a file containing the clear-text passphrase. For example:

```
$ bin/encrypt-file --input-file password.txt \
  --output-file password.txt.encrypted \
  --prompt-for-passphrase
```

Backing Up and Restoring the Encryption-Settings Definitions

If using data encryption in a Directory Server instance, do not lose the encryption-settings definitions used to encrypt data in the server. If an encryption-settings definition is lost, any data encrypted with that definition will be completely inaccessible. Make sure the encryption-settings definitions are backed up regularly.

The Directory Server provides two different mechanisms for backing up and restoring encryption-settings definitions. One or more encryption-settings definitions can be exported and imported using the **encryption-settings** tool. Or, the entire encryption-settings database can be backed up and restored using the Directory Server's **backup** and **restore** tools.

If a pin file is used to define a passphrase to the encryption-settings database, the passphrase must be backed up and kept secure independently of the userRoot and encryption-settings database backups. The passphrase in the pin file is needed if the encryption-settings database is to be restored into a different server root.

Exporting Encryption-Settings Definitions

To back up an individual definition (or to export it from one server so that you can import it into another), use the **export** subcommand to the **encryption-settings** command. The subcommand takes the following arguments:

- **--id {id}**. Specifies the ID for the encryption-settings definition to be exported. This argument can be specified multiple times. If it is omitted, all definitions are exported.
- **--output-file {path}**. Specifies the path to the output file to which the encryption-settings definition will be written. This argument is required.
- **--pin-file {path}**. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.

To Export an Encryption-Settings Definition

Steps

- Use the **encryption-settings** tool with the `export` subcommand to export the definition to a file.

```
$ bin/encryption-settings export --id
F635E109A8549651025D01D9A6A90F7C9017C66D \
  --output-file /tmp/exported-key
Enter the PIN to use to encrypt the definition:
Re-enter the encryption PIN:
```

```
Successfully exported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D to file /tmp/exported-key
```

Importing Encryption-Settings Definitions

To import an encryption-settings definition that has been previously exported, use the **encryption-settings** tool with the `import` subcommand. The subcommand takes the following arguments:

- input-file {path}**. Specifies the path to the file containing the exported encryption-settings definition. This argument is required.
- pin-file {path}**. Specifies the path to a PIN file containing the password to use to encrypt the contents of the exported definition. If this argument is not provided, then the PIN will be interactively requested from the server.
- set-preferred**. Specifies that the newly-imported encryption-settings definition should be made for the preferred definition for subsequent encryption-settings.

To Import an Encryption-Settings Definition

Steps

- Use the **encryption-settings** tool with the `import` subcommand to import the definition to a file.

```
$ bin/encryption-settings import --input-file /tmp/exported-key --set-
preferred
Enter the PIN used to encrypt the definition:
```

```
Successfully imported encryption settings definition
F635E109A8549651025D01D9A6A90F7C9017C66D from file /tmp/exported-key
```

Enabling Data Encryption in the Server

Encryption can be enabled during server setup, by defining an encryption key and passphrase. This configuration should be used across all servers in a topology. On legacy systems or post setup, data encryption can be configured by having at least one encryption-settings definition available for use. Then, set the value of the `encrypt-data` global configuration property to `true`.

Setting the global configuration property will automatically enable data encryption for all types of backends that support it (including the changelog backend and indexes), as well as for the replication server database. All subsequent write operations will cause the corresponding records written into any of these locations to be encrypted. Any existing data will remain unencrypted until it is rewritten by a write operation. If you wish to have existing data encrypted, then you will need to export that data to LDIF and re-import it. This will work for both the data backends, the changelog, and indexes, but it is not an option for the replication database, so existing change records will remain unencrypted until they are purged. If this is not considered acceptable in your environment, then follow the steps in [Dealing with a Compromised Encryption Key](#) to safely purge the replication database.

Configuration for backups and LDIF exports can be done with the following global properties:

- automatically-compress-encrypted-ldif-exports**. Indicates whether to automatically compress LDIF exports that are also encrypted. If set to `true`, any LDIF export that is encrypted

(either explicitly with `--encryptLDIF`, or implicitly with the `encrypt-ldif-exports-by-default` configuration property) will automatically be gzip-compressed. If this is false, encrypted LDIF exports can still be manually compressed using the `--compress` command-line argument.

- `backup-encryption-settings-definition-id`. The unique identifier for the encryption settings definition to use to generate the encryption key for encrypted backups by default. If this property is given a value, then a definition with that ID must exist in the server's encryption settings database. If this property is not given a value, but the server is configured with at least one encryption settings definition, then the preferred definition is used. If no encryption settings definitions are available, the server will use an internal key shared among servers in the topology. Regardless of this property's value, it can be overridden with the `backup` command-line tool. Providing one of the `--promptForEncryptionPassphrase` or `--encryptionPassphraseFile` arguments will generate the encryption key from the provided passphrase. Or, the `--encryptionSettingsDefinitionID` argument can be used to generate the key from the specified encryption settings definition.
- `encrypt-backups-by-default`. Indicates whether the server should encrypt backups by default. If set to true, a defined `backup-encryption-settings-definition-id` value will be used to generate the encryption key for the backup. If this property is true, and if a `backup-encryption-settings-definition-id` value is not specified, the server will try to use the preferred encryption settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, an internal key that is shared among instances in the topology is used. Regardless of this property's value, it can be overridden with the `backup` command-line tool's `--encrypt` argument, even if this property is set to false. The `--doNotEncrypt` argument will always cause the backup to be unencrypted, even if this property has a value of true.
- `encrypt-ldif-exports-by-default`. Indicates whether the server should encrypt LDIF exports by default. If set to true, and an `ldif-export-encryption-settings-definition-id` value is specified, then that encryption settings definition is used to generate the encryption key for the export. If this property is true, and an `ldif-export-encryption-settings-definition-id` value is not specified, the server will first try to use the preferred encryption settings definition to generate the encryption key. If the server is not configured with any encryption settings definitions, then an internal key that is shared among instances in the topology is used. Regardless of this property's value, the default behavior can be overridden with the `export-ldif` command-line tool. The tool's `--encryptLDIF` argument will always encrypt the export, and the `--doNotEncryptLDIF` argument will always create an unencrypted export.

To Enable Data Encryption in the Server

Steps

- Use `dsconfig` to set the global configuration property for data encryption to true.

```
$ bin/dsconfig set-global-configuration-prop --set encrypt-data:true
```

Using Data Encryption in a Replicated Environment

Data encryption is only used for the on-disk storage for data within the server. Whenever clients access that data, it is presented in unencrypted form (although the communication with those clients may itself be encrypted using SSL or StartTLS). Replication, the communication of updates between replication servers, is always encrypted using SSL. Each server may apply data encryption in a completely independent manner and have different sets of encryption-settings definitions. It is also possible to have a replication topology containing some servers with data encryption enabled and others with it disabled.

However, when initializing the backend of one server from another server with data encryption enabled, then the server being initialized must have access to all encryption-settings definitions that may have been used for data contained in that backend. To do this, perform an export of the encryption-settings database on the source server using `bin/encryption-settings export` and import it on the target server using `bin/encryption-settings import`.

Dealing with a Compromised Encryption Key

If an encryption-settings definition becomes compromised such that an unauthorized individual obtains access to the encryption key, then any data encrypted with that definition is also vulnerable because it can be decrypted using that key. It is very important that the encryption-settings database be protected (for example, using file permissions or file system ACLs) to ensure that its contents remain secure.

In the event that an encryption-settings definition is compromised, stop using the definition immediately. Any data encrypted with the compromised key should be re-encrypted with a new definition or purged from the server. This can be done on one server at a time to avoid an environment-wide downtime, but it should be completed as quickly as possible on all servers that had used that definition at any point in the past in order to minimize the risk of that data becoming exposed.

To Deal with a Compromised Encryption Key

About this task

The recommended process for responding to a compromised encryption settings definition is as follows:

Steps

1. Create a new encryption-settings definition and make it the preferred definition for new writes.
2. Ensure that client traffic is routed away from the server instance to be updated. For example, if the Directory Server is accessed through a Directory Proxy Server, then you may set the `health-check-state` configuration property for any LDAP external server definitions that reference that server to have a value of `unavailable`.
3. Ensure that external clients are not allowed to write operations in the directory server instance. This may be accomplished by setting the `writability-mode` global configuration property to have a value of `internal-only`.
4. Wait for all outstanding local changes to be replicated out to other servers. This can be accomplished by looking at the monitor entries with the `ds-replication-server-handler-monitor-entry` object class to ensure that the value of the `update-sent` attribute is no longer increasing.
5. Stop the directory server instance.
6. Delete the replication server database by removing all files in the `changeLogDb` directory below the server root. As long as all local changes have been replicated out to other servers, this will not result in any data loss in the replication environment.
7. Export the contents of all local DB and changelog backends to LDIF. Then, re-import the data from LDIF, which will cause it to be encrypted using the new preferred encryption settings definition.
8. Export the compromised key from the encryption settings database to back it up in case it may be needed again in the future (e.g., if some remaining data was later found to have been encrypted with the key contained in that definition). Then, delete it from the encryption settings database so that it can no longer be used by that directory server instance.
9. Start the directory server instance.
10. Allow replication to bring the server back up-to-date with any changes processed while it was offline.
11. Re-allow externally-initiated write operations by changing the value of the global `writability-mode` configuration property back to `enabled`.
12. Re-configure the environment to allow client traffic to again be routed to that server instance (e.g., by changing the value of the "health-check-state" property in the corresponding LDAP external instance definitions in the Directory Proxy Server instances back to "dynamically-determined").

Configuring Sensitive Attributes

Data encryption is only applied to the on-disk storage for a Directory Server instance. It does not automatically protect information accessed or replicated between servers, although the server offers other mechanisms to provide that protection (i.e., SSL, StartTLS, SASL). Ensuring that all client communication uses either SSL or StartTLS encryption and ensuring that all replication traffic uses SSL encryption

ensures that the data is protected from unauthorized individuals who may be able to eavesdrop on network communication. This communication security may be enabled independently of data encryption (although if data encryption is enabled, then it is strongly recommended that secure communication be used to protect network access to that data).

However, for client data access, it may not be as simple as merely enabling secure communication. In some cases, it may be desirable to allow insecure access to some data. In other cases, it may be useful to have additional levels of protection in place to ensure that some attributes are even more carefully protected. These kinds of protection may be achieved using sensitive attribute definitions.

Each sensitive attribute definition contains a number of configuration properties, including:

- **attribute-type** . Specifies the set of attribute types whose values may be considered sensitive. At least one attribute type must be provided, and all specified attribute types must be defined in the server schema.
- **include-default-sensitive-operational-attributes** . Indicates whether the set of sensitive attributes should automatically be updated to include any operational attributes maintained by the Directory Server itself that may contain sensitive information. At present, this includes the `ds-sync-hist` operation attribute, which is used for data required for replication conflict resolution and may contain values from other attributes in the entry.
- **allow-in-filter** . Indicates whether sensitive attributes may be used in filters. This applies not only to the filter used in search requests, but also filters that may be used in other places, like the assertion and join request controls. The value of this property must be one of:
 - `Allow` (allow sensitive attributes to be used in filters over both secure and insecure connections)
 - `Reject` (reject any request which includes a filter targeting one or more sensitive attributes over both secure and insecure connections)
 - `Secure-only` (allow sensitive attributes to be used in filters over secure connections, but reject any such requests over insecure connections)
- **allow-in-add** . Indicates whether sensitive attributes may be included in entries created by LDAP add operations. The value of this property must be one of:
 - `Allow` (allow sensitive attributes to be included in add requests over both secure and insecure connections)
 - `Reject` (reject any add request containing sensitive attributes over both secure and insecure connections)
 - `Secure-only` (allow sensitive attributes to be included in add requests received over a secure connection, but reject any such requests over an insecure connection)
- **allow-in-compare** . Indicates whether sensitive attributes may be targeted by the assertion used in a compare operation. The value of this property must be one of:
 - `Allow` (allow sensitive attributes to be targeted by requests over both secure and insecure connections)
 - `Reject` (reject any compare request targeting a sensitive attribute over both secure and insecure connections)
 - `Secure-only` (allow compare requests targeting sensitive attributes over a secure connection, but reject any such requests over an insecure connection)
- **allow-in-modify** . Indicates whether sensitive attributes may be updated using modify operations. The value of this property must be one of:
 - `Allow` (allow sensitive attributes to be modified by requests over both secure and insecure connections)
 - `Reject` (reject any modify request updating a sensitive attribute over both secure and insecure connections)
 - `Secure-only` (only modify requests updating sensitive attributes over a secure connection, but reject any such request over an insecure connection)

The `allow-in-returned-entries`, `allow-in-filter`, `allow-in-add`, `allow-in-compare`, and `allow-in-modify` properties all have default values of `secure-only`, which prevents the possibility of exposing sensitive data in the clear to anyone able to observe network communication.

If a client connection policy references a sensitive attribute definition, then any restrictions imposed by that definition will be enforced for any clients associated with that client connection policy. If multiple sensitive attribute definitions are associated with a client connection policy, then the server will use the most restrictive combination of all of those sets.

Note that sensitive attribute definitions work in conjunction with other security mechanisms defined in the server and may only be used to enforce additional restrictions on clients. Sensitive attribute definitions may never be used to grant a client additional access to information that it would not have already had through other means. For example, if the `employeeSSN` attribute is declared to be a sensitive attribute and the `allow-in-returned-entries` property has a value of `Secure-only`, then the `employeeSSN` attribute will only be returned to those clients that have both been granted permission by the access control rules defined in the server and are communicating with the server over a secure connection. The `employeeSSN` attribute will be stripped out of entries returned to clients normally authorized to see it if they are using insecure connections, and it will also be stripped out of entries for clients normally not authorized to see it even if they have established secure connections.

To Create a Sensitive Attribute

Steps

1. To create a sensitive attribute, you must first create one or more sensitive attribute definitions.

For example, to create a sensitive attribute definition that will only allow access to the `employeeSSN` attribute by clients using secure connections, the following configuration changes may be made:

```
$ bin/dsconfig create-sensitive-attribute \
--attribute-name "Employee Social Security Numbers" \
--set attribute-type:employeeSSN \
--set include-default-sensitive-operational-attributes:true \
--set allow-in-returned-entries:secure-only \
--set allow-in-filter:secure-only \
--set allow-in-add:secure-only \
--set allow-in-compare:secure-only \
--set allow-in-modify:secure-only
```

2. Associate those sensitive attribute definitions with the client connection policies for which you want them to be enforced.

```
$ bin/dsconfig set-client-connection-policy-prop --policy-name default \
--set "sensitive-attribute:Employee Social Security Numbers"
```

Configuring Global Sensitive Attributes

Administrators can assign one or more sensitive attribute definitions to a client connection policy. However, in an environment with multiple client connection policies, it could be easy to add a sensitive attribute definition to one policy but overlook it in another. The Directory Server supports the ability to define sensitive attributes as a global configuration option so that they will automatically be used across all client connection policies.

To Configure a Global Sensitive Attribute

Steps

- Run `dsconfig` to add a global sensitive attribute across all client connection policies. The following command adds the `employeeSSN` as a global sensitive attribute, which is applied across all client connection policies.

```
$ bin/dsconfig set-global-configuration-prop --add "sensitive-attribute:employeeSSN"
```

Excluding a Global Sensitive Attribute on a Client Connection Policy

Administrators can set a global sensitive attribute across all client connection policies. However, there may be cases when a specific directory server must exclude the sensitive attribute as it may not be needed for client connection requests. For example, in most environments it is good to declare the `userPassword` attribute to be a sensitive attribute in a manner that prevents it from being read by external clients. Further, this solution is more secure than protecting the `password` attribute using the server's default global ACI, which only exists for backwards compatibility purposes. If the Data Sync Server is installed, then it does need to be able to access passwords for synchronization purposes. In this case, the administrator can set `userPassword` to be a sensitive attribute in all client connection policies, but exclude it in a policy specifically created for use by the Data Sync Server. The Directory Server provides an `exclude-global-sensitive-attribute` property for this purpose.

To Exclude a Global Sensitive Attribute on a Client Connection Policy

Steps

- Run `dsconfig` to remove the global ACI that limits access to the `userPassword` or `authPassword` attribute. This is present for backwards compatibility.

```
$ bin/dsconfig set-access-control-handler-prop \
  --remove 'global-aci:(targetattr="userPassword || authPassword")
  (version 3.0; acl "Prevent clients from retrieving passwords from the
  server";
  deny (read,search,compare) userdn="ldap:///anyone";)'
```

- Run `dsconfig` to add the `userPassword` attribute as a global sensitive attribute, which is applied to all client connection policies. Do this by adding the built-in "Sensitive Password Attributes" Sensitive Attribute definition to the Global Configuration.

```
$ bin/dsconfig set-global-configuration-prop \
  --add "sensitive-attribute:Sensitive Password Attributes"
```

- If the server is designated to synchronize passwords with a Sync Server, then it is necessary to configure a client connection policy for the Sync User to exclude the global sensitive attribute. The following is an example on how to create a new policy if the Data Sync Server binds with the default DN of `cn=Sync User,cn=Root DNs,cn=config`.

```
$ bin/dsconfig create-connection-criteria \
  --criteria-name "Requests by Sync Users" \
  --type simple \
  --set user-auth-type:internal \
  --set user-auth-type:sasl \
  --set user-auth-type:simple \
  --set "included-user-base-dn:cn=Sync User,cn=Root DNs,cn=config"

$ bin/dsconfig create-client-connection-policy \
  --policy-name "Data Sync Server Connection Policy" \
  --set enabled:true \
  --set evaluation-order-index:9998 \
```

```
--set "connection-criteria:Requests by Sync Users" \
--set "exclude-global-sensitive-attribute:Sensitive Password Attributes"
```

Working with the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services.

This chapter will present the following topics related to the LDAP Changelog:

Overview of the LDAP Changelog

The Directory Server provides a client-accessible LDAP changelog (based on the Changelog Internet Draft Specification) for the purpose of allowing other LDAP clients to retrieve changes made to the server in standard LDAP format. The LDAP changelog is typically used by external software to maintain application compatibility between client services. For example, you can install the Data Sync Server that monitors the LDAP changelog for any updates that occur on a source directory server and synchronizes these changes to a target DIT or database server. The Directory Server provides an additional feature in that the LDAP changelog supports virtual attributes.

Note: The LDAP Changelog should not be confused with the Replication Changelog. The main distinction is as follows:

- The LDAP Changelog (i.e., the external changelog that clients can access) physically resides at `<server-root>/db/changelog`.
- The Replication Changelog Backend (i.e., the changelog that replication servers use) physically resides at `<server-root>/changelogDB`.

Key Changelog Features

As of version 3.2, the Directory Server supports two new Changelog Backend properties that allow access control filtering and sensitive attribute evaluation for targeted entries. External client applications can change the contents of attributes they can see in the targeted entry based on the access control rules applied to the associated base DN.

- **apply-access-controls-to-changelog-entry-contents.** Indicates whether the contents of changelog entry attributes (i.e., `changes`, `deletedEntryAttrs`, `ds-changelog-entry-key-attr-values`, `ds-changelog-before-values`, and `ds-changelog-after-values`) are subject to access control and/or sensitive attribute evaluation to limit data that LDAP clients can see. The client must have the access control permissions to read changelog entries to retrieve them in any form. If this feature is enabled and the client does not have permission to read an entry at all, or if that client does not have permission to see any attributes that were targeted by the change, then the associated changelog entries targeted by those operations will be suppressed. If a client does not have permission to see certain attributes within the target entry, then references to those attributes in the changelog entry will also be suppressed. This property only applies to standard LDAP searches of the `cn=changelog` branch.
- **report-excluded-changelog-attributes.** Indicates whether to include additional information about any attributes that may have been removed due to access control filtering. This property only applies to content removed as a result of processing performed by the `apply-access-controls-to-changelog-entry-contents` property. Possible values are:
 - **none** - Indicates that changelog entries should not include any information about attributes that have been removed.
 - **attribute-counts** - Indicates that changelog entries should include a count of user and/or operational attributes that have been removed. If any user attribute information was excluded from a

changelog entry, the number of the excluded user attributes will be reported in the `ds-changelog-num-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the number of the excluded operational attributes will be reported in the `ds-changelog-num-excluded-operational-attributes` attribute of the changelog entry. Both the `ds-changelog-num-excluded-user-attributes` and `ds-changelog-num-excluded-operational-attributes` are operational and must be explicitly requested by clients (or all operational attributes requested using "+") to be returned.

- **attribute-names** - Indicates that changelog entries should include the names of user and/or operational attributes that have been removed. If any user attribute information was excluded from a changelog entry, then the names of the excluded user attributes will be reported in the `ds-changelog-excluded-user-attributes` attribute of the changelog entry. If any operational attribute information was excluded from a changelog entry, then the names of the excluded operational attributes will be reported in the `ds-change-log-excluded-operational-attribute` attribute of the changelog entry. Both the `ds-changelog-excluded-user-attribute` and `ds-changelog-excluded-operational-attribute` attributes are operational and must be explicitly requested by clients (or all operational attributes requested via "+") to be returned.

To Enable Access Control Filtering in the LDAP Changelog

About this task

To set up access control to the LDAP Changelog, use the `dsconfig` tool to enable the properties to the Changelog Backend. Only admin users with the `bypass-acl` privilege can read the changelog.

Steps

1. Enable the `apply-access-control-to-changelog-entry-contents` property to allow LDAP clients to undergo access control filtering using standard LDAP searches of the `cn=changelog` backend.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "apply-access-controls-to-changelog-entry-contents:true"
```

Access control filtering will be applied regardless of the value of the `apply-access-controls-to-changelog-entry-contents` setting when the Changelog Backend is servicing requests from an PingDataSync Server that has the `filter-changes-by-user` Sync Pipe property set.

2. Optional. Set the `report-excluded-changelog-attributes` property to include a count of users that have been removed through access control filtering. The count appears in the `ds-changelog-num-excluded-user-attributes` attribute for users and the `ds-changelog-num-excluded-operational-attributes` attribute for operational attributes.

```
$ bin/dsconfig set-backend-prop --backend-name "changelog" \
  --set "report-excluded-changelog-attributes:attribute-counts"
```

Useful Changelog Features

The Directory Server provides two useful changelog configuration properties: `changelog-max-before-after-values` and `changelog-include-key-attribute`.

- **changelog-max-before-after-values.** Setting this property to a non-zero value causes all of the old values and all of the new values (up to the specified maximum) for each changed attribute to be stored in the changelog entry. The values will be stored in the `ds-change-log-before-values` and `ds-`

`changelog-after-values` attributes on the changelog entry. These attributes are not present by default.

Note: The `changelog-max-before-after-values` property can be expensive for attributes with hundreds or thousands of values, such as a group entry.

If any attribute has more than the maximum number of values, their names and number of before/after values will be stored in the `ds-changelog-attr-exceeded-max-values-count` attribute on the changelog entry. This is a multi-valued attribute whose format is:

```
attr=attributeName,beforeCount=100,afterCount=101
```

where "attributeName" is the name of the attribute and the "beforeCount" and "afterCount" are the total number of values for that attribute before and after the change, respectively. This attribute indicates that you need to reset the `changelog-max-before-after-values` property to a higher value. When this attribute is set, an alert will be generated.

Note: If the number of values for an attribute exceeds the maximum value set by the `changelog-max-before-after-values` property, then those values will not be stored.
